	`-through`: When you use this parameter without using the `-from` or `-to` options, all paths that go through the specified pins have the specified delay. When you use it with both the `-from` and `-to` options, any path starting at any pin on the `-from` list *and* going through any point on the `-through` pin list *and* going to any point on the `-to` list is affected by the constraint. By default, the `-through` option applies the constraint to both the rising and the falling edges.
	`-rise_through`: Applies the assertion at the rising edge of the signal on the through pins.
	`-fall_through`: Applies the assertion at the falling edge of the signal on the through pins.

`-to	-rise_to	-fall_to` *to_list*	Specifies a list of timing paths end points. The *to_list* argument can contain either object IDs or hierarchical names relative to the current module or clock names. The pins can be on intermediate hierarchical boundaries. The *pin_or_clock_list* argument can be a collection. The valid end points are: • Output port • Bidirectional port • Data pin of sequential cell Data pin of sequential cell is one of the following: • Structural data pin that is part of latch or flip-flop. • Inferred data pin in cells like macro cells. A pin is an inferred data pin if it is associated with one of the following: • Signal end of setup check • Signal end of hold check • Signal end of non-sequential setup check • Signal end of non-sequential hold check • Signal end of removal check • Signal end of recovery check • Pin associated with `set_external_delay` • Data pin of clock gating cell Select from one of the following:
	`-to`: Applies the minimum delay constraint to all paths ending in the `-to` pin list. If a clock is specified as the `-to` object, all primary outputs and registers clocked by that clock are used as endpoint. By default, the `-to` option applies the constraint to both the rising and the falling edges.
	`-rise_to`: Applies the minimum delay constraint at the rising edge of the signal on the to pins.
	`-fall_to`: Applies the minimum delay constraint at the falling edge of the signal on the to pins.
value	Specifies the minimum delay value.

Examples

- The following command specifies a minimum delay of `2.5` for paths from `in1` to `out1`:

  ```
  set_min_delay 2.5 -from in1 -to out1
  ```

- The following commands show the difference in `report_timing` results when you specify a minimum delay with and without path segmentation:
  set_min_delay 9 -from R1 -to R2/D

  ```
  set_min_delay 9 -from R1/Q -to R2/D
  ```

  The `report_timing` results for the first command with path segmentation are:

  ```
  report_timing -early -from R1

  Path 1: VIOLATED Hold Check with Pin R2/CK
  Endpoint: R2/D (v) checked with leading edge of 'CLK_W_1'
  Beginpoint: R1/Q (v) triggered by leading edge of 'CLK_W_1'
  Path Groups: {CLK_W_1}
  Other End Arrival Time 0.000
  + Hold -0.042
  + Path Delay 9.000
  = Required Time 8.958
  Arrival Time 0.212
  Slack Time -8.745
  Clock Rise Edge 0.000
  + Clock Network Latency (Ideal) 0.000
  = Beginpoint Arrival Time 0.000
  ------------------------------------------------------------
  Pin         Cell     Delay    Arrival  Required  Instance
                                Time     Time
  ------------------------------------------------------------
  R1/CK ->    -        -        0.000    8.745     R1

set_min_fanout

```
set_min_fanout
[-help]
fanout_limit
object_list
[-override]
```

Sets the minimum fanout load limit constraint on the specified input ports of the top cell.

When set on a port, the fanout load of the net connected to the port must be greater than or equal to the specified limit value to meet the constraint. The fanout load of a net is the sum of the fanout loads of the pins driven by the net. When set on a module, the limit applies to all the nets of that module. The libraries and library cell pins may also have the minimum fanout load limit. In this case the most constraining limit is applied to the nets.

The constraint will not be used in optimizations.

Fanout load limit can be asserted on input ports, output pins, bidirectional pins, or ports and library pins. The constraint cannot be applied on input pins and output ports.

Parameters

`-help`	Prints out the command usage.
fanout_limit	Specifies the value of the minimum fanout load limit constraint. The specified value must be greater than or equal to zero.
object_list	Specifies a list of objects - ports, instance pins, modules, or library cell pins.
`-override`	Overrides the minimum fanout load limit from other sources, such as, library or constraints. This parameter can be used to force a specific constraint value for a specified list of instance pins/port/library cell pins - this overrides the maximum/minimum values set prior to this setting. To enable this feature, make the following setting: `set timing_constraint_enable_drv_limit_override true`

Examples

- The following example sets a minimum fanout load limit of `0.001` units on all the ports of the top cell:
  set_min_fanout 0.001 [get_ports *]
- The following example shows a report of the minimum fanout load limit set on ports using the `report_ports` command, as shown in the following example:
  ```
  set_min_fanout 5.0 [get_ports *] report_ports -type fanout_load_limit -pin [get_ports *]
  ```

  Example: Minimum Fanout Load Limit Set On Ports Report

  ```
  > report_ports -type fanout_load_limit -pin [get_ports *]
  ------------------------------------------
  ```

```
Pin      Dir  Assertion           Value
Name
-----------------------------------------
CLK2     IN   fanout_load_limit   5.000
CLK1     IN   fanout_load_limit   5.000
in2      IN   fanout_load_limit   5.000
in1      IN   fanout_load_limit   5.000
-----------------------------------------
```

set_min_pulse_width

```
set_min_pulse_width
[-help]
[-low]
[-high]
[-waveform_aware_type {absolute | source_width_ratio}]
value
object_list
```

Selects the most restrictive value when multiple minimum pulse width checks are set.

Note: The `timing_disable_lib_pulsewidth_checks` global has no effect on pulse width checks created by the `set_min_pulse_width` command.

Parameters

`-help`	Prints out the command usage.
`-high`	Applies the minimum pulse width check to high signal levels only. If neither the `-low` or `-high` option is specified, the value is applied to both low and high signal levels.
list	Specifies a list of pins or clock waveforms to which the minimum pulse width check is to be applied. If the list is not specified, the minimum pulse width check applies to all the pins in the clock tree of the current design. If a clock waveform is specified, all the pins driven by the clock are affected.
`-low`	Applies the minimum pulse width check to low signal levels only. If neither the `-low` or `-high` option is specified, the value is applied to both low and high signal levels.
object_list	Specifies list of objects: pins, ports, or clocks.
value	Specifies a non-negative floating minimum pulse width check value. No default value is assumed for minimum pulse width checks.
`-waveform_aware_type {absolute | source_width_ratio}`	Specifies the type of waveform-aware pulse width check to apply as `absolute` or `source_width_ratio`.

Examples

- The following command sets a minimum pulse width, both low and high, check of `1.0` to the clock network of the current design:
  ```
  set_min_pulse_width 1.0
  ```
- The following command sets a minimum pulse width low check of `2.0` to all the pins clocked by the `CLK1` clock:

```
set_min_pulse_width -low 2.0 [get_clocks CLK1]
```

- The following command sets a minimum pulse width `-high` check of `1.0` to the `CP` clock pin of register `ff1`, as shown in the following example:

```
set_min_pulse_width 0.5 u55/CK -low
set_min_pulse_width 1.0 u55/CK -high
report_min_pulse_width -pin u55/CK

set_min_transition

```
set_min_transition
[-help]
transition_limit
object_list
[-clock_path]
[-data_path]
[-fall]
[-override]
[-rise]
```

Sets the minimum slew time limit (transition) on the specified ports of the top timing module and/or clock waveforms.

When set on a port, the slew time at the port must be greater than or equal to the specified limit. When set on a module, the limit applies to all the pins in the module and its ports if the module is the top timing module. The minimum transition limits on pins can come from library objects, which are the default minimum transition of the libraries or minimum transition on library cell pins. In this case, the most constraining limit, which is the largest, will apply on pins and ports.

Use the `report_ports -type slew_limit` command to view the minimum transition limits set on ports of the top timing module.

When limits are set on a clock waveform, you can use `-clock_path`, `-data_path`, `-rise`, and `-fall` parameters to provide more specifications.

The `set_min_transition` constraint on clock objects will be honored only by the `report_constraint` command for DRV violations. The constraint will not be used in optimizations.

Parameters

`-help`	Prints out the command usage.
`-clock_path`	Specifies all pins that are in the network of the specific clocks in the object list.
`-data_path`	Specifies all pins that are in the data paths launched by the specific clocks in the object list.
`-fall`	Specifies falling transition.
`object_list`	Specifies the list of objects - ports, instance pins, library cell pins, modules, and/or clock waveforms.
`-override`	Overrides the minimum transition limit from other sources, such as, library or constraints. This parameter can be used to force a specific constraint value for a specified list of instance pins/port/library cell pins - this overrides the maximum/minimum values set prior to this setting. To enable this feature, make the following setting: `set timing_constraint_enable_drv_limit_override true`
`-rise`	Specifies rising transition for all selected pins.
`transition_limit`	Specifies the value of the minimum slew time limit (minimum transition). This value must be less than or equal to zero. The minimum slew time limit is in time units from the target technology library.

Examples

- The following example sets a minimum transition limit of `0.9` units on all the ports of the top timing module, and a minimum transition limit of `0.7` units on the top timing module:

  ```
  set_min_transition 0.9 [get_ports *]
  set_min_transition 0.7 [current_design]
  ```

  The minimum limit that applies to ports is `0.9`, which is the most constraining value.

- The following example shows a report of the minimum transition limit set on ports using the `report_ports` command, as shown in the following example:

  ```
  set_min_transition 0.9 [get_ports *]
  report_ports -type slew_limit -pin [get_ports *]
  ```

  Minimum Transition Limit Set on Ports Report

  ```
  set_min_transition 0.9 [get_ports *]
  > report_ports -type slew_limit -pin [get_ports *]

slack : -0.897 ( VIOLATED )
```

Related Commands

- set_max_transition
- reset_min_transition
- report_ports
- report_constraint

set_mode

```
set_mode
[-type cell]
list_of_modes
object_list
```

Specifies the Liberty timing library modes to be active for a specific instance.

A library mode is a subset of active timing arcs that is defined in the timing library. Library modes are similar to conditional timing arcs, but do not require the application of constants to set. Instead of changing a cell's mode by applying constants to its input pins, you can use the `set_mode` command to refer to sets of active arcs by name (such as `READ` or `WRITE`, for a memory cell).

By default, all library modes in the timing library are active. If you specify one or more library modes using the `set_mode` command, only the timing arcs consistent with the specified mode(s) are active for the instance. All other library modes become inactive.

To reset the library modes for an instance, use the `reset_mode` command.

Parameters

object_list	Specifies the instances to which to apply the library mode.
list_of_modes	Specifies the name of the library mode value defined in the timing library. You can specify one or more mode values, but only one mode value per defined mode group in the Liberty library.
-type cell	Sets the library mode at the instance level. **Note:** Setting the library mode at the instance level is the only form of `set_mode` that is currently supported. This parameter exists to support constraints coming from external sources.

Examples

- The following command specifies the `test_mode` library mode active for instances of b1.

  ```
  set_mode test_mode [get_cells b1]
  ```

  The following command reports the status of all library modes associated with b1:

  ```
  tempus > report_mode b1
  -------------------------------
  Mode Group test_mode of b1
  -------------------------------
  Mode     Status     Condition
  Name
  -------------------------------
  test_B   Inactive   !(Y)
  test_A   ACTIVE      Y
  -------------------------------
  ```

  The above report shows that only the timing arcs consistent with the `test_A` library mode are active for instances of b1 - and `test_B` is inactive.

- If you specify the `report_inactive_arcs` command, the report shows the disabled arcs for the b1 instance are from the `test_mode` library mode:

  ```
  ------------------------------------------------------
  Flags :  const propagated constant
           snipped loop snipped arcs
           disable set_disable_timing
           disable_clock_gating set_disable_clock_gating
           library_disable set_disable_cell_timing
           Missing_Phase No Arc Phase Data
  From     To       DisableType   ArcType                 Reason
  ------------------------------------------------------------------
  u8/CK ^   u8/D ^   const        hold_rising_clk_rise    u8/D = 1
  u8/CK ^   u8/D v   const        hold_falling_clk_rise   u8/D = 1
  u8/CK ^   u8/D ^   const        setup_rising_clk_rise   u8/D = 1
  u8/CK ^   u8/D v   const        setup_falling_clk_rise  u8/D = 1
  ------------------------------------------------------------------
  ```

set_multicycle_path

```
set_multicycle_path
[-help]
<number_of_cycles>
[-comment <string>]
[-fall]
[-fall_through <through_list>]
[-hold]
[-rise]
[-rise_through <through_list>]
[-setup]
[-through <through_list>]
[-start  | -end ]
[-from <from_list> | -rise_from <from_list> | -fall_from <from_list>]
[-to <to_list]> | -rise_to <to_list> | -fall_to <to_list]>]
```

Specifies multicycle paths between specific timing paths in a design or between clock domains. The multicycle paths are timing paths that require more than one clock period for execution. By default, all the paths are considered as one cycle paths for setup and hold check evaluation. The `set_multicycle_path` command allows you specify additional cycles for the paths.

Parameters

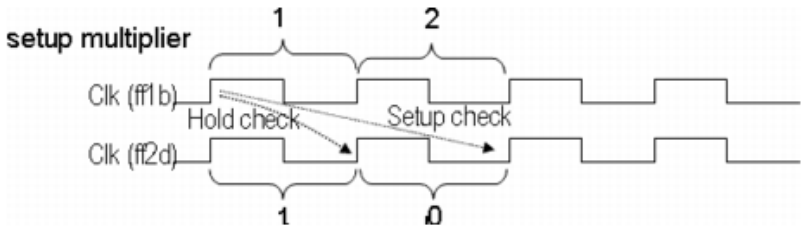
`-help`	Prints out the command usage.
number_of_cycles	Specifies the number of cycles allowed for the path.
`-comment` *string*	Allows you to insert comments. The comments are read but are ignored with a one-time warning message. They are not used during timing analysis reporting nor are they written out during saving of constraints.
`-fall`	Applies the assertion at the falling edge of the signal on the path endpoints.
`[-fall_through <through_list>]`	Applies the assertion at the falling edge of the signal on the through pins

`-from <from_list> | -rise_from <from_list> | -fall_from <from_list>`	Specifies the clocks, ports, pins, or sequential instances that are at the start of the multicycle paths. The port direction can be either input or inout. Pins must be valid path startpoints such as sequential instance clock pins, latch data pins or pins on which input delays have been specified. Pins can be on intermediate hierarchical boundaries. The *from_list* variable can contain either collection IDs or object names. If the `-from` option is used without the `-to` option, all paths originating from the `from_list` are multicycle paths. Use either the `-from`, `-to`, or `-through` option with the `set_multicycle_path` command to identify the paths. Specifying both the `-from` and `-to` options identifies a path with specific starting and ending points. Use only one `-from`, `-rise_from`, or `-fall_from` option per command.
`-hold | -setup`	Specifies whether the multicycle adjustment applies to setup/hold check. The `-setup` parameter applies multicycles to setup check. The hold check is affected but the hold multiplier does not change. The `-hold` parameter applies multicycles to hold check only. *Default:* If you do not specify `-setup` or `-hold` parameter, the software considers the specified multicycle value for setup check and uses 0 for the hold check.
`-rise`	Applies the assertion at the rising edge of the signal on the path endpoints.
`-rise_through <through_list>`	Applies the assertion at the rising edge of the signal on the through pins.
`-start | -end`	Specifies whether the multicycle adjustment is to be applied relative to the starting clock edge for the path or relative to the ending clock edge for the path. Use these options for multiple clocks designs. By default, the setup check is relative to the end clock and the hold check is relative to the start clock. **Note:** The `-start` and `-end` parameters are mutually exclusive; you cannot specify them together. You can set the `timing_enable_sdc_compatible_data_check_mcp` global variable to `true` to enable checking for SDC compatible data checks. When the `-start` parameter is specified, the parameter reverses the reference clock by one clock cycle.

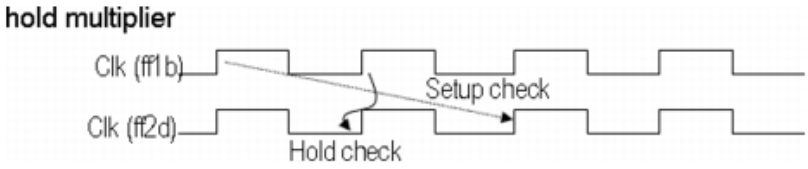
`-through <through_list>`	Applies the assertion to both the rising and the falling edges. This parameter specifies the ports, pins, instances, or nets that the path goes through. The pins can be on intermediate hierarchical boundaries. The *through_list* variable can contain either collection IDs or object names. When used without the `-from` or `-to` option, all paths that go through the `-through` pins are multicycle paths. When used with both the `-from` and `-to` options, any path starting at any pin on the `-from` list and going through any point on the `-through` pin list and going to any point on the `-to` list is affected by the assertion. You can use only one `-from` and `-to` option, but you can specify several `-through` options in the same command. By default, the `-through` option applies the assertion to both the rising and the falling edges. Using the `-rise_through` option applies the assertion at the rising edge of the signal on the through pins. Using the `-fall_through` option applies the assertion at the falling edge of the signal on the through pins.
`-to <to_list]> | -rise_to <to_list> | -fall_to <to_list]>`	Specifies the clocks, ports, pins, or sequential instances that are at the end of the multicycle paths. The port direction can be either output or inout. Pins must be valid path end-points such as sequential instance data pins or pins on which output delays have been specified. Pins can be on intermediate hierarchical boundaries. The *to_list* variable can contain either collection IDs or object names. If the `-to` option is used without the `-from` option, all paths ending in the `-to` pin list are multicycle paths. Use only one `-to` option per command. Use only one `-to`, `-rise_to`, or `-fall_to` option per command.

Examples

- The following command sets all paths between ff1b + ff2d to two cycles for setup:
  ```
  set_multicycle_path -setup 2 -from {ff1b} -to {ff2d}
  ```



- The following command moves hold check to start clock preceding edge:
  ```
  set_multicycle_path -hold 1 -from {ff1b} -to {ff2d}
  ```



- The following commands show setup multiplier values from -1 to 3:

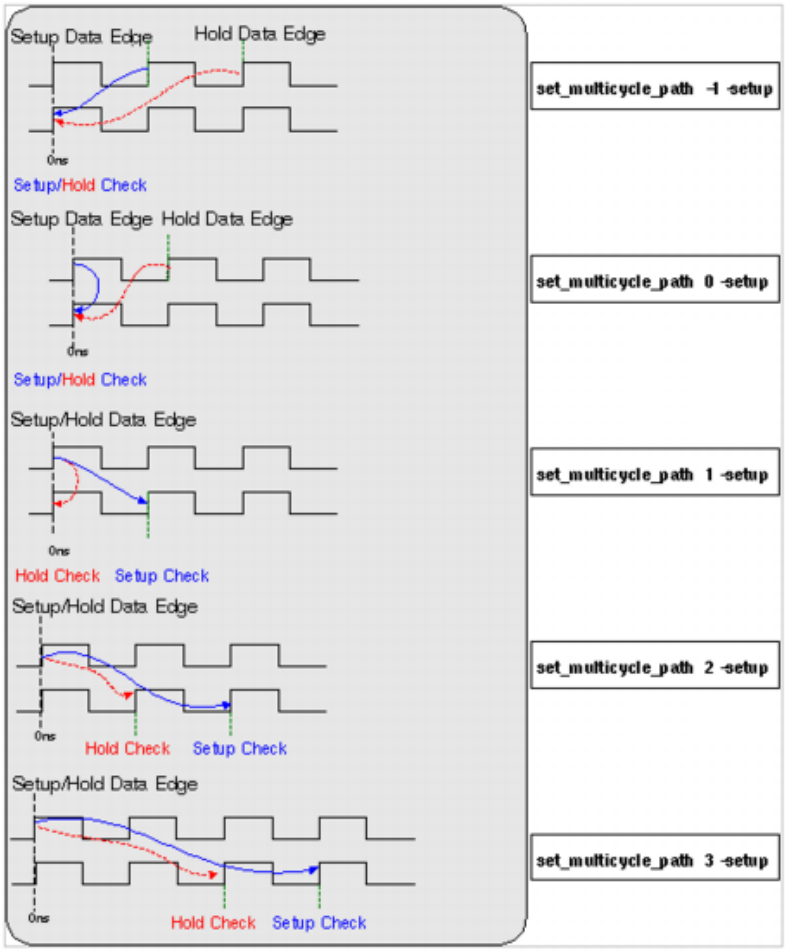
```
set_multicycle_path -1 -setup

set_multicycle_path 0 -setup

set_multicycle_path 1 -setup

set_multicycle_path 2 -setup

set_multicycle_path 3 -setup
```



- The following commands show hold multiplier values from -1 to 3:

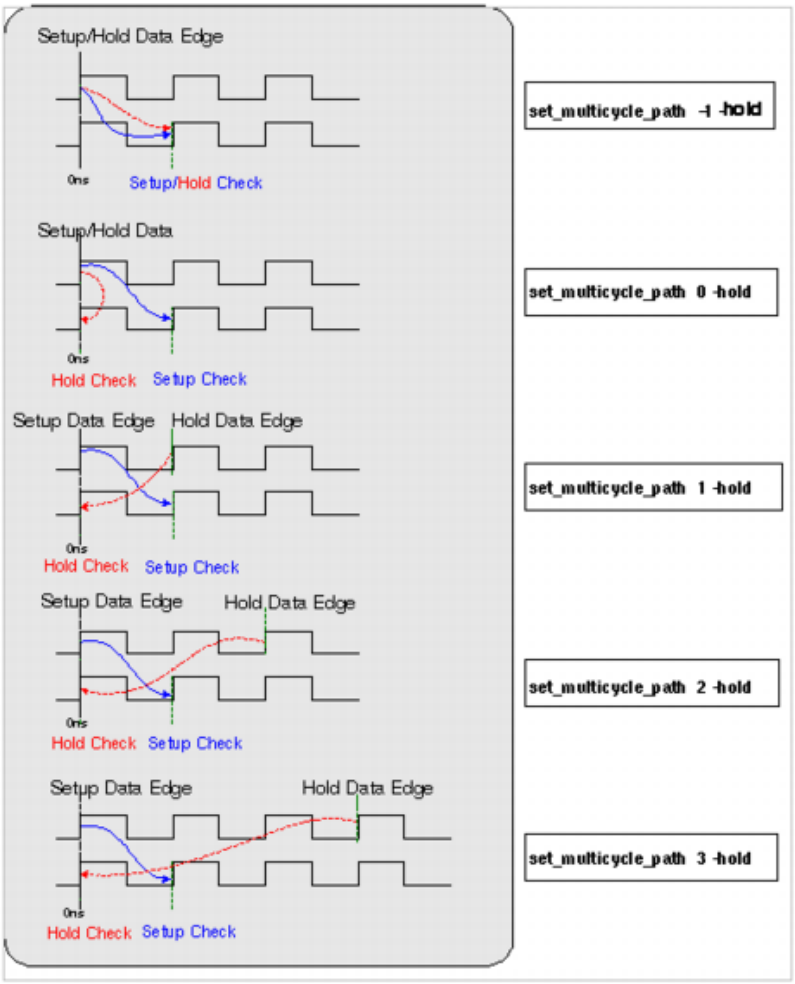
```
set_multicycle_path -1 -hold

set_multicycle_path 0 -hold

set_multicycle_path 1 -hold

set_multicycle_path 2 -hold

set_multicycle_path 3 -hold
```



Related Information

- set_false_path
- set_max_delay
- set_min_delay
- reset_path_exception

set_output_delay

```
set_output_delay
-clock clock_name
[-clock_fall]
[-rise] [-fall]
[-max] [-min]
[-add_delay]
[-network_latency_included]
[-source_latency_included]
[-reference_pin pin_name]
[-level_sensitive]
[-group_path group_name]
delay_value
port_or_pin_list
```

Specifies the data required time on output ports, hierarchical ports, or internal output pins.

Parameters

`-add_delay`	Adds delay information to the existing output delay. The additional delay information can be for multiple paths relative to different clocks or clock edges leading to an input port or internal input pins. If you do not use the `-add_delay` option, the software uses the last `set_output_delay` related to a pin when there are multiple `set_output_delay` statements for the same pin.
`-clock clock_name`	Specifies that the delay is relative to the specified clock. You cannot use the `set_output_delay` command without the `-clock` parameter. Such constraints are accepted but are ignored during timing analysis. When you specify multiple clocks, an error occurs and the constraint is ignored.
`-clock_fall`	Specifies that the delays are with respect to the falling edge of the clock waveform. If you do not specify the `-clock_fall` option, the delay is with respect to the rising edge of the clock waveform. You cannot specify the `-clock_fall` parameter without the `-clock` parameter.
`delay_value`	Specifies the value for the path delay.
`-fall`	Specifies that the output delay refers to the falling edge of the signal at specified ports or pins. If you do not specify the `-fall` option, the output delay applies to both the edges.

`-group_path` *group_name*	Specifies the group name where paths ending at the specified ports or pins are to be added. The `-group_path` parameter is not honored in multi-mode multi-corner (MMMC) designs. If specified, a warning is issued and the constraints are applied as if the `-group_path` parameter is not specified.
`-level_sensitive`	Models output delay that is captured by a positive level sensitive latch. For setup checks, the timing system checks the arrival time at the output port with the opening edge of the latch. The timing system treats any arrival time exceeding the opening edge as negative slack. For hold checks, the timing system performs the checks with respect to the closing edge of the latch. Use the `-clock` parameter to model a positive level sensitive latch, or the `-clock_fall` parameter to model a negative level sensitive latch. You cannot use the `-level_sensitive` parameter without the `-clock` parameter.
`-max`	Specifies that the delay refers to the setup analysis. If you do not specify the `-max` parameter, the output delay applies to both setup and hold analysis.
`-min`	Specifies that the delay refers to the hold analysis. If you do not specify the `-min` parameter, the output delay applies to both setup and hold analysis.
`-network_latency_included`	Specifies that the clock network latency should not be added to the output delay value. If you do not specify this option, the clock network latency of the related clock is added to the output delay value. This parameter has no effect if the specified clock is in propagated mode.
port_or_pin_list	Specifies a list of output port or pin names. The port_or_pin_list argument can be a collection.
`-reference_pin` *pin_name*	Adds source and network latency of the specified reference pin to the output delay value in propagated mode. A reference pin is a leaf pin in the fanout cone of the clock source of the clock that you specify using the `-clock` parameter. You cannot specify multiple pins for `-reference_pin` parameter. The command issues a warning and accepts the first pin. You cannot use the `-reference_pin` parameter with the `-network_latency_included` or `-source_latency_included` parameters. You cannot use the `-reference_pin` parameter to specify hierarchical pins.
`-rise`	Specifies that output delay refers to the rising edge of the signal at the specified ports or pins. If you do not specify the `-rise` option, the output delay applies to the both edges.

`-source_latency_included`	Specifies that the clock source latency should not be added to the output delay value. With different delay values for `-rise/-fall` and `-min/-max`, only the last specified combination of `-network_latency_included` and `-source_latency_included` parameters is honored. The specified combination can be one of the following: a) Either `-network_latency_included` or `-source_latency_included` b) Both the parameters c) None of these

Examples

- The following example sets the input and output delays for the bidirectional `INOUT2` port.The input signal arrives at `INOUT2` at `4.5` units after the falling edge of `CLKB`. The output signal is required at `INOUT2` at `2.5` units before the rising edge of `CLKD`:

```
set_input_delay 4.5 -clock CLKB -clock_fall { INOUT2 }
set_output_delay 2.5 -clock CLKD { INOUT1 }
```

- The following example shows how to use the `-group_path` option to add ports into a named group:

```
set_output_delay 2.5 -max -clock CLK -group_path busC {busC[*]}
```

Related Information

- `all_outputs`
- `create_clock`
- `report_ports`
- `set_input_delay`
- `set_load`

set_pll_timing

```
set_pll_timing
[-help]
inst_name
-feedback_pin feedback pin name
-output_clock clock name
-output_pin output pin name
[-reference_edge {rise | fall | both}]
-reference_pin reference pin name
```

This command identifies phase locked loop (PLL) insertion delays and the associated generated clock(s) that require adjustment. To remove the effect of clock tree latency, PLLs can be used to adjust the delay on the PLL output clock waveform so that the effective edges of the clock at the clock tree endpoints are aligned with the reference edges of the input clock to the PLL.

When you use the `set_pll_timing` command, the software uses the settings to automatically calculate and apply a delay offset to a PLL output clock to compensate for internal clock tree latency.

The `set_pll_timing` command works in conjunction with a generated clock definition to provide the correct clock timing at the output of the PLL. To use this command, you must first assert a generated clock on the `set_pll_timing -output_pin`. The `-source` option of the `create_generated_clock` command must also match the `-reference_pin` specified by the `set_pll_timing` command.

Parameters

`-help`	Prints out the command usage.
`inst_name`	Specifies the instance name or the object ID of a PLL cell, on the basis of which the reference pins, feedback pins, or the output pins will be searched.
`-feedback_pin` *`feedback pin name`*	Specifies the name of the PLL feedback pin.
`-output_clock` *`clock name`*	Specifies the generated clock on the PLL output.
`-output_pin` *`output pin name`*	Specifies the PLL clock output pin name.
`-reference_edge {rise | fall | both}`	Defines adjustment edge(s). When this parameter is specified, the software selects the edges of the clocks at the reference and feedback pins that need to be aligned. If the `rise` or `fall` option is specified, then the clock latency from that reference edge to the related edge at the feedback pin will be used. In this case, both the rise and fall edges will use the same latency adjustment. If both of these options are specified, then the software will measure separate latency adjustments for both the rise and fall edges. *Default*: `rise`
`-reference_pin` *`reference pin name`*	Specifies the PLL reference pin name.

Examples

Here are some examples.

- The following example shows the defined clocks in a sample design:

  ```
  create_clock [get_ports {clk_in}] -name CLK -period 6 -waveform {0 3}
  create_generated_clock -name GCLK1 -source [get_pins {mypll/CLK}] -multiply_by 1 -master_clock
  [get_clocks {CLK}] -add [get_pins {mypll/GCLK}]
  ```

  The following `report_timing` command shows the insertion delay values at various points in the timing report:

  ```
  report_timing -from_rise mypll/GCLK -to_rise mypll/CEN -point_to_point

  Path 1:Endpoint: mypll/CEN (^) (unconstrained output)

  Beginpoint: mypll/GCLK (^) triggered by leading edge of 'GCLK1'
  ```

```
Arrival Time 0.496
Analysis View: default_analysis_view_setup
------------------------------------------------------------
Pin           Cell      Delay   Arrival   Generated Clock
                                Time      Adjustment
------------------------------------------------------------
mypll/CLK                       0.112
mypll/GCLK ->  PLL       0.133  0.246     GCLK1 Adj. = 0.000
clkTreeL0/Y    CLKBUFX1  0.139  0.385
clkTreeL1_1/Y  CLKBUFX1  0.118  0.503
mypll/CEN ->   PLL      -0.007  0.496
------------------------------------------------------------
```

From the above table, it can be seen that the rise insertion delay of clock CLK at pin mypll/CLK is 0.112ns.

Now, the following command will adjust the source latency of clock GCLK1 such that the edges at mypll/CLK and mypll/CEN are aligned i.e. the clock's rising edge should reach mypll/CEN at 0.112ns only:

```
set_pll_timing [get_cells mypll] -reference_pin CLK -feedback_pin CEN -output_pin GCLK -
output_clock [get_clocks GCLK1]
```

- The following `report_timing` command shows the source latency of GCLK clock as -0.138ns, and the clock reaches mypll/CEN pin at 0.112ns (same as on mypll/CLK):

```
report_timing -from_rise mypll/GCLK -to_rise mypll/CEN -point_to_point

Path 1:Endpoint: mypll/CEN (^) (unconstrained output)
Beginpoint: mypll/GCLK (^) triggered by leading edge of 'GCLK1'
Arrival Time 0.112
Analysis View: default_analysis_view_setup
+ Source Insertion Delay 0.112
- PLL Feedback Delay 0.250
= Beginpoint Arrival Time -0.138
------------------------------------------------------------------
Pin             Cell       Delay    Arrival    Generated Clock
                                    Time       Adjustment
------------------------------------------------------------------
mypll/GCLK ->                       -0.138    GCLK1 Pll Adj. = 0.000
clkTreeL0/Y     CLKBUFX1   0.139    0.001
clkTreeL1_1/Y   CLKBUFX1   0.118    0.120
mypll/CEN ->    PLL       -0.007    0.112
------------------------------------------------------------------
```

Related Commands

- create_generated_clock
- create_clock
- reset_pll_timing

set_propagated_clock

```
set_propagated_clock
pin_clock_list
```

Puts the `propagated_clock` assertion on the specified pin, port, or clock object. This will cause all clock endpoints in the fanout of the specified object to receive propagated clock timing unless there is a `set_clock_latency` with higher precedence. If there are multiple `set_clock_latency` and `set_propagated_clock` assertions between the clock waveform, clock root and clock endpoint, the closest assertion to the clock endpoint takes precedence.

There are two methods of clock propagation: depending on whether the clock is ideal or propagated.

- When a clock is ideal, the delay from a clock port to a register clock pin (network insertion delay) comes from design constraints using the `set_clock_latency` command.
- When a clock is propagated, the network insertion delay is computed from the actual gates and interconnects in the clock network.

To set the propagated_clock property on all clock waveform objects, use the following command:

```
set_propagated_clock [all_clocks]
```

When `set_propagated_clocks [all_clocks]` command is asserted, it will apply to all the currently defined clock waveform objects. This setting will not apply to clocks created later in the script. Whether all the clock endpoints receive propagated or ideal timing depends on the precedence of `set_clock_latency` in the fanout.

The `set_propagated_clock [all_clocks]` command puts the `propagated_clock` assertion on all clocks except virtual clocks. When you put the assertion on a real clock that is used to define I/O timing (with `set_input_delay -clock` or `set_output_delay -clock`), the software does not take the specified network latency into account. Instead, the software calculates the network latency, which changes the I/O timing. You can change this behavior by using the following global variable:

```
set_global timing_io_use_clock_network_latency always
```

You can use this command after creating the clock with the create_clock command.

Parameters

pin_clock_list	Specifies the objects on which you want to put the `propagated_clock` assertion. The *pin_or_clock_list* argument can be a collection. When a pin is specified, it affects the propagation mode for all the registers in the transitive fanout (TFO) of the pin.

Examples

- The following command puts the `propagated_clock` assertion on the clock waveform `CLK1`:

  ```
  set_propagated_clock CLK1
  ```

- The following command puts the `propagated_clock` assertion on all clock waveforms:

  ```
  set_propagated_clock [all_clocks]
  ```

set_property

```
set_property
[-object_type {object_type}]
{object_list}
[-quiet]
property_name
property_value
```

Sets user-defined properties on objects.

The `set_property` command needs a property to be defined using the `define_property` command.

Parameters

object_list	Specifies a list of objects on which the property is to be applied.
-object_type {*object_type*}	Specifies the type of object on which the property is to be defined.
property_name	Specifies the name of the property.
property_value	Specifies the value of the property.
-quiet	Specifies to exit quietly without issuing an error.

Examples

- The following command applies a user-defined property `slk` to pins `C1/A`:

  ```
  set_property [get_pins C1/A] slk 2
  ```

- The following command applies aocv_weight property to library arcs:

  ```
  set_property [get_lib_arcs -of_objects slow/INVX1] aocv_weight 8
  ```

set_pulse_clock_max_transition

```
set_pulse_clock_max_transition
transition_limit
object_list
[-transitive_fanout]
[-rise]
[-fall]
```

Sets the maximum pulse clock transition constraint on the specified pulse generator cells, pulse generator library cells, clocks, and/or current design.

Parameters

`-fall`	Sets transition limit value for falling transition.
`object_list`	Specifies a list of objects - pulse generator cells, pulse generator library cells, clocks, or current design.
`-rise`	Sets transition limit value for rising transition.
`transition_limit`	Specifies the transition limit value.
`-transitive_fanout`	Specifies the transition limit value for transitive fanout.

Examples

The following example sets the max pulse clock transition constraint of 0.1ns on the input pins of all the instances of the lib cell PULSE_GEN_00:

```
set_pulse_clock_max_transition 0.1 PULSE_GEN_00
```

This constraint can be observed on the input pin 'A' of an instance 'pg_inst' of this lib cell using the following command:

```
report_constraint pg_inst/A -drv_violation_type pulse_clock_max_transition

Fragmented output:

Check type : pulse_clock_max_transition_rise
----------------------------
-----------------------------------------------
Pin Name Required Actual Slack
-----------------------------------------------
pg_inst/A 0.100 0.030 0.070

Check type : pulse_clock_max_transition_fall
----------------------------

- get_cells
- reset_pulse_clock_max_transition

set_pulse_clock_max_width

```
set_pulse_clock_max_width
pulse_width
object_list
[-transitive_fanout]
```

Sets the maximum pulse clock width constraint on the specified pulse generator cells, pulse generator library cells, clocks, and/or current design.

To report the maximum pulse clock width constraint, you can use the `report_constraint -check_type pulse_clock_max_width` command.

Parameters

object_list	Specifies a list of objects - pulse generator cells, pulse generator library cells, clocks, or current design.
pulse_width	Specifies the pulse width value.
-transitive_fanout	Specifies the pulse width value for transitive fanout.

Examples

The following example sets the max pulse clock width constraint of 1ns on the pulse generator instance 'pg_inst':

```
set_pulse_clock_max_width 1 pg_inst
```

This constraint can be observed using the following command:

```
report_constraint pg_inst/Y -check_type pulse_clock_max_width
```

Fragmented output:

```
-------------------------------------------
Pin Required Actual Pulse Slack Clock Type
Pulse Width Width
-------------------------------------------
pg_inst/Y (high) 1.000 0.366 0.634 PG
-------------------------------------------
```

set_pulse_clock_min_transition

```
set_pulse_clock_min_transition
transition_limit
object_list
[-transitive_fanout]
[-rise]
[-fall]
```

Sets the minimum pulse clock transition constraint on the specified pulse generator cells, pulse generator library cells, clocks, and/or current design.

Parameters

`-fall`	Sets transition limit value for falling transition.
`object_list`	Specifies a list of objects - pulse generator cells, pulse generator library cells, clocks, or current design.
`-rise`	Sets transition limit value for rising transition.
`transition_limit`	Specifies the transition limit value.
`-transitive_fanout`	Specifies the transition limit value for transitive fanout.

Examples

The following example sets the min pulse clock transition constraint of 0.05ns on the input pins of all the instances of the lib cell PULSE_GEN_00:

```
set_pulse_clock_min_transition 0.05 PULSE_GEN_00
```

This constraint can be observed on the input pin 'A' of an instance 'pg_inst' of this lib cell using the following command:

```
report_constraint pg_inst/A -drv_violation_type pulse_clock_min_transition
```

Fragmented output:

```
Check type : pulse_clock_min_transition_rise
---------------------------
-------------------------------------------
Pin Name Required Actual Slack
-------------------------------------------
pg_inst/A 0.050 0.030 -0.020

Check type : pulse_clock_min_transition_fall
---------------------------
-------------------------------------------
Pin Name Required Actual Slack
```

```
-------------------------------------------
pg_inst/A 0.050 0.030 -0.020
```

Related Information

- get_cells

set_pulse_clock_min_width

```
set_pulse_clock_min_width
[-help]
pulse_width
object_list
[-transitive_fanout]
```

Sets the minimum pulse clock width constraint on the specified pulse generator cells, pulse generator library cells, clocks and/or current design.

When you set this constraint on a clock, the settings are applied to all the pulse generators that are driven by the clock. When this constraint is used for a design, the software applies the constraint to all the clock networks in the design.

The specified minimum pulse width is expected to be larger than the pulse width value. The width is defined when a clock object is created and its waveform is defined in the current design (using the `create_clock -waveform` parameter).

In case of conflicting minimum width constraints, the more restrictive constraint is used. When applied on a non-pulse generator object, or a non-clock target, this constraint has no effect.

Note: You must specify `set_interactive_constraint_modes` constraint prior to running the `set_pulse_clock_min_width` command.

Parameters

`-help`	Prints out the command usage.
`object_list`	Specifies a list of objects - pulse generator cells, pulse generator library cells, clocks, or current design.
`pulse_width`	Specifies the minimum pulse width value.
`-transitive_fanout`	Specifies the pulse width value for transitive fanout.

Examples

- The following example sets the min pulse clock width constraint of 0.3 ns on the pulse generator instance `pg_inst`:

  ```
  set_pulse_clock_min_width 0.3 pg_inst
  ```

  This constraint can be observed using the following command:
  ```
  report_constraint pg_inst/Y -check_type pulse_clock_min_width
  ```

  Fragmented output:

  ```
  ----------------------------------------
  Pin Required Actual Pulse Slack Clock Type

  Pulse Width Width
  ----------------------------------------
  pg_inst/Y (high)    0.300 0.366 0.066 PG
  ----------------------------------------
  ```

set_resistance

```
set_resistance
-help
[-max]
[-min]
resistance_value
net_list
```

Sets the wire resistance value on the specified nets of the top cell, which is used to compute the net delay of the specified nets. The resistance that you specify using this command overrides the resistance from wire load models and SPEF.

Note: In the best-case worst-case (BC-WC) analysis mode, the minimum resistance is used to compute the early path delay and the late path delay for the minimum corner. The maximum resistance is used to compute the early path delay and the late path delay for the maximum corner.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `set_resistance` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_resistance`.
`-max`	Specifies that the asserted resistance is the maximum resistance. *Default*: If the `-max` (or `-min`) parameter is not specified, the resistance value is used as both minimum and maximum resistance.
`-min`	Specifies that the asserted resistance is the minimum resistance. *Default*: If the `-min` (or `-max)` parameter is not specified, the resistance value is used as both minimum and maximum resistance.
`net_list`	Specifies a list of nets on which the wire resistance is set.
`resistance_value`	Specifies the value for the wire resistance. This value (in units) is found in the target technology library.

Examples

- The following example set the maximum wire resistance of `2.0` units on the net `n1`:

  ```
  set_resistance -max 2.0 [get_nets n1]
  ```

- The following example set the minimum wire resistance of `1.2` units and a maximum wire resistance of `2.0` units on the net `n1`:

  ```
  set_resistance 1.2 -min [get_nets n1]
  ```

```
set_resistance 2.0 -max [get_nets n1]
```

Related Commands

- reset_resistance
- report_net

set_sense

```
set_sense
[-help]
pin_or_port_list
[-clocks clock_list]
{[-positive | -negative | -stop_propagation ] [-type <type_list> ]}
```

Selects which phase of the clock to filter at the specified point.

Parameters

`-help`	Prints out the command usage.
`-clocks` *`clock_list`*	Specifies a list of clocks passing through a specified point to which the constraint applies. When this parameter is not specified, the filtering of clock phase will be applicable to all the clocks passing through that specified point. This parameter must be used with a specified pin name and one of the parameters : `-positive`, `-negative`, or `-stop_propagation`.
`-negative`	Specifies that positive phase filtered clocks pass through pins in the *`pin_list`*.
`pin_or_port_list`	Specifies the list or collection of cell output pins. The unateness specified by the `set_sense` command is applied to clocks propagating through the specified point.
`-positive`	Specifies that negative phase filtered clocks pass through pins in the *`pin_list`*.
`-stop_propagation`	Stops the propagation of specified clocks and clock source data paths passing through the specified pins.

`-type type_list`	Applies clock sense to object types specified in the *`type_list`*. The type list options are - `all`, `clock`, `data`, `clock_source_data`, `default_data`. These are explained below: • `all`: Stops all phases from propagating. This is equivalent to specifying both the `clock` and `data` options. • `clock`: Stops clock phases launched by clock(s) specified in the *`clock_list`* from propagating. • `data`: Stops all data phases launched by clock(s) specified in *`clock_list`*, starting from the pins/ports specified in *`pin_or_port_list`*. The objects in the *`pin_or_port_list`* can be selected anywhere in the design - clock/data network. • `clock_source_data`: Stops only clock source data phases from propagating. The combination of `clock_source_data` and `clock` is equivalent to the existing `-stop_propagation` option. The `-type` parameter extends the capability of the `set_clocks_sense` command to selectively block data timing phases. This parameter provides a more generalized use model for selecting among all types of paths that should be filtered. The `-type` parameter is mutually exclusive with the `-positive`, `-negative`, and `-stop_propagation` options.

Examples

- The following command allows the positive phase clock CLK1 to pass through CLKBUF1/Z and filters out the negative phase clock CLK1:
  ```
  set_sense -positive -clocks CLK1 CLKBUF1/Z
  ```
- The following command stops clock phases starting from pin1:
  ```
  set_sense pin1 -type {clock}
  ```
- The following command stops data phases based only on CK1 and CK2 starting from pin1:
  ```
  set_sense pin1 -type {data} -clocks {CK1 CK2}
  ```
- The following command stops only the clock source data phases starting from pin1:
  ```
  set_sense pin1 -type {clock_source_data}
  ```
- The following command stops the clock and clock source data phases:
  ```
  set_sense pin1 -type {clock clock_source_data}
  ```
  or
  ```
  set_sense pin1 -stop_propagation
  ```

Related Commands

- `reset_sense`

reset_sense

```
reset_sense
[-help]
[-all | [[-clocks <clock_list>] <pin_or_port_list>]]
```

Resets clock sense constraint(s) specified using the `set_sense` command.

Parameters

`-help`	Prints out the command usage.
`-all`	Resets all the specified `clock_sense` constraints.
`-clocks` *clock_list*	Specifies the list of clocks for which the clock sense constraints are to be removed. The clocks must have previously been defined using the `set_sense -clocks` parameter.
pin_or_port_list	Specifies the list or collection of cell output pins or ports for which the clock sense constraints will be removed.

Examples

- The following command resets all the previously defined `clock_sense` constraints from a design:

  ```
  tempus > reset_sense -all
  ```

Related Commands

- `set_sense`

analyze_paths_by_basic_path_group

```
analyze_paths_by_basic_path_group
[-help]
[-master master_category_name]
[-predefined]
```

Categorizes the timing paths based on basic path groups. The basic path groups are fundamental to timing analysis and help the user in observing the timing information of different basic path groups easily. For instance, if user is only concerned about the paths from registers to registers, the user can analyze the paths in the category REG -> REG. The basic path groups categories are:

- Register to register
- Input to register
- Register to output
- Input to output

The following categories are created:

- `REG->REG`
- `IN->REG`
- `REG->OUT`
- `IN->OUT`

Timing debug can also convert user defined path groups into path categories. The command can be applied wherever the user loads the machine readable timing report.

Note: If your design does not have paths belonging to a type of path group, the software will not create that category.

For more information on creating path categories, see "Creating Path Categories" in the Debugging Timing Results chapter of *User Guide*.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `analyze_paths_by_basic_path_group` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man analyze_paths_by_basic_path_group`
`-master` *`master_category_name`*	Specifies that the analysis should be performed only for the specified master category.
`-predefined`	Creates path categories for user defined path groups.

Examples

- The following command create path categories based on basic path groups:
  `analyze_paths_by_basic_path_group`
  The following categories are created: REG->REG, IN->REG, REG->OUT, IN->OUT.
- The following command create path categories based on predefined path group "critical" :

```
group_path -name critical -from {ff*/CLK } -to {ff*/D} #create predefined path
group
analyze_paths_by_basic_path_group -predefined
```

  The category "critical" will be created based on the predefined path group name.

Related Topics

The Timing Budgeting chapter of the *Innovus User Guide* document.

analyze_paths_by_bottleneck

```
analyze_paths_by_bottleneck
[-help]
{-category n | -incr_delay {worst|total}}
[-path_num m]
[-max_slack float]
[-min_slack float]
[-master master_category_name]
```

Creates categories according to the bottleneck analysis of the critical paths and fixes the violation according to the bottleneck information. Bottleneck Analysis detects the instances that are often involved in the critical paths in the design. Any change in timing for these instances impacts multiple critical paths in the design. Therefore you can use this information to change your design (floorplan, placement, constraints etc.) around these instances. The bottleneck analysis computes the number of occurrences that an instance appears in the paths that you display in the Timing Debug window, and provides the following output:

- Colors most used instance based on number of occurrences.
- Creates *n* number of path categories for the instances with the highest number of occurrences. *n* is the number you specify using the `-category` parameter.

Users can also perform bottleneck analysis of the critical paths based on incremental delay. Categories will be created based on the worst *m* paths with:

- The biggest worst `incr_delay` contribution
- The biggest total `incr_delay` contribution

The command can be applied wherever the user loads the machine readable timing report. To delete the path categories created by this command, use `delete_path_category`.

For more information on creating path categories, see "Creating Path Categories" in the Debugging Timing Results chapter of *User Guide*.

Note: The categories created by `analyze_paths_by_bottleneck` cannot be saved using the `save_path_categories` command. Additionally, the related sub-categories will not be saved.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `analyze_paths_by_bottleneck` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man analyze_paths_by_bottleneck`
`-category` *n*	Specifies the number of categories to be created for most occurring instances.
`-incr_delay {worst|total}`	Specifies that the categories are created based on worst `incr_delay` contribution or total `incr_delay` contribution.
`-master` *master_category_name*	Specifies that the analysis should be performed only for the specified `master` category.
`-max_slack` *float*	Specifies the max slack value of the critical paths for bottleneck analysis based on incr_delay.
`-min_slack` *float*	Specifies the min slack value of the critical paths for bottleneck analysis based on incr_delay.
`-path_num` *m*	Specifies the number of critical paths to be analyzed when performing bottleneck analysis based on incr_delay.

Examples

- The following command creates path categories based on bottleneck analysis of the critical paths on the instances:
  ```
  analyze_paths_by_bottleneck -category 2
  ```
  The following categories are created: `BOT_instance1` and `BOT_instance2`. You can change the number of categories.
- The following command creates path categories based on bottleneck analysis of the critical 20 paths on the worst incr_delay:
  ```
  analyze_paths_by_bottleneck -path_num 20 -incr_delay worst
  ```
  The following category is created: `BOT_SI_WORST`.

analyze_paths_by_clock_domain

```
analyze_paths_by_clock_domain
[-help]
[-include_edges]
[-include_views]
[-include_mode]
[-master master_category_name]
```

To find the possible timing issues in clock combinations, the command creates categories according to launch clocks - capture clocks combinations.

Following categories are created:

- Paths with clock fully contained in a single domain, clk1.
- Paths with clocks starting one clock domain and ending at another, clk1-> clk2.

The command can be applied wherever the user loads the machine readable timing report by the `load_timing_debug_report` command.

For more information on creating path categories, see "Creating Path Categories" in the Debugging Timing Results chapter of *User Guide*.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `analyze_paths_by_clock_domain` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man analyze_paths_by_clock_domain`
`-include_edges`	Considers leading or trailing edge of the clock while defining categories.
`-include_mode`	Considers constraint mode while defining categories.
`-include_views`	Considers analysis views while defining categories.
`-master` *`master_category_name`*	
	Specifies that the analysis should be performed only for the specified master category.

Examples:

- The following command creates path categories based on clock domain analysis of the critical paths , and considers the edges of the clock:
  ```
  analyze_paths_by_clock_domain -include_edges
  ```
- The following command creates path categories based on clock domain analysis of the critical paths , and considers the analysis views:
  ```
  analyze_paths_by_clock_domain -include_views
  ```

analyze_paths_by_critical_false_path

```
analyze_paths_by_critical_false_path
[-help]
[-critical_false_paths {false_path_only | exclude_false_path}]
[-master string]
```

Identifies violating false paths, which are paths that appear as violations but cannot be exercised due to the structure of the netlist, and creates a category that contains them. With this command the user can, in advance, categorize the critical false paths together to analyze them.

The command can be applied wherever the user loads the machine readable timing report.

For more information on creating path categories, see "Creating Path Categories" in the Debugging Timing Results chapter of *User Guide*.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `analyze_paths_by_critical_false_path` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man analyze_paths_by_critical_false_path`
`-critical_false_paths`	Specifies which paths to analyze. You can select one of the following options: • `false_path_only` Includes only false paths when creating the category. • `exclude_false_path` Excludes false paths when creating the category. *Default*: `false_path_only`
`-master string`	Specifies that the analysis should be performed only for the specified master category.

Examples:

- The following command creates path categories based on the critical false paths:
  `analyze_paths_by_critical_false_path -critical_false_path false_path_only`
- The following category is created: `default_report_false_path_only`

analyze_paths_by_drv

```
analyze_paths_by_drv
[-help]
[[-load_cap_file capacitance_file] | [-generate_cap_file fileName]]
[[-load_tran_file transition_file] | [-generate_tran_file fileName]]
[-load_fanout_file fanout_file | [-generate_fanout_file fileName]]
[-master master_category_name]
```

Reads or generates a report containing max transition, max capacitance, and max fanout violations. Paths that are affected by the selected DRV type are grouped into a category. This command can be used if the user wants to debug the timing issues caused by DRV.

The command can be applied wherever the user loads the machine readable timing report.

For more information on creating path categories, see "Creating Path Categories" in the Debugging Timing Results chapter of *User Guide*.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `analyze_paths_by_drv` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man analyze_paths_by_drv`
`-load_cap_file` *`capacitance_file`*	
	Reads a file containing a list of paths containing max capacitance violations.
`-load_fanout_file` *`fanout_file`*	
	Reads a file containing a list of paths containing max fanout violations.
`-load_tran_file` *`transition_file`*	
	Reads a file containing a list of paths containing max transition violations.
`-generate_cap_file` *`fileName`*	
	Generates a file containing a list of paths containing max capacitance violations.
`-generate_fanout_file` *`fileName`*	
	Generates a file containing a list of paths containing max fanout violations.
`-generate_tran_file` *`fileName`*	
	Generates a file containing a list of paths containing max transition violations.
`-master` *`master_category_name`*	
	Specifies that the analysis should be performed only for the specified master category.

Examples:

The following command generates DRV report files, then creates path categories based on the critical paths which are affected by DRV:

```
analyze_paths_by_drv -generate_cap_file capViolation.rpt

-generate_tran_file tranViolation.rpt
```

```
-generate_fanout_file fanoutViolation.rpt
```

analyze_paths_by_hier_port

```
analyze_paths_by_hier_port
[-help]
{{-gen_hier_file string [-out_file string]} | {-load_hier_file string}}
[-master string]
```

Helps you to automatically group paths based on each hierarchical port of the given instances. You can use this command to perform the timing results analysis of a hierarchical design. For example, while looking at the setup/hold time at the same time of each port.

The command can be applied wherever the user loads timing report. To delete the path categories created by this command, use `delete_path_category`. For more information on creating path categories, see "Creating Path Categories" in the Debugging Timing Results chapter of *Innovus User Guide*.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `analyze_paths_by_hier_port` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man analyze_paths_by_hier_port`
`-gen_hier_file` *string*	
	Generates hier ports fanin/fanout file when the database is available based on the given InstanceName_list. Then uses that file to create the categories.
`-load_hier_file` *string*	
	Uses a previously saved hier ports fanin/fanout file when the database is not available.
`-master` *string*	Specifies that the timing paths should be categorized only for the specified master category.
`-out_file` *string*	Specifies the generated hier ports fanin/fanout file name.

Example

The following command categorizes paths based on hierarchical port of the instance `DTMF_INST/TDSP_CORE_INST`:

```
analyze_paths_by_hier_port -gen_hier_file DTMF_INST/TDSP_CORE_INST
```

stdcell2instgrp ] [-instgrp2port ] [-instgrp2macro ] [-instgrp2bbox ] [-instgrp2hinst ]
[-instgrp2stdcell ] [-instgrp2instgrp ]} | {-partitions string | -macros string}
```

Creates categories according to the hierarchical characteristics of the paths. User can use either a user specified floorplan file or current floorplan file of the design in memory and can create categories according to the hierarchy of the design. This way, the paths can be narrowed down to small group.

Use Floorplan Plan:

The software automatically extracts partition-boundary information from guides, regions, and fences in the floorplan file. Optionally you can specify option to sort paths based on the macros in the floorplan file.

- All paths fully contained in a single partition, Ptn1.
- Paths starting in one partition and ending in another partition, Ptn1–>Ptn2.
- Paths spanning several partitions, Ptn1–> Ptn2–>Ptn3.
- Top-level inputs to partitions, INPUT–>Ptn1.
- Paths from partitions to top-level outputs, Ptn1–>OUTPUT.

Use Current Floorplan:

This method categorizes paths based on the current floorplan of the design in memory. It will rely on the grouped/ungrouped as a basis for what level to view the hierarchy as well as what levels to create timing categories .

Grouped/ungrouped status of an Hinst means whether or not its children are shown on the floorplan view.

It categorizes paths starting and ending on/within these hierarchical entities:

- Port
- Hard Macro (ungrouped)
- Black Box (ungrouped)
- Hinst (regular, partition, Black Blob, or Flex Model) (highest grouped)
- Stdcell (ungrouped)

For more information on creating path categories, see "Creating Path Categories" in the Debugging Timing Results chapter of *User Guide*.

Parameters

`-all`	Creates categories of paths within all types *Default:* All types are categorized.
`-bbox2instgrp`	Creates categories of paths from black box to instance group. *Type:* Bool, optional
`-bbox2port`	Creates categories of paths from black box to port.
`-bbox2macro`	Creates categories of paths from black box to macro.
`-bbox2bbox`	Creates categories of paths from black box to black box.
`-bbox2hinst`	Creates categories of paths from black box to hierarchical instance.
`-bbox2stdcell`	Creates categories of paths from black box to standard cell.
`-fp_file floorplan_file`	Specifies the name of the floorplan file. *Default:* Uses the current floorplan file.

`-help`	Outputs a brief description that includes the type and default information for each `analyze_paths_by_hierarchy` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man analyze_paths_by_hierarchy`
`-hinst2port`	Creates categories of paths from hierarchical instance to port.
`-hinst2macro`	Creates categories of paths from hierarchical instance to macro.
`-hinst2bbox`	Creates categories of paths from hierarchical instance to black box.
`-hinst2hinst`	Creates categories of paths from hierarchical instance to hierarchical.
`-hinst2instgrp`	Creates categories of paths from hierarchical instance to instance group. *Type:* Bool, optional
`-hinst2stdcell`	Creates categories of paths from hierarchical instance to standard cell.
`-include_macros`	Includes macros in addition to guides and fences for creating categories. *Default:* Macros are not considered.
`-instgrp2bbox`	Creates categories of paths from instance group to black box. *Type:* Bool, optional
`-instgrp2hinst`	Creates categories of paths from instance group to hierarchical instance. *Type:* Bool, optional
`-instgrp2instgrp`	Creates categories of paths from instance group to instance group. *Type:* Bool, optional
`-instgrp2macro`	Creates categories of paths from instance group to macro. *Type:* Bool, optional

`-instgrp2port`	Creates categories of paths from instance group to port. *Type:* Bool, optional
`-instgrp2stdcell`	Creates categories of paths from instance group to standard cell. *Type:* Bool, optional
`-macros` *macro_list*	Specifies the names of the macros to be used. Use this parameter with the `-partitions` parameter.
`-macro2instgrp`	Creates categories of paths from macro to instance group. *Type:* Bool, optional
`-master` *master_category_name*	Specifies that the timing paths should be categorized only for the specified master category.
`-partitions` *partition_list*	Specifies the names of the partitions to consider for extracting hierarchical information.
`-port2instgrp`	Creates categories of paths from port to instance group. *Type:* Bool, optional
`-port2port`	Creates categories of paths from port to port.
`-port2macro`	Creates categories of paths from port to macro.
`-port2bbox`	Creates categories of paths from port to black box.
`-port2hinst`	Creates categories of paths from port to hierarchical instance.
`-port2stdcell`	Creates categories of paths from port to standard cell.
`-macro2port`	Creates categories of paths from macro to port.
`-macro2macro`	Creates categories of paths from macro to macro.
`-macro2bbox`	Creates categories of paths from macro to black box.
`-macro2hinst`	Creates categories of paths from macro to hierarchical instance.
`-macro2stdcell`	Creates categories of paths from macro to standard cell.
`-stdcell2port`	Creates categories of paths from standard cell to port.

`-stdcell2macro`	Creates categories of paths from standard cell to macro.
`-stdcell2bbox`	Creates categories of paths from standard cell to black box.
`-stdcell2hinst`	Creates categories of paths from standard cell to hierarchical instance.
`-stdcell2instgrp`	Creates categories of paths from standard cell to instance group. *Type:* Bool, optional
`-stdcell2stdcell`	Creates categories of paths from standard cell to standard cell.
`-types type_list`	Creates categories of paths within the type_list. Valid types are: `port`, `macro`, `bbox`, `hinst`, `stdcell`
`-use_current_floorplan`	Uses the current floorplan.

Examples:

- By default, it categorizes all the paths inter/intra in the 5 hierarchical entities by following command :

  ```
  analyze_paths_by_hierarchy -use_current_floorplan -all
  ```

- The following command categorizes all paths from "port" or to "port":

  ```
  analyze_paths_by_hierarchy -use_current_floorplan -type port
  ```

Related Topics

The Timing Budgeting chapter of the *Innovus User Guide* document.

analyze_paths_by_view

```
analyze_paths_by_view
[-help]
[-prefix string]
[-master master_category_name]
```

Categorizes the timing paths based on views which are included in the timing debug file, also known as the violation report. By arranging the timing information of different views quickly, the command helps in analyzing timing paths.

For more information on creating path categories, see "Creating Path Categories" in the Debugging Timing Results chapter of *User Guide*.

The command can be applied wherever the user loads the machine readable timing report. To delete the path categories created by this command, use `delete_path_category`.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `analyze_paths_by_view` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man analyze_paths_by_view`
`-master` *`master_category_name`*	Specifies that the timing paths should be categorized only for the specified master category.
`-prefix` *`string`*	Adds a prefix to the category name.

Example

The following command categorizes paths based on views, which are included in the timing debug file:

```
analyze_paths_by_view
```

Related Topics

The Timing Budgeting chapter of the *Innovus User Guide* document.

create_histogram_png

```
create_histogram_png
[-help]
[-height integer]
-name string
[-width integer]
```

Dumps out the timing histogram image from global timing debug in the PNG format without bringing up the GUI. It should open the Global Timing Debug window before the execution of the command. Earlier, this was done when the GUI was displayed by right-clicking the histogram window and selecting Snapshot. But that worked only when the snapshot was displayed in the GUI. This command has eliminated the necessity of bringing up the GUI to dump out the timing histogram.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `create_histogram_png` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man create_histogram_png`
`-height integer`	Specifies the height of the PNG image. *Minimum:* `1` *Maximum:* `10000`
`-name string`	Specifies the name of the PNG file.
`-width integer`	Specifies the width of the PNG image. *Minimum:* `1` *Maximum:* `10000`

```

Creates path categories using conditions for grouping paths according to analyzed timing results. The command can be applied wherever the user loads the machine readable timing report. For more information on creating path categories, see "Creating Path Categories" in the Debugging Timing Results chapter of *User Guide*.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `create_path_category` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man create_path_category`
`-clock {both | launch | capture}`	Helps you search the Clock Tree instead of the data path. If this option is not specified, the user searches the data path by default. You can use one of the following values: • `Both`: searches on launch or capture clock paths. • `Launch`: searches only on launch clock paths • `Capture`: searches only on capture clock paths **Note:** Supports simultaneous criteria on data path.

`-comment {`*`commentText`*`}`	Specifies a comment that is associated with the category.
`-master` *`existing_category_name`*	Specifies that the new category should be created as a nested category of the specified master category. The master category should be an existing category. *Default:* If you do not specify this parameter, the category is created as a new category at the top level.
`-name` *`group_name`*	Specifies the name of the category to be created.
`-overwrite`	Overwrites any predefined category with the same name in your category list.
`-sdc {`*`file_name line_number`*`}`	Creates a category based on the SDC constraint as per the specified SDC file name and line number. Creating a path category based on an SDC constraint helps you to analyze the affect of an SDC constraint by grouping the affected paths together.
`-check_type {Setup Check | Hold Check | Clock Gating Setup Check | Library Clock Gating Setup Check | Clock Gating Hold Check | Library Clock Gating Hold Check | External Delay Assertion | Latch Borrowed Time Check | PulseWidth Check | ClockPeriod Check | Recovery Check | Removal Check}`	Indicates that the check type matches the specified option. *Type:* String, optional **Note:** Use quotes (`""`) or curly braces (`{}`) to specify the value of this option.
`-critical_false_path` *`string`*	Specifies the critical false path. *Type:* String, optional
`-file` *`string`*	Specifies the file name. *Type:* String, optional

`-from_inst	-from_inst_pointer	-from_pin	-from_cell	-from_clock	-from_port	-from_port_pointer	-from_pd` *string*	Indicates that the path must be from the specified instance, pin, cell, clock, power domain, or port pattern.
`-from_clock_edge` *string*	Indicates that the path must be from the specified clock edge. *Type:* String, optional
`-incr_delay_of_any_net` *float*	Indicates that the incremental delay of at least a net that matches the specified *float* value.
`-incr_delay_of_every_net` *float*	Indicates that the incremental delay of every net that matches the specified *float* value. *Type:* String, optional
`-not_from_inst	-not_from_pin	-not_from_cell	-not_from_clock	-not_from_port	-not_from_pd string`	Indicates that the path must not be from the specified instance, pin, cell, clock, or port pattern.
`-through_inst	-through_pin	-through_cell	-through_net	-through_port	-through_pd` *string*	Indicates that the path must be through the specified instance, pin, cell, net, power domain, or port pattern.
`-not_from_clock_edge`	Indicates that the path must not be from the specified clock edge. *Type:* String, optional
`-not_through_inst	-not_through_pin	-not_through_cell	-not_through_net	-not_through_port	-not_through_pd` *string*	Indicates that the path must not be through the specified instance, pin, power domain, cell, net, or port pattern.
`-not_to_clock_edge`	Indicates that the path must not be to the specified clock edge. *Type:* String, optional
`-to_inst	-to_inst_pointer	-to_pin	-to_cell	-to_clock	-to_port	-to_port_pointer	-to_pd` *string*	Indicates that the path must be the specified instance, pin, cell, clock, power domain, or port pattern.

`-not_to_inst	-not_to_pin	-not_to_cell	-not_to_clock	-not_to_port	-not_to_pd` *string*	Indicates that the path must not be to the specified instance, pin, cell, clock, power domain, or port pattern.
`-slack` *float*	Indicates that the slack of the path must match the specified *float* value.
`-skew` *float*	Indicates that the skew of the path must match the specified *float* value.
`-launch_latency` *float*	Indicates that the launch latency of the path must match the specified *float* value.
`-capture_latency` *float*	Indicates that the capture latency of the path must match the specified *float* value.
`-uncertainty` *float*	Indicates that the uncertainty of the path must match the specified *float* value.
`-number_of_insts` *integer*	Indicates that the number of instances in the data segment (with launch and capture clock paths) must match the specified *integer* value.
`-number_of_insts_of_name` *string_plus_integer*	Indicates that the number of instances matching the specified instance name match the specified *integer* value.
`-number_of_insts_not_of_name` *string_plus_integer*	Indicates that the number of instances not matching the specified instance name match the specified *integer* value.
`-number_of_insts_of_celltype` *string_plus_integer*	Indicates that the number of instances matching the specified celltype match the specified *integer* value.
`-number_of_insts_not_of_celltype` *string_plus_integer*	Indicates that the number of instances not matching the specified celltype match the specified *integer* value.
`-to_clock_edge`	*Type:* String, optional
`-total_delay_of_insts` *float*	Indicates that the total delay of instances matches the specified *float* value.

-total_delay_of_level_of_chain_of_insttype	*Type:* String, optional
-total_delay_of_path *float*	Indicates that the total delay of path matches the specified *float* value.
-total_delay_of_nets *float*	Indicates that the total delay of nets matches the specified *float* value.
-total_delay_of_insts_of_name *string_plus_float*	Indicates that the total delay of instances matching the specified name matches the specified *float* value.
-total_delay_of_insts_not_of_name *string_plus_float*	Indicates that the total delay of instances not matching the specified name matches the specified *float* value.
-total_delay_of_insts_of_celltype *string_plus_float*	Indicates that the total delay of instances matching the specified celltype matches the specified *float* value.
-total_delay_of_insts_not_of_celltype *string_plus_float*	Indicates that the total delay of instances not matching the specified celltype matches the specified *float* value.
-total_delay_of_nets_of_name *string_plus_float*	Indicates that the total delay of nets matching the specified name matches the specified *float* value.
-total_delay_of_nets_not_of_name *string_plus_float*	Indicates that the total delay of nets not matching the specified name matches the specified *float* value.
-total_incr_delay_of_path *float*	Indicates that the total incremental delay of path matches the specified *float* value.
-delay_of_any_inst *float*	Indicates that the delay of any instance in the design matches the specified *float* value.
-delay_of_any_net *float*	Indicates that the delay of any net in the design matches the specified *float* value.

`-delay_of_every_inst` *float*	Indicates that the delay of every instance in the design matches the specified *float* value.
`-delay_of_every_net` *float*	Indicates that the delay of every instance in the design matches the specified *float* value.
`-delay_of_any_inst_of_name` *string_plus_float*	Indicates that the delay of any instance in the design matching the specified name matches the specified *float* value.
`-delay_of_any_inst_not_of_name` *string_plus_float*	Indicates that the delay of any instance in the design not matching the specified name matches the specified *float* value.
`-delay_of_any_inst_of_celltype` *string_plus_float*	Indicates that the delay of any instance in the design matching the specified celltype matches the specified *float* value.
`-delay_of_any_inst_not_of_celltype` *string_plus_float*	Indicates that the delay of any instance in the design not matching the specified celltype matches the specified *float* value.
`-delay_of_any_net_of_name` *string_plus_float*	Indicates that the delay of any net in the design matching the specified name matches the specified *float* value.
`-delay_of_any_net_not_of_name` *string_plus_float*	Indicates that the delay of any net in the design not matching the specified name matches the specified *float* value.
`-delay_of_every_inst_of_name` *string_plus_float*	Indicates that the delay of every instance in the design matching the specified name matches the specified *float* value.
`-delay_of_every_inst_not_of_name` *string_plus_float*	Indicates that the delay of every instance in the design not matching the specified name matches the specified *float* value.
`-delay_of_every_inst_of_celltype` *string_plus_float*	Indicates that the delay of every instance in the design matching the specified celltype matches the specified *float* value.

`-delay_of_every_inst_not_of_celltype` *`string_plus_float`*	Indicates that the delay of every instance in the design not matching the specified celltype matches the specified *`float`* value.
`-delay_of_every_net_of_name` *`string_plus_float`*	Indicates that the delay of every net in the design matching the specified name matches the specified *`float`* value.
`-delay_of_every_net_not_of_name` *`string_plus_float`*	Indicates that the delay of every net in the design not matching the specified name matches the specified *`float`* value.
`-view`	*Type:* String, optional

Examples:

- The following command categorizes paths whose source clock is `vclk1`:
  ```
  create_path_category -name vclk1 -from_clock vclk1
  ```
  The category `vclk1` is created.
- The following command categorizes paths whose skew is larger than 0.2:
  ```
  create_path_category -name worst_skew -skew {> 0.2}
  ```
  The category `worst_skew` is created.
- The following command creates paths from the macros in the design:
  ```
  create_path_category -name from_RAM_128x16 -from_inst RAM_128x16
  ```
- The following command creates paths to the macros in the design:
  ```
  create_path_category -name to_RAM_128x16 -to_inst RAM_128x16
  ```
- The following command creates paths between the macros in the design:
  ```
  create_path_category -name between_RAM_128_256 -from_inst RAM_128x16 -to_inst
  RAM_256x16
  ```

Related Topics

The Timing Budgeting chapter of the *Innovus User Guide* document.

delete_path_category

```
delete_path_category
[-help]
category_name
```

Deletes the names of the selected categories.

The command can be applied when categories are created in Global Timing Debug.

For more information, see the Debugging Timing Results chapter of *User Guide*.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `delete_path_category` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man delete_path_category`
`category_name`	Specifies the name of the category that is needed to be deleted.

Example

The following command deletes the category `worst_paths`:

```
delete_path_category worst_paths
```

Related Topics

The Timing Budgeting chapter of the *Innovus User Guide* document.

dump_histogram_view

```
dump_histogram_view
[-help]
-name string
[-type string]
```

Saves (dumps) the image of the histogram shown in *Global Timing Debug* automatically during the process.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `dump_histogram_view` parameter. For a detailed description of the command and all its parameters, use the man command: man `dump_histogram_view`.
`-name string`	Specifies the name of the image file to save the histogram.
`-type string`	Specifies the type of file (image format) to be saved. Options are `bmp/jpg/gif/ppm/tif/csv`. *Default*: `bmp`

Related Topics

highlight_timing_report

highlight_timing_report
`[-help]`
`[-append]`
`[-color_index integer]`
`[-file filename ]`
`[-noarrow]`
`[-path path_number | -all]`

This command enables you to highlight a specific number of paths in Global Timing Debug through user interface. The input timing report must be in a machine readable format that is understood by Global Timing Debug. For more information, see the Debugging Timing Results chapter of the *Innovus User Guide* document.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `highlight_timing_report` parameter. For a detailed description of the command and all its parameters, use the man command: `man highlight_timing_report`
`-all`	Highlights all the path in the Global Timing Debug through the user interface.
`-append`	Appends a path to the current highlight.
`-color_index integer`	Specifies the path's color index on a scale of 1 to 8.
`-file filename`	Reads the machine readable file and also specifies the name of the file. The option is of type string and is optional.
`-noarrow`	Removes the highlighted arrow. The option is of type boolean and optional.
`-path path_number`	Specifies the number of the path. The option is of type string and required. It is recommended to use positive integers for specifying the `path_number`.

Example

The following commands generate the worst 1000 paths to a machine readable report, and then highlight the top five paths in Global Timing Debug:

```
report_timing -machine_readable -max_points 1000 > foo.mtarpt
load_timing_debug_report foo.mtarpt
highlight_timing_report -file foo.mtarpt -path "1 2 3 4 5" -noarrow
```

Related Topics

The Debugging Timing Results chapter of the *Innovus User Guide* document.

load_path_categories

```
load_path_categories
[-help]
-filename filename
```

Loads the path category file in the Timing Debug form. The path category file contains category definitions that you saved in an earlier timing debug analysis. To save path categories, use the save_path_categories command.

For more information, see the Debugging Timing Results chapter of *User Guide*.

Note: Before loading the path category file, make sure that the path category name mentioned in the file does not exist in the existing path category list of the debugging session. To overwrite the existing categories, use the `create_path_category -overwrite` parameter for the path category file.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `load_path_categories` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man load_path_categories`
`-filename` *`filename`*	Specifies the name of the category file.

Example

The following command loads the path category file `category.cat`:

```
load_path_categories -filename category.cat
```

Related Topics

The Timing Budgeting chapter of the *Innovus User Guide* document.

load_timing_debug_report

```
load_timing_debug_report
[-help]
[-name report_name]
[{-proto [-additional_slack_past_wns number]  [-num_path number]}]
[-num_path]
filename
```

Loads the violation report in Innovus for debugging timing results.

Note: The violation report that you specify in this command has a special machine readable format. Use the `report_timing -machine_readable` command or `timeDesign-timingDebugReport` command to generate the machine readable violation report.

For more information on timing debug categories, see "Debugging Timing Results" in *Innovus User Guide*.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `load_timing_debug_report` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man load_timing_debug_report`
`filename`	Specifies the name of the timing debug file, also known as the violation report.
`-name`	Specifies the report name to load the machine readable timing report files incrementally. **Note:** The name can be specified using any string; it is not the file name.
`-num_path`	Specifies the number of paths to be reported in the detailed path violations.
`{-proto [-additional_slack_past_wns number]  [-num_path number]}`	
	Creates flex model categories and displays the top path of the top 8 (by default) categories. This option can be used for design that has flexModels. Use `-additional_slack_past_wns` to report all paths with slack worst than (WNS and additional specified slack value). Use `-num_path` to control the number of violation paths.

Examples:

- The following command loads the machine readable timing report `top.mtarpt`:

  ```
  load_timing_debug_report top.mtarpt
  ```

- The following commands load two machine readable timing reports `top1.mtarpt` and `top2.mtarpt` together:

  ```
  load_timing_debug_report -name default_report top1.mtarpt
  load_timing_debug_report -name default_report top2.mtarpt
  ```

  Global Timing Debug (GTD) will first load the report `top1.mtarpt`, then append `top2.mtarpt` incrementally to the current report.

Related Topics

The Timing Budgeting chapter of the *Innovus User Guide* document.

open_gtd

```
open_gtd
[-help]
```

Opens the global timing debugger for accessing the GTD files report.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `open_gtd` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man open_gtd`

save_path_categories

```
save_path_categories
[-help]
-filename filename
```

Saves the selected categories in a path category file. Use the category file to load the saved category definitions in a new timing debug session. To load the saved category definitions, use the `load_path_categories` command.

For more information, see the Debugging Timing Results chapter of *User Guide*.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `save_path_categories` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man save_path_categories`
`-filename filename`	Specifies the name of the saved category file.

Example

The following command saves the path category file `category.cat`:

```
save_path_categories -filename category.cat
```

Related Topics

The Timing Budgeting chapter of the *Innovus User Guide* document.

write_category_summary

```
  write_category_summary
[-help]
-report <string>
[[-ascend | -descend ]
[-byTNS | -byWNS ]]
[-csv | {-no_frame_fix_width [-no_split]}]
```

Writes a text file containing the following information.

- Category name
- Total number of paths
- Number of passing paths
- Number of failing paths
- Worst negative slack
- Total negative slack

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `write_category_summary` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man write_category_summary`
`-ascend`	Specifies that the report in ascending order, should specify option `-byTNS` or `-byWNS`.
`-byTNS`	The TNS value specified by the sorting key through the option `-ascend` or `-descend`.
`-byWNS`	The WNS value specified by the sorting key through the option `-ascend` or `-descend`.
`-csv`	Reports entries in csv format.

`-descend`	Specifies that the report in descending order, should specify option `-byTNS` or `-byWNS`.
`-no_frame_fix_width`	Specifies that the table columns have a fixed minimum width, but no maximum width (the data does not wrap). Column data that fits within the column's minimum width will left-justify and pad its location to fill the specified column space. Column data that is longer than the column's minimum width will take as much space in the table as needed. If a column is overwritten by the data from the preceding column, its data will begin on a new line at the correct column location.
`-no_split`	Specifies that each column follows the preceding column without splitting to a new line, if the data in one column overruns the next column. The wrapping behavior for data is controlled by the size of the display window. This format is useful for machine parsing the report. **Note:** You must specify `-no_frame_fix_width` in order to use this parameter.
`-report fileName`	Specifies the name of the category report file. *Default*: `category.rpt`

Examples

The following command writes a category summary file `category.rpt`:

```
write_category_summary -report category.rpt
```

Below is the sample report generated by the software:

Category name	Total path	Passing Path	Failing path	WNS	TNS

write_path_list_summary

```
  write_path_list_summary
[-help]
[-category string]
[-compress]
[-csv]
-report fileName
```

Writes the Path List categorized summary into a text and/or CSV file.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `write_path_list_summary` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man write_path_list_summary`
`-category string`	Specifies the category of paths to be stored into the CSV file.
`-compress`	Compresses the output file in the `.gzip` file format.
`-csv`	Reports entries in the CSV format.
`-report fileName`	Specifies the name of the output file in text, CSV, or compressed format.

Related Topics

The Timing Budgeting chapter of the *Innovus User Guide* document.

write_text_timing_report

```
write_text_timing_report
[-help]
[-mtarpt file.mtarpt | -category category_name]
[-format{{column1 width1} {column2 width2} ...}]
[-path_specification path_specification]
[-summary]
-report file.tarpt
```

Writes a text file containing information about paths that have been loaded from a `.mtarpt` file from Timing Debug, either with the `load_timing_debug_report command` or in the *Display/Generate Timing Report* form in the GUI.

Paths are selected as follows:

- If only one `.mtarpt` file is loaded and no other parameters are specified, then the tool writes all the paths contained in the loaded `.mtarpt` file.
- If there are several `.mtarpt` files loaded, you must specify the `.mtarpt` file from which the tool can select the paths, except if a category is specified.

You can use this report for performing timing analysis.

If only one machine-readable report file is loaded, then the tool writes all paths from that file into the output report. If more than one file is loaded, then the tools issues an error message.

Note: The generated report cannot be read back into the timing debug environment.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `write_text_timing_report` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man write_text_timing_report`
`-category` *`category_name`*	
	Specifies the category of paths to write to the text file. You cannot specify `-mtarpt` if you specify this parameter.
`-format{{`*`column1 width1`*`} {`*`column2 width2`*`} ...}`	
	Formats the report according to the specified column name and its width. The column-width pair specifies the column to display in the report and the width of that column. Multiple column names can be specified. *Default:* `{{name 35} {arc 10} {cell 10} {delay 10} {slew 10} {load 10} {arrival 10} {required 10}}` Available column list values are: `name arc cell delay slew load arrival required stolen fanout fedge tedge incr_delay type fpin_loc tpin_loc loc pin sum status ir_drop wire_len`
`-mtarpt` *`file.mtarpt`*	
	Specifies the name of the `.mtarpt` file to read and convert to a text file. You cannot specify this parameter if you specify `-category`.
`-path_specification` *`path_specification`*	
	Writes a single number or path range separated by blank space. A path range is two numbers separated by a minus "-" sign. You can use this parameter only if a single file is specified or loaded.
`-report` *`file.tarpt`*	
	Specifies the name of the text output file.
`-summary`	Writes each path file header (endpoint name and slack) only. Use this parameter if you do not need a detailed table.

Examples

- The following command loads machine-readable report `top.mtarpt`:

  ```
  load_timing_debug_report top.mtarpt
  ```

- The following command reads the `top.mtarpt` report and reports paths 1 through 50 in the `top_tarpt.txt` file.

  ```
  write_text_timing_report -mtarpt top.mtarpt -path_specification {1-50} -report
  top_tarpt.txt
  ```

Timing Global Commands

The following commands retrieve and set the timing global variable values:

- get_global
- report_globals
- set_global

get_global

```
get_global
global_variable_name
```

Retrieves the current value of the specified timing global variable. To set the value of a timing global variable, use the set_global command.

For a list of timing global variables, see Timing Global Variables.

Example

The following command retrieves the setting for the `timing_cppr_threshold_ps` global:

```
get_global timing_cppr_threshold_ps
```

report_globals

```
report_globals
[-help]
[pattern]
[-add global_name_list]
```

Generates a list of the officially supported global variables, with their current and default values.

Note: The `report_globals` command is now obsolete. This command will continue to be supported in the current release, but will be removed in the next major release of the software. To search for global variables, you can use the `find_global` command.

Parameters

`-help`	Prints out the command usage.
`-add` *`global_name_list`*	Adds the specified global variables to the generated list of supported global variables. When you use this parameter, the global variables will be included in the generated list along with their registered and current values.
`pattern`	Reports the global variables that match the specified pattern. Pattern matching can be used for application as well as user-specified global variables (registered using the `report_globals -add` parameter).

set_global

```
set_global
global_variable_name
value
```

Sets the specified timing global variable to a specified value. To retrieve the current value of a timing global variable, use the `get_global` command.

For a list of timing global variables, see Timing Global Variables.

Example

The following command sets the `timing_cppr_threshold_ps` global:

```
set_global timing_cppr_threshold_ps 25
```

aocv_chip_size

`aocv_chip_size` *`real_number`*

Default: Automatically calculated from SPEF file, if one is loaded.

Specifies the diagonal length of the chip, in microns.

The chip and core sizes specified with the `aocv_chip_size` and `aocv_core_size` global variables take priority over chip and core size values derived from the SPEF file, or through placement. In the case that there is no SPEF file loaded, or placement information available:

- If you specify `aocv_chip_size` but not `aocv_core_size`, the software considers the core size to

be equal to the `aocv_chip_size` value.

- If you specify `aocv_core_size` but not `aocv_chip_size`, the software ends the AOCV analysis and generates an error message.
- If both `aocv_chip_size` and `aocv_core_size` are not specified, the software ends the AOCV analysis and generates an error message.

To set this global variable, use the set_global command.

aocv_core_size

`aocv_core_size` *`real_number`*

Default: Automatically calculated from SPEF file, if one is loaded.

Specifies the diagonal length of the core area, in microns.

The chip and core sizes specified with the `aocv_chip_size` and `aocv_core_size` global variables take priority over chip and core size values derived from the SPEF file, or through placement. In the case that there is no SPEF file loaded, or placement information available:

- If you specify `aocv_chip_size` but not `aocv_core_size`, the software considers the core size to be equal to the `aocv_chip_size` value.
- If you specify `aocv_core_size` but not `aocv_chip_size`, the software ends the AOCV analysis and generates an error message.
- If both `aocv_chip_size` and `aocv_core_size` are not specified, the software ends the AOCV analysis and generates an error message.

To set this global variable, use the set_global command.

distributed_mmmc_disable_reports_auto_redirection

```
distributed_mmmc_disable_reports_auto_redirection
{true | false}
```

Default: `false`

Allows reports to be generated in the specified location.

When set to `true`, the software does not allow the reports for different views to get overwritten. When set to `false`, the reports are generated automatically in the DMMMC view directory structure.

To set this global variable, use the `set` command.

lib_build_asynch_de_assert_arc

```
lib_build_asynch_de_assert_arc
{true | false}
```

Default: `true`

Controls whether input to output arcs from the preset or clear pins transitioning to inactive state are included when the timing system is initialized.

When the control signal to the preset or clear pins transitions to inactive state (deassertion), in some cases, the output pin can subsequently transition. In the case of edge-triggered flip-flops, the `removal` timing check (a type of hold check) prevents the preset or clear from deasserting too close to the active edge of the clock; therefore, there is usually no chance of the output changing, and no need to have an additional arc to model this transition.

However, in the case of latches, it is possible that the `removal` constraint will still allow the signal to deassert when the latch is in transparent mode. If the input state of the latch is not equivalent to the state previously forced by the preset or clear, an output transition results. In these situations, an additional arc is required to model this transition. A similar corner-case can result when both preset and clear signals are asserted, and one of them is subsequently released.

Note: The `timing_enable_preset_clear_arcs` global variable has higher priority than `lib_build_asynch_de_assert_arc`. If both of these global variables are set to `true`, then all the asynchronous arcs are recognized. If `timing_enable_preset_clear_arcs` is set to `true` and `lib_build_asynch_de_assert_arc` is set to `false`, then only the assert asynchronous arcs are recognized. If `timing_enable_preset_clear_arcs` is set to `false`, then both the assert and de-assert asynchronous arcs will not be recognized.

> Because the `timing_enable_preset_clear_arcs` and `lib_build_asynch_de_assert_arc` global variables affect how the timing graph is built, it is important to set the desired state before performing any timing analysis.

To set this global variable, use the set_global command.

report_precision

`report_precision` *`integer`*

Default: `3`

Controls the number of digits appearing after the decimal point in the `report_timing`, `report_net`, `report_cell_instance_timing`, and `report_clocks` reports. The maximum value of *`integer`* is `8`.

To set this global variable, use the `set_global` command.

report_precision_capacitance

`report_precision_capacitance` *integer*

Default: 3

Controls the number of digits appearing after the decimal point in load values in the timing report output.

To set this global variable, use the `set` command.

report_precision_derate

`report_precision_derate` *integer*

Default: 3

Controls the number of digits appearing after the decimal point in derate values in the timing report output.

To set this global variable, use the `set` command.

report_precision_power

`report_precision_power` *integer*

Default: 3

Controls the number of digits appearing after the decimal point in power values in the timing report output.

To set this global variable, use the `set` command.

report_precision_sensitivity

`report_precision_sensitivity` *integer*

Default: 3

Controls the number of digits appearing after the decimal point in sensitivity values in the timing report output.

To set this global variable, use the `set` command.

report_timing_format

`report_timing_format {column_list}`

Specifies a `report_timing` format. See `report_timing -format` for more information.

Valid format columns are:

adjustment, abs_delay_err, abs_slew_err, annotation, aocv_adj_stages, aocv_derate, aocv_weight, arc, arrival, arrival_mean, arrival_sigma, cell, delay, delay_mean, delay_sigma, direction, edge, fanin, fanout, flags, hpin, incr_delay, instance, instance_location, latch_window, load, module, net, pct_delay_err, pct_slew_err, phase, phys_info, pin, pin_load, pin_location, power_domain, required, retime_delay, retime_delay_mean, retime_delay_sigma, retime_slew, retime_slew_mean, retime_slew_sigma, stage_count, slew, slew_mean, slew_sigma, socv_derate, spice_arrival, spice_delay, spice_slew, stolen, timing_point, total_derate, user_derate, voltage, when_cond, wire_load, wlmodel

For details on these format columns, refer to section Report Timing Column List.

Depending on the options specified, this global variable also enables the display of slew mean and retime slew mean details in the timing report.

For example, the following command tells `report_timing` to only list the instance, arc, delay, slew, arrival times in the report:

```
set_global report_timing_format {instance arc delay slew arrival}
```

To set this global variable, use the `set_global` command.

timing_all_registers_include_icg_cells

```
timing_all_registers_include_icg_cells
{true | false}
```

Default: `true`

Includes integrated clock gating (ICG) cell information from the `all_registers` report output.

When set to `false`, the global does not allow the `all_registers` report output to display ICG cell details.

To set this global variable, use the `set` command.

timing_allow_input_delay_on_clock_source

```
timing_allow_input_delay_on_clock_source
{true | false}
```

Default: `false`

When set to `true`, this global variable allows the software to apply input delay constraints on a pin where a clock was previously asserted.

To set this global variable, use the set_global command.

timing_analysis_precision_ps

```
timing_analysis_precision_ps
{0.1 | 0.01}
```

Default: 0.01 (in ps)

Allows you to set the delay precision value for the `write_sdf` command.

The `write_sdf` command shows a double digit value after the decimal point by default. You can use this global variable for more accuracy.

To set this global variable, you can use the `set` command.

timing_aocv_analysis_mode

```
timing_aocv_analysis_mode
{launch_capture | clock_only | separate_data_clock | combine_launch_capture}
```

Default: `launch_capture`

Controls handling of AOCV analysis modes.

When set to `launch_capture`, AOCV analysis will be performed for both data and clock paths, and the AOCV derating factor will be calculated based on both clock and data path stages.

When set to `clock_only`, AOCV analysis will be performed for clock paths only, and the AOCV derating factor will be calculated based on the clock path stage depth only.

When set to `separate_data_clock`, the software calculates the AOCV stage count for clock paths and data paths separately. Both clock and data paths have related AOCV derating factors.

When set to `combine_launch_capture`, the software calculates AOCV stage count using combined depth for launch and capture paths. This is achieved by summation of path depth on the launch and capture paths.

To set this global variable, use the `set` command.

timing_aocv_derate_mode

```
timing_aocv_derate_mode
{aocv_multiplicative | aocv_additive}
```

Default: `aocv_multiplicative`

Controls the AOCV derating mode.

When set to `aocv_multiplicative`, the derating factor will be calculated as AOCV derating * OCV derating, which is set using the `set_timing_derate` command.

When set to `aocv_additive`, the derating factor will be calculated as AOCV derating + OCV derating values.

When you use this global variable, the `report_timing` command shows the `total_derate` column in the timing report output, which allows you to view and cross-check the calculated total derate factor.

To set this global variable, use the `set_global` command.

timing_aocv_slack_threshold

`timing_aocv_slack_threshold integer`

Default: 0

Data Type: double

Analyzes AOCV slack that is based at the specified threshold.

To use this global variable, use the `set` command.

timing_aocv_stage_count_recalculate_on_timing_reset

```
timing_aocv_stage_count_recalculate_on_timing_reset
{true | false}
```

Default: false

Re-calculates the AOCV stage counts when timing is reset.

To set this global variable, use the `set` command.

timing_apply_check_derate_to_external_output_delay

```
timing_apply_check_derate_to_external_output_delay
{true | false}
```

Default: `false`

Applies check derate to output external delay.

The `set_timing_derate -cell_check` parameter by default does not apply check derate to output external delay (e.g., `set_ouput_delay`). To enable this feature, you can set the `timing_apply_check_derate_to_external_output_delay` timing global variable to `true`. The global applies cell (check) derate to the top boundary port.

To set this global variable, use the set_global command.

timing_apply_default_primary_input_assertion

```
timing_apply_default_primary_input_assertion
{true | false}
```

Default: `true`

When set to `true`, primary input and bidirectional ports that do not have an explicit arrival time specified (through the `set_input_delay` constraint), are provided a default arrival time. The arrival is referenced to an internal default clock that is indicated by the `@` sign in various timing reports.

If a `set_input_delay` constraint is assigned to the input port, but the `-clock` parameter was not specified, the software assumes the constraint to be with reference to the default clock.

When set to `false`, inputs ports with no explicit `set_input_delay` are unconstrained for sequential timing analysis.

To set this global variable, use the set_global command.

timing_apply_exceptions_to_data_check_related_pin

```
timing_apply_exceptions_to_data_check_related_pin
{true | false}
```

Default: `true`

Controls if false path assertions which block the data path to the related (-from) reference pin of the data-to-data check disable the data-to-data check.

When set to `false`, the data-to-data checks remain valid when a false path assertion blocks the data path to the related (-from) pin.

When set to `true`, any false path assertion which blocks the data path to the related (-from) pin of the data-to-data check also causes the check to be disabled.

The global variable has no effect on the data-to-data checks with a reference clock, where an exception blocks the clock reference signal at the reference pin. The data-to-data check will always be disabled in this situation.

To set this global variable, use the `set` command.

Examples

- In the following example, the data-to-data check is disabled:

  ```
  set timing_apply_exceptions_to_data_check_related_pin true
  set_data_check -from portA -to portB
  set_false_path -to portA
  ```

- In the following example, the data-to-data check is valid. This is the default situation:

  ```
  set timing_apply_exceptions_to_data_check_related_pin false
  set_data_check -from portA -to portB
  set_false_path -to portA
  ```

- In this case, the data check is always disabled. and is not affected by this global variables' settings:

  ```
  set_data_check -from portA -to portB
  set_false_path -to [get_clocks ClkA]
  ```

  where the path to `portA` is clocked by `ClkA`.

timing_apply_setup_hold_exceptions_to_data_check_related_pin

`timing_apply_setup_hold_exceptions_to_data_check_related_pin {true | false}`

Default: `true`

Disables the early signal data-to-data paths, when false path is applied on the late reference path.

When set to `true`, the `set_false_path -setup` parameter settings on the reference path disables early signal d2d path, and vice versa. If both the `-setup` and `-hold` parameters are set, the signal early/late d2d path is disabled, irrespective of this global variables settings.

When set to `false`, the `set_false_path` exceptions set on d2d reference path do not affect data path slack. When the `set_false_path` command is set on the reference d2d path with only `-setup` (or only `-hold`) parameter, the signal path of d2d check is not affected by these exceptions.

To set this global variable, use the `set` command.

timing_cap_unit

`timing_cap_unit` *`string`*

Default:" "

Specifies the capacitance units to be used for timing constraints and timing reports. The default unit for capacitance is inferred from the timing libraries. You can override this inference by explicitly setting the value to 1pf or 1ff. Setting this variable explicitly is the same as executing the `setLibraryUnit -cap` command to set the capacitance units.

To set this variable, use the `set` command.

For example,

```
set timing_cap_unit 1pf
```

timing_case_analysis_for_icg_propagation

```
timing_case_analysis_for_icg_propagation
{false | require_seq_prop | always}
```

Default: `false`

Determines the conditions in which the constants are propagated through the integrated clock gating (ICG) cells.

The available options are described below:

Option	Description
`always`	Enables constant propagation through ICGs, regardless of the value of the `timing_case_analysis_for_sequential_propagation` global variable, or the value of `setAnalysisMode -sequentialConstProp` setting. This allows the software to have constant propagation for ICG cells, even when this is disabled for other sequential devices.
`false`	Disables constant propagation through ICG cells.
`require_seq_prop`	When the `require_seq_prop` option is used, the software will treat ICG cells like other cells in the design from the perspective of constant propagation. This means that the `timing_case_analysis_for_sequential_propagation` global variable or `setAnalysisMode -sequentialConstProp` setting will act as a master switch and will control constant propagation through ICGs also.

To set this global variable, use the `set_global` command.

Related Topics

- `setAnalysisMode`
- `timing_case_analysis_for_sequential_propagation`

timing_case_analysis_for_sequential_propagation

```
timing_case_analysis_for_sequential_propagation
{true | false}
```

Default: `false`

Calculates constants on the outputs of sequential elements. When you change setting of this global variable, each time a complete timing update is required and incremental updates are abandoned. If the outputs evaluate to a constant, the check arcs and delay arcs are disabled regardless of the setting.

When this global is set to `true` (or the `setAnalysisMode -sequentialConstProp` parameter is specified), you can set `timing_case_analysis_for_icg_propagation` global variable to `require_seq_prop` to allow propagation of constants through ICG cells.

You can use the `setAnalysisMode -sequentialConstProp` parameter to determine whether constants will be propagated through sequential elements.

Note: The `timing_case_analysis_for_sequential_propagation` global variable should not be used with the `setAnalysisMode` command. This global setting precedes previous settings and controls constant propagation through ICG cells.

To set this global variable, use the set_global command.

timing_case_analysis_propagation

```
timing_case_analysis_propagation
{true | false}
```

Default: `true`

Enables case analysis propagation.

When set to `true`, the software overrides sequential and ICG propagation behavior.

When set to `false`, the software disables case analysis propagation.

To set this global variable, use the `set` command.

timing_check_timing_report_all_checks

```
timing_check_timing_report_all_checks
{true | false}
```

Default: `false`

Enables reporting of all the checks performed by the `check_timing` command.

When set to `true`, the `check_timing` command reports all the checks performed, even if there is no violation(s) for the corresponding check type.

When set to `false`, only the check types that have any violations will be reported.

To set this global variable, use the `set` command.

timing_check_timing_signal_level_high_to_low_threshold

`timing_check_timing_signal_level_high_to_low_threshold` d*ouble*

Default: `0`

Sets the threshold value for warning the signal level difference between driver and receiver voltages, when the driver is at a higher voltage than the receiver voltage.

The software shows the signal level warnings (`check_timing signal_level`) that report the net driver/receiver pin pairs for which the pin voltage does not match. The signal level warning messages can be filtered based on these threshold values.

To set this global variable, use the `set` command.

timing_check_timing_signal_level_low_to_high_threshold

`timing_check_timing_signal_level_low_to_high_threshold` d*ouble*

Default: `0`

Sets the threshold value for warning the signal level difference between driver and receiver voltages, when the driver is at a lower voltage than the receiver voltage.

The software shows the signal level warnings (`check_timing signal_level`) that report the net driver/receiver pin pairs for which the pin voltage does not match. The signal level warning messages can be filtered based on these threshold values.

To set this global variable, use the `set` command.

timing_clock_phase_propagation

```
timing_clock_phase_propagation
{positive | negative | both}
```

Default: `both`

Allows you to select the appropriate clock phases at register clock pins when both positive and negative phases of the same clock signal are seen in the clock network. For example, a register whose clock pin is fed by a two-input XOR gate where one input is a clock port and the other input is a data port. When the value of the data signal of the XOR gate is unknown, the XOR gate can see both positive and negative phases of the clock signal.

`both`	Selects both positive and negative clock phases at the register clock pins.
`positive`	Selects positive clock phases.
`negative`	Selects negative clock phases.

To set this global variable, use the set_global command.

timing_clock_source_use_driving_cell

```
timing_clock_source_use_driving_cell
{true | false}
```

Default: `true`

When set to `false`, delay calculation in propagated clock mode will use an idealized driver model at the `create_clock` root pin or port when it calculates delays for the first stage of the clock tree. The idealized model is a ramp input with the transition time set by the system default transition, which is normally 0ns.

When this variable is set to `true`, the drive characteristics of the cell output pin that `create_clock` is asserted on will be used to calculate the first stage clock tree delays and slews. The input slew used for this driver model is whatever slew has been propagated to the cell's input pins from upstream logic. The arrival time of the clock at the root pin is not modified in any way.

If you wish to specify the input slews to be used for the clock driver cell, that is, not use the upstream propagated slews - you can use the `set_annotated_transition` constraint on the cell's input pins to control this. Setting an input transition of 0ns on the input pins can be useful when trying to correlate analysis results with other applications which do not use the full propagated transition times.

To set this global variable, use the set_global command.

timing_clock_uncertainty_from_to_precedence

```
timing_clock_uncertainty_from_to_precedence
{true | false}
```

Default: `false`

Sets the clock uncertainty precedence.

When set to `true`, the software gives higher precedence to clock-to-clock uncertainty.

To set this global variable, use the `set` command.

timing_collection_all_fanin_fanout_traversal_mode

```
timing_collection_all_fanin_fanout_traversal_mode {true | false}
```

Default: `flat`

Range: `{hierarchical flat}`

Controls how the software processes netlists during `all_fanin`/`all_fanout` command processing.

To set this global variable, use the `set` command.

timing_collection_result_display_limit

`timing_collection_result_display_limit` *integer*

Default: `100`

Limits the number of objects of a collection to be displayed in the output report.

When set to an integer value, all the commands, such as, `get_cells`, `add_to_collection`, `query_objects` etc, that display collection objects in the output report will be impacted.

When set to `-1`, all the elements in the collection will be displayed in the output.

To set this global variable, use the set_global command.

timing_collection_variable_assignment_compatibility

```
timing_collection_variable_assignment_compatibility
{true | false}
```

Default: `true`

Disables printing the names of the output of `get_*` commands.

When set to `false`, the software prints the `get_*` command output on the shell. This global variable should be used for debugging purposes only.

To set this global variable, use the `set` command.

timing_constraint_disable_min_max_input_delay_worst_casing

```
timing_constraint_disable_min_max_input_delay_worst_casing
{true | false}
```

Default: `false`

Disables the override of the maximum value (set using the `set_input_delay -max` parameter) from the specified `-min` value.

To set this global variable, use the `set` command.

timing_constraint_enable_detailed_report_invalid_begin_end_points

```
timing_constraint_enable_detailed_report_invalid_begin_end_points
{true | false}
```

Default: `false`

Enables detailed reporting of invalid begin/end points specified with the `set_false_path`/`set_multicycle_path` constraints.

When set to `false`, the software checks only the structural end points.

To set this global variable, use the `set` command.

timing_constraint_enable_drv_limit_override

```
timing_constraint_enable_drv_limit_override {true | false}
```

Default: `true`

Controls support of the DRV override flow.

When set to `true`, the software allows you to override the limits from other sources, such as, library or constraints. To use this feature, you can specify the `-override` parameter with the following commands:

- `set_max_capacitance`
- `set_max_transition`
- `set_max_fanout`
- `set_min_capacitance`
- `set_min_transition`
- `set_min_fanout`

When specified, the software forces a specific constraint value for the specified list of instance pins, ports, or library cell pins to override the maximum/minimum values set prior to these constraint settings.

To set this global variable, use the `set` command.

timing_constraint_enable_logging

```
timing_constraint_enable_logging {true | false}
```

Default: `false`

Enables saving the constraint commands in the log file.

To set this global variable, use the `set` command.

timing_constraint_enable_report_invalid_begin_end_points

```
timing_constraint_enable_report_invalid_begin_end_points
{true | false}
```

Default: `false`

Enables reporting of invalid begin points/end points specified with `set_false_path` or `set_multicycle_path` constraint.

To set this global variable, use the `set` command.

timing_constraint_enable_search_path

```
timing_constraint_enable_search_path {true | false}
```

Default: `false`

Enables search of constraint files from the search path.

To set this global variable, use the `set` command.

timing_constraint_enable_separate_multicycle_data_checks

```
timing_constraint_enable_separate_multicycle_data_checks {true | false}
```

Default: `false`

Controls multicycle path constraint application on data checks.

To set this global variable, use the `set` command.

timing_constraint_load_minimal_set_for_automated_eco

```
timing_constraint_load_minimal_set_for_automated_eco {true | false}
```

Default: `false`

Skips loading the SDC constraints that are not required, when the `signoffOptDesign` command is used. The timing data is obtained from the ECO timing database - this global variable reduces the TAT for designs with complex constraint mode files.

To set this global variable, use the `set` command.

timing_constraint_path_delay_exclude_check_delay_from_ignore_clock_latency

`timing_constraint_path_delay_exclude_check_delay_from_ignore_clock_latency {true | false}`

Default: `false`

Excludes check arc delays from slack computation.

When set to `true`, the software excludes check arc delays from slack computation for paths constrained by the `set_max_delay`/`set_min_delay` `-ignore_clock_latency` command.

To set this global variable, use the `set` command.

timing_constraint_path_delay_exclude_io_delay_from_ignore_clock_latency

`timing_constraint_path_delay_exclude_io_delay_from_ignore_clock_latency {true | false}`

Default: `false`

Excludes the input/output delays from slack computation.

When set to `true`, the software excludes the input/output delays from slack computation for paths constrained by the `set_max_delay`/`set_min_delay` `-ignore_clock_latency` command.

To set this global variable, use the `set` command.

timing_constraint_path_delay_exclude_unconstrained_endpoints

`timing_constraint_path_delay_exclude_unconstrained_endpoints`

`{true | false}`

Default: `false`

Allows you to configure the valid endpoints.

When path delay exceptions are asserted (using the `set_min_delay` or `set_max_delay` commands) with a complete `-from` and `-to` specification, the exception can be applied between any two data path pins. If the constraint assertion includes only a `-from` and/or `-through` argument, then a set of valid endpoints must be established to define the constrained paths. This global variable allows you to configure the set of valid endpoints (inferred `-to` pins) that are selected.

When set to `false`, the set of allowed endpoints is simply all of the endpoints in the combinational fanout of the `-from` and/or `-through` arguments - essentially, wherever the path tracing stops. The path delay constraint will be applied as if there were a `-to` argument specified for each endpoint.

When set to `true`, the software uses different rules to determine the valid set of inferred `-to` endpoints. Only constrained pins in the fanout of `-from` and/or `-through` arguments are considered as valid `-to` endpoints for the constraint. A constrained endpoint will have some type of timing check - such as Setup or Hold already in force on that pin. Additionally, each transition at the endpoints will be examined to determine if each is individually constrained. The path exception will only be applied to the edges that are constrained. As an example, if a register preset or a clear pin was a potential endpoint, then only the edge constrained by the recovery or removal check will have the path delay applied. To apply the path delay constraint to unconstrained endpoints while in this mode, you must specify them explicitly with the `-to`, `-rise_to`, or `-fall_to` parameters of the `set_min_delay` and `set_max_delay` constraints.

To set this global variable, use the `set` command.

timing_constraint_path_delay_include_clock_pin_endpoints

```
timing_constraint_path_delay_include_clock_pin_endpoints
{true | false}
```

Default: `false`

Considers register clock pins as end-points for path delay constraints applied upstream.

When set to `true`, the `set_max_delay` command considers unconstrained paths ending at the register clock pins.

To set this global variable, use the `set` command.

timing_constraint_update_io_latency_averaging_mode

```
timing_constraint_update_io_latency_averaging_mode
{rise_fall | rise_only}
```

Default : `rise_fall`

Controls the analysis to update IO latency for both rise and fall, or for rise only. You can set one of the options - `rise_fall`, `rise_only`.

To set this global variable, use the `set` command.

timing_constraint_warn_for_timing_derate_exceeding_max_limit

`timing_constraint_warn_for_timing_derate_exceeding_max_limit` *`double`*

Default: 100

Value Range: 0 to 100

Sets a limit on derate values. If a larger derate value is applied, the derates are still processed. However, the software issues a warning.

Note: It is recommended to specify derate values within the acceptable value range, because large derate values may cause errors during processing.

To set this global variable, use the `set` command.

timing_context_apply_default_primary_input_assertion

```
timing_context_apply_default_primary_input_assertion
{true | false}
```

Default : `false`

Propagates the phase at block level for unmapped clocks.

When set to `true`, the nets in the fanout of data ports with unmapped clocks are considered to have infinite timing windows during SI context analysis.

When set to `false`, the unmapped top clock arrivals on data ports are dropped during context analysis.

To set this global variable, use the `set` command.

timing_context_clock_mapping_check_waveform

```
timing_context_clock_mapping_check_waveform
{true | false}
```

Default : `true`

Controls the waveform checking.

To set this global variable, use the `set` command.

timing_context_clock_mapping_percentage_tolerance

```
timing_context_clock_mapping_percentage_tolerance
{true | false}
```

Default : `false`

Controls the tolerance value in clock mapping.

To set this global variable, use the `set` command.

timing_context_port_based_clock_mapping

```
timing_context_port_based_clock_mapping {true | false}
```

Default: `false`

Enables clock mapping based on block ports.

When set to `true`, clock mapping is done depending solely on clock property of the top and block clock for each clock and data port separately. For enabling N-to-1 or 1-to-N clock mapping, this global variable should be set `true`.

When set to `false`, only 1-to-1 clock mapping is done. In such cases, the following rules are used to determine clock mapping:

- Rule1: Clocks with matching property (period/duty cycle)
- Rule2: Clocks with matching name
- Rule3: Clocks present on maximum number common ports
- Rule4: Any one of the matching clocks

To set this global variable, use the `set` command.

For example,

- Consider the following illustration:

  When set to `true`, the following mapping will be seen:

Block Port	Block Clock	Mapped top clock
P1	CLK	CLK, TCLK

  When set to `false`, CLK will be mapped to CLK according to Rule 2.

Notes:

- The context_data property of block port can be accessed only when this global variable is set

`true`.

- When set to `true`, the software may increase the pessimism as the worst latency/arrival will be picked for block context analysis.
- If there are multiple block clocks that can be mapped to same top clock on the same block port, then Tempus does not perform auto mapping (when set to `true`). Whereas for the `false` setting, clock mapping is done depending on the above mentioned rules.

timing_continue_on_error

```
timing_continue_on_error
{true | false}
```

Default: `false`

When set to `true`, the software continues to process if an error occurs when any constraints are used, or during timing analysis, or when a library is read. This global variable does not have any effect on other commands, except constraints or commands related to timing analysis.

When set to `false`, if an error occurs, during timing analysis, library reading, or defined constraints, the software stops processing and exits.

To set this global variable, use the `set` command.

timing_cppr_enable_mismatch_transition_mode

`timing_cppr_enable_mismatch_transition_mode {true | false}`

Default: `true`

Enables CPPR compatibility mode when transitions mismatch at the common pin.

This global variable controls the CPPR adjustment calculations that are computed at the common pin when transitions for the launch and capture paths mismatch at the common pin. The following case scenarios are possible:

- The launch and capture clocks at the common pin are different but match the launch and capture clocks reaching the endpoint, or, launch and capture clock at the common pin are same but different from the launch and capture clocks reaching the end point.
- The launch and capture clocks at the common pin are same and match the launch and capture clocks reaching the endpoint.

The following examples show the behavior for CPPR computations when this global variable is set to `true`:

- Consider a launch path with clock CK1, late rise transition and a capture path with clock GCK1 (related to CK1), early fall transition. The CPPR adjustment is computed by considering the late fall from clock CK1 and early rise from clock GCK1.

  When set to `false` (default), the software considers late fall from clock GCK1 and early rise from clock CK1.
- Consider a launch path with clock CK1, late rise transition and a capture path with clock CK1, early fall transition. The CPPR adjustment is computed by considering the late fall from the launch phase of CK1 and early rise from the capture phase of CK1.

  When set to `false`, the software considers the late fall from capture phase of CK1 and early rise from launch phase of CK1.

The CPPR adjustment is the minimum of the two CPPR adjustments computed for the rise and fall transitions.

All the other combinations of the launch and capture transitions at the common pin for late and early paths will show similar changes to the CPPR adjustment computation - when set to `true`.

To set this global variable, use the `set` command.

timing_cppr_opposite_edge_mean_scale_factor

```
timing_cppr_opposite_edge_mean_scale_factor
{0.0 | 1.0}
```

Default: `1.0`

Controls the mean delay component for CPPR credit for opposite transition edges at a common pin.

When this global variable is specified, the software provides a finer level configuration of the CPPR credit for reducing Common Path Pessimism Removal (CPPR) in timing analysis. The software allows a certain amount of CPPR credit in the case of opposite edge transitions to be scaled to a user-specified value, that is between zero credit or full credit provided by the existing controls.

You can use `timing_cppr_opposite_edge_sigma_scale_factor` global variable for adjustment of the sigma component of the CPPR credit. In SOCV analysis mode, you can use both of these global variables to separately control the adjustment of the mean and sigma components of the CPPR credit. In regular static-timing analysis (STA) mode (without SOCV), only the mean scale factor is considered for CPPR adjustment scaling.

You can use the `set` command to set this global variable.

timing_cppr_opposite_edge_sigma_scale_factor

```
timing_cppr_opposite_edge_sigma_scale_factor
{0.0 | 1.0}
```

Default: `1.0`

Value Range: 0 to 1

Controls the sigma delay component for CPPR credit for opposite transition edges at a common pin.

This global variable provides a finer level configuration of the CPPR credit for reducing Common Path Pessimism Removal (CPPR) in timing analysis.

You can use `timing_cppr_opposite_edge_mean_scale_factor` global variable for adjustment of the mean component of the CPPR credit. In SOCV analysis mode, you can use both of these global variables to separately control the adjustment of the mean and sigma components of the CPPR credit. In static-timing analysis (STA) mode, only the mean scale factor is considered.

You can use the `set` command to set this global variable.

timing_cppr_opposite_edge_sigma_scale_factor_cell

`timing_cppr_opposite_edge_sigma_scale_factor_cell` *double*

Default: `1`

Value Range: 0 to 1

Controls the cell sigma delay component for CPPR credit for opposite transition edges at the common pin.

The scale factors are applicable only when the common pin has mismatched transitions for the launch and capture paths.

To set this global variable, use the `set` command.

timing_cppr_opposite_edge_sigma_scale_factor_net

`timing_cppr_opposite_edge_sigma_scale_factor_net` *`double`*

Default: `1`

Value Range: 0 to 1

Controls the net sigma delay component for CPPR credit for opposite transition edges at the common pin.

The scale factors are applicable only when the common pin has mismatched transitions for the launch and capture paths.

To set this global variable, use the `set` command.

timing_cppr_propagate_thru_latches

```
timing_cppr_propagate_thru_latches
{true | false}
```

Default: `false`

When set to `true`, the CPPR of a timing path crossing a latch (or latches), for example, ff1 -> lat1 -> ff2, is calculated using the common point of the origin device (ff1) and the capture device at the end of the path (ff2).

When set to `false`, the segment-based CPPR calculation is performed, considering the common point of latch (lat1) and the capture device (ff2). This CPPR setting is considered only when the latch thru analysis mode is enabled and a latch thru path exists.

To set this global variable, use the `set` command.

timing_cppr_remove_clock_to_data_crp

```
timing_cppr_remove_clock_to_data_crp
{true | false}
```

Default: `false`

When set to `true`, removes clock reconvergence pessimism (CRP) for clock source paths.

To set this global variable, use the set_global command.

timing_cppr_self_loop_mode

```
timing_cppr_self_loop_mode
{true | false}
```

Default: `true`

When set to `true` in case of self-loop paths, computes CPPR adjustment by taking the difference between early and late clock arrival time of the common point; the clock pin of the flop. A self-loop path is a path that goes from a clock pin of a flop and ends at the data pin of the same flop. However detecting self-loop paths requires runtime, and is design dependant.

When set to `false`, does not detect self-loop paths. In this case, the software computes CPPR adjustment by using the common point as the output pin driving the clock pin of the flop. This might result in better runtime, but less accurate results. The loss of accuracy is the difference between early and late delay of the interconnect portion driving the clock pin.

To set this global variable, use the set_global command.

timing_cppr_skip_clock_reconvergence

```
timing_cppr_skip_clock_reconvergence
    {true | false}
```

Default: `false`

Specifies the branch point to use for computing clock path pessimism removal (CPPR) adjustment when there is reconvergence in the clock tree.

When set to `false`, the software uses the branch point closest to the register clock pins where the clocks reconverge. When set to `true`, the software uses the farthest branch point from the register clock pins (that is, the branch point closest to the clock root pin where the clocks diverge).

Note: The `timing_cppr_skip_clock_reconvergence` and `timing_enable_pessimistic_cppr_for_reconvergent_clock_paths` global variables are mutually exclusive.
Also, the `timing_cppr_skip_clock_reconvergence` global variable has precedence over `timing_enable_pessimistic_cppr_for_reconvergent_clock_paths`.

To set this global variable, use the `set` command.

timing_cppr_skip_clock_reconvergence_for_unmatched_clocks

```
timing_cppr_skip_clock_reconvergence_for_unmatched_clocks {true | false}
```

Default: `false`

Allows the software to skip re-convergence of unmatched clocks.

When set to `true`, the software uses the farthest branch point from the register clock pins when the launching and capturing clocks are different - the re-converge points are ignored and not searched.

To set this global variable, use the `set` command.

timing_cppr_threshold_ps

`timing_cppr_threshold_ps` *`float`*

Default: `20` ps

Specifies the maximum amount of pessimism that clock path pessimism removal (CPPR) analysis is allowed to leave in the path. The unit is pico seconds. Setting this global to a specified value means that all the paths might be reported without having their pessimism removed. This global can be used to speed up CPPR analysis run time. The larger the value of the global, the faster the run time.

To set this global variable, use the set_global command.

timing_cppr_transition_sense

```
timing_cppr_transition_sense
{normal | same_transition | same_transition_expanded}
```

Default: `normal`

Specifies the transition sense of the launching and capturing clocks at the common node, to calculate clock path pessimism removal (CPPR).

When set to `normal`, the CPPR analysis computes the CPPR value even if the launching and capturing clock transitions at the common node are in opposite directions. If the transition sense at the common node are in opposite directions, the pessimism is the minimum of the difference between late and early arrival times for rise and fall clock transitions.

When set to `same_transition`, the CPPR analysis computes the CPPR value only if the launching clock transition is same as the capturing clock transition at the common node. If the transitions are different, the CPPR value is zero.

When set to `same_transition_expanded`, the CPPR analysis computes the CPPR value only if the launching clock transition is the same as the capturing clock transition at the common node. If the transitions are different, the software searches until it finds a common point where the transitions are the same, and calculates the CPPR value from that point.

To set this global variable, use the set_global command.

timing_create_clock_default_propagated

```
timing_create_clock_default_propagated
{true | false}
```

Default: `false`

Enables clocks to be created in propagated mode.

By default, all clocks, created using `create_clock` and `create_generated_clock`, are in ideal mode.

When the global is set to `true`, all subsequently created regular clocks, derived clocks, and library generated clocks are in propagated mode.

There is no effect on the functionality of `set_propagated_clock` and `set_clock_latency` commands.

To set this global variable, use the set_global command.

timing_create_clock_use_ideal_slew

```
timing_create_clock_use_ideal_slew
{true | false}
```

Default: `false`

Enables the use of ideal slew at the inputs of the clock driver cells.

When set to `true`, the software detects created clocks, and uses zero input slew. Other slew values, including those set using set_annotated_transition command, will be ignored.

When set to `false`, the software honors `set_annotated_transition` command settings.

To set this global variable, use the `set` command.

timing_default_opcond_per_lib

```
timing_default_opcond_per_lib
{true | false}
```

Default: `true`

Determines the default operating condition behavior when there is no explicit user operating condition specified through the `setOpcond` command.

When set to `true`, each timing library uses its own internally-defined default operating condition specification.

When set to `false`, the default operating condition of the master library (that is, the first library in the library search list) is used to set the PVT operation point for the entire design. All timing libraries are accessed and derated to that operating point.

To set this global variable, use the set_global command.

timing_defer_mmmc_object_updates

```
timing_defer_mmmc_object_updates
{true | false}
```

Default: `false`

Allows a sequence of MMMC updates to be accumulated before new data is loaded and analyzed.

When set to `false`, the multi-mode multi-corner (MMMC) update commands, `update_constraint_mode` and `update_analysis_view`, actively load new data upon execution. Since all the timing information is reloaded with each update command, executing a sequence of updates can result in multiple reloads and a subsequent degradation of performance and turn-around-time.

If the `set_analysis_view -update_timing` parameter is specified, the software indicates that the MMMC object updates are complete and new configuration can be loaded and analyzed.

For example:

```
tempus > update_constraint_mode -name ioTiming -sdc_files {postCtsIO.sdc}
tempus > update_constraint_mode -name coreTiming -sdc_files {postCtsCore.sdc}
tempus > set_analysis_view -update_timing
```

For example:

```
update_constraint_mode -name ioTiming -sdc_files {postCtsIO.sdc}
update_constraint_mode -name coreTiming -sdc_files {postCtsCore.sdc}
set_analysis_view -update_timing
```

To set this global variable, use the `set` command.

timing_derate_aocv_dynamic_delays

```
timing_derate_aocv_dynamic_delays
{true | false}
```

Default: `true`

Controls AOCV derating of SI-induced delays.

When set to `false`, AOCV derates will not be applied on dynamic, SI-induced delays, that is, a value of `false` ensures AOCV derating is only applied to the static component of the delay.

When set to `true`, AOCV derating is applied to both static and dynamic arc delay components.

To set this global variable, use the `set_global` command.

timing_derate_aocv_reference_point

```
timing_derate_aocv_reference_point {1 | 0}
```

Default: `1`

Allows specification of reference point for AOCV factors. As per the current AOCV library definitions, the AOCV reference point is always expected to be set at `1.0`.

To set this global variable, use the set_global command.

timing_derate_dynamic_compatibility

```
timing_derate_dynamic_compatibility
{1 | 0}
```

Default: `1`

Controls how the `set_timing_derate` command factors that are not specified, using either `-static` or `-dynamic` options, are applied to the delay.

When this global is set to `1`, the behavior will be compatible with previous releases. In this mode, the static and dynamic components will be summed up before applying derating.

When set to 0, the static and dynamic components will be derated separately and then combined. A setting of 0 is equivalent to using separate derate assertions with the `-dynamic` and `-static` options explicitly specified.

To set the global variable, use the `set` command.

timing_derate_incremental_adjust_additive_mode

```
timing_derate_incremental_adjust_additive_mode
{true | false}
```

Default: `false`

Allows the software to accumulate incremental derate values instead of overwriting them.

When set to `false`, the successive application of incremental derating will overwrite any existing derate value with the new value.

When set to `true`, the successive application of the incremental derates will be accumulated into a final derate value.

To set this global variable, use the `set` command.

timing_derate_incremental_multiply_accumulative_mode

```
timing_derate_incremental_multiply_accumulative_mode
{true | false}
```

Default: `false`

Controls the overwrite or accumulative mode settings when the `set_timing_derate -multiply` parameter is specified. You can use this global variable when the `timing_derate_enable_incremental_multiplication_mode` is set to `true` (that is, `-multiply` support is enabled).

When set to `false`, the latest `set_timing_derate -multiply` command will overwrite the previous constraints at the same level.

When set to `true`, all the values in history will be accumulatively multiplied, when multiple `set_timing_derate -multiply` settings are made on the same object.

To set this global variable, use the `set` command.

Examples

- The following example shows that in overwrite mode, the multiplicative adjustment will be updated to 0.5:

```
set_global timing_derate_enable_incremental_multiplication_mode true
set_global timing_derate_incremental_multiply_accumulative_mode false
set_timing_derate -multiply 1.2
set_timing_derate -multiply 0.5
```

- The following example shows that in accumulative mode, the multiplicative adjustment will be updated to 1.2*0.5=0.6:

```
set_global timing_derate_enable_incremental_multiplication_mode true
set_global timing_derate_incremental_multiply_accumulative_mode true
set_timing_derate -multiply 1.2
set_timing_derate -multiply 0.5
```

timing_derate_negative_delay_backward_compatibility

`timing_derate_negative_delay_backward_compatibility {true | false}`

Default: `true`

Controls the effective derate calculation for negative delays. When effective derate is requested for negative delays, the value will be converted according to the negative delay scaling rule, e.g., 2 - positiveVal.

To set this global variable, use the `set` command.

timing_derate_ocv_reference_point

```
timing_derate_ocv_reference_point {1 | 0}
```

Default: `1`

Allows specification of reference point for OCV factors. As per the current OCV library definitions, the OCV reference point is always expected to be set at `1.0`.

To set this global variable, use the set_global command.

timing_derate_spatial_distance_unit

```
timing_derate_spatial_distance_unit
{default | 1um | 1nm}
```

Default: `default`

Specifies distance units in the SOCV and AOCV library formats.

This global variable supports 3 distance units - `default`, `1um`, and `1nm`. The default value is the default units that are derived from the current system units for distance (um/nm overrides the default).

To set this global variable, use the `set` command.

Note: The `timing_derate_spatial_distance_unit` global variable should be set before a design is loaded.

timing_derate_voltage_scaling_mode

```
timing_derate_voltage_scaling_mode {first_library | snap_to_nearest | interpolate}
```

Default: `first_library`

Controls how timing derates are computed when the analysis voltage is not at the characterization voltage of any of the currently loaded timing libraries. When the timing analysis environment is configured for interpolation, the MMMC library set will contain a list of timing libraries at different voltage characterizations points.

You can specify the following options:

`first_library`	Derates associated with the first library in the timing library list will be used.
`snap_to_nearest`	Allows the software to choose one set of derates from the library closest to the required analysis voltage.
`interpolate`	Allows the timer to perform interpolation of the derates associated with the two bounding reference libraries.

Consider the following example:

```
create_library_set -name ls_interp_1.50V_1.80V
-timing [list stdcell_1.50V.lib stdcell_1.75V.lib stdcell_1.80V.lib]
```

In this example, by default (`first_library`) the derates associated with the library stdcell_1.50V.lib will be used.

When set to `snap_to_nearest`, if the analysis voltage is 1.70V, the derates from the library stdcell_1p75V.lib will be used.

When set to `interpolate`, if the analysis voltage is 1.60V, then interpolation of derates from the libraries stdcell_1.50V.lib and stdcell_1.75V.lib will be used.

If interpolation mode is selected and the analysis voltage is beyond either the smallest or largest voltage, then the library derates will not be interpolated. The derates associated with the nearest bounding library will be used. If the analysis voltage is 1.90V, then only the derates from stdcell_1.80V.lib will be used.

If interpolation mode is enabled, but not all the bounding libraries have derate values, a default derate value of 1.0 will be assumed for the missing derates and used for interpolation. A TA-960 warning message will also be issued.

To set this global variable, use the `set` command.

timing_disable_bidi_output_timing_checks

```
timing_disable_bidi_output_timing_checks
{true | false}
```

Default: `true`

When set to `false`, timing checks on both the input and output sides of the bidirectional pin are analyzed.

When set to `true`, the software disables timing checks on the output side of bidirectional pins.

To set this global variable, use the set_global command.

timing_disable_black_box_endpoints

```
timing_disable_black_box_endpoints {true | false}
```

Default: `false`

Ignores any boundary model endpoints on black box instances.

When set to `false`, the fanout logic from the block's input ports is traced for storing as timed logic within the boundary model. If a pin is reached with no outgoing timing arcs, this is considered an endpoint of the model and the fanin to that endpoint will be included in the model.

When set to `true`, such pins are ignored when they are on cells for which no timing or LEF cell definition was loaded. This is intended to make the model generation more tolerant of missing libraries in cases where the power/ground connectivity is included in the netlist.

To set this global variable, use the `set` command.

timing_disable_bus_contention_check

```
timing_disable_bus_contention_check
{true | false}
```

Default: `false`

When set to `true`, disables propagation of maximum delay along three state disable timing arcs and minimum delay along three state enable arcs. If you know that bus contention conditions do not occur in your design, disable these checks by setting these globals to `true`.

Checks for setup and hold violations in three-state bus designs. Checks the worst delay path to ensure that the latched signals are stable and not unknown values - X. Ensures proper timing checks for bus contention.

To set this global variable, use the set_global command.

timing_disable_clock_gating_checks

```
timing_disable_clock_gating_checks
{true | false}
```

Default: `false`

When set to `true`, disables all clock gating checks, including those declared in the library on integrated clock gating cells, and those that are inferred on combinational gates in the clock path.

To set this global variable, use the set_global command.

Note: The `timing_disable_clock_gating_checks` global variable should not be used with the `setAnalysisMode` command.

If the `setAnalysisMode -clockGatingCheck` parameter is specified, then you need to set this global variable to `true`.

timing_disable_clockperiod_checks

```
timing_disable_clockperiod_checks
{true | false}
```

Default: `false` (performs checks)

When set to `true`, disables timing model clock period checks during timing analysis.

To set this global variable, use the set_global command.

timing_disable_constant_propagation_for_sequential_cells

```
timing_disable_constant_propagation_for_sequential_cells
{true | false}
```

Default: `false`

Controls constant propagation across sequential cells.

When set to `true`, the software disables constant propagation across sequential cells.

When set to `false`, the software enables constant propagation across sequential cells.

To set this global variable, use the `set` command.

timing_disable_drv_reports_on_constant_nets

```
timing_disable_drv_reports_on_constant_nets
{true | false}
```

Default: `false`

Disables DRV checks for nets that are disabled by constant propagation.

When set to `true`, the `report_constraint` command does not report DRV violations for constant nets.

To set this global variable, use the `set` command.

timing_disable_floating_bus_check

```
timing_disable_floating_bus_check
{true | false}
```

Default: `false`

When set to `true`, disables propagation of minimum delay through three state disable timing arcs and maximum delay through three state enable arcs. These checks are only valid during floating bus conditions.

To set this global variable, use the set_global command.

timing_disable_genclk_combinational_blocking

```
timing_disable_genclk_combinational_blocking
{true | false}
```

Default: `false`

Disables blocking of the latency path for a generated clock.

When set to `true`, allows the latency path to traverse through the upstream generated clock.

When set to `false`, if two back-to-back generated clocks are on the same path, and if the downstream generated clock is set using the `create_generated_clock -combinational` parameter, then the latency path for this generated clock is blocked by the upstream clock. The downstream generated clock is created with zero latency.

The software shows a warning if the source latency path to the upstream generated clock cannot be found. For example,

```
**WARN: (TA-1018): A source latency path to the generated clock GC2 through source pin
clk1 to target pin GC2_1/Y in view default_emulate_view cannot be found. Timing
analysis will use 0 ns source latency for the generated clock and will interpret the
master clock based on the polarity at the master clock source pin.
```

To set this global variable, use the `set` command.

timing_disable_inferred_clock_gating_checks

```
timing_disable_inferred_clock_gating_checks
{true | false}
```

Default: `false` (performs checks)

When set to `true`, disables clock gating checks that are inferred on combinational elements in the clock path. Explicit clock gating checks that are described in the timing library are not affected by this global variable.

To set this global variable, use the set_global command.

timing_disable_internal_inout_cell_paths

```
timing_disable_internal_inout_cell_paths
{true | false}
```

Default: `true`

When set to `false`, enables internal bidirectional feedback paths that are completely contained in one instance.

To set this global variable, use the set_global command.

timing_disable_internal_inout_net_arcs

```
timing_disable_internal_inout_net_arcs
{true | false}
```

Default: `true`

When set to `true`, this global disables internal bidirectional feedback paths that span multiple instances.

When set to `false`, this global enables internal bidirectional feedback paths, which are feedback paths that you might not want to use during analysis and optimization.

This global applies only to paths that span multiple instances. The global has no impact on internal feedback paths that are completely contained in one instance.

To set this global variable, use the set_global command.

timing_disable_lib_pulsewidth_checks

```
timing_disable_lib_pulsewidth_checks
{true | false}
```

Default: `false` (performs checks)

When set to `true`, disables timing model pulse width checks during timing analysis.

To set this global variable, use the set_global command.

timing_disable_library_data_to_data_checks

```
timing_disable_library_data_to_data_checks
{true | false}
```

Default: `false`

When set to `true`, this global disables data-to-data checks that are coded in the library as non-sequential timing checks. Data-to-data checks are distinguished from other non-sequential timing checks because both the reference pin and constrained pin side of the timing check are data pins rather than clock pins. You should use the `timing_disable_non_sequential_checks` global to control other types of non-sequential checks where the reference pin is a clock pin.

To set this global variable, use the set_global command.

timing_disable_library_tiehi_tielo

```
timing_disable_library_tiehi_tielo
{true | false}
```

Default: `false`

Disables constant functions in a library.

When set to `false`, the software considers constant propagation from library tie high/low cells prior to those from logical netlist and constraints. There may be cases where programmable tie cells are used whose value can be changed later in the flow, assuming the programmable tie cells are modelled with constant output functions.

When set to `true`, the library constants are not propagated during timing analysis or timing optimization.

To set this global variable, use the set_global command.

timing_disable_netlist_constants

```
timing_disable_netlist_constants
{true | false}
```

Default: `false`

When set to `true`, ignores constants defined in the Verilog netlist. This includes all uses of the in-place constant notation, such as `1'b0`, and the use of power and ground nets. Constants from `set_case_analysis` assertions and from tie-hi and tie-lo cells are still recognized.

When set to `false`, the software recognizes all constants.

To set this global variable, use the set_global command.

timing_disable_nochange_checks

```
timing_disable_nochange_checks
{true | false}
```

Default: `false` (performs checks)

When set to `true`, disables no change timing model checks during timing analysis.

To set this global variable, use the set_global command.

timing_disable_non_sequential_checks

```
timing_disable_non_sequential_checks
{true | false}
```

Default: `false`

When set to `true`, disables the timing arcs between any data-to-clock or clock-to-clock checks which have a `timing_type` attribute equal to one of the following:

- `non_seq_setup_rising`
- `non_seq_setup_falling`
- `non_seq_hold_rising`
- `non_seq_hold_falling`

This global only affects non-sequential checks where the reference pin of the timing check is a clock pin. Data-to-data checks - where the reference pin of the timing check is a data pin - are not affected by this global. To disable data-to-data checks you must use the `timing_disable_library_data_to_data_checks` global.

To set this global variable, use the set_global command.

timing_disable_output_as_clock_port

```
timing_disable_output_as_clock_port
{true | false}
```

Default: *false*

Allows a clock path to be considered as a data path.

When set to `true`, this global causes a clock source path, leading to an output or bidi port, to be treated as a data path, irrespective of any constraint like `set_output_delay`, `set_data_check`, or `set_max_delay` asserted on that port.

To set this global variable, use the set_global command.

timing_disable_parallel_arcs

```
timing_disable_parallel_arcs
{true | false}
```

Default: `true`

Enables the software to automatically perform reduction of parallel delay arcs and check arcs to improve efficiency.

When set to `false`, parallel delay and check arc reduction will be disabled.

To set this global variable, use the `set` command.

timing_disable_pulsewidth_same_edge_si_cppr_mode

`timing_disable_pulsewidth_same_edge_si_cppr_mode`
`{true | false}`

Default: `true`

Enables SI CPPR credit up to the last divergent pin for pulse width checks for zero width pulse clocks. By default, the software credits minimum of rise and fall transition CPPR up to the common pin as the transitions mismatch at the common pin.

When set to `true`, the software computes base delay CPPR up to the common pin as CPPR credit for the path. The software then finds an alternate common timing pin in the clock network where the transition for launch and capture match. If a match is found, the software includes the SI delay up to this pin in the CPPR credit as well.

To set this global variable, use the `set` command.

timing_disable_recovery_removal_checks

```
timing_disable_recovery_removal_checks
{true | false}
```

Default: `false` (performs checks)

When set to `true`, disables recovery and removal timing model checks during timing analysis.

To set this global variable, use the set_global command.

timing_disable_report_header_info

```
timing_disable_report_header_info {true | false}
```

Default: `false`

Controls whether timing reports are generated using a common report header.

When set to `false`, the software generates timing reports with a report header that includes the following information:

- Innovus software version number
- Platform on which the software is being run
- Time when the report was generated
- Command used to generate the report

Any report-specific banner information is included in the same header box, but listed after the common header information.

When set to `true`, the software generates backward-compatible timing reports without the additional header information.

To set this global variable, use the set_global command.

timing_disable_retime_clock_path_slew_propagation

```
timing_disable_retime_clock_path_slew_propagation
{true | false}
```

Default: `true`

When set to `true`, path based analysis is performed on data paths only and the clock segments are not considered.

When set to `false`, analysis is performed on both data and clock paths.

To set this global variable, use the `set` command.

timing_disable_sdf_retain_arc_merging

```
timing_disable_sdf_retain_arc_merging
{true | false}
```

Default: `false`

Controls handling of retain arcs in SDF2.1.

When set to `false`, the Retain information is merged into SDF 2.1, as Retain represents a valid minimum path timing for a cell.

When set to `true`, the Retain arc merging will be disabled.

To set this global variable, use the set_global command.

timing_disable_skew_checks

```
timing_disable_skew_checks
{true | false}
```

Default: `false`

When set to `true`, disables library skew checks for timing analysis.

To set this global variable, use the set_global command.

timing_disable_test_signal_arc

```
timing_disable_test_signal_arc
{true | false}
```

Default: `false`

When set to `true`, timing analysis will not analyze the signal arcs coming from or going to the test pin. Such pins are marked in the timing library with either the `test_scan_in`, the `test_scan_enable` attribute for the input pin, the `test_scan_clock` attribute for the input clock pin, or the `test_output_only` attribute for the output pin.

The following are the equivalent Liberty and TLF pin attributes:

Table 41-1 Liberty and TLF Pin Attributes

Type	Liberty TLF
enable	`test_scan_enable` `SCAN_PINTYPE` (ENABLE)
input	`test_scan_in` `SCAN_PINTYPE` (INPUT)
input clock	`test_scan_clock` `SCAN_PINTYPE` (CLOCK)
output	`test_output_only` `SCAN_PINTYPE` (OUTPUT)

To set this global variable, use the set_global command.

timing_disable_timing_model_latch_inferencing

```
timing_disable_timing_model_latch_inferencing
{true | false}
```

Default: `true`

Controls whether latch behavior is inferred for cell descriptions tagged with the Liberty `timing_model_type` attribute, including all values: `abstracted`, `extracted`, or `qtm`.

When set to `false`, the software infers latch behavior from the timing check and timing delay arc relationships in the model's description.

When set to `true`, latch inferencing does not happen for cells with the `timing_model_type` attribute. Explicit Liberty latch modelling constructs must be coded into the description in order to model latch behavior.

This global does not affect Liberty timing model cells that do not contain the `timing_model_type` attribute. Standard cell core libraries generally do not have this attribute specified; therefore, they typically are not be affected by this global setting.

To set this global variable, use the set_global command.

timing_disable_tristate_disable_arcs

```
timing_disable_tristate_disable_arcs
{true | false}
```

Default: `false`

When set to `true`, disables all 0/1->Z transitions of tristate arcs during timing analysis. By default, all tristate arcs are enabled.

To set this global variable, use the set_global command.

timing_disable_user_data_to_data_checks

```
timing_disable_user_data_to_data_checks
{true | false}
```

Default: `false`

When set to `true`, disables data to data checks that are created by the `set_data_check` command. This global variable does not affect non-sequential timing checks described in the timing library.

To set this global variable, use the set_global command.

timing_driving_cell_override_library

```
timing_driving_cell_override_library
{true | false}
```

Default: `false`

Controls the selection of library cells specified using the `set_driving_cell` command.

When set to `true`, a driving cell will be picked up from the Max Library for max drive cell adjustment and Min Library for min drive cell adjustment, irrespective of the library specified with the `set_driving_cell -library` parameter.

When set to `false`, the libraries are selected as specified with the `set_driving_cell` command.

To set this global variable, use the set_global command.

timing_dynamic_loop_breaking

```
timing_dynamic_loop_breaking
{true | false}
```

Default: `false`

Enables dynamic loop breaking.

By default (`false`), when the timing engine encounters combinational loops in the design, it breaks the loop by disabling a timing arc along the path. The heuristics used in breaking the loop cannot guarantee that a real path through the disabled arc will not be blocked as a consequence. Therefore, users must carefully investigate the arcs that have been disabled to ascertain that the loop break was done safely. If loop breaks are not then added to the master constraint file, they could move to other locations as the design matures.

When set to `true`, the timing system performs a more sophisticated analysis of the design, and ensures that no valid paths are broken inadvertently due to loops.

Note: Setting this global variable to `true` will add additional run time to the analysis.

To set this global variable, use the set_global command.

timing_enable_all_fanin_fanout_levels_compatibilit y

```
timing_enable_all_fanin_fanout_levels_compatibility
{true | false}
```

Default: `true`

Enables computation of gate level count (for `all_fanout`/`all_fanin` commands) when an input pin is specified using the `all_fanout -from` parameter and output pin is specified using the `all_fanin -to` parameter. When the initial gate is traversed, the count is computed as 1.

When set to `false`, the global computes the gate level count as 0.

To set this global variable, use the set_global command.

timing_enable_aocv_slack_based

`timing_enable_aocv_slack_based {0 | 1}`

Default: 0

Enables AOCV analysis using slack-based method.

When set to `true`, the software will try to remove excess pessimism from the graph-based analysis (GBA) AOCV stage counts. The paths to endpoints, which are under the specified slack criteria (default 0.0 ns), are considered when computing stage counts. This allows the stage counts and subsequent AOCV derates to be aligned with the failing paths – and not unnecessarily punished by derates coming from related short paths that meet timing requirements.

Note: A `true` setting is recommended when performing Setup optimizations in Innovus – where over pessimism can cause sub-optimal results.

See `timing_aocv_slack_threshold`.

To use this global variable, use the `set` command.

timing_enable_case_analysis_conflict_warning

```
timing_enable_case_analysis_conflict_warning
{true | false}
```

Default: `true`

Displays a warning when propagated and asserted constant values are not the same when a full timing update is performed.

When set to `true`, a report file, named `CTE_constant_mismatch.rpt`, is generated that contains details of pins and the reason for constant mismatch. This report is over-written each time a full timing update takes place.

To set this global variable, use the set_global command.

timing_enable_clock2clock_clockgating_check

```
timing_enable_clock2clock_clockgating_check
{true | false}
```

Default: `false`

Enables clock-to-clock clock gating checks.

When set to `true`, the software performs clock to clock gating checks at gating elements. For clock to clock gating checks, the frequency of a clock arriving at the reference side of a check should be equal to or greater than the frequency of the clock arriving at the signal side of the check.

To set this global variable, use the `set_global` command.

timing_enable_clock_phase_based_rise_fall_derating

```
timing_enable_clock_phase_based_rise_fall_derating
{true | false}
```

Default: `false`

Determines the interpretation of edge-specific derating factors for clock paths, specified using the `set_timing_derate -rise/-fall` parameters.

When set to `false`, the `set_timing_derate -rise/-fall` parameter refer to the direction of the transition from the perspective of each individual output pin along the clock path.

When set to `true`, the `-rise/-fall` parameter refers to which edge (or phase) of the clock is triggering the transition as viewed from the source of the clock where the clock waveform is defined.

To set this global variable, use the set_global command.

timing_enable_data_through_clock_gating

```
timing_enable_data_through_clock_gating
{true | false}
```

Default: `true`

When set to `false`, blocks signals arriving on the enable of the clock-gating check.

When set to `true`, allows both data and clock signals at the enable pin of a clock-gating check to propagate forward past the check.

To set this global variable, use the set_global command.

timing_enable_derating_for_pulsewidth_checks

```
timing_enable_derating_for_pulsewidth_checks
{true | false}
```

Default: `false`

Controls whether the cell check derates, set by `set_timing_derate -cell_check` command, can be applied for pulse width checks.

When set to `true`, the pulse width checks honor cell check derate factors.

To set this global variable, use the `set_global` command.

timing_enable_early_late_data_slews_for_setuphold_mode_checks

```
timing_enable_early_late_data_slews_for_setuphold_mode_checks
{true | false}
```

Default: `false`

Controls calculated delays.

When set to `true`, the software allows use of both the minimum and maximum data slews for setup and hold checks. By default, the minimum or maximum slew values for clock pins are considered, and for data pins only the maximum slew value is considered while calculating the setup/hold timing check values.

This global variable enables an eight-way timing check for:

- Early/late libraries
- Clock/data pins
- Min/max slews

You can use this global variable in simultaneous setup or hold mode only. To enable this mode, you need to set `timing_enable_simultaneous_setup_hold_mode` to `true`. In this mode, you can use the `reportDelayCalculation` command (`-from` and `-to` parameters) to report all the setup/hold check values corresponding to minimum/maximum combination of clock and data slews.

To set this global variable, use the `set_global` command.

timing_enable_genclk_divide_by_inherit_parent_duty_cycle

```
timing_enable_genclk_divide_by_inherit_parent_duty_cycle
{true | false}
```

Default: `false`

Controls inheritance of duty cycle from master clock for generated clocks (generated using the `create_generated_clock -divide_by` parameter).

To set this global variable, use the `set` command.

timing_enable_genclk_edge_based_source_latency

```
timing_enable_genclk_edge_based_source_latency
{true | false}
```

Default: `true`

Controls how the software chooses generated clock source latency paths. Certain specifications of the `create_generated_clock` constraint imply a cause-and-effect relationship between the edges of the master clock and those of the generated clock.

When set to `true`, the software checks whether a path being analyzed has the correct cause-effect relationship consistent with the specified constraint. Paths that are found to be inconsistent are ignored. Only the paths that are in agreement with the required edge relationship are considered for source latency. If no such path exists, the software uses a source latency of `0` ns. This selection is done independently for each edge of the generated clock; therefore the result might be different for each edge.

The edge-to-edge sufficiency checks are performed assuming a Rise-to-Rise, Rise-to-Fall relationship between the master clock and the generated clock with an even number `-divide_by` factor. For the odd `-divide_by` factors, the sufficiency check is performed assuming a Rise-to-Rise, Fall-to-Fall relationship. The sufficiency checking is not performed for `-multiply_by` options.

When set to `false`, the software does not check paths for the correct cause-effect relationship.

To set this global variable, use the set_global command.

timing_enable_genclk_source_path_register_limit

```
timing_enable_genclk_source_path_register_limit
{true | false}
```

Default: `false`

Limits the generated clock source latency path to traverse across one register only.

When set to `false`, the software allows master clock latency path to traverse across any number of sequential devices to reach the generated clock target pin.

When set to `true`, the software restricts the master clock latency path for a generated clock to traverse exactly one sequential device.

To set this global variable, use the `set` command.

timing_enable_get_object_escaped_name_backward_compatible

```
timing_enable_get_object_escaped_name_backward_compatible
{true | false}
```

Default: `false`

Enables printing of escape characters in the `get_object_name` command output.

When set to `false`, the `get_object_name` command does not print escape characters (starting with a backslash) in the object name.

To set this global variable, use the set_global command.

timing_enable_get_objects_regexp_compatibility

```
timing_enable_get_objects_regexp_compatibility {true | false}
```

Default: `false`

Defines the pattern search scope to boundaries deduced from hierarchy separation characters specified in the search pattern.

When set to `false`, the commands with `-regexp` parameter will search at the top level only (unless used with the `-hier` parameter).

When set to `true`, the commands will search the specified pattern within the hierarchies based upon the given pattern hierarchy (similar to pattern search without the `-regexp` parameter). The `-hier` along with the `-regexp` parameter shows the same behavior similar to when the command is used without the `-regexp` option - only the leaf level object name is compared to the pattern match.

To set this global variable, use the `set` command.

Examples

Command behavior when this global variable is `false`:

```
get_pins -regexp seg2/.*/QN
**WARN: (TCLCMD-513): The software could not find a matching object of the specified
type for the pattern '.*/.*'
**ERROR: (TCLCMD-917): Cannot find 'pins' that match 'seg2/.*.*/QN'

get_pins -regexp seg2/.*/QN -hier
seg2/u3/QN seg2/u9/QN seg2/u14/QN

get_pins -regexp .*/QN -hier
seg1/u3/QN seg1/u9/QN seg1/u14/QN seg2/u3/QN seg2/u9/QN seg2/u14/QN seg3/u3/QN
seg3/u9/QN seg3/u14/QN u2/QN u5/QN u8/QN
```

Command behavior when this global variable is `true`:

```
get_pins -regexp seg2/.*/QN
seg2/u3/QN seg2/u9/QN seg2/u14/QN

get_pins -regexp seg2/.*/QN -hier
**WARN: (TCLCMD-513): The software could not find a matching object of the specified
type for the pattern '.*/.*'
**ERROR: (TCLCMD-917): Cannot find 'pins' that match 'seg2/.*.*.*.*.*/QN'

get_pins -regexp .*/QN -hier
seg1/u3/QN seg1/u9/QN seg1/u14/QN seg2/u3/QN seg2/u9/QN seg2/u14/QN seg3/u3/QN
seg3/u9/QN seg3/u14/QN u2/QN u5/QN u8/QN
```

timing_enable_hierarchical_get_nets_support

```
timing_enable_hierarchical_get_nets_support {true | false}
```

Default: `false`

Enables hierarchical segment support for the `get_nets` command.

When set to `false`, the `get_nets` command will report only flat nets.

To set this global variable, use the `set` command.

timing_enable_latch_thru_mode

```
timing_enable_latch_thru_mode {true | false}
```

Default: `false`

Enables the latch through analysis mode in which timing paths can propagate across latches, depending on their arrival time with respect to the latch transparency window.

When set to `true`, the arrival and required times will be propagated across a latch if it is in transparent mode. The reporting will show the entire flow through the path, rather than individual segments. This allows the overall path slack to be seen through upstream borrowing latch stages. The timing analysis, timing optimization, and reporting will consider the sequence of borrowing latch stages as a single path. As a result, the timing optimization reaches the target slack by viewing the entire path.

This feature provides better visibility into the overall context of latch path timing issues - for both the stage and path-level slacks. Additionally, this improves usability for debugging and manual ECOs, and shows better quality of result for Tempus ECO timing closure.

To set this global variable, use the `set` command.

timing_enable_latency_through_clock_gating

```
timing_enable_latency_through_clock_gating
{true | false}
```

Default: `true`

Allows propagation of latency phases across clock gating elements.

When set to `true`, the software allows propagation of clock latency phase across clock gating elements.

When set to `false`, the software suppresses propagation of clock latency across clock gating elements from the enable pin. The enable pin of the clock gating element should not be in the clock network for any other clocks. This is not recommended because the enable path (through the 'inferred' clock gates, such as, AND, NAND, OR) is either for clock latency or data paths. If the gated clock check is met, then the enable should not pass through to the output.

In case of ICGs, there is no arc from the EN to the CLKOUT on ICGs that have an incoming enable signal latched. In case of ICG/AND, using the enable path may not be correct for determining latency paths. If no latency paths are found, then the generated clocks definition will need to be re-checked.

To set this global variable, use the `set` command.

timing_enable_mmmc_loop_handling

```
timing_enable_mmmc_loop_handling
{true | false}
```

Default: `true`

When set to `true`, loop breaking is handled independently per analysis view, according to the following rules in order of precedence:

- If an analysis view does not contain a combinational loop, it does not inherit any loop breaking done for other views.
- If a loop exists, and the user has supplied specific case analysis and `set_disable_timing` constraints to break the loop at a certain place, the specified loop break is honored.
- If a loop is still detected, the software automatically selects a point to break the loop, and applies the loop break consistently to any views where the loop exists.

When set to `false`, if a combinational loop is detected in any analysis view, the timing system breaks the loop by disabling an arc along the looping path. These combinational loop breaks are reflected in all analysis views, even if those views by themselves do not contain these looping paths.

> Cadence strongly recommends that all combinational loops detected by the software be evaluated, to ensure that the loop is broken at the most ideal location. Automatic loop breaking decisions are made based on how the design is traversed. Small changes in the design can influence where loop breaking decisions are made.

To set this global variable, use the set_global command.

timing_enable_multi_drive_net_reduction_with_assertions

```
timing_enable_multi_drive_net_reduction_with_assertions
{none | delay | all}
```

Default: `none`

Allows reduction of multi-drive networks when constraint assertions are present on the network elements:

The following options are available:

`none`: Reduction is not performed on portions of the network where constraints have been asserted.

`delay`: Reduction of the multi-drive network will still be applied if only`set_annotated_delay` and `set_annotated_transition` constraints have been applied. Other constraints present on the multi-drive network can still prevent full reduction.

`all`: The software ignores the presence of any assertions on the multi-drive network and forces reduction to occur.

To set this global variable, use the set_global command.

timing_enable_multifrequency_latch_analysis

```
timing_enable_multifrequency_latch_analysis
{true | false}
```

Default: `false`

Enables multi-frequency latch timing analysis of the latch time borrowing for when a data signal coming to a latch is controlled by a clock with a frequency different to a clock of the latch enabling signal.

When set to `true`, the edges of all sending and receiving clocks are analyzed at every latch, which results in less pessimistic, and more detailed timing analysis.

When set to `false`, latch time borrowing analysis uses the worst case relationship between sending and receiving clocks at the latch, which can produce paths with pessimistic slack.

Note: Enabling advanced latch analysis can result in some performance penalty.

To set this global variable, use the set_global command.

timing_enable_path_delay_to_unconstrained_endpoints_compatibility

```
timing_enable_path_delay_to_unconstrained_endpoints_compatibility
{true | false}
```

Default: `false`

When set to `true`, the software does not constrain paths with path delay - if the path ends at an unconnected input pin of a combination cell.

To set this global variable, use the `set` command.

timing_enable_pessimistic_cppr_for_reconvergent_clock_paths

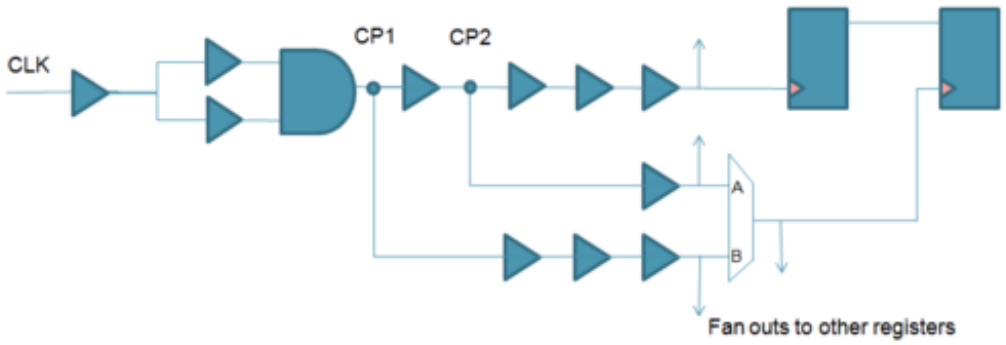
```
timing_enable_pessimistic_cppr_for_reconvergent_clock_paths
{true | false}
```

Default: `false`

When set to `true`, the software will consider all combinations of launch and capture clock path pairs to identify all possible common pins, and then selects the pin with minimum CPPR adjustment over all such common pins as the common pin.

When set to `false`, the default, the software will choose the CPPR common pin based on the commonality of the worst launch and worst capture path only.

Consider the following example,



In the above diagram, both capture paths are considered along with the single launch path, and the common pin is chosen as the pin with the least CPPR adjustment. The pin CP1 is chosen as a common pin and CPPR is reported up to this pin. The same common pin, CP1, will be used for CPPR adjustment whether the capture clock path goes through the mux A pin or the mux B pin. When this global variable is set to `false`, CPPR common pin is chosen by the commonality in the worst-case launch and worst-case capture paths. so CP2 is chosen as the common pin and CPPR is reported up to this pin.

Note:
The `timing_cppr_skip_clock_reconvergence` and `timing_enable_pessimistic_cppr_for_reconvergent_clock_paths` global variables are mutually exclusive.
Also, the `timing_cppr_skip_clock_reconvergence` global variable has precedence over `timing_enable_pessimistic_cppr_for_reconvergent_clock_paths`.

To set this global variable, use the set_global command.

timing_enable_power_ground_constants

```
timing_enable_power_ground_constants
{true | false}
```

Default: `false`

Determines if case analysis is inferred from power and ground rail connections/nets, e.g., VDD and GND.

When set to `true`, the software recognizes the constants that come from power and ground rail connections.

When set to `false`, the software ignores these constants. This provides the most intuitive behavior with logical style netlist (and other tools that do not read physical data).

To set this global variable, use the `set_global` command.

timing_enable_preset_clear_arcs

```
timing_enable_preset_clear_arcs
{true | false}
```

Default: `false`

Determines whether the timing arcs are created to model the transition to active state (assertion) of the preset or clear pin, and the subsequent transition of the output to a controlled state.

When set to `true`, the software builds the arcs and the timer automatically analyzes paths through them (enable clock propagation through preset clear pins).

When set to `false`, the software does not build these arcs, because they are associated with analyzing the reset mode timing paths. Filtering them prevents unwanted interaction with functional mode timing analysis.

You can use the `lib_build_asynch_de_assert_arc` global variable to control whether input to output arcs from the preset or clear pins transitioning to inactive state are included when the timing system is initialized. If both the `timing_enable_preset_clear_arcs` and the `lib_build_asynch_de_assert_arc` global variables are set to `true`, all asynchronous arcs are recognized. However, if `timing_enable_preset_clear_arcs` is set to `true` and `lib_build_asynch_de_assert_arc` is set to `false`, only assert asynchronous arcs are recognized.

Note: The `timing_enable_preset_clear_arcs` global variable can also impact delay calculation results of a design. When an arc is disabled, the software will calculate delay using the linear table lookup. When an arc is not disabled, the delay calculations are made based on the quadratic table lookup.

Note: This global variable should be set to `true` when reset checks are performed on a dedicated reset SDC.

To set this global variable, use the `set_global` command.

timing_enable_pulsed_latch

```
timing_enable_pulsed_latch
{true | false}
```

Default: `true`

Enables pulse-latch analysis.

When set to `true`, the pulse-latch analysis mode provides several additional pulse-clock specific constraint specifications and reporting capabilities.

When in pulse-latch mode, you can use the following pulse clock constraints:

- `set_pulse_clock_max_width`
- `set_pulse_clock_min_width`
- `set_pulse_clock_max_transition`
- `set_pulse_clock_min_transition`

Additionally, in this mode, the `report_constraint` command supports the following pulse clock check types:

- `pulse_clock_max_width`
- `pulse_clock_min_width`
- `pulse_clock_max_transition`
- `pulse_clock_min_transition`

To set this global variable, use the set_global command.

timing_enable_sdc_compatible_data_check_mcp

```
timing_enable_sdc_compatible_data_check_mcp
{true | false}
```

Default: `false`

Enables checking for SDC compatible data checks when `set_multicycle_path -start` parameter is specified.

When set to `true`, the `-start` parameter shifts (or reverses) the reference clock back by one clock cycle.

When set to `false`, the `set_multicycle_path -start` and `-end` parameters use the same number of cycles, even though the actual adjustment is computed using the signal clock for `-start` and reference clock for `-end` parameters. Additionally, the software computes adjustments for `set_data_check -hold` checks between multiple frequency clocks with the `set_multicycle_path -start -setup` setting.

To set this global variable, use the `set_global` command.

timing_enable_si_cppr

```
timing_enable_si_cppr
{true | false}
```

Default: `true`

Enables more accurate CPPR analysis when incremental delays are present and the `timing_remove_clock_reconvergence_pessimism` global variable is set to `true`.

When set to `true`, the incremental delay is not included in the CPPR calculation during setup analysis, but is included in the CPPR calculation during hold analysis.

When set to `false`, the incremental delay is included in both setup and hold CPPR calculations.

To set this global variable, use the set_global command.

timing_enable_simultaneous_setup_hold_mode

```
timing_enable_simultaneous_setup_hold_mode
{true | false}
```

Default: `false`

Controls whether setup and hold checks are analyzed separately, or together on the same timing graph.

When set to `false`, the setAnalysisMode `-checkType setup` and `hold` parameters are used to switch the system from analyzing setup slacks to analyzing hold slacks.

When set to `true`, setup and hold slacks are analyzed concurrently. As a consequence, both `-early` and `-late` queries for reporting commands such as `report_timing` can be satisfied immediately, without additional calculation. Simultaneous mode is useful for immediately understanding the consequences to both setup and hold slacks from what-if operations and manual ECOs to the design.

Note: Simultaneous setup and hold mode can be used only for timing analysis; it cannot be used for any physical implementation steps.

> Simultaneous setup/hold mode has the following behavior differences, with respect to the default mode:

- `setAnalysisMode -checkType setup` and `hold` do not function in simultaneous mode.
- The `write_timing_windows` command does not generate timing window information using the min and max libraries. Instead, by default, it uses only the max libraries.

To set this global variable, use the set_global command.

timing_enable_spatial_derate_mode

```
timing_enable_spatial_derate_mode
{true | false}
```

Default: `false`

Enables the spatial derate mode.

When set to `true`, the software allows access to the GBA spatial modes (`bounding_box` or `chip_size`) specified with the `timing_spatial_derate_distance_mode` global variable.

When set to `false`, the software allows you to specify only the `bounding_box` option.

To set this global variable, use the `set` command.

timing_enable_tristate_clock_gating

```
timing_enable_tristate_clock_gating
{true | false}
```

Default: `false`

The timing system infers gated-clock checks in the design where a data and clock path intersect at a combinational device. When this global is set to `true`, inferred gated-clock checks are added when clock and data signals converge through the tristate enable and data input of tristate buffers. By default (a setting of `false`), gated-clock checks are not added for these situations.

To set this global variable, use the set_global command.

timing_enable_uncertainty_for_clock_checks

```
timing_enable_uncertainty_for_clock_checks
{true | false}
```

Default: `true`

Considers clock uncertainty when performing clock checks.

When set to `true`, the `set_clock_uncertainty` command supports clock uncertainty for period, pulse width, skew, and separation checks. This global setting affects all the clock_style checks including pulse_width.

Note: The `timing_enable_uncertainty_for_clock_checks` global variable overrides `timing_enable_uncertainty_for_pulsewidth_checks` setting.

To set this global variable, use the `set` command.

timing_enable_uncertainty_for_pulsewidth_checks

```
timing_enable_uncertainty_for_pulsewidth_checks
{true | false}
```

Default: `false`

When set to `true`, considers clock uncertainty when performing minimum pulse width checks. Clock uncertainty is considered during checks of both user-defined minimum pulse widths (using the `set_min_pulse_width`), and minimum pulse widths that are defined in the timing model (`.lib`).

Note: Specifying a value of `true` affects the following commands that take minimum pulse width checks into account:

- `report_timing -check_type pulse_width`
- `report_timing -check_clocks`
- `report_min_pulse_width`
- `report_analysis_coverage`

To set this global variable, use the set_global command.

timing_extract_model_aocv_mode

```
timing_extract_model_aocv_mode
     {graph_based | path_based | none}
```

Default: `none`

Allows you to specify AOCV derating mode.

The valid values are:

- `graph_based`: Specifies that the delays in the timing model are derated using the graph-based stage counts.
- `path_based`: Specifies that the delays in the timing model are derated using the total path stage count of worst path between those pin pairs.
- `none`: Specifies that the delays in the timing model are non-AOCV derated base delays.

Note: Before setting this global to `graph_based or path_based` mode, it is mandatory that the AOCV libraries are read in and AOCV analysis is enabled (by setting `set_analysis_mode -aocv true`).

timing_extract_model_case_analysis_in_library

```
timing_extract_model_case_analysis_in_library
{true | false}
```

Default: `true`

Enables the software to model the constants as a function in the extracted timing model.

When set to `true`, the software models constants as functions in the library if these propagate to the output port.

When set to `false`, instead of modeling constants as functions inside the library, these are written as `set_case_analysis` in the constraints file (*.asrt).

To set this global variable, use the `set` command.

timing_extract_model_check_arcs_as_lvf

```
timing_extract_model_check_arcs_as_lvf {true | false}
```

Default: `true`

Enables check arcs to be modeled as LVF arcs. By default, the check arcs will be written as nSigma numbers.

Innovus allows you to write mean+/-nSigma values for constraint arcs, while writing separate mean and sigma values for delay and transition data. This can be enabled by setting `timing_extract_model_check_arcs_as_lvf` global variable to `false` and `timing_extract_model_write_lvf` to `true`.

This global variable will not have any impact if `timing_extract_model_write_lvf` is set to `false`.

To set this global variable, use the `set` command.

timing_extract_model_consider_design_level_drv

`timing_extract_model_consider_design_level_drv`
`{true | false}`
Default : `true`

Considers `set_max_capacitance` and `set_max_transition` DRV constraints, that have been applied on the current design during model extraction.

When set to `true`, these constraints applied at the design level will be considered during model extraction. However, the maximum capacitance and maximum transition from various DRV constraints applied/inferred on the ports is considered.

When set to `false`, the software extracts the worse-case DRV values and the constraints applied on the current design will be ignored.

To set this global variable, use the set_global command.

timing_extract_model_disable_cycle_adjustment

```
timing_extract_model_disable_cycle_adjustment
{true | false}
```

Default: `false`

Controls cycle adjustment for multi-cycle paths.

When set to `false`, if the multi-cycle paths specified in the SDC at the block-level cannot be pushed out to the ports (since there are other paths going through these paths), then the Tempus software adjusts the delay/check numbers in the ETM to take into account the cycle adjustment.

When set to `true`, the cycle adjustment for the multi-cycle paths in ETM arc delay are disabled.

To set this global variable, use the `set` command.

timing_extract_model_exhaustive_validation_dir

`timing_extract_model_exhaustive_validation_dir` *`string`*

Default: `" "`

Specifies the output directory where the additional validation reports generated during ETM Extremity Validation (but not generated during normal validation) will be written.

To set this global variable, use the `set` command.

timing_extract_model_exhaustive_validation_mode

```
timing_extract_model_exhaustive_validation_mode
{true | false}
```

Default: `false`

Enables extracted timing model (ETM) validation at the minimum and maximum indices of the slew load indices.

When set to `false`, the ETM validation is done only for the input slews/output-loads that have been asserted on the design during timing model extraction.

When set to `true`, the software uses the “Extremity-Validation” (EV-ETM) methodology that allows ETM to model the timing arcs in the design for a range of discrete input slews/output-loads, thus providing a more comprehensive validation.

To set this global variable, use the `set` command.

timing_extract_model_gating_as_nochange_arc

```
timing_extract_model_gating_as_nochange_arc
{true | false}
```

Default: `true`

Disables conversion of clock gating checks to nochange arcs.

When set to true, the software disables conversion of clock gating checks to nochange arcs in the extracted timing model.

To set this global variable, use the set command.

timing_extract_model_ideal_clock_latency_arc

```
timing_extract_model_ideal_clock_latency_arc
{true | false}
```

Default: `true`

When set to `true`, the latency arcs for the generated clocks that are defined ideal are extracted with reference as master clock during ETM extraction.

When set to `false`, the arcs are not extracted for generated clocks that are defined ideal during ETM extractions.

To set this global variable, use the `set` command.

timing_extract_model_include_applied_load_in_characterization_range

```
timing_extract_model_include_applied_load_in_characterization_range
{true | false}
```

Default: `true`

Specifies that the actual load visible to the timer that will be included in the load characterization range for path end points.

To set this global variable, use the `set` command.

timing_extract_model_include_applied_slew_in_characterization_range

```
timing_extract_model_include_applied_slew_in_characterization_range
{true | false}
```

Default: `true`

Specifies that the actual timer slew must be included in the characterization range timing model.

To set this global variable, use the `set` command.

timing_extract_model_max_feedthrough_characterization_load

```
timing_extract_model_max_feedthrough_characterization_load
{true | false}
```

Default: `false`

Specifies that the load is used by the model extractor for feed-through path characterization.

To set this global variable, use the `set` command.

timing_extract_model_non_borrowing_latch_path_as_setup

```
timing_extract_model_non_borrowing_latch_path_as_setup
{true | false}
```

Default: `false`

Models the non-borrowing interface latch paths as setup checks.

To set this global variable, use the `set` command.

timing_extract_model_slew_propagation_mode

```
timing_extract_model_slew_propagation_mode
{worst_slew | path_based_slew}
```

Default: `worst_slew`

Specifies the type of slew propagation to use for generating extracted timing model (ETM).

In worst slew propagation mode, the software propagates the worst slew of all the incoming arcs at a converging point for extracting the arcs.

In path based slew propagation mode, the software propagates the actual slew for the path elements for extracting the arcs.

To set this global variable, use the set_global command.

timing_extract_model_write_clock_checks_as_arc

```
timing_extract_model_write_clock_checks_as_arc
{true | false}
```

Default : `false`

When set to `true`, the clock checks (min_period and min_pulse_width) are modelled as arcs in the extracted timing models (ETM). Clock check arcs will be modelled as a single dimensional table with constrained and reference pin as clock pin itself.

When set to `false`, clock checks are modelled as scalar numbers in the extracted ETM.

To set this global variable, use `set` command.

timing_extract_model_write_clock_checks_as_scalar_tables

```
timing_extract_model_write_clock_checks_as_scalar_tables
{true | false}
```

Default: `false`

Allows the extracted timing model to write the minimum pulse width or minimum period checks as scalar arcs.

To set this global variable, use the `set` command.

timing_extract_model_write_lvf

```
timing_extract_model_write_lvf {true | false}
```

Default: `false`

Generates extracted timing model (ETM) containing Liberty Variation Format (LVF) model.

When set to `true`, this global variable enables writing separate mean and variation tables for all the delay/constraint and transition tables.

When set to `false`, the variation data will be merged with the mean values. The mean +/- nsigma values of delay/constraint/transition data will be written in the ETM.

To set this global variable, use the `set` command.

timing_extract_model_write_min_max_clock_tree_path

```
timing_extract_model_write_min_max_clock_tree_path
{true | false}
```

Default: `true`

Writes the minimum/maximum worst latency for each clock source.

To set this global variable, use the `set` command.

timing_generate_normalized_driver_waveform

```
timing_generate_normalized_driver_waveform
{0 | 1}
```

Default: 1

Generates the analytical normalized driver waveform for timing library if the waveform is not specified in the library. The waveform is generated by weighed mean of linear and exponential waveform.

To set this global variable, use the `set` command.

timing_generated_clocks_allow_nested_assertions

```
timing_generated_clocks_allow_nested_assertions {true | false}
```

Default: `false`

Controls clock latency handling for nested generated clocks that are created on the same timing pin as the master clock.

When set to `true`, the software handles generation of multiple nested generated clocks that are asserted on the same pin, such that the child clock inherits the clock latency value of its parent clock.

When set to `false`, the nested generated clocks asserted on the same pin do not inherit the latency values and are created with 0ns master clock latency. Any full clock timing path reported using these clocks will show the clock path up to the target pin of the generated clock.

To set this global variable, use the `set` command.

timing_generated_clocks_inherit_ideal_latency

```
timing_generated_clocks_inherit_ideal_latency
{true | false}
```

Default: `false`

When set to `true`, the software makes the generated clocks to inherit the ideal network latency of the parent clock.

To set this global variable, use the `set` command.

timing_get_of_objects_hier_compatibility

```
timing_get_of_objects_hier_compatibility
{true | false}
```

Default: `false`

When set to `true`, the `get_pins -of_objects` parameter will return leaf pins connected to the specified objects.

When set to `false`, the `get_pins -of_objects` parameter will return hierarchical pins and leaf pins connected to the specified objects. In order to return leaf pins only when the global is set to `false`, the `-leaf` option must be specified along with the `get_pins -of_objects` parameter.

When set to `true`, the `get_cells -objects` parameter returns cells connected to the net at the same level of hierarchy as the net itself. Hierarchical ports will be returned if the net is connected to a hierarchical module.

To set this global variable, use the set_global command.

timing_hier_object_name_compatibility

```
timing_hier_object_name_compatibility
{true | false}
```

Default: `true`

Controls how hierarchical delimiters are interpreted in the search pattern, when the `-hier` parameter is used with the `get_*` collection commands.

When set to `true`, the software interprets the hierarchical delimiter as part of the search pattern itself, and tries to match names that include the delimiter. For example, if you specify:

The software searches at every level of the hierarchy for instances with the name `L1/R*`, completely ignoring the hierarchy separator:

When set to `false`, hierarchical delimiters are interpreted as hierarchy separators. For example, if you specify:

The software searched for instances with names matching `R*` in the hierarchy level below `L1`:

To set this global variable, use the set_global command.

timing_hierarchical_context_continue_on_top_block_clock_mismatch

```
timing_hierarchical_context_continue_on_top_block_clock_mismatch
{true | false}
```

Default: `false`

Allows loading of the timing context model with unmapped clocks.

When set to `true`, the software allows the script to process even if there are any mismatches between the top and block-level clocks. The mismatches are reported in the *timing_context_clock_mapping_data.rpt* file, which shows data that allows you to determine if corrections or additions are required to the clock mapping file.

When set to `false`, the software will show an error condition if any of the top-level clocks cannot be matched with a block-level clock.

To set this global variable, use the `set` command.

timing_ignore_clock_based_path_delay_on_data_checks

```
timing_ignore_clock_based_path_delay_on_data_checks
{true | false}
```

Default: `false`

Disables clock-based path delay application on data checks.

When set to `true`, the Tempus software enables the data checks to be reported by disabling the applied path delay. The "Data Check Setup" details are displayed in the timing report output.

When set to `false`, the timing reports display the "Path Delay" details. By default, this global variable is set to `false`.

To set this global variable, use the `set` command.

timing_ignore_lumped_rc_assertions

```
timing_ignore_lumped_rc_assertions
{true | false}
```

Default: `false`

When set to `false`, the `set_load` and `set_resistance` values override the actual extracted representation. A warning message is issued stating that the specified constraints on internal nets will override extracted parasitics on those nets.

When set to `true`, instructs the software to ignore `set_load` and `set_resistance` assertions on internal nets in the design. Parasitic data for internal nets normally should be provided by Innovus RC extraction, or external SPEF annotation.

Using `set_load` to specify I/O boundary loading on ports is supported by either setting of this global.

To set this global variable, use the set_global command.

timing_io_use_clock_network_latency

```
timing_io_use_clock_network_latency
[always | ideal]
```

Default: `ideal`

Controls whether network latency of a reference clock is added or not to the data arrival time on the port.

When set to `ideal`, the `set_input_delay` and the `set_output_delay` constraints will not add the network latency of the reference clock to the data arrival time on the port if the clock is in `propagated` mode.

When set to `always`, network latency is added to the data arrival time on the port regardless of the clock propagation mode.

To set this global variable, use the `set` command.

timing_library_convert_async_setuphold_to_recrem

```
timing_library_convert_async_setuphold_to_recrem
[1 | 0]
```

Default: `1`

Controls whether single-edged setup and hold checks on asynchronous pins in the Liberty library are inferred as recovery and removal checks.

This global variable provides support for older modeling styles in legacy libraries.

To set this global variable, use the `set` command.

timing_library_genclk_use_group_name

```
timing_library_genclk_use_group_name
{true | false}
```

Default: `false`

When set to `true`, the software uses the generated_clock group name when creating a generated clock from a library-generated clock group. When set to `false`, the software uses the pin name when creating the generated clock.

For example, assume the cell for instance `a/b` in the timing library contained the following generated clock group:

```
generated_clock(genclk2) {
clock_pin : clk1;
master_pin : "int/clk";
multiplied_by : 2;
duty_cycle : 50.0;
}
```

By default (`false`), the software creates a generated clock with the following name:

```
a/b/clk1
```

If the timing_prefix_module_name_with_library_genclk global variable is set to `true`, and you set this global variable to `true`, the software creates a generated clock with the following name:

```
a/b/genclk2
```

If the `timing_prefix_module_name_with_library_genclk` global variable is set to `false`, and you set this global variable to `true`, the software creates a generated clock with the following name:

```
genclk2
```

To set this global variable, use the set_global command.

timing_library_hold_constraint_corner_sigma_multiplier

`timing_library_hold_constraint_corner_sigma_multiplier` *double*

Default: 0

Applies user control multiplier to generate a constraint table using sigma values applied for hold arc.

To set this global variable, use the `set` command.

timing_library_hold_sigma_multiplier

`timing_library_hold_sigma_multiplier` *double*

Default: 0

Applies user control multiplier to generate a constraint table applied for hold arc.

To set this global variable, use the `set` command.

timing_library_infer_async_pins_from_timing_arcs

```
timing_library_infer_async_pins_from_timing_arcs
{true | false}
```

Default: *false*

When set to `true`, a pin is marked clear if it has timing arcs with type “clear” to output pins. The sequential block is not required to be present in the cell for marking a pin as clear.

To set this global variable, use the set_global command.

timing_library_infer_cap_range_from_ccs_receiver_model

```
timing_library_infer_cap_range_from_ccs_receiver_model
{true | false}
```

Default: `false`

Infers the rise or fall of capacitance range values from CCS receiver capacitance model.

When set to `false`, the rise/fall CCS capacitance range values are not inferred. The NLDM pin capacitance range values defined in the library are honored.

To set this global variable, use the `set_global` command.

timing_library_infer_cap_range_from_ecsm_receiver_model

```
timing_library_infer_cap_range_from_ecsm_receiver_model {true | false}
```

Default: false

Infers the rise or fall of NLDM pin capacitance range from the ECSM capacitance range while calculating the total loading capacitance during switching power computation. If the global is set to `true` and the capacitance range is not defined in the library, the rise/fall capacitance range is inferred from the ECSM receiver capacitance models. The capacitance range values are derived either from the pin-level ECSM cap models or the timing-level ECSM cap models.

When this global is set to `false`, the rise/fall capacitance range values are not inferred, and the library values are honored.

To set this global variable, use the `set_global` command.

timing_library_infer_socv_from_aocv

```
timing_library_infer_socv_from_aocv {true | false}
```

Default: `false`

Controls the transformation of AOCV data.

This global variable infers sensitivity data from AOCV libraries, and must be set before loading any timing library data.

To set this global variable, use the `set` command.

timing_library_read_ccs_noise_data

```
timing_library_read_ccs_noise_data
{true | false}
```

Default: `true`

Allows CCS noise constructs to be read from a library.

This global variable can be used when the CCS library contains noise models, and SI glitch analysis is being performed.

To set this global variable, use the `set_global` command.

timing_library_read_without_power

```
timing_library_read_without_power
{true | false}
```

Default: `false`

When set to `true`, this global variable allows the software to read timing libraries without power information.

When set to `false`, the software reads power data also.

To set this global variable, use the `set` command.

timing_library_scale_aocv_to_socv_to_n_sigma

```
timing_library_scale_aocv_to_socv_to_n_sigma
 <n_sigma value>
```

Default: 3

Derives AOCV derates based on 3-sigma variation.

To set this global variable, use the `set` command.

timing_library_setup_constraint_corner_sigma_multiplier

`timing_library_setup_constraint_corner_sigma_multiplier` *`double`*

Default: 0

Applies user control multiplier to generate a constraint table using sigma values applied for setup arc.

To set this global variable, use the `set` command.

timing_library_setup_sigma_multiplier

`timing_library_setup_sigma_multiplier` *double*

Default: 0

Applies a user control multiplier to generate a constraint table using sigma values applied for setup arcs.

To set this global variable, use the `set` command.

timing_library_use_trilib_drv_values

```
timing_library_use_trilib_drv_values
{true | false}
```

Default: `false`

Allows the software to use a range of trilib DRV values for performing delay calculations.

When set to `false`, the DRV values are picked up from the first library of a trilib set and are used for DRV reporting. In some cases, the DRV constraints may not be the same across multi-voltage libraries. For this you can use a range of trilib DRV values, by setting the `timing_library_use_trilib_drv_values` global variable to `true`.

When set to `true`, the trilib (or voltage scaling) mechanism allows more accurate delay calculation in case timing libraries are not characterized at operating voltage. Through this mechanism, the bounding libraries of the operating voltage are obtained from the trilib set and the worst value is used in delay calculations.

This global variable is supported for `report_constraint` based DRVs. The global will impact the `report_constraint` command when there is a voltage scaling setup and the command is issued with the `-drv_violation_type` parameter.

To set this global variable, use the `set` command.

timing_library_use_two_piece_receiver_cap

```
timing_library_use_two_piece_receiver_cap {true | false}
```

Default: `false`

Enables the use of 2-piece receiver capacitance constructs, if a library contains both the N-piece and 2-piece receiver capacitance construct.

When set to `true`, if a library has 2-piece and multi-piece pin capacitance, then the software gives priority to 2-piece models.

When set to `false`, the software reads the N-piece receiver capacitance constructs.

To set this global variable, use the `set` command.

timing_library_zero_negative_timing_check_arcs

```
timing_library_zero_negative_timing_check_arcs
{true | false}
```

Default: `false`

When set to `true`, converts any negative timing check values in the timing library to zero.

timing_max_transition_use_si_transition

```
timing_max_transition_use_si_transition {true | false}
```

Default: `false`

Enables reporting of noisy slew in DRV flows.

To set this global variable, use the `set` command.

timing_multifrequency_clock_rounding_factor

```
timing_multifrequency_clock_rounding_factor
{1e-04 | 1e-05}
```

Default: 1e-05

Rounds off irrational numbers so that they can be read appropriately. The "round off factor" helps improve the level of accuracy of floating point numbers.

To round off clock period numbers accurate to the fourth decimal place, you can use the following command:

set_global timing_multifrequency_clock_rounding_factor 1.0e-4

To set this global variable, use the set_global command.

timing_normalized_driver_waveform_clip_linear_part

```
timing_normalized_driver_waveform_clip_linear_part
{0 | 1}
```

Default: `0`

When set to 1, the linear ramp component in the normalized driver waveform is saturated to the maximum value, while generating the normalized driver waveform.

To set this global variable, use the `set` command.

timing_normalized_driver_waveform_weight_factor

```
timing_normalized_driver_waveform_weight_factor
<float value>
```

Default: 0.5

Defines the value of the weight of linear components in the algorithm for generation of normalized driver waveform.

When set to `1`, the waveform will be purely linear. When set to `0`, the waveform will be purely exponential. You can specify values within the range of 0 to 1.

To set this global variable, use the `set` command.

timing_null_collection_return_compatibility

```
timing_null_collection_return_compatibility
{true | false}
```

Default: `false`

Allows you to migrate previous release scripts to the new use model.

When the global is set to `true`, the software returns "NA" values that are consistent with the previous release. The nil return values are returned as an empty collection. This allows the return value to be used directly by collection iterators, such as `foreach_in_collection`.

The default value is `false`, which is consistent with the current release.

Note: This compatibility option may be removed from future releases. You should update your scripts to the new use model to avoid future problems.

To set this global variable, use the set_global command.

timing_path_based_enable_bounding_box_for_io_paths

```
timing_path_based_enable_bounding_box_for_io_paths
{true | false}
```

Default : `false`

Enables the bounding box mode for input-output paths.

To set this global variable, use the `set` command.

timing_path_based_enable_closest_common_pin_driver_for_bounding_box

```
timing_path_based_enable_closest_common_pin_driver_for_bounding_box
{true | false}
```

Default : `false`

Enables bounding box calculation using closest common pin driver from the clock mesh.

To set this global variable, use the `set` command.

timing_path_based_enable_exhaustive_depth_bounded_by_gba

```
timing_path_based_enable_exhaustive_depth_bounded_by_gba
{true | false}
```

Default: `true`

Enables the timing report to bound PBA results by GBA slacks of the respective leftover nworst paths, whenever exhaustive depth for an endpoint is exhausted.

When set to `true`, during exhaustive PBA, if you specify exhaustive depth as N, and an endpoint has nworst paths greater than N, then the timing report will show the worst path corresponding to worst slack out of worst PBA slack (out of first N paths) and GBA slack (for the (N+1)th path). Here, the variable N refers to exhaustive PBA depth and can be set using the `timing_pba_exhaustive_path_nworst_limit` global variable.

When set to `false`, during exhaustive PBA, if you specify exhaustive depth as N, and an endpoint has nworst paths greater than N, then the software will ignore the paths with depth greater than N, which may result in reporting an optimistic PBA slack for the endpoint reaching the depth.

To set this global variable, use the `set` command.

timing_path_based_enable_report_launch_clock_path

```
timing_path_based_enable_report_launch_clock_path {true | false}
```

Default: `true`

Allows the reporting launch clock path in path-based analysis (PBA) path type full report.

When set to `false`, the software does not report these paths in the timing reports.

To set this global variable, use the `set` command.

timing_path_based_enable_verbose_mode

`timing_path_based_enable_verbose_mode` *value*

Default: `1`

Controls printing of verbose messages during and at the end of path-based analysis (PBA).

You can specify one of the three values - 0, 1, and 2. These are described below:

- `0`: Verbose messages are not reported during exhaustive PBA analysis. For default PBA analysis, the path count will be reported.
- `1`: Reports the final message for PBA path count and max depth reached during exhaustive PBA. Progress messages are not reported.
- `2`: Reports multiple progress messages after regular intervals (in addition to the final message for PBA path count and max depth).

This global variable impacts messages when the `report_timing` and `report_constraint` commands are used in PBA mode.

To set this global variable, use the `set` command.

Examples

- The following commands print messages during and after PBA analysis:

  ```
  set timing_path_based_enable_verbose_mode 2
  report_timing -retime path_slew_propagation -retime_mode exhaustive -max_paths
  500000 -nworst 1
  ```

  The following progress messages are displayed during PBA analysis:

  ```
  INFO: Path Based Analysis (PBA) currently performed on '108455' paths
  INFO: Path Based Analysis (PBA) currently performed on '217574' paths
  INFO: Path Based Analysis (PBA) currently performed on '327511' paths
  INFO: Path Based Analysis (PBA) currently performed on '437472' paths
  ....
  ```

  The following messages are displayed at the end of PBA analysis mentioning the PBA path count and max depth reached during exhaustive PBA:

  ```
  INFO: Path Based Analysis (PBA) performed on total '2660526' paths
  INFO: Max depth 9460 reached for end point 'top/hier1/hier2/flop/d' during Path
  Based Analysis
  ```

timing_path_based_exhaustive_enable_design_coverage

```
timing_path_based_exhaustive_enable_design_coverage
{true | false}
```

Default: `false`

Enables exhaustive path-based analysis (PBA) to automatically pick up and analyze all the violating endpoints in the design, irrespective of the specified maximum paths.

When set to `true`, exhaustive PBA analysis automatically picks up and analyzes the violating design endpoints instead of N endpoints (specified with the `report_timing -max_paths` parameter). After analyzing the violating endpoints, the software reports the top N worst endpoints - depending on the specified value of N.

When set to `false`, exhaustive PBA analysis restricts analysis (using the `-max_paths` parameter) to the specified number of N endpoints.

Note: When this global variable is enabled, there may be an increase in run time because the software will analyze all the violating endpoints and analysis will not be restricted to the specified N endpoints.

To set this global variable, use the `set` command.

timing_path_based_exhaustive_max_paths_limit

`timing_path_based_exhaustive_max_paths_limit` *integer*

Default: `2000000`

Specifies the maximum number of paths that can be internally analyzed during exhaustive path-based analysis (PBA).

If the number of candidate paths during exhaustive PBA is greater than the specified max paths limit, then the software will skip path-based analysis of these paths beyond this limit. The paths exceeding the specified max paths limit will then be included as GBA in the final report output so that real violations are not missed.

To set this global variable, use the `set` command.

timing_path_based_report_analysis_summary_max_paths_limit

`timing_path_based_report_analysis_summary_max_paths_limit` *integer*

Default: `2000000`

Sets a limit on the maximum number of paths that can be reported in PBA mode with the `report_analysis_summary` command.

To set this global variable, use the `set` command.

timing_pba_exhaustive_path_nworst_limit

`timing_pba_exhaustive_path_nworst_limit` *value*

Default: `10000`

Specifies the maximum number of paths per endpoint (nworst) that will be re-timed in exhaustive path-based analysis (PBA).

In exhaustive PBA mode, the value specified with the `report_timing -nworst` parameter is used only during the final reporting. The value specified with the `timing_pba_exhaustive_path_nworst_limit` global variable (and not the `report_timing -nworst` value) is used to specify the maximum number of paths to be re-timed per endpoint.

If the limit specified by `timing_pba_exhaustive_path_nworst_limit` is reached and `timing_path_based_enable_exhaustive_depth_bounded_by_gba` global variable is set to:

- `true`: The worst of the current PBA slack is used and N+1th GBA path is reported.
- `false`: The current PBA slack is reported - which may be optimistic.

To set this global variable, use the `set` command.

timing_pll_clock_use_driving_cell

```
timing_pll_clock_use_driving_cell
{true | false}
```

Default : `false`

Uses delay calculation of all the enabled arcs to the PLL clock output to compute the transition.

When set to `true`, the delay calculation of all enabled arcs to the PLL clock output will be used to compute the transition. If no driving arcs are available in the model or if they are disabled, the same idealized transition will be used.

When set to `false`, the software considers the PLL clock output to be electrically isolated from the input-side reference clock, and creates the output clock with an idealized transition. You can use the `set_annotated_transition` command to customize the output clock transition.

To set this global variable, use the `set` command.

timing_prefix_module_name_with_library_genclk

```
timing_prefix_module_name_with_library_genclk
{true | false}
```

Default: `true`

When set to `true`, the software appends the instance name to the clock pin name when creating a generated clock. When set to `false`, the software uses only the clock pin name when creating a generated clock.

For example, assume the cell for instance `a/b` in the timing library contained the following generated clock group:

By default (`true`), the software creates a generated clock with the following name:

If you set the global to `false`, the software creates a generated clock with the following name:

If you set this global to `false`, and the timing_library_genclk_use_group_name global variable is set to `true`, the software creates a generated clock with the following name:

To set this global variable, use the set_global command.

timing_propagate_latch_data_uncertainty

```
timing_propagate_latch_data_uncertainty
{true | false}
```

Default: `false`

When set to `true`, uses the clock phase associated with a flush latch's data pin as the "from" clock phase for downstream uncertainty timing calculations

When set to `false`, the downstream uncertainty calculations are based on the clock phase of the flush latch's clock signal.

To set this global variable, use the `set` command.

timing_property_arrival_clocks_consider_clock_source_data_phase

```
timing_property_arrival_clocks_consider_clock_source_data_phase
{true | false}
```

Default : `true`

Considers the clock source data phases.

The `get_property` and `report_property` commands support the `arrival_clocks` collection property on pin objects. The `arrival_clocks` property considers data phases, clock source data phases, and latency phases.

To set this global variable, use the `set` command.

timing_property_arrival_clocks_consider_data_phase

```
timing_property_arrival_clocks_consider_data_phase
{true | false}
```

Default: `true`

Returns the pure data phase.

The `get_property` and `report_property` commands support the `arrival_clocks` collection property on pin objects. The `arrival_clocks` property considers data phases, clock source data phases, and latency phases.

To set this global variable, use the `set` command.

timing_property_arrival_clocks_consider_latency_phase

```
timing_property_arrival_clocks_consider_latency_phase
{true | false}
```

Default: `true`

Returns the latency phase.

The `get_property` and `report_property` commands support the `arrival_clocks` collection property on pin objects. The `arrival_clocks` property considers data phases, clock source data phases, and latency phases.

To set this global variable, use the `set` command.

timing_property_arrival_window_enable_tcl_dict_format

```
timing_property_arrival_window_enable_tcl_dict_format
{true | false}
```

Default : `false`

Allows the software to print new format of the `arrival_window` property (see `get_property` command).

To set this global variable, use the `set` command.

timing_property_clock_used_as_data_unconstrained_clock_source_paths

```
timing_property_clock_used_as_data_unconstrained_clock_source_paths
{true | false}
```

Default: `true`

Returns a value of true for `is_clock_used_as_data` timing property (set using the `get_property` command).

When set to `true`, the `is_clock_used_as_data` timing property returns a value of `true` (irrespective of whether the clock source path is constrained or unconstrained), if the pin lies in the clock source path and at least one of the clocks arriving at the pin is used as data in the downstream network of the pin.

When set to `false`, the pins lying in the constrained clock source data paths are reported as true. For example, if there is a path from clock source to output port and the output port is unconstrained, then the `is_clock_used_as_data` property will not return `true`.

To set this global variable, use the `set_global` command.

timing_property_return_null_collection_with_quiet

```
timing_property_return_null_collection_with_quiet
{true | false}
```

Default: `false`

Allows you query values of all the properties.

When set to `true`, the software enables returning values of properties of all the objects, when the `get_property -quiet` parameter is specified.

To set this global variable, use the `set` command.

timing_rail_swing_checks_high_voltage_threshold

`timing_rail_swing_checks_high_voltage_threshold d`*`ouble`*

Default: `0.95`

Specifies the voltage threshold values for high rail swing checks.

To set this global variable, use the `set` command.

timing_rail_swing_checks_low_voltage_threshold

`timing_rail_swing_checks_low_voltage_threshold d`*`ouble`*

Default: `0.05`

Specifies the voltage threshold values for low rail swing checks.

To set this global variable, use the `set` command.

timing_read_library_without_ecsm

```
timing_read_library_without_ecsm
{true | false}
```

Default: `false`

Disables loading ECSM data.

When set to `true`, the loading of ECSM data is disabled. If the timing library contains NLDM, ECSM, or CCS data in the same file, then ECSM data will not be read.

Note: This global variable does not disable CCS data loading.

To set this global variable, use the `set_global` command.

timing_read_library_without_sensitivity

```
timing_read_library_without_sensitivity
{1 | 0}
```

Default: `0`

Disables loading of ECSM timing sensitivity data.

When set to `1`, the global skips loading of all the data pertaining to ECSM timing sensitivity constructs when libraries are read.

To set this global variable, use the `set` command.

timing_recompute_sdf_in_setuphold_mode

```
timing_recompute_sdf_in_setuphold_mode
{true | false}
```

Default: `false`

Controls the recomputing of SDF delays when the software is in simultaneous setup and hold analysis mode.

When the software is not in simultaneous setup and hold analysis mode, only one corner of data is stored at a time; therefore additional delay calculation is required for `write_sdf`. When the software is in simultaneous setup and hold analysis mode, both sets of data are in memory at the same time, and additional delay calculation is not necessary.

If set to `false`, `write_sdf` will write out the delays from memory, instead of calling delay calculation.

Note: This global variable must be used with `timing_enable_simultaneous_setup_hold_mode true`.

To set this global variable, use the `set_global` command.

timing_reduce_multi_drive_net_arcs

```
timing_reduce_multi_drive_net_arcs
{true | false}
```

Default: `true`

Controls whether multi-drive or mesh networks are reduced to simpler, single driver models.

When set to `true`, the nets that meet the drivers' receivers arc threshold (defined using `timing_reduce_multi_drive_net_arcs_threshold` global variable), are reduced. The net arcs are created only from one driver or from the drivers for which you have set the constraints.

If you specify constraints on the net driven by parallel buffers, it might result in increased run time and memory degradation. By specifying timing constraints through nets, the constraints are moved to the drivers. This leads to the creation of net arcs from all the drivers, thus disabling net arc reduction. In such cases, you can select one driver of the net and use that driver to specify the constraints.

When set to `false`, the number of net arcs created for timing analysis for nets driven by parallel buffers are not reduced. If a net is driven by `n` parallel buffers and is connected to `m` sink pins, then the total number of net arcs created is `n*m`. For example, if `n` is `100` and `m` is `20000`, the number of net arcs created for timing analysis will be two million. This may result in increased run time and memory usage.

To set this global variable, use the `set_global` command.

timing_reduce_multi_drive_net_arcs_threshold

`timing_reduce_multi_drive_net_arcs_threshold` *int*

Default: `10000`

Sets a threshold number that is used to trigger the reduction of timing arcs of nets driven by parallel buffers. The reduction takes place if the number of arcs is greater than the threshold value and when the `timing_reduce_multi_drive_net_arcs` global variable is set to `true`.

To set this global variable, use the `set_global` command.

timing_remove_clock_reconvergence_pessimism

```
timing_remove_clock_reconvergence_pessimism
{true | false}
```

Default: `false`

Enables Clock Path Pessimism Removal (CPPR) analysis during timing analysis. When set to `true`, the timing analysis commands remove pessimism from slack calculation. Clock path pessimism is the difference of launching and capturing clock arrival times at the common node. This pessimism can be due to difference in minimum and maximum cell delays along the clock paths or due to the reconvergent clock paths. If the launching and capturing registers are triggered by the same clock and there is no common node between the launching and capturing clock paths, the pessimism is the difference between late and early clock source latencies.

To set this global variable, use the set_global command.

Note: The `timing_remove_clock_reconvergence_pessimism` global should not be used with the `setAnalysisMode` command. Use this global only when the `setAnalysisMode` command is not available. When the `setAnalysisMode` command is available, use the `-cppr` parameter to set or reset the CPPR analysis.

timing_report_analysis_summary_csv_extended_new_format

```
timing_report_analysis_summary_csv_extended_new_format
{true | false}
```

Default: `false`

Keeps the analysis summary CSV extended report in sync with the summary timing report. These reports are available when the respective `report_timing` parameters are specified:

- `-analysis_summary_csv_extended_file`
- `-analysis_summary_file`

When set to `true` (and when the `report_timing -analysis_summary_csv_extended_file` parameter is specified), the column name sequence will be from fromClk to toClk, that is, fromClk will be printed first, and then toClk. Also, the timing report will show "-", if toClk or fromClk is not present (and when the `report_analysis_summary -expanded_summary_clocks` parameter is set to `false`).

When set to `false`, the missing toClk or fromClk column will be represented as “*”.

To set this global variable, use the `set` command.

timing_report_begin_end_pair_max_path_limit

`timing_report_begin_end_pair_max_path_limit` *integer*

Default: `2000000`

Sets a limit on the maximum number of paths that can be reported when the `report_timing -begin_end_pair` parameter is specified.

Note: Higher maximum paths limit may lead to high memory usage and runtime.

To set this global variable, use the `set` command.

timing_report_check_timing_unconstrained_endpoints_due_to_constants

```
timing_report_check_timing_unconstrained_endpoints_due_to_constants {true | false}
```

Default: `false`

Enables the software to flag unconstrained signals arriving at the end points due to case analysis.

When set to `false`, the `check_timing` command output will show warnings for the unconstrained endpoints.

When set to `true`, the command output will also show warnings for unconstrained endpoints due to case analysis under the subcategory `uncons_endpoints_due_to_case_analysis`. For more details, see `check_timing`.

To set this global variable, use the `set` command.

timing_report_clock_pin_as_begin_point

```
timing_report_clock_pin_as_begin_point
{true | false}
```

Default: `false`

Allows the software to report clock pins as begin points.

To set this global variable, use the `set` command.

timing_report_constraint_enable_extended_drv_format

```
timing_report_constraint_enable_extended_drv_format
{true | false}
```

Default: `false`

Enables the software to report data as per clock/data and rise/fall phases.

To set this global variable, use the `set` command.

timing_report_constraint_format

`timing_report_constraint_format` *`string`*

Default: " "

Specifies the DRV fields that will be reported with the `report_constraint` command. For valid format column options, refer to `report_constraint -drv_fields`.

If DRV fields are not specified with this global variable (or with `report_constraint -drv_fields`), then the default set of DRV fields will be displayed. By default, the constraint report will display the pin names, the required and actual DRC values, and the view names.

Note: The reporting fields specified with the `report_constraint -drv_fields` parameter will override the global variable settings.

To set this global variable, use the `set` command.

timing_report_constraint_rise_fall_clock_period_check

```
timing_report_constraint_rise_fall_clock_period_check
{true | false}
```

Default: `false`

Enables reporting of rise-to-rise and fall-to-fall clock_period checks separately for the `report_constraint` command.

When set to `false`, the software reports the rise-to-rise and fall-to-fall clock period checks under the same table in the report. With the `false` setting, when the `report_constraint -check_type clock_period` option is specified, the software reports violations that are the worst amongst all the rise-fall transitions for each point.

To set this global variable, use the `set` command.

timing_report_constraint_use_infinity_slack_for_unconstrained

`timing_report_constraint_use_infinity_slack_for_unconstrained {true | false}`

Default: `false`

Reports the timing slacks of unconstrained paths through the DRV violating pin as “INFINITY”. By default, the timing slacks of unconstrained paths are reported as * (asterisk).

To set this global variable, use the `set` command.

timing_report_disable_max_paths_per_group

```
timing_report_disable_max_paths_per_group {true | false}
```

Default: `false`

Controls the interpretation of the `report_timing -max_paths` parameter when you request reporting across a set of path groups. By default (`false` setting), the specified `-max_paths` will be reported per path group. With the `true` setting, a total of the specified `-max_paths` will be reported across all of the specified path groups.

For Stylus flow cross-tool compatibility – you should specify a setting of `true`. For backward compatibility with the legacy UI flow – you should use a value of `false`.

For example,

When set to `false`:

Legacy UI: `report_timing -path_group {reg2reg in2reg} -nworst 2 ...`
Stylus UI: `report_timing -group {reg2reg in2reg} -nworst 2 ...`

The `report_timing` command will return up to 2 paths for the reg2reg group and also up to 2 paths for the in2reg group.

When set to `true`:

Legacy UI: `set timing_report_disable_max_paths_per_group true`
Stylus UI: `set_db timing_report_disable_max_paths_per_group true`

A total of 2 paths will be reported across both path groups. The paths may come entirely from one or the other group – or both, based on the slack value.

To set this global variable, use the `set` command.

timing_report_drv_enable_clock_source_as_clock

```
timing_report_drv_enable_clock_source_as_clock {true | false}
```

Default: `false`

Enables the clock DRV for pure clock source path instead of data DRV.

To set this global variable, use the `set` command.

timing_report_drv_enable_frequency_per_view

```
timing_report_drv_enable_frequency_per_view
{true | false}
```

Default : `false`

Enables view-based frequency DRV flow.

When set to `true`, in the MMMC DRV flow, the software performs frequency computation for design pins as per the clock period of specific analysis views reaching a pin. In case of non-activity based flow, the frequency is computed as per the fastest clock of all the views.

When set to `false`, in the propagate activity flow, the software performs frequency computation for design pins from propagated activity on that pin.

For other flows. the software performs frequency computation for design pins as per the smallest clock period (largest clock frequency) from all the active analysis views.

To set this global variable, use the `set` command.

timing_report_drv_enable_ghz_notation_for_drv_fields

```
timing_report_drv_enable_ghz_notation_for_drv_fields {true | false}
```

Default: `false`

Enables reporting of clock frequency in GigaHertz (Ghz). The default frequency unit is MegaHertz (MHz).

To set this global variable, use the `set` command.

timing_report_drv_enable_slew_threshold_scaling

```
timing_report_drv_enable_slew_threshold_scaling {true | false}
```

Default: `false`

Enables the transition constraints scaling as per the slew threshold value.

To set this global variable, use the `set` command.

timing_report_drv_use_worst_timing_slack

```
timing_report_drv_use_worst_timing_slack
{true | false}
```

Default: `false`

Enables reporting of the worst DRV slack across all the views for configurable DRV report.

When set to `true`, the software shows a non-default special case report, where timing slacks for MMMC flow is the worst among all active views.

To set this global variable, use the `set` command.

timing_report_enable_clock_unrolling

```
timing_report_enable_clock_unrolling
{true | false}
```

Default : `false`

Enables the clock unrolled reporting format that shows more intuitive timing reports with respect to constraints.

When set to `true`, the `report_timing` command provides an optional format where the clock edge arrival times in the detailed path section show the worst-case clock edge pair used for the analysis. This format can provide a more intuitive understanding of the clock edges used - especially in cases where the launch and capture clocks have different frequencies.

When set to `false`, the detailed path section shows clock edge arrival times with respect to the base cycle of the clocks. Any required cycle-accounting adjustments are provided by the Phase Shift and Cycle Adjustment entries in the timing report summary section.

To set this global variable, use the `set` command.

timing_report_enable_cppr_point

```
timing_report_enable_cppr_point { true | false}
```

Default: `false`

Enables the timing report to output CPPR point details.

When set to `true`, the `report_timing` command output shows the CPPR point field.

To set this global variable, use the `set` command.

timing_report_enable_lead_trail_to_rise_fall_map

```
timing_report_enable_lead_trail_to_rise_fall_map
{true | false}
```

Default: `false`

Enables reporting of rise/fall edge times, instead of lead/trail edge times of a clock (that are reported using the `report_clocks` command).

To set this global variable, use the `set` command.

timing_report_enable_markers

```
timing_report_enable_markers
      {true | false}
```

Default: true

Enables display of markers in reports.

When set to `true`, the report_timing output format displays markers that identify pins specified using the `-from`, `-to`, or `-through` parameters. The markers, displayed as '`->`', show up in the 'timing point' or ' hpin' column (if the 'timing point' column is not available) of the timing report. This feature provides better readability. When set to `false`, the timing report does not display markers.

To set this global variable, use the set_global command.

timing_report_enable_max_capacitance_drv_for_constants

```
timing_report_enable_max_capacitance_drv_for_constants
{true | false}
```

Default: `false`

When set to `true`, performs max_capacitance design rule violation check on constant elements.

Note: This global variable will be honored only when `timing_disable_drv_reports_on_constant_nets` is set to `true`.

To set this global variable, use the `set_global` command.

timing_report_enable_max_path_limit_crossed

```
timing_report_enable_max_path_limit_crossed
{true | false}
```

Default: `false`

Determines if the number of reported paths for a particular clock group equals the specified maximum paths limit.

When set to `true`, the software will issue a warning message in case the number of reported paths for a clock group is equal to the given maximum paths limit. This applies to both graph- and path-based reporting modes.

This variable is supported in clock group-based non-statistical reporting flows only. The clock group-based reporting mode can be enabled by setting `timing_report_group_based_mode` global variable to `true`.

To set this global variable, use the `set` command.

timing_report_enable_report_clock_timing_across_clock_pin

```
timing_report_enable_report_clock_timing_across_clock_pin {true | false}
```

Default: `false`

Enables fanout tracing across clock pins if any combinational arc is present.

To set this global variable, use the `set` command.

timing_report_enable_si_debug

```
timing_report_enable_si_debug
{true | false}
```

Default: `false`

Allows the software to capture signal integrity (SI) related details for each stage of a path being analyzed during path-based analysis in the form of attributes.

To set this global variable, use the set_global command.

timing_report_enable_slack_summary_at_bottom

```
timing_report_enable_slack_summary_at_bottom {true | false}
```

Default: `false`

Prints additional time details, such as, Required time, Arrival, and Slack, at the bottom of the timing report. For example,

```
Req Time = 0.262  (-3.00S) | 0.544  | 0.094 | 0.141
Arr Time = 2.238  (+3.00S) | 1.774  | 0.155 | 0.131
Slk Time = -1.773 (-3.00S) | -1.230 | 0.181 | 0.181
```

To set this global variable, use the `set` command.

timing_report_enable_unique_pins_multiple_capture_clock_paths

`timing_report_enable_unique_pins_multiple_capture_clock_paths`

Default: `false`

Enables reporting of different paths with respect to the reference clocks in the unique pins.

To set this global variable, use the `set` command.

timing_report_enable_use_valid_start_end_points

```
timing_report_enable_use_valid_start_end_points
{true | false}
```

Default: `false`

Shows valid start/end points in the timing report.

When set to `true`, the valid start/end points are included in the timing report. The paths are reported with the `report_timing` command - when the pins passed (-from and -to) are the actual begin and end pins of the data path. For example, for a register the begin pin is register's CK pin and the end pin is register's D pin. Similarly, an input pin in a path is the path's begin pin and output pin is the path's end pin.

When set to `false`, any point in a path can be used as a -from point and is considered as a -through point internally. All the pins using -from/-to are treated as -through pins. Therefore, a path is reported with register's Q pin as a from pin, even though the correct start pin is a CK pin. Or any intermediate pin belonging to a path can be passed as -from/-to and the path will still be reported to correct start/end pins with the given pin lying somewhere in between of path.

To set this global variable, use the `set` command.

timing_report_generated_clock_info

```
timing_report_generated_clock_info
{true | false}
```

Default: `true`

Generated clock information is automatically added to the report, if generated clocks are encountered in either the launching or capturing clock paths.

The generated clock information column is displayed if the `Delay' field exists. If the `Delay' field does not exist, then the generated clock adjustment column is added to the report only when explicitly specified using the `report_timing -format` command or by setting the `report_timing_format` global variable.

To set this global variable, use the set_global command.

timing_report_group_based_mode

```
timing_report_group_based_mode
{true | false}
```

Default: `false`

Groups paths by clock domain.

When set to `true`, the behavior of the following reporting commands will change as follows:

report_timing

The behavior of the following report_timing parameters changes as follows:

- `-max_points`: In this mode you are not required to specify this parameter. If specified, the parameter is mapped to -max_paths option.
- `-max_paths M`: Reports M paths per clock group.
- `-nworst N`: Limits the number of paths per endpoint per clock group. By default, the value of -nworst is 1.

The report_timing command will have the following four types of groups (if design does not have user-defined path groups):

- Asynch group: Recovery/removal checks.
- Clock gating group: Inferred and library clock gating checks.
- Default group: Combinational max delay or min delay paths.
- Clock Groups: Groups for all design clocks. For a design with three clocks, three groups will be reported, one group for each clock. Endpoints sharing the same reference clock will be part of the same group. If an endpoint belongs to multiple groups then it will be reported separately in each group.

Note: If user-defined path groups are specified, the software will override the path groups described above.

report_min_pulse_width

The `report_min_pulse_width` command reports pulse width slacks of all the clocks for a pin. In summary mode, the "clock" column will be displayed. In verbose mode (with `path_type` option), the behavior will be similar to the `report_timing` output in group-based mode.

report_constraint

The `report_constraint` command will perform the following checks:

- For max_delay/setup and min_delay/hold type checks paths will be reported for each clock group separately.
- The behavior of pulse width check types will be the same as `report_min_pulse_width` command.

report_analysis_coverage

The `report_analysis_coverage` command will report a check at end point for all the clocks. In verbose mode, the "clock" column will be displayed.

To set this global variable, use the set_global command.

timing_report_max_transition_check_using_nsigma_slew

```
timing_report_max_transition_check_using_nsigma_slew
{true | false}
```

Default: `false`

Enables the `report_constraint` command to use mean and sigma slew values for reporting transition values in DRV checks.

When set to `true`, in the SOCV flow the `report_constraint` command uses the mean plus n-sigma slew values for DRV checks.

When set to `false`, the `report_constraint` command will report only the mean slews.

To set this global variable, use the `set` command.

timing_report_property_fastest_clock_consider_data_phase

`timing_report_property_fastest_clock_consider_data_phase`

`{true | false}`

Default : `false`

Considers the data signals while determining the fastest clock arriving on any given pin.

When set to `false`, the clocks arriving in clock phase form will be considered.

When set to `true`, the clocks arriving in clock phase as well as data phase form will be considered for determining the fastest clock.

To set this global variable, use the `set` command.

timing_report_pulse_width_matching_launch_capture_paths

`timing_report_pulse_width_matching_launch_capture_paths {true | false}`

Default: `false`

Reports pulse width paths that have matching launch and capture paths - the count of pins and the pins must match exactly. The paths that do not meet this condition will not be reported.

When set to `true`, the software will impact the minimum pulse width report that is generated with the `report_min_pulse_width` command along with the `-path_type short` and `-path_type full_clock` options.

To set this global variable, use the `set` command.

timing_report_redirect_message_types

```
timing_report_redirect_message_types
{none | info}
```

Default: `none`

Redirects reporting messages to a report file.

When set to `info`, the path count and max depth (displayed when the `report_timing` command is run in PBA mode) will be appended to the final report output.

When set to `none`, the reporting messages are not redirected to a report file.

To set this global variable, use the `set` command.

timing_report_retime_formatting_mode

```
timing_report_retime_formatting_mode
{manual | retime_compare | retime_replace}
```

Default: `manual`

Controls retiming fields to be displayed in the timing report.

You can set one of the following options to change the reporting columns:

- `manual`: Does not change the `report_timing` format.
- `retime_compare`: If GBA columns are present in the report format, then the corresponding retime options are added. If PBA columns are already present, then there is no change in the format.
- `retime_replace`: If GBA columns are present in the report format, then the GBA columns are replaced by the corresponding PBA columns. If PBA columns are already in the report, then there is no change in the format.

Note: The report format is also controlled through the `report_timing -retime_format` parameter. The `report_timing` command setting has precedence over this global variable.

To set this global variable, use the `set_global` command.

timing_report_skip_constraint_loop_check

```
timing_report_skip_constraint_loop_check
{true | false}
```

Default: `false`

Allows you to skip loop checking when the `check_timing` command is used.

When set to `true`, the software skips reporting of loops in case the timing graph inside a loop is broken. This may happen if some of the commands, such as, `create_clock`, `set_input_delay`, or `set_output_delay` are defined inside a loop.

Note: When this global variable is set to `true`, the `check_timing` command will report lesser loops than the ones reported in the CTE_loops.rpt report - which reports all the loops.

To set this global variable, use the `set` command.

timing_report_socv_summary_mean_sigma

`timing_report_socv_summary_mean_sigma {true | false}`

Default: `false`

Prints the report header in new format when the `report_timing` command is run in SOCV mode. The new header contains nsigma, mean, and sigma details.

To set this global variable, use the `set` command.

timing_report_timing_header_detail_info

```
timing_report_timing_header_detail_info
{default | extended}
```

Default: `default`

Controls the timing report (generated using the `report_timing` command) header format. You can specify one of the following options:

- When set to `default`, the software generates timing reports with a report header that includes the following information:
  - Tempus software version number
  - Platform on which the software is being run
  - Time when the report was generated
  - Command used to generate the report
- When set to `extended`, the software generates timing reports with additional header information given below:
  - The analysis mode - best case worst case or on chip variation
  - The active views (displayed only in MMMC mode)
  - The clock reconvergence pessimism (CPPR)
  - The latch slack mode
  - The specified clock propagation value
  - The specified delay calculation engine

Note: You can use this global variable when `timing_disable_report_header_info` is set to `false`.

To set this global variable, use the `set_global` command.

Examples

Here are some sample report headers.

- The following report header is displayed when the default option is specified:
  ```
  innovus 1> set_global timing_report_timing_header_detail_info default
  ```

```
#####################################################################
# Generated by: Cadence Innovus <version>
# OS: Linux x86_64(Host ID sjkrhn)
# Generated on: <date>
# Design: TEST_CHIP
# Command: report_timing
#####################################################################
```

- The following sample report header is displayed the extended option is specified:

```
innovus 3> set_global timing_report_timing_header_detail_info extended

#####################################################################
# Generated by: Cadence <version>
# OS: Linux x86_64(Host ID sjkrhn)
# Generated on: <date>
# Design: TEST_CHIP
# Command: report_timing
#####################################################################
#
# Timing Analysis:
# Analysis Mode : onChipVariation
# Active Views : test_view_setup
# CPPR : on
# Latch Slack Mode : max_borrow
# Clock Propagation : sdcControl
# Delay Calculation:
# Engine : default
#
#####################################################################
```

timing_report_unconstrained_path_early_late_header

```
timing_report_unconstrained_path_early_late_header
{true | false}
```

Default: `false`

When set to true, the software provides information in the timing report header that indicates whether an unconstrained path is a late or early path.

To set this global variable, use the `set` command.

timing_report_unconstrained_paths

```
timing_report_unconstrained_paths
{true | false}
```

Default: `false`

When set to `true`, the `report_timing` command reports unconstrained paths if the software cannot find any constrained paths to report.

When set to `false`, the `report_timing` command reports only the constrained paths.

Note: The behavior of `timing_report_unconstrained_paths` global variable is not the same as the behavior of `report_timing -unconstrained` command. If there are several paths to the same endpoint from different beginpoints, including constrained and unconstrained paths, the `report_timing -unconstrained` parameter always reports unconstrained paths, even if a constrained path can be reported. Whereas the `timing_report_unconstrained_paths` global reports constrained paths but not unconstrained paths.

To set this global variable, use the set_global command.

timing_report_use_receiver_model_capacitance

```
timing_report_use_receiver_model_capacitance {true | false}
```

Default: `false`

Enables the max_capacitance violations based on dynamic pin capacitance.

When set to `true`, the software checks for both the input level and timing arc level dynamic pin capacitance tables for worst-case pin capacitance table for given input slew. If conditional pin capacitance tables (or timing_arcs) exist, the worst-case is used among all the conditions.

This global variable performs static pin capacitance inference after delay calculation, so the delay computation is not impacted. The pin capacitance is used only for reporting and max_cap violations.

To set this global variable, use the `set` command.

timing_report_use_worst_parallel_cell_arc

```
timing_report_use_worst_parallel_cell_arc
{true | false}
```

Default: `false`

When set to `false`, setting the `-nworst` parameter reports several paths by selecting parallel arcs in the library cell between two pins.

When set to `true`, only a single worst path is reported by selecting the worst delay arc among all parallel arcs of a cell. For example, for reporting timing through A to Y pins (where the cell is a 2-input cell), the parallel arc is applicable for the same input and output pin. So the worst arc for A->Y is chosen from all arcs of A->Y.

To set this global variable, use the set_global command.

timing_resolve_driver_conflicts

```
timing_resolve_driver_conflicts
{conservative | aggressive}
```

Default: `aggressive`

Resolves constant propagation results on nets with multiple drivers.

When set to `conservative` mode, the net values are as follows:

- If all the drivers are 1, the net will be driven to value `1`
- If all the drivers are 0, the net will be driven to value `0`
- In other cases, the net value will be `Undefined`

When set to `aggressive` mode, the net values are as follows:

- If some of the drivers are 0, the net value will be `0`
- If some of the drivers are 1, but none are 0, then the net value will be `1`
- In other cases, the net value will be `Undefined`

To set this global variable, use the `set_global` command.

timing_sdf_adjust_negative_setuphold

```
timing_sdf_adjust_negative_setuphold
{true | false}
```

Default: `false`

Controls how the setup and hold check values are adjusted when both are initially negative in the SDF file.

When set to `true`, the software sets the smaller check delay value to a negated larger check delay value. For example, if the initial setup/hold value is equal to -1/-2. then the value -2 from the setup is smaller and it is reset to a negated value of the larger one (-1 from hold). So the adjusted setup/hold value is equal to -1/1.

When set to `false`, both the negative setup and hold check values are set to 0.

The command order for using this global variable is as follows:

- `read_sdf`
- `timing_sdf_adjust_negative_setuphold {true | false}`
- `write_sdf`

The timing report (`report_timing`) results are not impacted.

To set this global variable, use the `set` command.

timing_sdf_enable_setuphold_scond_ccond

```
timing_sdf_enable_setuphold_scond_ccond
{true | false}
```

Default: `false`

When set to `true`, enables proper generation of SDF (Standard Delay Format) with scond and ccond qualifiers on `SETUPHOLD` and `RECREM` timing checks:

Since some SDF readers do not accept scond and ccond qualifiers this global is set to `false` by default.

To set this global variable, use the set_global command.

timing_self_loop_paths_no_skew

```
timing_self_loop_paths_no_skew
{true | false}
```

Default: `false`

When set to `true`, factors the skew on self loops. The software ignores the skew on the clock pin for hold analysis for data paths originating on sequential elements (for example, Q-pin of a flip flop) and ending on the data pins of the same element (D-pin of the same flip flop). Use this variable to eliminate pessimism due to skew when the launch and the capture edge of the clock are the same.

To set this global variable, use the set_global command.

Note: The `timing_self_loop_paths_no_skew` global should not be used with the `setAnalysisMode` command. Use this global only when the `setAnalysisMode` command is not available. When the `setAnalysisMode` command is available, use the `-timingSelfLoopsNoSkew` parameter to enable skew factoring on self loops.

timing_self_loop_paths_no_skew_max_depth

`timing_self_loop_paths_no_skew_max_depth` *value*

Default: 10

Identifies self-loop paths at the specified depth.

To set this global variable, use the set_global command.

For example:

set_global timing_self_loop_paths_no_skew_max_depth 20

Lets the timer traverse 20 timing arcs (10 stages of logic) before abandoning the search for a self loop.

timing_self_loop_paths_no_skew_max_slack

`timing_self_loop_paths_no_skew_max_slack` *value*

Default: `0`

Identifies self-loop paths at the specified threshold.

To set this global variable, use the set_global command.

For example:

set_global timing_self_loop_paths_no_skew_max_slack 1.0

In this case, all timing endpoints with a worst slack less than `1.0` are considered for self loop skew removal.

timing_set_clock_source_to_output_as_data

```
timing_set_clock_source_to_output_as_data
{true | false}
```

Default: `false`

When set to `true`, causes a clock source path leading to an output or bidi port to be treated as a data path if there is a `set_output_delay` or `set_data_check` assertion on the port.

To set this global variable, use the set_global command.

timing_set_nsigma_multiplier

`timing_set_nsigma_multiplier` *`value`*

Default: 3

Controls the sigma multiplier to be used in SOCV mode.

This global variable allows a single N value for both setup and hold reporting. For example,

```
set timing_set_nsigma_multiplier 4.5
```

To set this global variable, use the `set` command.

Note: The `timing_set_nsigma_multiplier` global variable is obsolete and has been replaced with the `set_socv_reporting_nsigma_multiplier` command. You can use this global variable by setting `timing_socv_view_based_nsigma_multiplier_mode` to `false`. For future compatibility, you should migrate your scripts to use the new view-based methodology.

timing_set_scaling_for_negative_checks

```
timing_set_scaling_for_negative_checks
{default | divider | multiplier}
```

Default: `default`

When set to default, the derated check is the negative check * (2.0 - derating factor), where the derating factor is the value that you set using the `set_timing_derate` command.

Modifies the scaling of the negative timing analysis check value. This variable does not affect the positive checks. When set to `divider`, divides the negative check value by the derating factor. When set to `multiplier`, multiplies the negative check value by the derating factor.

To set this global variable, use the set_global command.

timing_set_scaling_for_negative_delays

```
timing_set_scaling_for_negative_delays
{default | divider | multiplier}
```

Default: `default`

Modifies the scaling of the negative delay value to be used during timing analysis. This variable does not affect the positive delay.

When set to `default`, the derated check/delay = negative check/delay * (2.0 - derating factor), where the derating factor is the value that you set using the set_timing_derate command.

When set to `divider`, divides the negative delay value by the derating factor. When set to `multiplier`, multiplies the negative delay value by the derating factor.

Currently, constraints are used during timing in the flattened mode, so the internal ILM instances are seen instead of the LEF pins of the ILMs. Therefore, reading the bounding box constraints causes errors without this variable set. Notice that if you want to see the LEF pins of the ILM in GUI, the design must be in the unflattened mode.

To set this global variable, use the set_global command.

timing_socv_preserve_variation_with_annotations

```
timing_socv_preserve_variation_with_annotations
{true | false}
```

Default: `false`

Preserves the sigma value computed by delay calculation along with the annotation from SDC.

In the clock mesh flow, it is possible to preserve sigma values even after applying annotation on slew/delay through SDC.

When this global variable is set to `true`, the software accepts the sigma value computed by delay calculation (for nets that have delay/slew annotations from SDC, e.g., clock-mesh), along with the annotation from SDC.

To set this global variable, use the `set` command.

timing_socv_rc_variation_mode

```
timing_socv_rc_variation_mode
{true | false}
```

Default: `false`

Enables modeling of interconnect variation in SOCV mode.

The SOCV flow provides support for RC variation on the interconnect.

To set this global variable, use the `set` command.

timing_socv_statistical_min_max_mode

```
timing_socv_statistical_min_max_mode
{statistical | mean_and_three_sigma_bounded}
```

Default: `mean_and_three_sigma_bounded`

Determines how worst cases will be computed in SOCV mode.

You can select one of the following options:

- `statistical`: The mean and standard deviation for the result of worst-cases is computed to get the greatest or smallest of normal distributions.
- `mean_and_three_sigma_bounded`: The worst mean value is chosen as the mean of the resulting distribution. The standard deviation is computed as a bound from the worst (mean+/-3*sigma) value. This ensures that the 3-sigma value of the result always bounds the worst 3-sigma value.

  Note: The `mean_and_three_sigma_bounded` option is required for SOCV-based optimization in Innovus. It is also highly recommended for analysis in Tempus due to improved bounding properties.

To set this global variable, use the `set` command.

timing_socv_view_based_nsigma_multiplier_mode

```
timing_socv_view_based_nsigma_multiplier_mode {true | false}
```

Default: `true`

Enables setting of view-based separate setup and hold sigma multipliers.

By default or with an explicit `true` setting, the timing system is configured to support different N-sigma multiplier values for Setup vs. Hold – and for different analysis views. The specific N-sigma multipliers can be set using the `set_socv_reporting_nsigma_multiplier` command.

In earlier releases, the `timing_set_nsigma_multiplier` global variable was used to specify a single N-sigma value that was used for both Setup and Hold analysis across all analysis views. To continue using older scripts with this control, you can set the `timing_socv_view_based_nsigma_multiplier_mode` global variable to `false`.

Note: This backward compatibility option will not be supported in future releases. It is recommended to migrate your scripts to use the new view-based methodology.

To set this global variable, use the `set` command.

timing_spatial_derate_chip_size

`timing_spatial_derate_chip_size` *`value_in_microns`*

Default: `1e+30`

Allows you to define the chip size.

The chip size is the diagonal length of a rectangle that is formed by the chip's length and width. You can obtain the diagonal distance by calculating the square-root of the Length^2 x Width^2. The diagonal distance should always be specified in units of microns.

The chip size can be picked in the following ways (in order of highest to lowest precedence):

- When set to a value other than `1e+30`, the specified value will have the highest precedence.
- If the physical floorplan information is available, the chip size will be derived automatically from the floorplan.
- If the SPEF parasitic files containing the coordinate information are loaded, then the chip size will be automatically derived.

To set this global variable, use the `set` command.

timing_spatial_derate_distance_mode

```
timing_spatial_derate_distance_mode
{bounding_box | chip_size}
```

Default: `bounding_box`

Allows you to select the graph-based analysis (GBA) spatial mode. The allowed values are - `bounding_box` or `chip_size`.

This global variable can be used when the spatial derate mode is enabled using `timing_enable_spatial_derate_mode true` setting.

To set this global variable, use the `set` command.

timing_suppress_escape_characters

```
timing_suppress_escape_characters
{true | false}
```

Default: `true`

Supresses the reporting of escape characters in timing object names.

When the global is set to `true`, all the reporting and collection commands report the timing objects names (e.g., pins, ports, or instances) without the escape characters.

To set this global variable, use the set_global command.

timing_suppress_ilm_constraint_mismatches

```
timing_suppress_ilm_constraint_mismatches
{true | false}
```

Default: `false`

When set to `true`, the software suppresses all error and warning messages related to objects not found when loading SDC constraint files for the ILM flow.

In the current ILM flow, SDC constraints originally specified against the complete flat netlist for the design do not get filtered when being applied against the ILM view of the design. Constraints that reference parts of the design that were pruned cause warnings and errors during constraint loading.

To set this global variable, use the set_global command.

timing_time_unit

`timing_time_unit` *`string`*

Default: `none`

Specifies the timing units to be used for timing constraints and timing reports. The default units for timing are inferred from the timing libraries. You can override this inference by explicitly setting the value to `none`, `1ns`, `1ps`, `10ps`, or `100ps` .

Setting this variable explicitly is the same as executing the `setLibraryUnit -time` command to set time units.

To set this global variable, you can use the `set` command.

timing_timing_window_pessimism_removal_include_si_delay

`timing_timing_window_pessimism_removal_include_si_delay {true | false}`

Default: `false`

Controls inclusion of SI delay in timing window pessimism removal between the attacker and victim pins in the design.

The cross-talk analysis of a net depends on the relative positioning of attacker and victim arrival times. To compute the worst case switching times, the arrival windows of attacker and victim are considered. If the attacker and victim share a common clock path, then considering the original arrival windows will be pessimistic, and the common path contribution in these arrival windows needs to be adjusted.

When set to `false`, the software adjusts the elongated timing windows with the difference in the minimum-maximum base delay of the common clock path at the top level - while calculating the closest switching time, and the SI incremental delay differences are not adjusted.

When set to `true`, the software adjusts the timing windows with the SI incremental delay differences as well, in addition to the base delay. When this global variable is enabled, the timing window calculation can be optimistic, especially for cases where the attacker and victim are triggered by different clock edges. But for cases where all the attacker and victim nets are triggered by the same clock edge, then real pessimism will be removed from the timing window calculation.

Note: The `timing_timing_window_pessimism_removal_include_si_delay` global variable applies only when `timing_enable_timing_window_pessimism_removal` is set to `true`.

To set this global variable, use the `set` command.

timing_use_clock_pin_attribute_for_clock_net_marking

```
timing_use_clock_pin_attribute_for_clock_net_marking
{true | false}
```

Default: `false`

Allows the software to use clock pin attribute settings for clock net marking.

The timing system determines which nets are recognized as clock nets by considering different heuristics - including having an upstream path to clock sources and a downstream path to clock targets.

When set to `true`, the pins that have the Liberty timing library pin attribute setting ‘clock:true’ will be interpreted as additional clock targets for the clock marking algorithm.

When set to `false`, the set of clock targets includes pins that are the launching point for sequential paths or are the reference pin for sequential timing checks - typically register clock pins.

To set this global variable, use the `set` command.

timing_use_incremental_si_transition

```
timing_use_incremental_si_transition {true | false}
```

Default: `false`

Enables usage of incremental slew during DRV violation reporting.

To set this global variable, use the `set` command.

timing_use_latch_early_launch_edge

```
timing_use_latch_early_launch_edge
{true | false}
```

Default: `true`

Enables the latch use early launch edge feature.

During timing analysis when time borrowing and clock path pessimism removal (CPPR) is enabled, the given time is calculated using both borrow time and CPPR time. This may result in unnecessary timing violations. Since CPPR is an accurate means of pessimism removal, you are required to set the `timing_use_latch_early_launch_edge` global variable to `false` so that CPPR is applied to all the paths in the design.

When set to `true`, the launch clock path of timing paths starting at a latch is timed in early mode for setup analysis, and late mode for hold analysis. No CPPR credit is given to the timing path.

When set to `false`, the behavior is like for any other path. The launch clock path of timing paths starting at a latch is timed in late mode for setup analysis, and early mode for hold analysis. The CPPR credit is given to the path according to the global CPPR settings.

To set this global variable, use the set_global command.

timing_use_latch_time_borrow

```
timing_use_latch_time_borrow
{true | false}
```

Default: `true`

When set to `false`, does not consider time borrowing during timing analysis. Time borrowing is the amount of time borrowed by a previous logic.

To set this global variable, use the set_global command.

Note: The `timing_use_latch_time_borrow` global should not be used with the `setAnalysisMode` command. Use this global only when the `setAnalysisMode` command is not available. When the `setAnalysisMode` command is available, use the `-timeBorrowing` parameter to control time borrowing consideration.

timing_use_verilog_for_model_netlist

```
timing_use_verilog_for_model_netlist
{true | false}
```

Default: `false`

Allows you to choose whether to write the scope and boundary model netlists in Verilog format instead of binary.

When set to `true`, the software will use Verilog format for saving model nets.

To set this global variable, use the `set` command.

timing_waveform_aware_pulse_width_checks_high_voltage_level

`timing_waveform_aware_pulse_width_checks_high_voltage_level` *double*

Default: 0.95

Range: `{}`

Specifies the high voltage level to be used for waveform-aware pulse width checks.

To set this global variable, use the `set` command.

timing_waveform_aware_pulse_width_checks_low_voltage_level

`timing_waveform_aware_pulse_width_checks_low_voltage_level` *double*

Default: `0.05`

Range: `{}`

Specifies the low voltage level to be used for waveform-aware pulse width checks.

To set this global variable, use the `set` command.

timing_write_sdf_no_escape_backslash_control

```
timing_write_ sdf_no_escape_backslash_control
{true | false}
```

Default: `false`

Controls how the `write_sdf` command handles escape characters when the `-no_escape` parameter is specified.

For example, consider the following input Verilog expression:

\a/b\/c\/d

When the global is set to `true`, the `write_sdf` command removes the first escape character and outputs `a/b\/c\/d` in the SDF file.

When set to `false`, the command removes all the escape characters and outputs `a/b/c/d`.

To set this global variable, use the set_global command.

write_global_slack_worst_trigger_path_on_clocks

```
write_global_slack_worst_trigger_path_on_clocks
{true | false}
```

Default: `false`

Specifies whether the `write_global_slack_report` command reports worst slack on the register clock pins or not. When set to `true`, the `write_global_slack_report` command reports worst slack due to triggering paths.

A CLK pin might drive a Q pin of the same register, and have a setup or hold check arc with respect to the D pin. In the default setting, when the global is set to false, the `write_global_slack_report` command reports no slacks along the clock paths. When the global is set to `true`, the command will report the worst slack on register clock pins due to the related trigger paths and not due to the related timing checks.

To set this global variable, use the `set_global` command.

43

Timing Modeling Commands

- compare_model_timing
- do_extract_model
- merge_model_timing
- write_model_timing

compare_model_timing

```
compare_model_timing
-help
-ref string
-compare string
-outFile string
[-ignore_view]
[-percent_tolerance float ]
[-percent_cap_tolerance float ]
[-absolute_cap_tolerance float ]
[-percent_tran_tolerance float ]
[-absolute_tran_tolerance float]
[-absolute_tolerance float ]
```

Compares two reports that contain interface timing characteristics generated by the write_model_timing command.

This command compares the interface timing report generated by using the write_model_timing command on the original netlist with the timing report generated by using the write_model_timing command on the model extracted by the do_extract_model command for the same design.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `compare_model_timing` parameter. For a detailed description of the command and all of its parameters, use the man command: `man compare_model_timing`.
`-absolute_cap_tolerance` *float*	Specifies the tolerance value for capacitance (as an absolute value) while comparing two report files. This parameter specifies the permissible difference, as an absolute value, between the capacitance values of two report files. If the difference in the value of capacitance exceeds the absolute tolerance value specified, the comparison status is set to `FAIL`. **Note:** When this parameter is not specified, the software uses the absolute value specified with the `-absolute_tolerance` parameter. If the `-absolute_tolerance` parameter is not specified, the value defaults to `0`.  When the `-percent_cap_tolerance` and `-absolute_cap_tolerance` parameters are used together, the comparison status is set to `FAIL`only when the difference in the value of capacitance exceeds the specified absolute as well as percentage tolerance values.
`-absolute_tolerance` *float*	Specifies the absolute tolerance value. The tolerance value is used when there is a difference between the timing characteristics of the reference file (`-ref`) and the file that is being compared (`-compare`) to determine the `PASS` or `FAIL` status of the comparison. If the difference in the value of a timing characteristic exceeds the absolute tolerance value, the comparison status is set to `FAIL`. **Note:** When used with the `-percent_tolerance` option, the difference in the value of a timing characteristic should exceed both absolute and percentage tolerance values for the comparison result status of an arc to be `FAIL`. *Default*: `0`

`-absolute_tran_tolerance` *float*	Specifies the name of the report file that contains the interface timing characteristics extracted from the model created using the `do_extract_model` command. The timing characteristics of this file are compared with the timing characteristics of the reference file that you specify with the `-ref` option.
`-compare` *string*	Specifies the name of the report file that contains the interface timing characteristics extracted from the model created using the `do_extract_model` command. The timing characteristics of this file are compared with the timing characteristics of the reference file that you specify with the `-ref` option.
`-ignore_view`	Compares non-MMMC design `write_model_timing` output report with the MMMC design output report (of `write_model_timing` command). When you specify this parameter, the software ignores the view information while comparing the reports. So you do not require to create dummy views for timing model validation flow.
`-outFile` *string*	Specifies the name of the output file in which the comparison results will be generated. This file contains the `PASS` or `FAIL` status for the timing data comparison.

`-percent_cap_tolerance` *float*	Specifies the tolerance value for capacitance (as a percentage) while comparing two report files. This parameter specifies the permissible difference, in percentage, between the capacitance values of two report files. If the percentage difference in the value of capacitance exceeds the percentage tolerance value specified, the comparison status is set to `FAIL`. **Note:** When this parameter is not specified, the software uses the percentage value specified with the `-percent_tolerance` parameter. If the `-percent_tolerance` parameter is not specified, the value defaults to `0`. When the `-percent_cap_tolerance` and `-absolute_cap_tolerance` parameters are used together, the comparison status is set to `FAIL` only when the difference in the value of capacitance exceeds the specified absolute as well as percentage tolerance values.
`-percent_tolerance` *float*	Specifies the percentage tolerance value for comparing the timing data of two report files. The percentage tolerance value is used when there is a difference between the timing characteristics of the reference file (`-ref`) and the file that is being compared (`-compare`) to determine the `PASS` or `FAIL` status of the comparison. If the percentage difference in the value of a timing characteristic exceeds the percentage tolerance value, the comparison status is set to `FAIL`. **Note:** When used with the `-absolute_tolerance` option, the difference in the value of a timing characteristic should exceed both percentage and absolute tolerance values for the comparison result status of an arc to be `FAIL`. *Default*: `0`

`-percent_tran_tolerance` *`float`*	Specifies the tolerance value for transition time at ports (as a percentage) while comparing two report files.This parameter specifies the permissible difference, in percentage, between the transition time at ports of two report files. If the percentage difference in the transition time exceeds the percentage tolerance value specified, the comparison status is set to `FAIL`. **Note:** When this parameter is not specified, the software uses the percentage value specified with the `-percent_tolerance` parameter. If the `-percent_tolerance` parameter is not specified, the value defaults to `0`. When the `-percent_tran_tolerance` and `-absolute_tran_tolerance` parameters are used together, the comparison status is set to `FAIL` only when the difference in the value of transition exceeds the specified absolute as well as percentage tolerance values.
`-ref` *`string`*	Specifies the name of the reference file that is used for comparison. This is the report file that was generated by using the `write_timing_model` command on the original design. The file specified with the `-compare` option is compared with this file.

Example

- The following command compares the timing characteristics of the `sample_compare.rpt` file with the `sample_reference.rpt` file and generates the comparison results in the `sample_output.rpt` file:

```
compare_model_timing -ref sample_reference.rpt -compare sample_compare.rpt
-outFile sample_output.rpt

```

Builds a Liberty (`.lib`) format model for the top cell, which is the timing model equivalent of the original design. The model is extracted for the given analysis modes, PVT conditions, and parasitics. If any one of these parameters change, then you must extract the model again. The model is extracted for a range of input slews and load capacitances. If you do not specify these ranges, the software automatically computes the default values. The extracted model defines all of the top-level ports of the design as pins. Additionally, all other design pins that are targets of `create_clock` or `create_generated_clock` are retained as internal pins.

For model extraction, your design must be properly constrained. For example, no clock or data conflicts can be present. Use the `check_timing` command and correct all errors prior to model extraction.

Parameters

`-help`	Prints out the command usage.
`-abs_tol_val` *float*	Specifies the absolute tolerance value to be used during the validation of the extracted timing model. For more details, refer to the `compare_model_timing -absolute_tolerance` command option. This parameter can be used only when the `-validate` option is specified. The integer value specified with this option is read as ns/ps depending upon the time unit. *Default*: 3ps
`-abs_tol_val_optimistic` *float*	Specifies the absolute tolerance limit for flagging an optimistic failure. An optimistic path violating the absolute as well as percentage tolerance limit will be flagged as FAIL in the `compare_model_timing` command output report. You can use the this parameter when the `-validate` is used with model extraction. *Default*: 15ps
`-abs_tol_val_pessimistic` *float*	Specifies the absolute tolerance limit for flagging a pessimistic failure. A pessimistic path violating the absolute as well as percentage tolerance limit will be flagged as FAIL in the `check_timing_model` command output report. You can use the this parameter when the `-validate` is used with model extraction. *Default*: 15ps

`-assertions` *`constraint filename`*	Dumps the constraints for a model, which is used in the validation flow. *Default*: `model.asrt`
`-cell_name` *`cell_name`*	Specifies the cell name used in the timing model. *Default:* The name of the top cell to be extracted.
`-check`	Checks the extracted timing model for any possible liberty related issue. When specified, the command displays detailed error and warning messages, and their summary.
`-clock_slews {`*`clk_slew1 clk_slew2...`*`}`	Specifies a range of slew values used at all clock pins. The list of values must be enclosed by curly braces. If this parameter is not specified, the software automatically computes the appropriate values.
`-format` *`string`*	Specifies the format for the extracted model in tlf, dotlib, or syntech.
`-gain` *`integer`*	Represents an increase in the number of delay arcs if a pin is removed. This option reduces the extracted model size in scenarios where removing a pin can result in increased model size. The gain at an internal pin can be defined as: `(number of incoming delay arcs * number of outgoing delay arcs) - (number of incoming delay arcs + number of outgoing delay arcs` If an internal pin has a gain greater than the specified number, then that pin needs to be preserved in order to reduce the extracted model size. *Default*: `0`

`-include_aocv_weights`	Writes the stage weight on individual arcs. Before using this option, it is mandatory that the AOCV libraries are read in and AOCV analysis is enabled (by using `setAnalysisMode -aocv true`). The weights written in ETM are not meant to derate the model. Model itself will be containing the derated delays. The stage weight extracted on arcs will be used to calculate the stage count of chip level paths going across the ETM. The stage weights in the extracted model are dumped as user defined attributes. This will require defining two attributes at arc level.
	• `define ("aocv_weight","timing","float");`
	• `define ("clock_aocv_weight","timing","float");`
	The first attribute will be used for combinational and trigger arc and will be dumped at arc level as below.
	`timing () {`
	`timing_type : combinational;`
	`timing_sense : positive_unate;`
	`aocv_weight : 4;`
	`.`
	`}`
	`The check arcs will be dumped with two separate stage weights for data and clock.`
	`timing () {`
	`timing_type : setup_rising;`
	`aocv_weight : 4;`
	`clock_aocv_weight : 3;`
	`.`
	`}`

`-input_slews {`*`input_slew1 input_slew2 ...`*`}`	Specifies a range of slew values used at all input pins. Enclose the list of values with curly braces. If this parameter is not specified, the software automatically computes the appropriate values.

`-lib_name` *lib_name*	Specifies the library name used in the timing model. Write extracted timing models in the liberty format by specifying the `.lib` file suffix. *Default:* The name of the top cell to be extracted.
`-max_num_loads` *value*	Specifies the maximum number of output load values used for delay arc characterization. A low value of 1 or 2 improves runtime and memory usage but may significantly degrade model accuracy. Use this parameter only if the model size or model extraction time is critical. *Default:* `64`
`-max_num_slews` *value*	Specifies the maximum number of input slews or clock slews used for delay and check arc characterization. Specifying a low value of 1 or 2 improves runtime and memory but may significantly degrade model accuracy. Using the `-max_num_slews` parameter has a larger impact on runtime and memory than the `-max_num_loads` parameter. Use this parameter only if the model size or the model extraction time is critical. *Default:* `64` The `max_num_slews` and `max_num_loads` parameters specify only the maximum limits on how many slew and load points are chosen. The software scans the gates connected to the input and output ports to calculate the number of points.
model_filename	Specifies the name of the output file. Avoid problems with rebind by using the `-lib_name` and `-cell_name` parameters instead of using the default names.
`-output_loads {`*output_load1 output_load2* `...}`	Specifies a range of load values used at all output pins. Enclose the list of values by curly braces. If this parameter is not specified, the software automatically computes the appropriate values.

`-per_tol_val` *float*	Specifies the percentage tolerance value to be used during the validation of extracted ETM. This option can be used only when `-validate` option is also specified. For more details refer to `compare_model_timing -percent_tolerance`. Default: 3%
`-per_tol_val_optimistic` *float*	Specifies the percentage tolerance limit for flagging an optimistic failure. An optimistic path violating percentage as well as absolute tolerance limit will be flagged as FAIL in the `compare_model_timing` command output report. You can use the this parameter when the `-validate` is used with model extraction. *Default*: 3%
`-per_tol_val_pessimistic` *float*	Specifies the percentage tolerance limit for flagging a pessimistic failure. A pessimistic path violating percentage as well as absolute tolerance limit will be flagged as FAIL in the `compare_model_timing` command output report. You can use the this parameter when the `-validate` is used with model extraction. *Default*: 3%
`-pg`	Allows power or ground related pin information to be extracted inside the extracted model.
`-precision` *integer*	Specifies the floating point precision used for the timing model. For example, the floating point precision for 3.0089 can be changed as follows:
	Precision Data Value in .lib 4 3.0089 3 3.009 2 3.01 1 3.0 *Default:* `4`

`-resolution` *float*	Specifies the magnitude of delay difference that can be ignored by the extractor. *Default:* `0.001` *Type*: Float
`-tolerance` *float*	Specifies the accuracy level of extractor in percent. For example, 5.0 represents a plus or a minus 5.0 percent allowable error in the extracted model. The higher the tolerance, the faster the extraction time. *Default:* `1.0` *Type:* Float
`-validate` *string*	Validates the timing model generated for the corresponding view and displays the number of failures corresponding to setup and hold checks
`-view` *string*	Specifies the current active view.
`-verilog_shell_file` *filename*	Generates a Verilog shell file that instantiates the timing model. This parameter is useful for validating the model. Use the `-verilog_shell_module` parameter to specify the name of the top module in this Verilog file.
`-verilog_shell_module` *top_module_name*	Specifies the top module name of the Verilog shell file. *Default:* `test_shell`

Examples

- The following command builds a `.lib` model (`block.lib`) for the block:

  ```
  do_extract_model block.lib
  ```

- The following command creates the timing model for the `test_model` cell belonging to the `test_lib` library, and writes the model into the `test.lib` liberty file:

  ```
  do_extract_model -cell_name test_model -library_name test_lib test.lib
  ```

merge_model_timing

```
merge_model_timing
[-help]
[-keep_separate_arc]
-library_file string
-mode_group string
-modes string
[-outfile string]
[-pin_cap_tolerance float]
[-tolerance float]
```

Merges extracted timing models (ETM) for various analysis views into a single output.

The `merge_model_timing` command should be the last command in the run script. Also, this command should be run separately in a Tempus session when a design is not loaded.

When the DRV values are different in the libraries that are merged, then Tempus saves the worst value of the DRV with a warning message.

If the DRV values are not equal, the greater value is stored for the following:

- Minimum transition
- Minimum capacitance
- Minimum fanout

The smaller value is stored for the following, in case of unequal DRVs:

- Maximum transition
- Maximum capacitance
- Maximum fanout
- Fanout load

Parameters

`-help`	Prints out the command usage.
`-keep_separate_arc`	Enables creating separate timing arcs with respective modes.
`-library_file` *string*	Specifies input library files that are to be merged.
`-modes` *string*	Specifies the mode names required for merging the libraries. The number of mode names should be equal to the number of input libraries.
`-mode_group` *string*	Specifies the name of the mode group.
`-outfile` *string*	Specifies the name of the merged library output file name. By default, the output file name is `merge.lib`.
`-pin_cap_tolerance` *float*	Specifies the pin capacitance tolerance for making tolerance comparison for library merging.
`-tolerance` *float*	Specifies the tolerance value for making tolerance comparison for library merging.

Examples

- The following command merges library files `model1.view1.lib` and `model1.view1.lib.ref` into a single output file:

```
merge_model_timing -library_file "model1.view1.lib model1.view1.lib.ref"
-modes "v1 v2" -mode_group v1_v2
```

Related Information

- See "Extracting Timing Models" in the *Innovus User Guide*.
- `write_model_timing`
- `compare_model_timing`

write_model_timing

```
write_model_timing
[-help]
[model_timing_report_file]
[-inputs string]
[-nworst integer]
[-outputs string]
[-slew_propagation {worst | path_based}]
[-type {arc | slack}]
[-verbose]
[-view string]
-setup string | -hold string
```

Writes the interface timing characteristics of the design in the specified timing model report file.

The report file contains the following sections:

- `Worst-Case Arc/Slack`: Contains details about the extracted arcs and the slack or delay across them depending on the argument specified with the `-type` option.
- `Transition Time`: Contains information about transition time at ports.
- `Capacitance`: Contains the capacitance values for the ports.
- `Design Rules`: Contains the design rules applied to the ports.

The command reports unconstrained arcs delays by default.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `write_model_timing` parameter. For a detailed description of the command and all of its parameters, use the man command: `man write_model_timing`.
`-hold string`	Writes the paths corresponding to early analysis.

`-inputs {`*`port_list`*`}`	Restricts the `write_model_timing` report to the input ports specified with this parameter. As a result, the software considers the timing paths related to the specified input ports only, while generating the report. If this parameter is not specified, all the input ports in the design are considered while generating the report.
`model_timing_report_file`	Specifies the name of the interface timing model report file that will be generated with the interface timing characteristics of the loaded design.
`-nworst` *`value`*	Specifies the number of paths to be enumerated for each end point. **Note:** The extracted model will contain greater number of setup/hold paths per end point because it will have lesser end points compared to the original netlist. Therefore, it is recommended that you use a greater `-nworst` value such as `40` while writing a timing report for the extracted model to derive better correlation.
`-outputs {`*`port_list`*`}`	Restricts the `write_model_timing` report to the output ports specified with this parameter. As a result, the software considers the timing paths related to the specified output ports only, while generating the report. If this parameter is not specified, all the output ports in the design are considered while generating the report.
`-slew_propagation { worst | path_based }`	Sets the slew propagation mode to use for dumping the timing characteristics of the design.
`-setup` *`string`*	Writes the paths corresponding to late analysis.
`-type { arc | slack }`	Determines whether to report arc delay values (`arc`) or the worst-slack values (`slack`).
`-view` *`view_name`*	Specifies a view name. The report can be generated for a specific view name.
`-verbose`	Prints the command progress details.

Example

- The following command extracts the interface timing characteristics of the currently loaded design and writes out the report file named `sample.rpt` with the arc delay information:

```
write_model_timing -type arc sample.rpt
```

```
Output:

#################################################################
# write_model_timing report
# Design : netlist = .//case1.v topcell = set_propagated_clock_tc2
# Version : 07.10-dev.indfe_cm
# Analysis Mode : setup

addRepeaterByRule

```
addRepeaterByRule
[-help]
[-copyNetAttribute]
[-excNet excludeNetFile]
[-netMapping fileName]
[-nets list_of_nets]
[-outDir directoryName]
[-preRoute | -postRoute | -alongRoute]
[-reportIgnoredNets ignoredNetFile]
[-rule fileName]
[-selNet selNetFile]
[-selected]
[-template]
```

Inserts buffers and/or inverters to nets, as defined in a rule file. By default, inserts available buffers and/or inverters with the smallest total area cost while satisfying the rules. As compared to DRV fixing, `addRepeaterByRule` does not consider transition violations (maxTran) or any timing information. Instead, it constrains max total net length, max radius length, max capacitance, max fanout count, and so on. Also, `addRepeaterByRule` does not legalize newly added buffers. You need to legalize the added buffers to a legal location.

The command provides an efficient, buffering method for top-level designs.

Note: Max radius length refers to the sum of wire lengths from the driver to the farthest sink and max total net length refers to the total (sum) wire lengths throughout the target net.

The command has the following features:

- Supports multiple buffer/inverter/AO cells simultaneously
- Supports multiple types of constrains simultaneously
- Provides complete MSV compatibility solution
- It is multithreaded

The rule file may contain two categories of constraints, where each category further breaks down to several constraint types. All constraints share the same syntax of ‘command value’.

1. Individual repeaters’ rule: constrains each repeater’s driving capability.
   - max net total length (um): SetInverterMaxNetLength, SetBufferMaxNetLength, SetBufferMinLayerMaxNetLength, SetInverterMinLayerMaxNetLength
   - max radius length (um): SetInverterMaxRadiusLength, SetBufferMaxRadiusLength
   - max capacitance (pF): SetInverterMaxCap, SetBufferMaxCap
   - max fanout count: SetInverterMaxFanout, SetBufferMaxFanout
   - max fanout at sink count: SetMaxFanoutAtSink
   - max wirelength (um) of the net driving the sink term: SetMaxNetLengthAtSink
2. Global default rule: constrains all other instances beyond those newly inserted repeater instances.
   - default max net total length (um): SetDefaultMaxNetLength, SetDefaultMinLayerMaxNetLength
   - default max radius length(um): SetDefaultMaxRadiusLength
   - default max cap length (pF): SetDefaultMaxCap
   - default max fanout count: SetDefaultMaxFanout
   - default max sink radius length (um): SetDistLastRepToSink
   - default max wirelength (um) of the net driving the sink term: SetMaxNetLengthAtSink

Those constraints can be used individually or combined. However, at least one valid repeater must be specified in the rule file. If the global default rule for certain constraint type is omitted from the rule file, the command automatically picks the tightest constraint from the repeaters defined in the rule file under the ***same*** type of constraint as the default constraint. A sample rule file is shown in the "Example" section.

The following three layer-based rules are provided to support specifying net length constraints independently for each user specified layer:

- minimum layer for max net total length (um): SetBufferMinLayerMaxNetLength and SetInverterMinLayerMaxNetLength
- default minimum layer for max net total length (um): SetDefaultMinLayerMaxNetLength

Note: You must specify the bottom_preferred_routing_layer/top_preferred_routing_layer attribute for the nets that need layer-based buffering. If no attribute is present, the net will be routed with the default rule on default layers.

Use Model

When max layer constraint is specified:

```
SetBufferMaxNetLength BUF_X4M_A9TR 300.0
```

In the above scenario, ARR will buffer the net with `BUF_X4M_A9TR` at length intervals of `300um`.

When minimum layer support is also specified along with max layer constraint, then the following two scenarios are possible:

Example 1:

```
SetBufferMaxNetLength          BUF_X4M_A9TR     300.0
SetBufferMinLayerMaxNetLength  BUF_X4M_A9TR 6   500.0
```

In the above example, layers 2-5 will have a `300um` max length, and becasue there is a minimum layer constraint on the net of layer 6 or higher, the length constraint will be increased from `300` to `500um`.

Example 2:

When multiple minimum layer constraints are specified:

```
SetBufferMaxNetLength            BUF_X4M_A9TR     300.0
SetBufferMinLayerMaxNetLength    BUF_X4M_A9TR 6   500.0
SetBufferMinLayerMaxNetLength    BUF_X4M_A9TR 11  800.0
```

In the above example, layers 2-5 will have a `300um` max length; layers 6-9 will have a `500um` max length; and 11+ will have an `800um` max length.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `addRepeaterByRule` parameter. For a detailed description of the command and all of its parameters, use `man addRepeaterByRule`.
`-alongRoute`	Allows repeater insertion along the route. The database should be global-routed with preRoute RC extraction before calling this option. **Note**: Run `refinePlace` and `ecoRoute` if you specify this parameter.
`-copyNetAttribute`	
	When this parameter is specified, the net attributes set on the original nets are copied to the nets inserted by this command.
`-excNet` *`fileName`*	Specifies a file that contains the names of hierarchical nets to exclude from rule violation repair. If a net appears in the files specified by both `-excNet` and `-selNet`, it is excluded from rule violation repair.
`-netMapping` *`fileName`*	

	When specified, generates a file that maps the original net names to the nets inserted by this command. An example of the file format is provided below. In this example, `netA` is split into two nets; `FE_new_net1_netA` and `FE_new_net2_netA`.
	`netA FE_new_net1_netA`
	`netA FE_new_net2_netA`
	If, in the next iteration, `FE_new_net1_netA` is split again, the file would contain the following:
	`FE_new_net1_netA FE_new_net1_FE_new_net1_netA`
	`FE_new_net1_netA FE_new_net2_FE_new_net1_netA`

`-nets` *`list_of_nets`*	Specifies the list of nets to be considered for adding buffers and/or inverters. **Note**: The `-nets`, `-selNet`, and `-selected` parameters are mutually exclusive.

`-outDir` *directoryName*	Specifies the directory where the software writes detailed failure reason report that is generated when this command runs. By default, the failure reason report is dumped in the `timingReports/ARRFailureReason/<design>` directory. For example, `timingReports/ARRFailureReason/<design>.arr.preRoute.rpt.gz` *Default*: `timingReports`
`-postRoute`	Allows repeater insertion along the route. The database should be detailed-routed with detailed RC extraction before calling this option. Preserves routing so that changes are minimized. **Note**: Run `refinePlace` and `ecoRoute` if you specify this parameter.
`-preRoute`	Allows repeater insertion with different routing topologies. The database should be global-routed with preRoute RC extraction before calling this option. When this parameter is specified, the software explores different typologies to optimally insert repeaters.
`-reportIgnoredNets` *fileName*	
	Reports the nets where no buffers were inserted and the reason the nets were ignored.
`-rule` *fileName*	Specifies a file you create that should list the buffers and inverters and the length and capacitance rules for inserting each of them. Only buffers and inverters included in the rule file are inserted.
`-selected`	When this parameter is specified, the `addRepeaterByRule` command operates only on nets that are selected either by the `selectNet` command or in the GUI. **Note**: The `-nets`, `-selNet`, and `-selected` parameters are mutually exclusive.
`-selNet` *fileName*	Specifies a file that contains the names of hierarchical nets considered by this command. If a net appears in the files specified by both `-excNet` and `-selNet` , it is excluded from rule violation repair. **Note**: The `-nets`, `-selNet`, and `-selected` parameters are mutually exclusive.
`-template`	Writes a template rule file. **Note**: When the `-template` parameter is specified, the software does not honor any other parameters for this command.

Examples

- The following command explores different typologies to optimally insert repeaters:
  ```
  addRepeaterByRule -rule rule1 -preRoute
  ```
- In a detailed routed database with RC extraction, the following command inserts repeaters along the route and preserves routing, so that changes are minimized:
  ```
  addRepeaterByRule -rule rule1 -postRoute
  ```
- The following command inserts repeaters on those nets specified in the file, `net_file1`:
  ```
  addRepeaterByRule -rule rule1 -selNet net_file1
  ```
- The following is an example of a template rule file:
  ```
  ##############################################################################
  ################### addRepeaterByRule template rule file ####################
  ##############################################################################
  # constraintType            cellName              constraint value

addTieHiLo

```
addTieHiLo
[-help]
[-cell cellNames]
[-createHierPort {true | false}]
[-keepExisting {true | false}]
[-matchingPDs {true | false}]
[-postMask {true | false}]
[-powerDomain powerDomainName]
[-prefix prefixName]
[-reportHierPort {true | false}]
[-cellPin cellName:cellPin | -instancePin fileName | -excludePin fileName]
```

Adds instances of specified tie-off cells to the logical hierarchy of the design and connects the tie-off pins of netlist instances to the tie-off pins of the added instances. Thus, these instances provide the connectivity between the tie-high and tie-low pins of the netlist instances to power and ground. Use this command after placing the standard cells in the flow.

Note: If you omit the `-powerdomain` option, the command will insert tie-hilo on default power domains. To add tie-off cells to all domains, you need to use the `-matchingPDs` option.

Note: If you do not specify parameters, this command uses the global parameters specified by the `setTieHiLoMode` command.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `addTieHiLo` parameter. For a detailed description of the command and all of its parameters, use the man command: `man addTieHiLo`.
`-cell` *cellNames*	Specifies the tie cells to add. You can only specify a maximum of two tie-cells, where one cell must be a tie-high driver, and the other a tie-low driver. The two tie-cell names must be surrounded by quotation marks. This parameter overrides cell name(s) specified by the `setTieHiLoMode` command. *Default*: `""` (empty string)
`-cellPin` *cellName:cellPin*	Specifies the cell pins that are to be tied. The cell format could be "cellName1:cellPin cellName2:cellPin cellName3:cellPin". Only the cell pins that have tie 0/1 connections and are specified in `-cellPin` are changed to the tie cell. The left tie connections do not change. *Default*: `""`
`-createHierPort {true | false}`	Allows the added tie cells to connect to tie pins across hierarchical boundaries if other constraints, such as maximum fanout and maximum distance, allow it. *Default:* `false`
`-excludePin` *fileName*	Specifies the excludePin file name. The file format is "instanceName/instancePin". Each line in the file contains one instance pin. Only the instance pins that have tie 0/1 connections and are not defined in this file are changed to the tie cell. The left tie connections do not change. *Default*: `""`
`-instancePin` *fileName*	Specifies the instance pins file name. The file format is "instanceName/instancePin". Each line in the file contains one instance pin. Only the instance pins that have tie 0/1 connections and are defined in this file are changed to the tie cell. The left tie connections do not change. *Default*: `""`

`-keepExisting {true | false}`	When set to `true`, preserves the existing tie-offs, added in the previous run, in the design and adds new ones. *Default:* `false`
`-matchingPDs {true | false}`	Adds tie-off cells to all power domains that have library binding containing the specified tie-off cell(s). *Default:* `false`
`-postMask {true | false}`	Insert tie cells in post mask flow. Instructs the software to reuse existing tie cells to tie off a newly created spare instance in the design instead of adding or deleting tie cells. Searches for input pins that are tied to logical 1 or logical 0 and attempts to tie them off to tie high or tie low cells. *Default:* `false`
`-powerDomain` *powerDomainName*	Inserts tie-off cell to the named PD. *Default*: `""` **Note:** When this option is not specified, tool only inserts tie cells in the "default" power domain
`-prefix` *prefixName*	Specifies a prefix for the added tie-cell instances. *Default*: `""`
`-reportHierPort {true | false}`	When the value of `-createHierPort` is `true`, reports created port connections to a file named `tiehilo.rpt`. *Default:* `false`

Examples

- The following command adds tie-high and tie-low connectivity for designs with libraries that have cell named TIEOFF that provides both tie-high and tie-low connections. The instances added are prefixed with `tieOff`:

  ```
  addTieHiLo -cell TIEOFF -prefix tieOff
  ```

- The following command adds tie-high and tie-low connectivity for designs with libraries that have separate tie-high and tie-low cells named `TIEHI` and `TIELO` respectively:

  ```
  addTieHiLo -cell "TIEHI TIELO"
  ```

- The following commands add tie-off connectivity for MSV designs with two power domains named `PD1` and `PD2`. The last command is necessary for the part of the design that is not in either of the two specified power domains.

  ```
  addTieHiLo -cell "TIEHI TIELO" -powerDomain PD1
  addTieHiLo -cell "TIEHI TIELO" -powerDomain PD2
  addTieHiLo -cell "TIEHI TIELO"
  ```

- The following command add tie-off connectivity for MSV designs where all power domains whose library binding contains `TIEOFF` cell:

  ```
  addTieHiLo -cell TIEOFF -matchingPDs true
  ```

- The following command will connect all MUX/S and NOR/A pins that have the tie 0/1 connections to the tie cells. The left tie connections do not change.

  ```
  addTieHiLo -cellPin "MUX:S NOR:A"
  ```

- The following topic in the *Innovus User Guide*
  - Using Cell Footprints in Timing Optimization

createBasicPathGroups

```
createBasicPathGroups
[-help]
[-expanded]
[-reset]
```

Explicitly creates standard path groups irrespective of the design stage. The following path groups are created:

- reg2reg (register-to-register)
- reg2cgate (register-to-clock-gate)
- default

Note:

- If a design does not have any reg2reg paths, or reg2cgate paths, this command will create the corresponding path group(s).
- If the specified path group, say `reg2reg`, already exists, the software will give the following warning:

  ```
  **WARN: (IMPOPT-3666): Path group reg2reg already exists. Skipping the creation of this path group.
  ```

Parameters

`-help`	Outputs a brief description that includes type and default information for each `createBasicPathGroups` parameter. For a detailed description of the command and all of its parameters, use the man command: `man createBasicPathGroups`.
`-expanded`	When this parameter is specified, the following path groups are created: • reg2reg • reg2cgate • in2reg • reg2out • in2out When this parameter is not specified, only the default path groups, reg2reg and reg2cgate, are created. **Note**: Timing optimization will consider these path groups in the same way as paths grouped using the `group_path` command. In addition, if a design does not have any reg2reg or reg2cgate paths, this command will not create the corresponding path groups.
`-reset`	Deletes all existing path groups. This is equivalent to running the `reset_path_group` command. **Note**: After deleting the existing path groups, new path groups, reg2reg and reg2cgate are created.

Examples

- The following command is used to create the standard path groups and assigns an effort level to each group:

  ```
  createBasicPathGroups
  ```

  The software returns the following information:

  ```
  Created reg2reg path group
  Effort level <high> specified for reg2reg path_group
  Created reg2cgate path group
  Effort level <high> specified for reg2cgate path_group
  ```

- The following commands are used to set the effort level for the reg2reg path group to high, and report the parameters of the path groups that are created:

  ```
  setPathGroupOptions reg2reg -effortLevel low
  reportPathGroupOptions
  ```

  The software prints the following report:

  ```
  ------------------------------------------------------------------------------------------------
  |Path Group|Effort|Adjustment(early/late)|Target Slack|weight|SkewingSlackCons|view              |
  ------------------------------------------------------------------------------------------------
  |reg2reg   | high | 0.1    /-0.2         | 0          |  2   |    0.3         |AV_HL_FUNC_MIN_RC1 |
  |reg2cgate | high | 0.2    /0            | 0          |  1   |    0.5         |AV_HL_FUNC_MAX_RC1 |
  ```

createTBOptFile

```
createTBOptFile
[-help]
-bottleneckInstanceNumber integer
[-early]
[-max_paths integer]
[-max_slack float]
[-min_slack float]
-outFile filename
[-path_group groupname_list]
[-timingFile filename]
```

This command creates a target-based optimization (TBOpt) file for use with postRoute targeted optimization. Once created, this file is passed to the `setOptMode -opt_target_based_opt_file` command. You can either provide the name of the binary timing report on which you want to base the critical instance analysis by using the `-timingFile` parameter or let the command generate the timing report internally by using the values specified for the `-min_slack`, `-max_slack`, and `-max_paths` parameters or the internal default values for these parameters.

Based on this timing report, a bottleneck analysis is performed and the critical instances are stored in a file that is specified using the `-outFile filename` parameter. This file uses the TBOpt format with the INSTS token. The bottleneck analysis computes the number of times an instance appears (on only the failing paths by default) and creates "n" number of path categories for the instances with the highest number of occurrences. Note that "n" is the number you specify using the `-bottleneckInstanceNumber` parameter of this command.

Also note that by default, multiple instances per path are allowed. This means that if there are multiple critical instances on a path, all of them will be returned, therefore, leading to the generation of the most accurate list of critical instances.

For more information on using the TBOpt file, see Performing Target-Based Optimization in the *Innovus User Guide.*

Parameters

`-help`	Outputs a brief description that includes type and default information for each createTBOptFile parameter. For a detailed description of the command and all of its parameters, use the man command: `man createTBOptFile`
`-bottleneckInstanceNumber` *`integer`*	
	Specifies the number of critical bottleneck instances to be generated. This is a required parameter.

`-early`	Specifies that the TBOpt file will be created based on hold timing's critical nodes. This parameter can be specified along with the following commands to generate and use a hold target file for hold TBOpt. For example:
	`createTBOptFile -early -bottleneckInstanceNumber 5 -outFile TBOpt_bottleneck_5_hold.txt`
	`setOptMode -opt_target_based_opt_hold_file TBOpt_bottleneck_5_hold.txt`
	`optDesign -postRoute -targeted -hold`

`-max_paths` *`integer`*	Specifies the number of worst paths to be considered, regardless of the endpoint. By default, the value is `100,000`.
`-max_slack` *`float`*	Specifies that only those paths should be considered that have a slack equal to or less than the specified float value in `ns`. By default, the value is `0.0` to ensure that only paths with negative slacks are considered.
`-min_slack` *`float`*	Specifies that only those paths should be considered that have a slack greater than the specified float value in `ns`.
`-outFile` *`filename`*	Specifies the name of the TBOpt file that will be generated. This is a required parameter.
`-path_group` *`groupname_list`*	
	Specifies that only those paths should be considered that are from the specified path groups on which you want to base the critical instance analysis.
`-timingFile` *`filename`*	Specifies the name of the binary timing report on which you want to base the critical instance analysis. If this parameter is not specified, the command generates its own file with the `-max_slack` value of `0.0` and `-max_paths` value of `100,000`.

Example

- The following command generates a TBOpt file with five critical instances using the default values for `-min_slack`, `-max_slack`, and `-max_paths` that will be written to the file, `TBOpt_bottleneck_5.txt`:

  ```
  createTBOptFile -bottleneckInstanceNumber 5 -outFile TBOpt_bottleneck_5.txt
  ```

  The `TBOpt_bottleneck_5.txt` file will contain five critical instances with the appropriate syntax for target-based postRoute optimization.
  For example,

  ```
  INSTS : {mod_i/i_mod_glm_cluster_0/U586} {mod_i/i_mod_glm_cluster_2/U535} {mod_i/i_mod_glm_cluster_1/U596}
  {mod_i/ser_en/U92} {mod_i/ser_en/U101}
  ```

- The following command generates a TBOpt file with six critical instances based on only the `reg2reg` path group with the maximum number of worst paths as 3000:

  ```
  createTBOptFile -bottleneckInstanceNumber 6 -outFile TBOpt_bottleneck_6.txt -path_group reg2reg -max_paths 3000
  ```

- The following command generates a TBOpt file with nine critical instances based on a timing analysis of the worst 10,000 paths between `+0.025ns` and `-1.0ns`:

  ```
  createTBOptFile -bottleneckInstanceNumber 9 -outFile TBOpt_bottleneck_9.txt -min_slack -1.0 -max_slack +0.025 -
  max_paths 10000
  ```

deleteBufferTree

```
deleteBufferTree
[-help]
[-excNetFile excFileName]
[-footprint footPrintName]
[-preserveRoute]
[-selNetFile selFileName | -net list_of_nets]
[-verbose]
```

Removes all buffers (except clock path buffers) and inverter pairs, of all footprint types, on all nets in the design. With specific settings, this command can remove buffers and inverter pairs of the specified footprint type, or on specified nets only.

Note:

1. place_opt_design will automatically call `deleteBufferTree` in the beginning, before global placement.
2. If you want to have a clean design with reduced density, or just clear all buffers and inverter pairs of a certain list of nets, it is recommended to call this command. This may allow you to do ECO on those nets.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `deleteBufferTree` parameter. For a detailed description of the command and all of its parameters, use the man command: `man deleteBufferTree`
`-excNetFile` *excFileName*	Specifies the input file that contains the names of nets to exclude from buffer removal. If a net appears in the files specified by both `-excNetFile` and `-selNetFile`, it is excluded.
`-footprint` *footprintName*	Specifies the footprint of buffers to remove. If you do not specify this parameter, the Innovus software removes buffer instances with one input and one output terminal, and whose timing arc is not `SPECIAL`.
`-net` *list_of_nets*	Specifies the hierarchical nets to include during buffer removal. **Note**: The `-net` and `-selNetFile` parameters are mutually exclusive.
`-preserveRoute`	Specifies that nets not impacted by the buffer/inverter deletion process must have their routing unchanged. By default, the tool removes all the routes after running this command.
`-selNetFile` *selFileName*	Specifies the file that contains the names of hierarchical nets to include during buffer removal. The software excludes all other nets. If a net appears in the files specified by both `-excNetFile` and `-selNetFile`, it is excluded. **Note**: The `-net` and `-selNetFile` parameters are mutually exclusive.
`-verbose`	When specified, displays additional debug messages in log file. For example, the failure reason for deletion of buffer and inverter pairs.

Examples

- The following command removes all buffers and inverter pairs, of all footprint types:

```
deleteBufferTree
*** Start deleteBufferTree ***
Info: Detect buffers to remove automatically.
Analyzing netlist ...
Updating netlist

*summary: 79 instances (buffers/inverters) removed
*** Finish deleteBufferTree (0:00:09.6) ***
```

- The following command removes all buffers of footprint type `B_1P`:

```
deleteBufferTree -footprint B_1P
```

  - Using the Footprintless Flow

deleteTieHiLo

```
deleteTieHiLo
[-help]
[-cell tieCellName | "listOfTieCellNames"]
[-prefix prefixName ]
```

Deletes placed tie cells from the netlist and reconnects the tie input pins back to `1'b1` and `1'b0`. Use this command if there are existing tie cells in design.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `deleteTieHiLo` parameter. For a detailed description of the command and all of its parameters, use the man command: `man deleteTieHiLo`.
`-cell tieCellName | "listOfTieCellNames"`	
	The *`tieCellName`* argument specifies the cell name to delete. The " *`listOfTieCellNames`* " argument specifies the list of cell names to be deleted, which must be surrounded by quotation marks. **Note**: The *`tieCellName`* and "*`listOfTieCellNames`*" arguments are mutually exclusive.
`-prefix prefixName`	Specifies the prefix of the instances to delete.

Note: If you do not specify any parameters, the command uses the global cell names if they were set previously with the `setTieHiLoMode` command.

Example

- The following command deletes all placed tie-off cell instances with the prefix `ABC`:
  ```
  deleteTieHiLo -prefix ABC
  ```
- The following command deletes all placed tie-off cells named: `TIEOFF`:
  ```
  deleteTieHiLo -cell TIEOFF
  ```

Related Information

  - Adding Logical Tie-Off Cells

dumpMultiBitFlopMappingFile

```
dumpMultiBitFlopMappingFile
[-help]
[-mapOutputPins {false | true | all}]
[-output directory]
[-prefix fileName_prefix]
```

Dumps the multi-bit flip-flop (MBFF) mapping files in the specified directory with the specified prefix name. The following files are dumped:

- `multi_bit_pin_mapping`

  includes multi-bit input pin mapping information by default. In addition, it appends the output pins when the `-mapOutputPins` option is specified.

- `multi_bit_mapping`

  includes multi-bit optimization mapping information

The `multi_bit_pin_mapping` file has two columns. The first column provides the full path name of the flop input D pin as it was in the initial netlist. The second column provides the full path name of flop input D pin in the current state of the database that corresponds to the first column. For example, if SBF1, SBF2, SBF3, SBF4 are single-bit flip-flops, and MBF1, and MBF2 are two-bit flip-flops, then,

The **multi_bit_mapping** file contains the following:

```
SBF1(SBCell1), SBF2(SBCell2) merged to MBF1(MBCell1)

MBF2(MBCell2) split to SBF3(SBCell3), SBF4(SBCell4)
```

The **multi_bit_pin_mapping** file by default contains the following**:**

```
SBF1/D    MBF1/D1

SBF2/D    MBF1/D2

MBF2/D1   SBF3/D

MBF2/D2   SBF4/D
```

Note:

- The `multi_bit_pin_mapping` file contains all information of the flops whose input D pin names have changed. For example, see the "Examples" section below.
- To generate a proper report for merge/split mapping information, the command should be executed as part of the flow in the live session, for example, after running `place_opt_design`. If the command is run on a restored session, it will generate an empty "`multi_bit_mapping`" file because the merge/split mapping information is not saved while saving the design.
- You can use the `write_do_lec` command to facilitate the Logical Equivalence Checking (LEC) checking of the MBFF instances. This command writes out a `dofile` that contains the name mapping information of the MBIT flops against their split/single bit candidate.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `dumpMultiBitFlopMappingFile` parameter. For a detailed description of the command and all of its parameters, use the man command: `man dumpMultiBitFlopMappingFile`.

`-mapOutputPins {false | true | all}`	When set to `true`, the software writes out only the mapped output terms in the MBFF pin mapping file.
	When set to `false`, the software writes out only input pin mapping in the pin mapping file. This is the default setting.
	When set to `all`, the software writes out both input and output pin mapping in the pin mapping file.
	Example of **multi_bit_pin_mapping** file when `-mapOutputPins` parameter is set to `false`:
	`MBF1/D1  SBF1/D`
	`MBF1/D2  SBF2/D`
	Example of **multi_bit_pin_mapping** file when `-mapOutputPins` parameter is set to `true`:
	`MBF1/Q1 SBF1/Q`
	`MBF1/Q2 SBF2/Q`
	Example of **multi_bit_pin_mapping** file when the `-mapOutputPins` parameter is set to `all`:
	`MBF1/D1 SBF1/D`
	`MBF1/D2 SBF2/D`
	`MBF1/Q1 SBF1/Q`
	`MBF1/Q2 SBF2/Q`
	Default: `false`

`-output` *directory*	Specifies the directory in which to dump the MBFF mapping files. *Default*: ./
`-prefix` *fileName_prefix*	Specifies the prefix to the MBFF mapping files. *Default*: `without prefix`

Examples

Consider a scenario in which the original netlist contains the following information:

```
4BitMBF1        (4 bit MBF, D1-4)
SBF1            (single bit FF)
```

Example of merging is as follows:

If the incoming netlist has `4BitMBF1/D4` dangling (no signal attached) and MERGE, merged `SBF1/D` into `4BitMBF1/D4`. The following line will be included in `multi_bit_pin_mapping` file:

```
SBF1/D          4BitMBF1/D4
```

Example of splitting is as follows:

If incoming netlist has valid signals for all 4 bits of `4BitMBF1` and splits `4BitMBF1/D4` out to `SDF2/D` leaving `4BitMBF1/D4` dangling, then the following lines will be included in `multi_bit_pin_mapping` file:

```
*VOID*          4BitMBF1/D4
4BitMBF1/D4     SBF2/D
```

ecoClone

```
ecoClone
[-help]
[-allow_sequential]
[-auto]
[-balance num]
[-cells list_of_cells]
[-delete_buffer_trees]
[-dont_legalize]
[-dont_resize]
[-force]
[-from pin names]
[-instances instance names]
[-locs list_of_locations]
[-loop number]
[-max_levels integer]
[-max_num_loads integer]
[-min_num_loads integer]
[-nets list_of_nets]
[-numClones number]
[-preview]
[-radius number]
[-same_hier_only]
[-terms list_of_term_lists]
[-to pin names]
[-verbose]
```

Clones combinational logic if logic does not have any user constraints like don’t size/touch and so on. This command is used when you want to clone combinational logic as manual ECO. It does not work for sequential logic like flops. The `-from` and `-to` parameters are used to specify the 'from' and 'to' pins for cloning.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `ecoClone` parameter. For a detailed description of the command and all of its parameters, use the man command: `man ecoClone`
`-allow_sequential`	Used with `-auto` to try cloning at the sequential gates too.
`-auto`	Applies cloning and buffering automatically. The software identifies and clones combinational logic based on critical endpoints distance-based clustering.
`-balance number`	When specified, forces the number of loads on each clone to be within the specified number percentage (*num* `%`). The default balance is 10%.

`-cells` *list_of_cells*	Specifies the list of cells to use for the clones. **Note**: ◦ If this parameter is not specified, the clones have the same cell as the original gate. ◦ If only one cell is specified in the list, all the clones are created with that cell. ◦ If the `-locs` and `-terms` parameters are not specified, you can only specify one cell in that list. ◦ If the `-locs` and/or `-terms` parameters are specified, you can also specify numClones cells, which is one cell for each clone. ◦ It is not possible to specify a new cell for the original gate, so the original gate is not resized.
`-delete_buffer_trees`	When specified, the software attempts to delete buffer trees driven by instances to clone. **Note**: The deletion of buffer trees with user constraints is skipped.
`-dont_legalize`	When specified, the software may leave cloned instances overlapped with the original ones. This means the software will not try to legalize instances. This means that if space is available, it will place legally, otherwise it will leave cloned instances overlapped with the original ones.
`-dont_resize`	Specifies that neither the original nor the new (cloned) instances should be resized.
`-force`	When specified, forces instance cloning, even if it worsens QoR or causes illegal placement.
`-from` *pin names*	Specifies 'from' pins. You can specify a single pin or a list of pins.
`-instances` *instance names*	Specifies the instances to be cloned. You can specify a single instance or a tcl list of instances to be cloned.
`-locs` *list_of_locations*	Specifies the location of each clone. This parameter is used along with the `-numClones` parameter. When this parameter is specified, a location should be specified for each clone, so the length should be numClones. The length can be numClones+1, in which case, the first location is used for the original gate. When the locations are specified, the sink partitions are assigned to the closest clone.
`-loop` *number*	Repeat cloning at most *number* times, as far as new instances are being created. The original and new instances within the min/max number of loads range are valid targets at each iteration. *Default*: `0` (means no limit)
`-max_levels` *integer*	Specifies the level of instances that the software needs to traverse for cloning. Zero value means the software will clone everything till the origin of logic. *Default*: 0 (meaning infinite)
`-max_num_loads` *integer*	Specifies that cloning should be skipped for instances driving more than the specified number of loads. *Default*: `50000`
`-min_num_loads` *integer*	Specifies that cloning should be skipped for instances with less than or equal to the specified number of loads. **Note**: The `-min_num_loads` and `-numClones` parameters are mutually exclusive.
`-nets` *list_of_nets*	Specifies the nets to be cloned. You can specify a single net or a tcl list of nets to be cloned. **Note**: The `-nets` and `-instances` parameters are mutually exclusive. Wildcards are allowed for this parameter.

`-numClones` *number*	Specifies the number of clones to create. The default value is `0` and in that case, it is computed from the `-min_num_loads` parameter. **Note**: The `-min_num_loads` and `-numClones` parameters are mutually exclusive. *Default:* `0`
`-preview`	When specified, provides a preview of what would be done, while leaving the netlist untouched. This means that the software will report instances that will be cloned and the changes that will be applied to the netlist without actually changing the netlist.
`-radius` *number*	Specifies that the clones should be placed within a radius of the specified number of rows from their preferred location based on the original instance location and the center of mass of the new set of loads. *Default*: `10`
`-same_hier_only`	Specifies that only those loads will be considered that are in the same hierarchy as the driver.
`-terms` *list_of_term_lists*	Specifies the partitions, so it is a list of term lists. This parameter is used along with the `-numClones` parameter. When this parameter is specified, there should be one partition for each clone, so the length should be numClones. The terms that are not in any partition are assigned to the partition driven by the original gate. The length can be numClones+1, in which case the first partition is for the original gate. In that case, all the sinks should be in a partition.
`-to` *pin names*	Specifies 'to' pins. You can specify a single pin or a list of pins.
`-verbose`	When specified, verbose messages are displayed during the cloning of instances.

Example

The following command will clone logic till `$to` pins with more then `6` loads, while forciby deleting the buffer tree:

```
ecoClone -to $to -verbose  -min_num_loads 6 -delete_buffer_trees -force
```

Related Information

- `ecoCloneFlop`
- `setOptMode`

ecoCloneFlop

```
ecoCloneFlop
[-help]
[-force]
-instances flopInstName
[-max_num_loads num_of_loads]
[-numClones number]
[-radius num_of_rows]
[-verbose]
```

Clones flop instances as long as the flops meet the following criteria:

- They are not FIXED
- They are allowed to be resized
- When they do not share synchronization signals with some other instance

This command is used when you want to clone a flop as manual ECO. Manual flop cloning is usually performed on control signal flip-flops, when the output needs to reach sections of the floorplan that are spread out. Cloning the flip-flops allows you to place each clone close to its sink points, thereby reducing the timing closure effort.

This command should not be used to clone a flop that drives a clock net, which is a net with the attribute `isDefInclock`, because this may lead to problems during optimization or timing. The default behavior of the command may reject the flip-flop cloning due to design constraints or QOR impact.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `ecoCloneFlop` parameter. For a detailed description of the command and all of its parameters, use the man command: `man ecoCloneFlop`.
`-force`	When specified, forces the flop instance to clone. This parameter is used when flop cloning is rejected by the software.
`-instances` *`flopInstName`*	Specifies the list of instances to be cloned. This is a required parameter.
`-max_num_loads` *`num_of_loads`*	Specifies that cloning should be skipped for instances driving more than the specified number of loads. *Default*: `50000`
`-numClones` *`number`*	Specifies the cloned numbers for the flop instance.
`-radius` *`num_of_rows`*	Specifies that the clones should be placed within a radius of the specified number of rows from their preferred location based on the original instance location and the center of mass of the new set of loads. *Default*: `10`
`-verbose`	When specified, verbose messages are displayed during the cloning of flop instances.

Example

The following command will clone the flip-flop `$inst` 3 times:

```
ecoCloneFlop -instances $inst -numClones 3
```

ecoMergeCombinationalCell

```
ecoMergeCombinationalCell
[-help]
[-area]
[-force]
-inst comboInstName | -listFile instNamesFile | -all
[-power]
-preCTS | -postCTS
```

Merges combinational cells into multi-bit cells for the specified instance. You can specify the names of the combinational instances to be merged or you can specify the file containing names of single bit instances to merge.

Naming Convention During Merging

When the combinational cells in the specified file are merged, the corresponding instance names are combined as follows:

- `hier1/hier2/i_0 + hier1/hier2/i_1 + hier1/hier2/i_2 + hier1/hier2/i_3`

  TO

  `hier1/hier2/CDN_MB_i_0_MB_i_1_MB_i_2_MB_i_3`

- `abc_x[0] + abc_x[1] + abc_x[2] + abc_x[3]`

  TO

  `CDN_MB_abc_x[0]_MB_x[1]_MB_x[2]_MB_x[3]`

Parameters

`-help`	Outputs a brief description that includes type and default information for each `ecoMergeCombinationalCell` parameter. For a detailed description of the command and all of its parameters, use the man command: `man ecoMergeCombinationalCell`.
`-all`	Specifies that all single-bit cell instances should be merged into multi-bit cell instances. This parameter is mutually exclusive with the `-listFile` and `-all` parameters. At least one of these parameters must be specified.
`-area`	Specifies to merge the combinational cells for area purposes. *Default*: `false`
`-force`	Forces the merging of the combinational cell regardless of the timing gains. *Default*: `false`
`-inst` *comboInstName*	Specifies the name of the combinational instance to be merged. This is a required parameter. This parameter is mutually exclusive with the `-listFile` and `-all` parameters. At least one of these parameters must be specified.
`-postCTS`	Specify this parameter if the design stage is postCTS. **Note**: This parameter is mutually exclusive with the `-preCTS` parameter. One of the two parameters must be specified.
`-listFile` *instNamesFile*	Specifies the file containing the names of single bit instances to merge. Specify one instance on one line. Comment with Instance name should not contain spaces or backslashes This parameter is mutually exclusive with the `-inst` and `-all` parameters. At least one of these parameters must be specified.
`-power`	Specify this parameter to merge the combinational cells for power purposes. *Default*: `false`
`-preCTS`	Specify this parameter if the design stage is preCTS. **Note**: This parameter is mutually exclusive with the `-postCTS` parameter. One of the two parameters must be specified.

  - Multi-Bit Combinational Cell Optimization

ecoSplitCombinationalCell

```
ecoSplitCombinationalCell
[-help]
[-force]
[-fullSplit]
[-legal]
[-skipRoute]
-inst combInstName | {{Mbcb1 combCell1} {Mbcb2 combCell2}...} | -listFile fileName | -all
-preCTS | -postCTS | -postRoute
```

Splits all multi-bit combinational cell instances to single-bit combinational cells. You can specify the names of the combinational instances to be merged or you can specify the file containing names of multi-bit instances to be split.

Naming Convention During Splitting

When splitting Multibit combinational cells, it will split the names as follows:

- `hier1/hier2/i_[0:3]`

  TO

  `hier1/hier2/i_[0:3]__0, hier1/hier2/i_[0:3]__1, hier1/hier2/i_[0:3]__2, hier1/hier2/i_[0:3]__3`

- `CDN_MB_abc_MB_def`

  TO

  `abc, def`

Parameters

`-help`	Outputs a brief description that includes type and default information for each `ecoSplitCombinationalCell` parameter. For a detailed description of the command and all of its parameters, use the man command: `man ecoSplitCombinationalCell`.
`-all`	Splits all multi-bit combinational cell instances to SBFF instances. This parameter is mutually exclusive with the `-inst` and `-listFile` parameters. At least one of these parameters must be specified. *Default*: `false`
`-force`	Forces the splitting of the combinational cell regardless of the timing gains. *Default*: `false`
`-fullSplit`	Set this parameter to completely split the multi-bit combinational cells to single bits.
`-inst` *comboInstName* `{{`*Mbcb1 combCell1*`} {`*Mbcb2 combCell2*`}...}`	
	Specifies the names of the combinational instance to be split. If the input is a string of multi-bit combinational (MBCB)/Cell pairs list, it will split the MBCB to the specified cell without evaluation This parameter is mutually exclusive with the `-listFile` and `-all` parameters. At least one of these parameters must be specified.
`-legal`	Specifies to place the split flip-combinational cells at legal location. *Default*: `false`
`-listFile` *fileName*	Specifies the file containing names of MBCB instances to split. Specify one instance on one line. Comment with #. Instance name should not contain spaces or backslashes. And if one instance and one cell is specified on one line, it will split the MBCB to the specified cell without evaluation. This parameter is mutually exclusive with the `-inst` and `-all` parameters. At least one of these parameters must be specified.
`-postCTS`	Specify this parameter if the design stage is postCTS. This is a required parameter. One of these parameters, `-preCTS`, `-postCTS`, or `-postRoute` must be specified.
`-postRoute`	Specify this parameter if the design stage is postRoute. This is a required parameter. One of these parameters, `-preCTS`, `-postCTS`, or `-postRoute` must be specified.
`-preCTS`	Specify this parameter if the design stage is preCTS. This is a required parameter. One of these parameters, `-preCTS`, `-postCTS`, or `-postRoute` must be specified.
`-skipRoute`	Specify this parameter if the design stage is postRoute and globalDetailRoute is not required after the split.

  - Multi-Bit Combinational Cell Optimization

ecoSplitComplexFlop

```
ecoSplitComplexFlop
[-help]
[-force]
{-inst {inst1, inst2,...} | -listFile instNamesFile | -all}
[-legal]
[-preCTS | -postCTS | -postRoute]
[-power]
[-skipRoute]
```

Splits a complex flip-flop into a simple flip-flop and combinational logic for the specified instance. A complex flip-flop means the D side has some combinational logic, such as AND, OR, MUX, AOI, and so on. By default, a specific flip-flop is split only if equivalent simple flip-flops and combinational logic can be found in libraries and there is timing gain or power gain after the split.

You can also specify that the split flip-flops should be placed in legal locations. By default, the positions of the split flip-flops are not guaranteed to be legal.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `ecoSplitComplexFlop` parameter. For a detailed description of the command and all of its parameters, use the man command: `man ecoSplitComplexFlop`
`-all`	Specifies that all flop instances in the design should be processed. **Note**: The `-inst`, `-listFile`, and `-all` parameters are mutually exclusive. One of these parameters must be specified.
`-force`	When specified, forces the complex flip-flops to split regardless of the timing gains.
`-inst {inst1, inst2,...}`	
	Specifies the names of the flop instances to be split. You can specify a single instance or a tcl list of instances to be split. **Note**: The `-inst`, `-listFile`, and `-all` parameters are mutually exclusive. One of these parameters must be specified.
`-listFile instNamesFile`	
	Specifies the file containing the names of the flop instances to be split. Specify one instance on one line. Comment with #. Instance name should not contain spaces or backslashes. **Note**: The `-inst`, `-listFile`, and `-all` parameters are mutually exclusive. One of these parameters must be specified.
`-legal`	When specified, places the split flip-flops and combinational cells at a legal location.
`-preCTS`	Specify this parameter, if the design stage is preCTS.
`-postCTS`	Specify this parameter, if the design stage is postCTS.
`-postRoute`	Specify this parameter, if the design stage is postRoute.
`-power`	When specified, complex flops are split to reclaim power. By default, the flops are split for timing.
`-skipRoute`	Skip globalDetailRoute after split in postRoute stage.

Examples

- Use the following command to force the flip-flop split for power for all instances during the preCTS stage.
  ```
  ecoSplitComplexFlop -force -preCTS -power -all
  ```
- Use the following command for flip-flop split for timing for the instance ff1 during the preCTS stage.
  ```
  ecoSplitComplexFlop -inst ff1 -preCTS
  ```

Related Information

ecoSplitFlop

```
ecoSplitFlop
[-help]
[-batch]
[-force]
[-fullSplit]
{-inst flopInstName | {{Mbff1 flopCell1} {Mbff2 flopCell2}...} | -listFile <fileName> | -all}
[-legal]
[-power]
{-preCTS | -postCTS | -postRoute}
[-skipRoute]
```

Splits a multi-bit flip-flop (MBFF) into single-bit flip-flops for the specified instance. By default, a specific flip-flop is split only if equivalent single-bit flip-flops can be found in libraries and there is timing gain after the split. You can also specify that the split flip-flops should be placed in legal locations. By default, the positions of the split flip-flops are not guaranteed to be legal.

Note:

- This command is not controlled by the `-multiBitFlopOpt` parameter setting of `setOptMode`.
- The command calls refinePlace at the end. To disable this, use `setEcoMode -refinePlace false`.
- MBFFs must be identified by the command, `reportMultibit`.
- A placeable location for the split FFs is required.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `ecoSplitFlop` parameter. For a detailed description of the command and all of its parameters, use the man command: `man ecoSplitFlop`
`-all`	When specified, splits all MBFFs into smaller-bit flip-flops including single-bit flip-flops (SBFFs). Only timing critical bits are split into single-bit flops, and the remaining, non-critical bits, are split into smaller bit width MBFFs, to preserve power as much as possible. For example, a 4-bit MBFF may be split into two single-bit flops and one 2-bit flop. **Note**: The `-all`, `-inst` and `-listFile` parameters are mutually exclusive. If the `-all` parameter is not specified, one of these two parameters, `-inst` or `-listFile`, must be specified. *Default*: `false`
`-batch`	When specified, splits the MBFFs in batches. For example, `ecoSplitFlop -listFile list -postCTS -batch -force` *Default*: `false`
`-force`	Forces the flip-flop splits irrespective of timing gains. **Note**: • If there is no timing gain and this parameter is not specified, the flip-flops for the specified instance will not be split. • If this option is set along with the `-legal` option, the software will first look for legal locations. However, the flip-flops will be split even if no legal location is found. *Default*: `false`

`-fullSplit`	Forces the MBFFs to be completely split into all single-bit flip-flops.
`-inst` *`flopInstName`* `| {{Mbff1 flopCell1} {Mbff2 flopCell2}...}`	
	Specifies pairs of MBFFs to be split and the corresponding single-bit flops to be used. You can also specify the names of the flop instances to be split. You can specify a single instance or a tcl list of instances to be split. **Note**: The `-all`, `-inst` and `-listFile` parameters are mutually exclusive. If the `-all` parameter is not specified, one of these two parameters, `-inst` or `-listFile`, must be specified.
`-listFile` *`fileName`*	
	Specifies the file containing pairs of MBFFs to be split and the corresponding single-bit flops to be used. You can also just specify the names of MBFF instances to be split. You can specify up to 50,000 instances to split. Specify each instance on a line and comment with #. Instance name should not contain spaces or backslashes. **Note**: The `-all`, `-inst` and `-listFile` parameters are mutually exclusive. If the `-all` parameter is not specified, one of these two parameters, `-inst` or `-listFile`, must be specified.
`-legal`	Places the split flip-flops at legal locations. **Note**: If both the `-legal` and `-force` parameters are specified, the software will first look for legal locations. However, the flip-flops will be split even if no legal location is found. In this case, the split instances will be placed in the original location of the MBFFs. *Default*: `false`
`-power`	Splits the flip-flop for power purpose. *Default*: `false`
`-preCTS`	Specify this parameter, if the design stage is preCTS. *Default*: `-postRoute`
`-postCTS`	Specify this parameter, if the design stage is postCTS. *Default*: `-postRoute`
`-postRoute`	Specify this parameter, if the design stage is postRoute. This is the default setting. **Note**: One of the three options, `-preCTS`, `-postCTS`, or `-postRoute` must be specified.
`-skipRoute`	Specify if the stage is postRoute and globalDetailRoute is not required to be performed after the split. Since postRoute is also the default stage, globalDetailRoute is also skipped when the stage is default and `-skipRoute` is specified. However, for the default case, when the stage is postRoute but this parameter is not specified, after splitting the instances, globalDetailRoute will be called. *Default*: `false`

Example

- The following command will force the flip-flop split for the instance, `ff_0` during the `preCTS` stage:

  ```
  ecoSplitFlop -preCTS -inst ff_0 -force
  ```

- The following command will will try to split for power all MBFFs during the `postCTS` stage:

  ```
  ecoSplitFlop -power -all -postCTS
  ```

findLefEquivalentCells

```
findLefEquivalentCells
[-help]
-cells string
[-outfile filename]
```

Provides support to debug certain cells that may be non-equivalent without detailed analysis of the LEF. For example, if two cells have the same function and size they still may not be LEF equivalent.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `findLefEquivalentCells` parameter. For a detailed description of the command and all of its parameters, use the man command: `man findLefEquivalentCells`
`-cells` *`string`*	Specifies the cell names. You can also use wildcards or specify individual cells.
`-outfile` *`filename`*	Specifies the output file name for reporting LEF equivalent cells. All the equivalent and non-equivalent cells are saved in the output file.

Examples

- The following example command reports equivalence information on all cells and outputs to a file:
  ```
  findLefEquivalentCells -cells * -outFile equivalency_file.txt
  ```
- To report equivalence information on a specific cell, say `SCBUF1X`, you can use the following command:
  ```
  findLefEquivalentCells -cells SCBUF1X
  ```
- To report equivalence information on all cells that begin with `SCBUF`, you can use the following command:
  ```
  findLefEquivalentCells -cells SCBUF*
  ```

getLatencyFile

```
getLatencyFile
[-help]
```

Returns the name of the latency file used by the timing engine. If no latency file name is set, `getLatencyFile` returns nothing, but if you have already run `skewClock`, this command reports the default file name. If you have specified or changed the latency file name by using the `setLatencyFile` command, `getLatencyFile` reports this name.

To view the above description in the software, use `man getLatencyFile`.

```

Returns information about the specified `setOptMode` parameter in the Innovus log file and the console. The following information is returned:

- Parameter name
- Current value
- Type (Boolean, string, and so on)
- Whether the current value was set by user

If you do not specify a parameter, the Innovus software returns values for all of the `setOptMode` parameters.

Parameters

parameter_names	Returns information for the specified parameter. You can specify one or more parameters. See `setOptMode` for descriptions of the parameters you can specify.
`-nonDefault`	Returns the current settings of the `setOptMode` parameters that are not default.
`-quiet`	Returns the current settings for the specified parameters in Tcl list format only. If you specify `-quiet` without any parameters, the software returns the current settings of all `setOptMode` parameters in Tcl list format.

Examples

- The following command returns the current setting of the `-addInst` parameter:

  ```
  getOptMode -opt_add_insts
  ```

  The software returns the following information:

  ```
  -opt_add_insts true # bool, default=true
  true
  ```

- The following command returns the current setting of the `-addInst` parameter in Tcl list format only:

  ```
  getOptMode -opt_add_insts -quiet
  ```

  The software returns the following information:

  ```
  true
  ```

getSchedulingFile

```
getSchedulingFile
[-help]
```

Returns the name of the current scheduling file used by the `skewClock` command. If no scheduling file name is set, `getSchedulingFile` returns nothing. If you have already run `skewClock`, this command reports the default file name. If you have specified or changed the scheduling file name using `setSchedulingFile`, then this command returns this name.

To view the above description in the software, use `man getSchedulingFile`.

getTieHiLoMode

```
getTieHiLoMode
[-cell]
[-createHierPort]
[-honorDontTouch]
[-maxDistance]
[-maxFanout]
[-modulePrevention]
[-prefix]
[-reportHierPort]
[-quiet]
[-nonDefault]
```

Returns information about the specified `setTieHiLoMode` parameter in the Innovus log file and the console. The following information is returned:

- Parameter name
- Current value
- Type (Boolean, string, and so on)
- Whether the current value was set by user

If you do not specify a parameter, the Innovus software displays values for all of the `setTieHiLoMode` mode parameters.

Parameters

parameter_names	Returns information for the specified parameters. You can specify one or more parameters. See `setTieHiLoMode` for parameter descriptions.
`-nonDefault`	Returns the current settings of the `setTieHiLoMode` parameters that are not default.
`-quiet`	Returns the current settings for the specified parameters in Tcl list format only. If you specify `-quiet` without any parameters, the software returns the current settings of all `setTieHiLoMode` parameters in Tcl list format.

Examples

- The following command returns the current setting for the `-cell` parameter in Tcl list format:
  ```
  getTieHiLoMode -cell -quiet
  ```
  The software returns the following information:
  ```
  {a16lvt16_tie1_a1 a16lvt16_tie0_a1}
  ```
- The following command returns the current settings for the `-cell` and `-honorDontTouch` parameters:
  ```
  getTieHiLoMode -cell -honorDontTouch
  ```
  The software returns the following information:
  ```
  -cell {a16lvt16_tie1_a1 a16lvt16_tie0_a1} # string, default=""
  -honorDontTouch false # bool, default=false
  {cell {a16lvt16_tie1_a1 a16lvt16_tie0_a1}} {honorDontTouch false}
  ```
- The following command returns the current settings for the `-cell` and `-honorDontTouch` parameters in Tcl list format:
  ```
  getTieHiLoMode -cell -honorDontTouch -quiet
  ```

The software returns the following information:

```
{cell {a16lvt16_tie1_a1 a16lvt16_tie0_a1}} {honorDontTouch false}
```

- The following command returns the current settings for all `setTieHiLoMode` parameters in Tcl list format:

  ```
  getTieHiLoMode -quiet
  ```

  The software returns the following information:

  ```
  {cell {a16lvt16_tie1_a1 a16lvt16_tie0_a1}} {createHierPort false} {honorDontTouch false} {maxDistance 0} {maxFanout 0} {prefix {}} {reportHierPort false}
  ```

getUsefulSkewMode

```
getUsefulSkewMode
[-help]
[-nonDefault]
[-opt_skew_apply_delay_limits_to_full_flow]
[-opt_skew_delay_pre_cts]
[-opt_skew_macro_only]
[-opt_skew_max_allowed_delay]
[-opt_skew_min_allowed_delay]
[-opt_skew_no_boundary]
[-quiet]
```

Returns the current setting of the `setUsefulSkewMode` command. The `setUsefulSkewMode` command is used to set global paramaters for clock skewing during optimization.

If you do not specify a parameter, the software returns information for all of the `setUseFulSkewMode` mode parameters.

Parameters

parameter_names	Returns information for the specified parameter. You can specify one or more parameters. See `setUsefulSkewMode` for parameter descriptions.
`-nonDefault`	Returns the current settings of the `setUsefulSkewMode` parameters that are not default.
`-quiet`	Returns the current settings for the specified parameters in Tcl list format only. If you specify `-quiet` without any parameters, the software returns the current settings of all `setUsefulSkewMode` parameters in Tcl list format.

Examples

- The following command returns the current setting of the `setUsefulSkewMode -opt_skew_delay_pre_cts` parameter:

  ```
  getUsefulSkewMode -opt_skew_delay_pre_cts
  ```

  The software returns the following information:

  ```
  -opt_skew_delay_pre_cts true # bool, default=true

  true
  ```

- The following command returns the current settings for all the `setUsefulSkewMode` parameters:

  ```
  getUsefulSkewMode
  ```

  The software returns the following information:

  ```
  -opt_skew_apply_delay_limits_to_full_flow false # bool, default=false
  -opt_skew_delay_pre_cts true                    # bool, default=true
  -opt_skew_macro_only false                      # bool, default=false
  -opt_skew_max_allowed_delay 1                   # float, default=1, min=0, max=1000
  -opt_skew_min_allowed_delay 0                   # float, default=0, min=0, max=1000
  -opt_skew_no_boundary false                     # bool, default=false

  {opt_skew_apply_delay_limits_to_full_flow false} {opt_skew_delay_pre_cts true} {opt_skew_macro_only false}
  {opt_skew_max_allowed_delay 1} {opt_skew_min_allowed_delay 0} {opt_skew_no_boundary false}
  ```

- The following command returns the current setting of the `setUsefulSkewMode -opt_skew_delay_pre_cts` parameter in Tcl list format only:

  ```
  getUsefulSkewMode -opt_skew_delay_pre_cts -quiet
  ```

The software returns the following information:

```
true
```

- The following command returns the current settings for all `setUsefulSkewMode` parameters in Tcl list format only:

  ```
  getUsefulSkewMode -quiet
  ```

  The software returns the following information:

  ```
  {opt_skew_apply_delay_limits_to_full_flow false} {opt_skew_delay_pre_cts true} {opt_skew_macro_only false}
  {opt_skew_max_allowed_delay 1} {opt_skew_min_allowed_delay 0} {opt_skew_no_boundary false}
  ```

- The following command returns the current non-default settings of the `setUsefulSkewMode` command:

  ```
  getUsefulSkewMode -nonDefault
  -opt_skew_macro_only true              # bool, default=false, user setting

  {opt_skew_macro_only true}
  ```

Related Information

- `setUsefulSkewMode`
- `skewClock`
- The following topic in the *Innovus User Guide*
  - Optimizing Timing using Useful Skew

loadFootPrint

```
loadFootPrint
[-help]
-infile fileName
```

Loads a footprint file to update the footprint information, which is obtained from the timing library file during design import. Loading a footprint file takes precedence over what is currently defined in the Innovus session. That is, after a footprint file is loaded for a session, only the cells in the footprint file are considered. This feature lets you run individual timing optimization commands with a limited set of cell footprints.

When the command is run successfully, the software gives the following message:

```
----------------------------------------
Clearing footprints for all libraries
Loading footprints for all corners.
----------------------------------------
```

Parameters

`-help`	Outputs a brief description that includes type and default information for each `loadFootPrint` parameter. For a detailed description of the command and all of its parameters, use the man command: `man loadFootPrint`.
`-infile` *`fileName`*	Specifies the name of the footprint file.

Examples

- The following command loads the footprint file `INV.fpt`:

  ```
  loadFootPrint -infile INV.fpt
  ```

  After loading the footprint file, the Innovus software ignores the previous footprint information.
- When the `loadFootPrint` command reads the output from the `reportFootPrint` command, the `loadFootPrint` command ignores all other fields except the library name, cell name, and the footprint name. The footprint file format for the `loadFootprint` command is as follows:

  ```
  Library:library_name
  cell_name footprint_name
  cell_name footprint_name
  ```

  For example:

  ```
  Library:stdcellLib
  xr03d1 xr03_5
  xr03d2 xr03_5
  ```

  - Using Cell Footprints in Timing Optimization

optDesign

```
optDesign
[-help]
[-drv]
[-excludeNets fileName]
[-expandedViews]
[-hold [-holdVioData fileName]]
[-idealClock]
[-incr]
[-noEcoRoute]
[-outDir directoryName]
[-preCTS | -postCTS | -postRoute]
[-prefix fileNamePrefix]
[-selectedNets fileName]
[-selectedTerms fileName]
[-setup]
[-targeted]
[-timingDebugReport]
[-useTransitionFiles]
```

Performs timing optimization before or after the clock tree is built, or after routing and generates timing reports. You can optimize with or without useful skew.

In multi-mode, multi-corner mode, `optDesign` optimizes all analysis views concurrently.

Performs the following optimizations:

- Corrects design rule violations.
- Reduces total negative slack.
- During the initial pass, optimizes setup time by working on the design's worst paths until the slack cannot be further improved, then, if the worst slack is not on a register-to-register path, optimizes the register-to-register paths on the second pass.
- Corrects hold time violations (optional).
- Optimizes useful skew (optional).
- Reclaims area (optional).
- Optimizes leakage and or/dynamic power (optional).
- Merges flops to multi-bit FFs, or split the multi-bit FFs (optional).

Uses some or all of the following techniques, depending on the design stage (that is, before or after CTS, or after routing) and the specified parameters:

- Adds buffers.
- Resizes gates.
- Restructures the netlist.
- Remaps logic.
- Swaps pins.
- Deletes buffers.
- Moves instances.
- Applies useful skew.
- Applies layer promotion and/or NDR assertions.
- Applies flip-flop merge and split.

Sets the minimum recommended and appropriate set of parameters for the following modes:

- `setAnalysisMode`
- `setRouteMode`
- `setOptMode`
- `setExtractRCMode`

Tip: You can set additional parameters by specifying parameters for the appropriate `set*Mode` command before using `optDesign`.

Before running `optDesign`, complete the following steps:

- Generate the default and detailed extraction scale factors by using the following command:
  - `generateRCFactor`
- Set input transitions for the high fanout nets for delay calculation to use on high fanout networks.

Note: The `simplifyNetlist` parameter is allowed to remove unnecessary or redundant level shifter/isolation instances although those would be internally set as `dont_touch` by `optDesign`.

Parameters

Note: The "optDesign Parameter Matrix" section shows which parameters can be used together.

`-help`	Outputs a brief description that includes type and default information for each `optDesign` parameter. For a detailed description of the command and all of its parameters, use the man command: `man optDesign`
`-drv`	When specified, corrects `max_cap` and `max_tran` violations. To correct `fanout_load` violations, specify `setOptMode -opt_fix_fanout_load` before you specify `optDesign`. You cannot use this parameter if you specify `-incr`. When this parameter is specified, `optDesign` will fix only the DRVs and not the setup/hold timing violations.
`-excludeNets` *`fileName`*	
	Specifies the file that contains the hierarchical names of nets. Timing optimization excludes nets specified in the -excludeNets file. If a net appears in both `-excludeNets` and `-selectedNets`, it is excluded. Note: Excluded nets, especially those with large fanout, might still be buffered to fix Setup timing problems. Use the dont_touch option in the SDC constraints file to prevent optDesign from modifying selected nets. For Hold Optimization however, the nets specified will be excluded when optimizing the Hold Timing.
`-expandedViews`	When specified, detailed view-specific timing reports are generated on all active views at the end of optimization. A separate directory is created for each view. For example, if a design has two analysis views, `view1` and `view2`, then the output reports are generated in the `./timingReports/view1` and `./ timingReports/view2` directories. If the views were pruned during optimization, they will be restored at the end by using this parameter and a view-specific summary and data will be reported on all the active views in the design.

`-hold`	When specified, corrects the hold violations. This parameter cannot be used if you specify the`-preCTS` parameter. You can use this parameter with the `-selectedNets` or `-selectedTerms` options. This parameter creates a summary file in the output directory of the design. The file is named `prefix_hold.summary`. Use the `-prefix` parameter to specify the prefix. To report detailed debugging information, specify the `setOptMode -opt_verbose true` parameter. For more information, see `setOptMode`. **Note**: Even though the hold-timing violation fixing algorithm is setup-timing aware, some setup timing degradation may appear due to different route topology during the postCTS stage. In most cases, this can be overlooked because the violations will be easily fixed during the optDesign -postRoute flow step. **Note**: You need to use the `setFillerMode` command to identify the filler cells. The `optDesign` command will remove filler cells that have been identified with the `setFillerMode` command at the beginning of optimization and add them back at the end of optimization.
`-holdVioData` *`fileName`*	
	Generates the following report files for the violation data that remains after hold fixing: • *`fileName.txt`:* provides a list of the top 50 hold violation paths (text format) • *`fileName.csv`*: provides a list of the top 50 hold violation paths (csv format) • *`fileNameDetailed.txt`*: provides detailed information for the top 50 hold violation paths This parameter is used with the `-hold` paramater. **Example**: `optDesign -postRoute -hold -holdVioData` *`fileName`*
`-idealClock`	Performs timing optimization in postCTS or postRoute modes using ideal clocks instead of propagated clocks. Using ideal clocks enables you to optimize timing without building a clock tree first, or ignore the existing clock tree, to close ideal timing. If this parameter is not specified, the software assumes the clock tree has been built, and optimizes timing based on propagated clocks.
`-incr`	Performs setup optimization incrementally on the violated paths until they cannot be optimized any more. Both, WNS and TNS are optimized. Both, high-effort and low-effort path groups are optimized. Area reclaim may also take place if `-postRoute` is not specified. A setup recovery is called depending on the timing bump after the re-route. This parameter has the following limitations: • You cannot use it if you also specify `-drv` or `-hold`. • You must have already run `optDesign` on all path groups before running it with `-incr`. • When specified, this option disables power optimizations
`-noEcoRoute`	Prohibits the Innovus software from performing ECO routing with the NanoRoute® router during postRoute optimization.
`-outDir` *`directoryName`*	Specifies the directory where the software writes timing reports generated when this command runs. *Default*: `timingReports`
`-postCTS`	Performs timing optimization on a design whose clock tree has been created. By default, `-postCTS` repairs design rule violations and setup violations. If the worst negative slack does not occur on a register-to-register path, `-postCTS` performs an additional optimization pass on the register-to-register critical paths when clock domains are not set. It does not repair maximum fanout design rule violations unless you first specify `setOptMode -opt_fix_fanout_load`.

`-postRoute`	Performs timing optimization on a design whose routing is complete. By default, `-postRoute` repairs design rule violations, glitch violations and setup violations on Base & SI Delay. If the worst negative slack does not occur on a register-to-register path, `-postRoute` performs an additional optimization pass on the register-to-register critical paths when clock domains are not set. Maximum fanout design rule violations are not repaired by default. To do this, first specify `setOptMode -opt_fix_fanout_load`. The `optDesign -postRoute` command provides accurate results when Innovus runs using the footprintless flow methodology. By default, Innovus creates an internal footprint structure based on cell functionality. This methodology does not require you to specify a footprint file. For library database (LDB) conversion, this is the recommended methodology since all of it is automated. For more information, see the "Using the Footprintless Flow" section in the *Innovus User Guide*. **Note**: The clock DRV fixing performed by running `optDesign -postRoute` and by the `ccopt_pro` command do not work when “signoff” effort level for extraction is specified using `setExtractRCMode -effortLevel signoff`. The “signoff” effort level for extraction should be used only for ECO flows, after post-route optimization. To use “`signoff`” effort level inside `optDesign -postRoute` without fixing clock DRV’s, you can turn off CCOpt PRO by setting the `-opt_post_route_fix_clock_drv` parameter of the `setOptMode` command to `false`.
`-preCTS`	Performs timing optimization on the placed design, before the clock tree is built. By default, `-preCTS` repairs design rule violations and setup violations. If the worst negative slack does not occur on a register-to-register path, `-preCTS` performs an additional optimization pass on the register-to-register critical paths when clock domains are not set. Maximum fanout design rule violations are not repaired by default. To do this, first specify `setOptMode -opt_fix_fanout_load`. **Note**: Before optimizing a design in preCTS mode, you must break all timing loops by disabling arcs in the constraint file. If you do not disable the arcs, the software cannot make a valid comparison of WNS between two different runs since it might not break the loops at the same point each time. To disable the arcs, use the `set_disable_timing` command.
`-prefix` *`fileNamePrefix`*	
	Specifies a prefix for `optDesign` report file names. *Default:* *`DesignName_DesignStage`*, where *`DesignStage`* is `preCTS`, `postCTS`, or `postRoute`.
`-selectedNets` *`fileName`*	
	Specifies the file that contains the hierarchical names of nets to consider for design-rule violation repair or hold-timing violations fixing. Timing optimization excludes all other nets. If a net appears in both `-excludeNets` and `-selectedNets`, it is excluded. This option is only accepted when either `-drv` or `-hold` is selected. **Note**: The `-selectedNets` parameter forces `optDesign` to work on all the selected nets, except the ones set using dont_touch.
`-selectedTerms` *`fileName`*	
	Specifies the file that contains the hierarchical names of instance terminals to consider for timing optimization. Only nets connected to those terminals are optimized; for example, during hold fixing, delay cells are added only on the nets driving the terminals specified in the file.
`-setup`	Corrects setup violations for the postRoute optimization flow. When specified along with the `-hold` parameter, a combined setup and hold optimization is performed. For example, `optDesign -postRoute -setup -hold` **Note**: This parameter is only applicable to the postRoute optimization flow and should be used along with the `-hold` parameter.

`-targeted`	This parameter is used only along with the `-postRoute` parameter. Specifying this parameter invokes target-based optimization (TBOpt), which is a fine grain local optimization functionality. This will target critical nodes at the postRoute stage and optimize these by giving worst negative slack (WNS), area, power, max transition, and signal integrity (SI) glitch improvements with minimum disturbance to NanoRoute. This parameter can be used optionally along with the `setOptMode -opt_target_based_opt_file` *`filename`* and `setOptMode -opt_target_based_opt_file_only` parameters. **Note**: Area, power, max transition, and SI glitch targeting can only be done using the above settings. For more information on the syntax of a sample TBOpt file, see the `setOptMode -opt_target_based_opt_file` documentation. Target-based optimization is best used after postRoute optimization is already completed and there are still some violating paths or nodes that might need further improvement.
`-timingDebugReport`	When specified, generates a machine-readable timing debug report after completing optimization. This report is used for debugging timing results using the timing debug feature in Innovus. **Note**: You can select the number of paths that should be reported per path group in the final summary reports by specifying the `setOptMode -opt_time_design_num_paths` parameter. The default number of paths is 50.
`-useTransitionFiles`	Uses the transition file specified by the `readTransitionFile` command for transition violation fixing during postRoute SI optimization.

optDesign Parameter Matrix

The table below shows the compatibility of `optDesign` parameters.

optDesign	-pre CTS	-post CTS	-post Route	-drv	-setup	-hold	-ideal Clock	-incr	-noECORoute
-preCTS	NA	-	-	+	-	-	-	+	-
-postCTS	-	NA	-	+	-	+	+	+	+
-postRoute	-	-	NA	+	+	+	+	+	+
-drv	+	+	+	NA	-	-	+	-	+
-setup	-	-	+	-	NA	+	+	-	+
-hold	-	+	+	-	+	NA	+	-	+
-idealClock	-	+	+	+	+	+	NA	+	+
-incr	+	+	+	-	-	-	+	NA	+
-noECORoute	-	+	+	+	+	+	+	+	NA

Legend

+	You can use this parameter in the row with the parameter in the column.
-	You cannot use this parameter in the row with the parameter in the column.
NA	The parameters in the row and column are identical.

Examples

PreCTS Optimization

- To optimize timing for first time, use the following command:
  ```
  optDesign -preCTS
  ```
- To repair design rule violations only, use the following command:
  ```
  optDesign -preCTS -drv
  ```
- To run incremental setup-only optimization, use the following command:
  ```
  optDesign -preCTS -incr
  ```
  The `optDesign` command performs gate resizing and global buffer insertion, but does not perform netlist restructuring or design rule violation repair.
- To run optimization with useful skew, use the following commands:
  ```
  setOptMode -opt_skew true -opt_skew_pre_cts true
  optDesign -preCTS
  ```
- To run optimization on specific path groups, use the following commands:
  ```
  group_path -name path_group_name -from from_list -to to_list -through through_list
  setPathGroupOptions  ..
  optDesign -preCTS
  ```
  Or you can use:
  ```
  createBasicPathGroups
  setPathGroupOptions ..
  optDesign -preCTS
  ```
  For example, to run optimization on reg2reg & reg2gate paths only, use the following commands:
  ```
  createBasicPathGroups -expanded
  setPathGroupOptions reg2out -targetSlack -1000.0
  setPathGroupOptions in2reg -targetSlack -1000.0
  ```

```
setPathGroupOptions in2out -targetSlack -1000.0
optDesign -preCTS
```

Note: If you specify a path group, `optDesign` preserves the path group setting. In the previous example, subsequent commands may affect the reg2reg & reg2cgate path groups only. To set new groups, specify `reset_path_group -all`, followed by the definition of the groups you want to use.
For example, to reset the path group to a specific group of paths, use the following commands after you run `optDesign`:

```
reset_path_group -all
group_path -name pathgroup1 -through an1/Z -through an2/Z -through an3/Z
```

To just specify all path groups again, use the following command:

```
reset_path_group -all
```

- To reclaim area during optimization, use the following commands:

```
setOptMode -opt_area_recovery true
optDesign -preCTS
```

- To run incremental optimization with useful skew, use the following commands:

```
setOptMode -opt_skew true
optDesign -preCTS -incr
```

- To run an incremental optimization including reclaiming area, use the following commands:

```
optDesign -preCTS
setOptMode -opt_area_recovery true
optDesign -preCTS -incr
```

PostCTS Optimization

- To optimize timing after the clock tree is built, use the following commands:

```
optDesign -postCTS
```

The `optDesign` command corrects design rule violations, then setup violations.

Note: The software does not correct fanout violations in `-postCTS` and `-postRoute` modes. To repair fanout violations, specify the following parameter before you run `optDesign`:

```
setOptMode -opt_fix_fanout_load true
```

- To repair setup and hold violations, use the following commands:

```
optDesign -postCTS
optDesign -postCTS -hold
```

- To repair design rule violations only, use the following command:

```
optDesign -postCTS -drv
```

- To repair hold violations only, use the following command:

```
optDesign -postCTS -hold
```

- To run optimization on specific path groups, use the following commands:

```
group_path -name path_group_name -from from_list -to to_list -through through_list
setPathGroupOptions  ..
optDesign -postCTS
```

Or you can use:

```
createBasicPathGroups
setPathGroupOptions ..
optDesign -postCTS
```

For example, to run optimization on reg2reg & reg2gate paths only, use the following commands:

```
createBasicPathGroups -expanded
```

```
setPathGroupOptions reg2out -targetSlack -1000.0
setPathGroupOptions in2reg -targetSlack -1000.0
setPathGroupOptions in2out -targetSlack -1000.0
optDesign -postCTS
```

- To reclaim area during optimization, use the following commands:

  ```
  setOptMode -opt_area_recovery true
  optDesign -postCTS
  ```

- To take advantage of useful skew when optimizing timing in postCTS mode, use the following commands:

  ```
  setOptMode -opt_skew true
  optDesign -postCTS
  ```

  If you specify `-noECORoute`, the software uses early global routing to estimate clock delays.

- To run postCTS optimization if your design has a clock mesh, use the following commands:

  ```
  setOptMode -opt_skew false
  optDesign -postCTS
  ```

- To run incremental optimization on specific path groups, use the following commands:

  ```
  group_path -name path_group_name -from from_list -to to_list -through through_list
  setPathGroupOptions  ..
  optDesign -postCTS -incr
  ```

  For example, to run incremental optimization reg2reg & reg2gate paths only, use the following commands:

  ```
  createBasicPathGroups -expanded
  setPathGroupOptions reg2out -targetSlack -1000.0
  setPathGroupOptions in2reg -targetSlack -1000.0
  setPathGroupOptions in2out -targetSlack -1000.0
  optDesign -postCTS -incr
  ```

- To optimize setup time incrementally and reduce area, use the following commands:

  ```
  setOptMode -opt_area_recovery true
  optDesign -postCTS -incr
  ```

- To take advantage of useful skew when optimizing timing in incremental postCTS mode, use the following commands:

  ```
  setOptMode -opt_skew true
  optDesign -postCTS -incr
  ```

- To run incremental postCTS optimization if your design has a clock mesh, use the following commands:

  ```
  setOptMode -opt_skew false
  optDesign -postCTS -incr
  ```

PostRoute Optimization

- To optimize base and SI timing after detailed routing (repair setup violations), use the following command:

  ```
  optDesign -postRoute
  ```

- To optimize only the base timing after detailed routing, use the following commands:

  ```
  setDelayCalMode -SIAware false
  optDesign -postRoute
  ```

- **Note:** The software does not correct fanout violations in `-postCTS` and `-postRoute` modes. To repair fanout violations, specify the following command before you run `optDesign`:

  ```
  setOptMode -opt_fix_fanout_load true
  ```

- To correct hold base and SI timing violations, specify the following commands:

  ```
  optDesign -postRoute -hold
  ```

- To correct setup and hold (both base and SI) violations, use the following commands:
  ```
  optDesign -postRoute
  optDesign -postRoute -hold
  ```
  The software repairs a hold violation only if it does not make setup slack worse than the setup target slack on a path. An alternative way is to run setup and hold fixing within one command, and this may reduce the number of ecoRoute(s):
  ```
  optDesign -postRoute -setup -hold
  ```
- To take clock path pessimism removal (CPPR) into consideration when running timing optimization, use the `setAnalysisMode` command before you run `optDesign`. For example:
  ```
  setTimingDerate -max -clock -early 0.8 -late 1.2
  setTimingDerate -min -clock -early 0.8 -late 1.2
  setAnalysisMode -analysisType onChipVariation -cppr both
  optDesign -postRoute
  ```
- To perform a fine grain target-based optimization at the postRoute stage, use the following command to identify the timing bottleneck nodes automatically and optimize them:
  ```
  optDesign -postRoute -targeted
  ```
- To perform a fine grain target based optimization at the postRoute stage on the nodes provided by the TBOpt file, `tb_opt.txt` as well as any other timing nodes that the code identifies as being critical, use the following ocmmands:
  ```
  setOptMode -opt_target_based_opt_file tb_opt.txt
  optDesign -postRoute -targeted
  ```
- To perform a fine grain target-based optimization at the postRoute stage on the nodes provided by the TBOpt file, `tb_opt.txt` only, use the following commands:
  ```
  setOptMode -opt_target_based_opt_file tb_opt.txt -opt_target_based_opt_file_only true
  optDesign -postRoute -targeted
  ```

optPower

```
optPower
[-help]
[-allowResizing]
[-effortLevel {high}]
[-force]
[-preCts | -postCts | -postRoute]
[-prePlace]
[-seqOnly]
```

Optimizes the power consumption of the design by swapping gates for those with lower power, or deleting buffers/inverters without degrading timing. This works in conjunction with the `setOptMode -opt_leakage_to_dynamic_ratio` command to determine the type of optimization being performed - leakage, dynamic, or a combination of both.

Since the default for `setOptMode -opt_leakage_to_dynamic_ratio` parameter is 1.0, `optPower` will perform leakage optimization only by default using LEF-safe optimization (if no other switch is set). It is vital to set up the design correctly before starting power optimization. For more information, see the Optimizing Power During optDesign section of the Optimizing Timing chapter in the Innovus User Guide.

The setup steps include the following:

- Setting the correct power views for both leakage and dynamic optimization
- Ensuring that the libraries contain `cell_leakage_power` information
- Ensuring that the switching activity has been correctly specified either through `read_activity_file -format { VCD | TCF | SAF }` file_name or the `set_default_switching_activity` command

Parameters

`-help`	Outputs a brief description that includes type and default information for each `optPower` parameter. For a detailed description of the command and all of its parameters, use the man command: `man optPower`.
`-allowResizing`	Specifies that optimization uses resizing for power reclaim and, if needed, for recovery. Since the cells will be of different physical footprint, placement refinement and routing ECO will be used. The DRV and timing recovery steps will also be performed, as required. These extra steps will result in an increase in runtime. As this is a more aggressive optimization, the power savings should be superior to the default `optPower` values, but this may cause timing degradations in some cases. When this parameter is set, the `setOptMode -opt_post_route_check_antenna_rules true` setting will be ignored and the software will give a warning to that effect.
`-effortLevel {high}`	Specifies the effort level as `high`. When this parameter is specified, power optimization uses aggressive reclaim. The software performs a timing recovery step and there is a large increase in runtime on an average as compared to when regular power optimization is performed.
`-force`	Resizes each instance to a cell with the lowest leakage power, disregarding design rule violations and optimum timing. This only works when `setOptMode -opt_leakage_to_dynamic_ratio` is set to `1.0`.
`-preCts`	Performs power optimization on the placed design, before the clock trees are created.
`-postCts`	Performs power optimization on a design whose clock trees have already been created.
`-prePlace`	When specified, performs power optimization on an unplaced design. This parameter must be used with the `-force` parameter.
`-postRoute`	Performs power optimization on a design whose routing is complete.
`-seqOnly`	Specifies that dynamic power optimization should be done on sequential cells only. This option works with the `-force` parameter in all modes; `preCts`, `prePlace`, `postCts`, and `postRoute`.

Examples

- Use the following commands to optimize the design targeting total power at the preCts stage:
  ```
  setOptMode -opt_leakage_to_dynamic_ratio 0.5
  optPower -preCts
  ```
- Use the following command to optimize the design, targeting leakage power only at the postCts stage (assuming that `setOptMode -opt_leakage_to_dynamic_ratio` has been untouched or has been set to the default value of 1.0):
  ```
  optPower -postCts
  ```
- Use the following commands to optimize dynamic power only at the postRoute stage:
  ```
  setOptMode -opt_leakage_to_dynamic_ratio 0.0
  optPower -postRoute
  ```
- Use the following commands to perform resizing for total power optimization in the design at the preCts stage:
  ```
  setOptMode -opt_leakage_to_dynamic_ratio 0.5
  optPower -preCts -allowResizing
  ```
- Use the following commands to perform aggressive dynamic power optimization in the design at the postCts stage:
  ```
  setOptMode -opt_leakage_to_dynamic_ratio 0.0
  optPower -postCts -effortLevel high
  ```
- Use the following commands to optimize leakage power by forcing all cells to their lowest leakage equivalent, disregarding DRV and timing degradations at the preCts stage:

```
setOptMode -opt_leakage_to_dynamic_ratio 1.0
optPower -preCts -force
```

- Use the following commands to optimize dynamic power by swapping sequential cells only in the design at the preCts stage:
  ```
  setOptMode -opt_leakage_to_dynamic_ratio 0.0
  optPower -preCts -seqOnly
  ```
- Use the following commands to allow the tool to swap gates, including the gates with negative slack, up to the current negative slack at the postRoute stage:
  ```
  setOptMode -opt_setup_target_slack current_negative_slack
  optPower -postRoute
  ```
- To prevent power optimization from working on near critical paths, you can set a different target to that of the timing optimization. A typical example is shown below where power optimization will not work on paths less than `0.1ns` but the target for timing will remain `0.0` :
  ```
  setOptMode -opt_setup_target_slack 0.0
  setOptMode -opt_area_recovery_setup_target_slack 0.1
  setOptMode -opt_leakage_to_dynamic_ratio 0.5
  optPower -preCts
  ```

  - Optimizing Power

optVirtual

```
  optVirtual
[-help]
[-outDir dirName]
[-timingReports]
```

This command is based on the gigaOpt infrastructure and it provides prototyping capability at several steps of the hierarchical flow to specify and refine the top-level timing constraints and floorplan. It performs, at preRoute stages, fast virtual optimization using buffering and driver resizing. This command updates the timing graph without modifying the netlist. Using gigaOpt infrastructure, the command has the following capabilities:

- Provides a good QoR (AAE DC, gigaOpt global optimizer, and DRV-based)
- Run in multi-threaded mode
- Supports masters and clones

Parameters

`-help`	Outputs a brief description that includes type and default information for each `optVirtual` parameter. For a detailed description of the command and all of its parameters, use the man command: `man optVirtual`.
`-outDir` *dirName*	Specifies the name of the directory where the software writes timing reports. This parameter is used only when the `-timingReports` parameter is specified
`-timingReports`	Generates timing reports that reflect virtual optimization.

reclaimArea

```
reclaimArea
[-help]
[-noDeclone]
[-noDeleteBuffer]
[-noDownsize]
[-maintainHold]
```

Creates space in the design by downsizing and deleting buffers, without worsening the slack or increasing the design rule violations.

Note: Cadence recommends using the `optDesign` command to correct timing violations during timing optimization instead of using this command. For information on using `optDesign`, see Optimizing Timing in the *Innovus User Guide*.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `reclaimArea` parameter. For a detailed description of the command and all of its parameters, use the man command: `man reclaimArea`
`-noDeclone`	Stops Innovus from decloning instances to reclaim area. By default, the software declones instances to reclaim area.
`-noDeleteBuffer`	Prohibits Innovus from deleting buffers to reclaim area. *Default:* The software deletes buffers to reclaim area.
`-noDownsize`	Prohibits Innovus from downsizing instances to reclaim area. *Default:* The software downsizes instances to reclaim area.
`-maintainHold`	Runs the hold aware area reclaim. This is only supported after the design has been routed.

Example

By default area reduction is happening only on positive slack instances. To allow the tool to reclaim area on instances that have a negative slack, you can set a negative setup target slack:

```
setOptMode -opt_setup_target_slack current_negative_slack
reclaimArea
```

Related Command

- `optDesign`

reportAlwaysOnBuffer

```
reportAlwaysOnBuffer
[-help]
[-all]
[-powerDomain domainName]
[-verbose]
```

Reports the available always-on buffers and inverters per domain.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `reportAlwaysOnBuffer` parameter. For a detailed description of the command and all of its parameters, use the man command: `man reportAlwaysOnBuffer`.
`-all`	Reports the always-on buffers and inverters for all domains. If you specify no parameter, even then it reports the always-on buffers and inverters for all domains.
`-powerDomain` *`domainName`*	Reports the always-on buffers and inverters for the specified domain. **Note**: Parameters `-all` and `-powerDomain` are mutually exclusive.
`-verbose`	Reports the possible reason why a domain does not have always-on buffers and inverters. It can also report the always-on cell list per domain if the always-on cells are available for the domain.

Examples

- The following command displays all the available always-on buffers and inverters for each power domain.
  ```
  reportAlwaysOnBuffer
  ```
  ```
  Always on buffers found for each power domain:
        PowerDomain "TDSPCore" (pd tag = "1") has 1 always on buffer(s) to use
        PowerDomain "PLL" (pd tag = "2") has 1 always on buffer(s) to use
        PowerDomain "AO" (pd tag = "3") has 1 always on buffer(s) to use
  ```
- The following command reports the always-on buffers and inverters for the `PD1` domain:
  ```
  reportAlwaysOnBuffer -powerDomain PD1
  ```
  The software displays the following message:
  ```
  PowerDomain "PD1" (pd tag = "1") has 2 always on buffer(s) to use
  ```

Related Commands

- `optDesign`

reportCapViolation

```
reportCapViolation
[-help]
[-all | -noGlobalNets]
[-max]
[-min]
[-outfile fileName]
[-selNetFile fileName]
[-excNetFile fileName]
[-significant_digits integer]
[-useDrcMargin]
```

After timing analysis, reports nets that exceed the maximum capacitance constraints in the timing library and timing constraints file. Run this command after running timing analysis (`timeDesign`) or timing optimization (`optDesign`).

Parameters

`-help`	Outputs a brief description that includes type and default information for each `reportCapViolation` parameter. For a detailed description of the command and all of its parameters, use the man command: `man reportCapViolation`
`-all`	Reports capacitance violations for all nets in the design. This is the default option.
`-excNetFile fileName`	Specifies the file that contains the hierarchical net names that are excluded from the capacitance violation report.
`-noGlobalNets`	Reports capacitance violations on all nets except for power and ground nets. **Note**: The parameters, `-all` and `-noGlobalNets` are mutually exclusive.
`-max`	Reports only maximum capacitance violations. This is the default option.
`-min`	Reports only minimum capacitance violations. **Note**: The parameters, `-min` and `-max` are mutually exclusive.
`-outfile fileName`	Specifies the name of the file to which the results are written.
`-selNetFile fileName`	Specifies the file that contains the hierarchical net names for the report. Only these net names are considered for inclusion in the capacitance violation report. **Note**: The parameters, `-selNetFile` and `-excNetFile` are not mutually exclusive. If both parameters are specified, the `-excNetFile` parameter overides the `-selNetFile` parameter.
`-significant_digits integer`	Allows the user to specify the number of significant digits. *Default*: 3
`-useDrcMargin`	Generates the report using the margin value that you specify using the `-drcMargin` parameter of the `setOptMode` command.

Example

The following command reports nets that exceed the maximum capacitance constraints in the report file `maxcap.report`:

```
reportCapViolation -outfile maxCap.report
```

Related Commands

- optDesign
- reportFanoutViolation
- reportLengthViolation
- reportTranViolation
- setOptMode

reportCritInstance

```
reportCritInstance
[-help]
-outfile fileName
[-view viewName]
[-targetSlack slackValue]
```

Reports instances in critical paths where the slack is less than the target slack.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `reportCritInstance` parameter. For a detailed description of the command and all of its parameters, use the man command: `man reportCritinstance`.
`-outfile` *`fileName`*	Specifies the report output file. **Note:** See Examples, which show the file format.
`-targetSlack` *`slackValue`*	Reports paths with slack less than the specified *`slackValue`*. Specify the value in nanoseconds (ns). *Default:* 0
`-view` *`viewName`*	Generates the report based on the specified analysis view only. You can specify this parameter only when the software is in multi-mode multi-corner timing analysis mode.

Command Order

Use this command after the timing graph is built by `timeDesign/optDesign`.

Examples

- The following command generates an output file named `inst.rpt`, which includes all the instance names and cell names. The instances are on the critical paths whose slack is less than 0 ns.
  ```
  reportCritInstance -outfile inst.rpt
  ```
- The following command generates an output file named `inst.rpt2`, which includes all the instance names and the cell names. The instances are on critical paths whose slack is less than `-0.3` ns.
  ```
  reportCritInstance -outfile inst.rpt2 -targetSlack -0.3
  ```
- The following shows the file format for `reportCritInstance`:
  ```
  Instance name:Cell name
  SUBCHIP1/XBUS_IO_REG1/XPMT12_0INV1/XPMTINV1_WFDO02XINV: IV170
  SUBCHIP1/XBUS_IO_REG1/XPMT12_0INV1/XPMTINV1_WFDO07XINV: IV170
  SUBCHIP1/XBUS_IO_REG1/XPMT12_0INV1/XPMTINV1_WFDO06XINV: IV170
  SUBCHIP1/XBUS_IO_REG1/XPMT12_0INV2/XPMTINV2_WFDO07XINV: IV170
  SUBCHIP1/XBUS_IO_REG1/XPMT12_0INV2/XPMTINV2_WFDO06XINV: IV170
  SUBCHIP1/XBUS_IO_REG1/XPMT12_0INV2/XPMTINV2_WFDO02XINV: IV17
  ```

Related Commands

- optDesign
- setOptMode
- timeDesign

reportCritNet

```
reportCritNet
[-help]
[-nrCritNets integer]
[-outfile fileName]
[-targetSlack double]
[-view viewName]
```

Generates a file containing a list of nets which have critical slack for the currently specified (setup or hold) timing analysis mode.

Parameters

`-help`	Prints a brief description that includes type and default information for each `reportCritNet` parameter. For a detailed description of the command and all of its parameters, use the man command: `man reportCritNet`
`-nrCritNets integer`	Restricts the number of critical nets reported to the first *`integer`* most critical nets.
`-outfile fileName`	Specifies the name of the report file.
`-targetSlack double`	Reports nets with slack less than the specified slack value.
`-view viewName`	Generates the report based on the specified analysis view only. You can specify this parameter only when the software is in multi-mode multi-corner timing analysis mode.

Command Order

Use this command after the timing graph is built.

Example

The following command generates a report named `critnet` that lists critical nets:

```
reportCritNet -outfile critnet
```

Related Commands

- optDesign
- setOptMode
- timeDesign

reportCritTerm

```
reportCritTerm
[-help]
-outfile fileName
```

Performs slack analysis and writes the names of all critical terminals to the specified file. As a result, deterioration of setup slack can be avoided while the Innovus software repairs hold time violations.

Parameters

`-help`	Prints a brief description that includes type and default information for each `reportCritTerm` parameter. For a detailed description of the command and all of its parameters, use the man command: `man reportCritTerm`
`-outfile` *`fileName`*	Specifies the name of report file.

Command Order

Use this command after the timing graph is built by `timeDesign/optDesign`.

Example

- The following commands write the setup critical terminals into a file called `critTerm`:

  ```
  setAnalysisMode -checkType setup
  reportCritTerm -outfile critTerm
  ```

Related Commands

- optDesign
- setOptMode
- timeDesign

reportFanoutViolation

```
reportFanoutViolation
[-help]
[-all | -noGlobalNets]
[-excNetFile fileName]
[-min]
[-max]
[-outfile fileName]
[-selNetFile fileName]
[-significant_digits integer]
[-useDrcMargin]
```

After timing analysis, reports all the pins that exceed the fanout constraints in the timing library and timing constraints file. Run this command after running timing analysis (`timeDesign`) or timing optimization (`optDesign`).

Parameters

`-help`	Prints a brief description that includes type and default information for each `reportFanoutViolation` parameter. For a detailed description of the command and all of its parameters, use the man command: `man reportFanoutViolation`
`-all`	Reports fanout violations on all nets in the design.
`-excNetFile fileName`	
	Specifies a file that lists the names of hierarchical nets to exclude from the report.
`-max`	Reports violations of maximum fanout constraints.
`-min`	Reports violations of minimum fanout constraints. **Note**: Parameters `-min` and `-max` are mutually exclusive.
`-noGlobalNets`	Reports fanout violations on all nets except for power and ground nets. **Note**: Parameters `-all` and `-noGlobalNets` are mutually exclusive.
`-outfile fileName`	Specifies the report file.
`-selNetFile fileName`	
	Specifies a file that lists the names of hierarchical nets that are considered for the report. Only these net names are considered for inclusion in the violation report. **Note**: The parameters, `-selNetFile` and `-excNetFile` are not mutually exclusive. If both parameters are specified, the `-excNetFile` parameter overides the `-selNetFile` parameter.
`-significant_digits integer`	
	Allows the user to specify the number of significant digits. *Default*: 3
`-useDrcMargin`	Generates a report using the margin value that you specify with the `-opt_drv_margin` parameter of the `setOptMode` command.

Example

The following command reports the pins that exceed the maximum fanout constraints in a file named `maxFanout.report`:

```
reportFanoutViolation -outfile maxFanout.report
```

Related Commands

- optDesign
- reportLengthViolation
- reportCapViolation
- reportTranViolation
- setOptMode
- timeDesign

reportFootPrint

```
reportFootPrint
[-help]
[-outfile fileName]
[-dontTouchNUse]
[footprint]
```

Creates a file that contains footprint attribute information from the timing library. Use this file to check your design for missing footprint function names and timing information. You can edit the output file and use it to load the correct footprint information.

Parameters

`-help`	Prints a brief description that includes type and default information for each `reportFootPrint` parameter. For a detailed description of the command and all of its parameters, use the man command: `man reportFootPrint`
`-dontTouchNUse`	When this parameter is specified, cell footprints are reported for all cells, including those cells that have dont_touch or dont_use attribute. When this parameter is not specified, cell footprints are reported for only those cells that do not have dont_touch and dont_use attributes.
footprint	Specifies the footprint to report. If you do not specify this parameter, reports all footprints.
`-outfile` *fileName*	Specifies the footprint report file.

Command Order

Use this command after importing the design or after using the `loadFootPrint` command.

Examples

- The following command creates a footprint report file named `INV.rpt`:

  ```
  reportFootPrint -outfile INV.rpt
  ```

- The following output from the `reportFootPrint` command shows the format of the footprint file:

  ```
  # Format:
  # Library:<library name>
  # cell footprint drvResR drvResF functions

  # footPrint: INV nrCell: 1 Library: dp_ram128x32_4x1
  Library:stdCellLib
  inv_2 INV     1            110.983    89.427    x=(~a)
  ```

  Lines beginning with a # are comment lines, which are ignored when the footprint file is loaded. The header shows the meaning of each field:

  - `Library`: `stdCellLib` (with no spaces in the string) is the library where the footprint is defined.
  - `inv_2` is a footprint cell.
  - `INV` is the footprint name.

- `1` is the number of functions.
- `110.983` is the average rise driving resistance.
- `89.427` is the average fall driving resistance.
- `x=(~a)` is the output function of the cell.

- `setDelayFootPrint`
- The following topic in the *Innovus User Guide*
  - Using Cell Footprints in Timing Optimization

reportIgnoredNets

```
reportIgnoredNets
[-help]
-outfile fileName
```

Generates a report that lists the nets that are ignored by timing optimization (`optDesign`) or that might impact timing closure. You can use this command after loading a design with timing constraints.

The report lists the following types of nets:

- Nets that are ignored by timing optimization
- Nets that might impact timing closure but are not ignored

Nets that are ignored by timing optimization are listed below:

`dontTouchNets`	Nets set as don't touch by the `set_dont_touch` SDC constraint
`externalNets`	Nets connected to I/O pad or area I/O instances
`topLevelPotentialTriStateNets`	Nets connecting tristate drivers to top-level I/Os
`clockNets`	Nets marked `clock` by the timing engine
`specialNets`	Nets that have the attribute `specialnet`
`pwrGndNets`	Nets that have the attribute `power/ground`
`analogNets`	Nets that have the attribute `analog`
`noDriverNets`	Nets that do not have a driver
`Fixed Wires/Cover Wires`	Nets that have a `Fixed/Cover` wire attribute

Nets that might impact timing closure but are not ignored are listed below:

`multiDriverNets`	Nets that have multiple drivers

Parameters

`-help`	Prints a brief description that includes type and default information for each `reportIgnoredNets` parameter. For a detailed description of the command and all of its parameters, use the man command: `man reportIgnoredNets`
`-outfile` *`fileName`*	Specifies a file name for the report.

Related Commands

- optDesign
- setOptMode

reportLengthViolation

```
reportLengthViolation
[-help]
[-all | -noGlobalNets]
[-selNetFile selNetFileName]
[-excNetFile excNetFileName]
[-histogram]
[-outfile fileName]
[-significant_digits integer]
```

Runs timing analysis and reports nets that exceed the maximum length constraint set by `setOptMode -opt_max_length` parameter.

Parameters

`-help`	Prints a brief description that includes type and default information for each `reportLengthViolation` parameter. For a detailed description of the command and all of its parameters, use the man command: `man reportLengthViolation`
`-all`	Reports violations on all nets.
`-noGlobalNets`	Reports violations on all nets except for power, ground, and clock nets. **Note**: The parameters, `-all` and `-noGlobalNets` are mutually exclusive.
`-excNetFile` *excNetFileName*	Specifies a file that lists the names of hierarchical nets that are to be excluded from the report.
`-outfile` *fileName*	Specifies the report file name.
`-selNetFile` *selNetFileName*	Specifies a file that lists the names of hierarchical nets to consider in the report. Only violations on the nets listed in the file are considered in the report. **Note**: The parameters, `-selNetFile` and `-excNetFile` are not mutually exclusive. If both parameters are specified, the `-excNetFile` parameter overides the `-selNetFile` parameter.
`-histogram`	Generates a histogram in addition to the default reporting.
`-significant_digits` *integer*	Allows you to specify the number of significant digits. *Default*: 3

reportMultibit

```
reportMultibit
[-help]
[-bit bit_width]
[-outFile file_name]
[-cell cell_name | -library | -reasonNotMerged unmerged_reason | -notMergedSummary | -equiv]
[-cell cell_name | -type {comb | latch | flop | seq | iso | ls}]
[-hinst hinst_name | -library | -cell <cell name> | -equiv]
```

Reports all the multi-bit flip-flops that have been identified during loading the design. Use this command after all the libraries are loaded. When this command is specified with no parameters, a default summary report is printed. By default, the sequential cells will be reported. Both, the multi-bit percentages of flops that are merged, and a summary of flops that are not merged is printed.

There are three basic types of multibit: sequential, combo, and isolation/level shifter. This command supports specifying the type of multibit to report. The `-type` parameter is a global filter for all other options.

The default option is `seq`. If `-type` option is not specified then reporting will take place for sequential cells.

A set of options separated by a "`|`" in one "`[ ]`" listed below cannot be used together and the software will report an error in that case. Although options from different "`[ ]`" can be coupled together. The sets of mutually exclusive options are provided below.

- `[-cell <cell name> | -library | -reason_not_merged <unmerged reason> | -not_merged_summary | -equiv ]`
- `[-cell <cell name> | -type <type>]`
- `[-hinst <hinst> | -library | -cell <cell name> | -equiv ]`

Parameters

`-help`	Prints a brief description that includes type and default information for each `reportMultibit` parameter. For a detailed description of the command and all of its parameters, use the man command: `man reportMultibit`.
`-bit bit_width`	Reports the multibit iso/ls cells for the specified bit width. The value *bit_width* can be an integer that represents the bit-width of the queried isolation/level shifter (iso/ls) cell. This parameter is required to be specified when reporting the multibit iso/ls cells. Example: To report 2-bit MB isolation (iso) cells in the design, use the following command: `reportMultibit -type iso -bit 2`
`-cell cell_name`	Reports the cell details and equivalence information of a single library cell.
`-equiv`	Reports equivalence summary of the library cells of the selected type.
`-hinst hinst_name`	Specifies the hinst on which the reporting is to be done. The default is the design.
`-library`	Reports the flip-flop/latch equivalence. This parameter honors the `-type` parameter setting.
`-notMergedSummary`	When specified, reports the summary of unmerged instances.
`-outFile file_name`	Specifies the name of the output file.
`-reasonNotMerged {Partition CellEquivalent Constraint ScanConnection Location Timing Power User Legalization Bus BankLabelRegister BankLabelPartition All}`	

	Reports the instances that could not be merged for the specified reason. Specify any of the reasons in the argument or specify `all` to report all instances along with the reason why they could not be merged. `Partition`: odd number of flops in one partition `CellEquivalent`: no usable equivalent multi-bit flip-flop cell `Constraint`: Constraints by sdc, rule, or user settings `ScanConnection`: no scan connection to other flops in the same group `Location`: too far away with other flops in the same group `Timing`: exceed critical path threshold or MBFF merging that degrades timing `Power`: all available multi-bit cells causing power degradation `User`: user set to be excluded in flop merge `Bus`: non-bus flops `All`: all the reasons of not merged
`-type {comb | latch | flop | seq | iso | ls}`	Reports for the specified type of cells. By default, only sequentials are reported. You can specify anyone of the following reports: `comb`: reports all multibit cells implementing a combinational function. For example, a cell implementing 3 ANDs – so, 6 inputs and 3 outputs `latch`: reports multi-bit latches in the design. `flop`: reports multi-bit flops. `seq`: reports all sequential cells. isolation/level shifter (`iso/ls`): reports multi-bit cells implementing a low power function. For example, as 8-bit level-shifter cell. *Default*: `seq`

Examples

Use the following command to print a default summary report. By default, the sequential cells will be reported..

```
reportMultibit
```

The software returns the following information:

```

reportPathGroupOptions

```
reportPathGroupOptions [-help]
```

Reports the values for each parameter (pathgroupName, effortLevel, slackAdjustment, and targetSlack) for each path group. If no path groups are created, the software issues a warning.

To report the names of the path groups, use the `report_path_groups` command.

Parameter

`-help`	Prints a brief description that includes type and default information for the `reportPathGroupOptions` command. For a detailed description of the command, use the `man` command: `man reportPathGroupOptions`

Example

Use the following set of commands to create the basic path groups, set the parameters, and report the values of these parameters:

```
createBasicPathGroups

Created reg2reg path group

Effort level <high> specified for reg2reg path_group

Created reg2cgate path group
Effort level <high> specified for reg2cgate path_group

setPathGroupOptions reg2reg -effortLevel low -skewingSlackConstraint 0.3 -view AV_HL_FUNC_MIN_RC1
setPathGroupOptions reg2cgate -effortLevel high -skewingSlackConstraint 0.5 -view AV_HL_FUNC_MAX_RC1
reportPathGroupOptions
```

The following report is generated by the software:

```
-------------------------------------------------------------------------------------------------
|Path Group|Effort|Adjustment(early/late)|Target Slack|weight|SkewingSlackCons|view               |
-------------------------------------------------------------------------------------------------
|reg2reg   | high | 0.1    /-0.2         | 0          |  2   |    300         |AV_HL_FUNC_MIN_RC1 |
|reg2cgate | high | 0.2    /0            | 0          |  1   |    500         |AV_HL_FUNC_MAX_RC1 |
```

For detailed descriptions of the above columns, see the table in `setPathGroupOptions`.

reportRouteTypeConstraints

```
reportRouteTypeConstraints
[-help]
[-file fileName]
[-svr]
[-svrOnly]
[-threshold value]
[-summary  | -detailed ] [-detailed  [-timing ]]
```

Reports the route type constraints that are being added on nets during the Innovus flow. It allows you to monitor the number of constraints, the preferred bottom layer used, the adherence of the different constraint type by the router, and the type of non-default rule (NDR) being used.

The command extracts information about the following groups of route type constraints:

- **INNOVUS**: includes all route types being added by the software and that are using a bottom preferred layer and the default rule.
- **INNOVUS_NDR**: includes all route types being added by the software and that are using an NDR. `setOptMode -opt_pre_route_ndr_aware` makes this type of constraint.
- **INNOVUS_CLK**: includes all route types of clock nets that are being added by the software and that are using default rule. `create_route_type` without `-non_default_rule` and ccopt_property `route_type` make this type of constraint.
- **INNOVUS_CLK_NDR**: include all route types of clock nets that are being added by the software and that are using an NDR. `create_route_type` with `-non_default_rule` and ccopt_property `route_type` make this type of constraint.
- **USER**: includes all route types being added by the user. This can be done using the `setAttribute` command.
- **USER_NDR**: includes all route types being added by the user and that are using an NDR. This can be done using the `setAttribute` command.

When via pillar report is enabled, using the `-svr`/`-svrOnly` parameters, the command checks via pillar assigned on data/clock nets and on the secondary PG nets. For sample reports, see Use Model Scenarios.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `reportRouteTypeConstraints` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man reportRouteTypeConstraints`
`-detailed`	Prints detailed information on each net with a route type constraint such as the wire length, the routing adherence, some timing information, and so on. **Note**: The parameters, `-detailed` and `-summary` are mutually exclusive.
`-file file`*`Name`*	
	Specifies the file name in which the results will be written. If this parameter is not specified, the information is written out in the console and the log file.
`-svr`	When specified, reports pins with stack via rule constraints.
`-svrOnly`	When specified, reports only those pins that have stack via rule constraints.
`-summary`	Prints a summary of the layer constraint usage per layer, per NDR, and per constraint type. **Note**: The parameters, `-detailed` and `-summary` are mutually exclusive.
`-threshold` *`value`*	Specifies the maximum routing adherence for a net to be included in detailed report. This parameter is specified along with the `-detailed` paramater. The default value is 80, which means only nets with adherence < 80 % will be included in detailed report. **Note**: It is recommended that you do not use the `-threshold` parameter along with the `-svrOnly` parameter because stack via rule has no “routing adherence ratio” metric.
`-timing`	When this parameter is specified, the report will display timing information on the nets such as slack, delay, and incremental delay while generating the detailed information.

Use Model Scenarios

The use model scenarios for reports including via pillar constraints applied on secondary PG pins are provided below.

Reporting stack via rule (including stack via rule used on secondary PG pins) and bottom layer constraint:

```
reportRouteTypeConstraints -svr
```

The following information is included in the summary report:

```
**INFO (OILAM) : Summary of current layer assignment usage:
        # num nets with bottom preferred layer constraint                  : 38225
        List NDR used                                                      : TrunkNDR LeafNDR
        List stack via rule used                                           :
        Num nets with incorrect stack via rule constraint applied on driver : 0
        Num nets with incorrect stack via rule constraint applied on sinks  : 0
        Num library cells with stack via rule defined                      : 0
        Num library cells with required stack via rule defined             : 0
        Num instances with pillar rule list associated to them             : 0
        List stack via rule used on second PG pins                         : VPPERF_M2_M4_1_3_1 VPPERF_M2_M4_1_2_1
        Num second PG pins with stack via rule constraint                  : 24785
```

Reporting only stack via rule

```
reportRouteTypeConstraints -svrOnly
```

The above command prints information about only stack via rule including the summary of via pillar rule applied on secondary PG pins.

```
**INFO (OILAM) : Summary number of stack via rule constraint applied on second PG pins:
        +---------------------+--------------+--------------+----------+--------------+
        | Stack via rule name | Routing Cost | # stack via rule applied               |
        +                     +              +--------------+----------+--------------+
        |                     |              | Not required | Required                |
        +                     +              +              +----------+--------------+
        |                     |              |              | cell pin | instance pin |
        +---------------------+--------------+--------------+----------+--------------+
        | VPPERF_M2_M4_1_3_1  | 104.0        | NA           | 435      | NA           |
        | VPPERF_M2_M4_1_2_1  | 88.0         | NA           | 24350    | NA           |
        +---------------------+--------------+--------------+----------+--------------+
        | Total               |              | 0            | 24785    | 0            |
        +---------------------+--------------+--------------+----------+--------------+
```

When no via pillar are found on 2nd PG pin, the table will be replaced by following line:

```
**INFO (OILAM) : Summary number of stack via rule constraint applied on second PG pins:
        No stack via rule found
```

When the `-detailed` parameter is specified while reporting via pillar usage, a new table is generated in the report with the list of secondary PG pins with a via pillar constraint. This is shown below.

```
**INFO (OILAM) : List of second PG pins with stack via rule constraint 'VPPERF_M2_M4_1_2_1':
        +-------+---------------------+--------------+-------------------------------------+
        | ID    | Stack via rule name | Rule type    | Instance PG pin name                |
        +-------+---------------------+--------------+-------------------------------------+
        | 1     | VPPERF_M2_M4_1_2_1  | Cell Required | FE_OCPC96413_FE_OFN15677_TC_13/TVDD |
        | 2     | VPPERF_M2_M4_1_2_1  | Cell Required | FE_OCPC96403_TC_447/TVDD            |

```

- The following command prints the detailed route type constraints information:

  ```
  reportRouteTypeConstraints -detailed
  ```

  The report below summarizes the percentage of respect of the route type constraint (bottom preferred layer) by the current router. For example, in the report below, for the INNOVUS constraints between 90% and 100% respect of the constraint, there are 100.0% of the nets. While INNOVUS_CLK constraints between 90 - 100% respect of the constraint, there are 98.33% of the nets.

```
**INFO (OILAM) : Summary min layer respect by router:

reportTranViolation

```
reportTranViolation
[-help]
[-all | -noGlobalNets]
[-max]
[-min]
[-selNetFile fileName]
[-excNetFile fileName]
[-significant_digits]
[-useDrcMargin]
[-outfile fileName]
```

After timing analysis, reports pins and ports that exceed the transition constraints in the timing constraints file.

Run this command after running timing analysis (`timeDesign`) or timing optimization (`optDesign`).

Parameters

`-help`	Prints a brief description that includes type and default information for each `reportTranViolation` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man reportTranViolation`
`-all`	Reports violations on all nets in the design. *Default:* `-all`
`-excNetFile fileName`	
	Specifies a file that lists the names hierarchical nets that are excluded from the transition violation report.
`-noGlobalNets`	Reports violations on all nets except for power and ground nets. **Note**: The parameters, `-all` and `-noGlobalNets` are mutually exclusive.
`-max`	Reports violations of maximum transition constraints.
`-min`	Reports violations of minimum transition constraints. **Note**: The parameters, `-max` and `-min` are mutually exclusive.
`-outfile fileName`	Specifies name of the output file.
`-selNetFile fileName`	
	Specifies a file that lists the names of hierarchical nets to consider in the transition violation report. **Note**: The parameters, `-selNetFile` and `-excNetFile` are not mutually exclusive. If both parameters are specified, the `-excNetFile` parameter overides the `-selNetFile` parameter.
`-significant_digits`	Allows the user to specify the number of significant digits. *Default*: 3
`-useDrcMargin`	Generates a report using the margin value that you specify with the `-drcMargin` parameter of the `setOptMode` command.

Example

The following command runs timing analysis and generates a `module1.tran` report file that lists the pins and ports that exceed the transition constraints:

```
reportTranViolation -outfile module1.tran
```

Related Commands

- optDesign
- setOptMode
- timeDesign

reportVtInstCount

```
reportVtInstCount
[-help]
[-area]
[-detailed]
[-leakage]
[-outFile fileName]
```

Reports the instance distribution across the VT partitions in the design. By default, the Innovus software partitions the design into either two or three VT buckets. Each library, cell, and instance falls into one of these buckets and is reported by this command.

Parameters

`-help`	Prints a brief description that includes type and default information for each `reportVtInstCount` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man reportVtInstCount`
`-area`	Prints the area information across libraries in each VT partition.
`-detailed`	Prints complete details in the specified file. **Note**: Before specifying this parameter, you must specify the file name using the `-outFile` parameter.
`-leakage`	Prints the leakage distribution across the libraries in each VT partition. When you specify this parameter, a complete leakage power analysis is performed on the design, which takes a little long to run.
`-outFile` *fileName*	
	Prints the output in the specified file in the format required for user-defined VT partitioning. **Note**: To print the same report that is output to the log that includes all leakage and instance information, specify the `-detailed` parameter. If you do not specify the `-detailed` parameter, the `-outFile` parameter will only print the VT partitions.

Examples

- The following command outputs the Vt partitions to the file `VT_Partitions.rpt`:

  ```
  reportVtInstCount -outFile Vt_Partitions.rpt
  ```

  The `Vt_Partitions.rpt` file contains the following information:

```
#################################################################
#  Generated by:      Cadence Encounter <version>
#  OS:                Linux x86_64(Host ID <machine name>)
#  Generated on:      <date>
#  Design:            <design name>
#  Command:           reportVtInstCount -outFile VT_Partitions.rpt
#################################################################

LVT

    Lib at28nm_hvt_scan_s_p125_11v : inst = 700 (1.5%), leakage = 0.010 mW (1.0%)
```

resetPathGroupOptions

```
resetPathGroupOptions
[-help]
[pathGroupName]
[-early]
[-effortLevel]
[-late]
[-skewingSlackConstraint]
[-slackAdjustment]
[-slackAdjustmentPriority]
[-targetSlack]
[-view]
```

Resets the parameters of a specified path group, or of all path groups, to their default values.

- If no group name and no parameters are provided, the command resets all parameters for all path groups to their default values.
- If only the group name is provided, the command resets all parameters of that path group to their default values.
- If a path group and a parameter are provided, then only that parameter of that path group is reset to its default value.

See `setPathGroupOptions` for parameter descriptions.

Note: This command does not provide the option to reset the weights. Use `setPathGroupOptions` *`pathgroupName`* `-weight 0` to reset the weights.

Parameters

`-help`	Prints a brief description that includes type and default information for each `resetPathGroupOptions` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man resetPathGroupOptions`
`pathGroupName`	Specifies a path group for which to reset parameters.
`parameter_names`	Specifies the parameters to reset to the default value.

Examples

- To reset all parameters of all path groups to the default values, specify the following command:
  ```
  resetPathGroupOptions
  ```
- To reset all the parameters of the `reg2reg` path group to their default values, but leave the parameters of all other path groups unchanged, specify the following command:
  ```
  resetPathGroupOptions reg2reg
  ```

Related Commands

route_opt_design

```
route_opt_design
[-help]
[-drv]
[-hold]
[-ideal_clock]
[-num_paths number_of_paths]
[-opt]
[-out_dir directory_name]
[-prefix file_name_prefix]
[-route]
[-setup]
[-timing_debug_report]
```

Combines the routing and post-route optimization flows into a single flow. The benefit of this approach is to interleave the optimization step with routing step. When this command is run, the software performs global and detail routing, setup/hold timing optimization, and DRV fixing. The `route_opt_design` command can be used instead of using two separate commands listed below:

- `routeDesign`
- `optDesign -postRoute -setup -hold`

Note: The `route_opt_design` flow is different from `routeDesign` followed by `optDesign -postRoute -setup -hold` in that the `route_opt_design` command performs more optimization during the routing stage.

The `route_opt_design` command has parameters to split the routing part (`-route`) and the optimization part (`-opt`). When these parameters are specified, the flow exits the interleaved mode, and goes back to the traditional flow with separate commands. This means that `route_opt_design -route` is equivalent to `routeDesign`, and `route_opt_design -opt` is equivalent to `optDesign -postRoute -setup -hold`.

By default, the optimization step of `route_opt_design` fixes both setup and hold timing in the interleaved mode with routing. To fix setup timing only, use `route_opt_design -setup`. When the `-setup` parameter is specified, the software performs setup timing optimization, and skips hold timing fixing.

Any partial optimization, using the `-drv` or `-hold` parameters cannot be worked in the interleaved mode. Therefore, if any of these parameters are specified, the software redirects to the `optDesign -postRoute` command with the specified option.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `route_opt_design` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man route_opt_design`
`-drv`	Fixes the max_cap and max_tran violations by using the postRoute optimization flow. This is equivalent to `optDesign -postRoute -drv`. **Note**: • Ensure that the design is routed before using this parameter. • The `-drv` parameter can only be used with the `-opt` parameter.

`-hold`	When this parameter is specified without `-setup`, the software exits the interleaved mode, and fixes hold timing violations with the postRoute optimization flow. This is equivalent to `optDesign -postRoute -hold`. **Note**: Ensure that the design is routed before using this parameter. When this parameter is specified along with the `-setup` parameter, either `-hold -setup` or `-setup -hold`, both the setup and hold timing violations are fixed in the interleaved mode. This is the default behavior of `route_opt_design`. **Note**: • The design should be in the post CCOpt stage to use `route_opt_design`. • The `-hold` and `-drv` parameters are mutually exclusive. • The `-hold` parameter can only be used with the `-opt` parameter.
`-ideal_clock`	Performs timing optimization using ideal clocks instead of propagated clocks. Using ideal clocks enables you to optimize timing without building a clock tree first, or ignore the existing clock tree, to close ideal timing. If this parameter is not specified, the software assumes the clock tree has been built, and optimizes timing based on propagated clocks.
`-num_paths` *`number_of_paths`*	Specifies the number of timing paths generated in the timing report. By default, all timing paths are reported.
`-out_dir` *`directoryName`*	Specifies the directory where the software writes timing reports generated when this command runs. *Default*: `timingReports`
`-opt`	When specified, uses the `optDesign -postRoute -setup -hold` command and fixes both setup and hold violations for the postRoute optimization flow. The software exits the interleaved mode, and skips routing. **Note**: Ensure that the design is routed before using this parameter. By default, both setup and hold timing violations are fixed. To limit the scope of the optimization, use the `-setup`, `-hold`, and `-drv` parameters along with `-opt` parameter. **Note**: The parameters `-route` and `-opt` are mutually exclusive.
`-prefix` *`fileNamePrefix`*	
	Specifies a prefix for `route_opt_design` report file names. *Default:* *`DesignName_DesignStage`*, where *`DesignStage`* is `postCTS`, or `postRoute` for `route_opt_design`.
`-route`	Specifies that only routing should be done. This is equivalent to `routeDesign` without performing track optimization in the interleaved mode. **Note**: The design should be in the post CCOpt stage. Note: The -route parameter and the following parameters are mutually exclusive; `-opt`, `-setup`, `-hold`, and `-drv`.
`-setup`	Corrects setup violations in the interleaved mode. When specified without the `-hold` parameter, the software skips the fixing of hold timing violations. **Note**: The design should be in the post CCOpt stage. **Note**: The `-setup` and `-drv` parameters are mutually exclusive.

`-timing_debug_report`	When specified, generates a machine-readable timing debug report after completing routing and postRoute optimization. This report is used for debugging timing results using the timing debug feature in Innovus. **Note**: You can specify the number of paths to be reported using the `-num_paths` parameter.

Examples

- Use the following command to enable interleaved track optimization during the routing stage, for fixing setup violations only:
  ```
  route_opt_design -setup
  ```
- Use the following command to enable interleaved track optimization during the routing stage, for fixing both setup and hold violations:
  ```
  route_opt_design
  ```
  or
  ```
  route_opt_design -setup -hold
  ```
- Use the following command to exit interleaved track optimization mode and perform routing only:
  ```
  route_opt_design -route
  ```
- Use the following command to exit interleaved track optimization mode and perform postRoute optimization only for fixing setup timing:
  ```
  route_opt_design -opt -setup
  ```
  This is equivalent to `optDesign -postRoute` or `optDesign -postRoute -setup`
- Use the following command to exit interleaved track optimization mode and perform postRoute optimization for fixing both setup and hold timing:
  ```
  route_opt_design -opt
  ```
  This is equivalent to `optDesign -postRoute -setup -hold`

- The following topic in the *Innovus User Guide*
  - Using the route_opt_design Flow

setBufFootPrint

```
setBufFootPrint
[-help]
names
[-library libName]
```

Sets the buffer cell footprint name. This footprint name is usually assigned during design import. The software uses buffer footprint names during timing optimization and top-level buffer insertion in a partitioned design. You can specify the library that contains the footprint.

Use this command before running timing optimization.

Parameters

`-help`	Prints a brief description that includes type and default information for each `setBufFootPrint` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setBufFootPrint`
names	Specifies the buffer cell footprint name or a buffer cell name. When you specify a buffer cell name the Innovus software automatically finds the cell footprint name.
`-library` *libName*	Specifies the library that contains the buffer footprint. You must insert a colon (`:`) between the library name and the buffer name when you use this parameter.

Example

- The following command sets the buffer cell footprint name to `B_1P`:

  ```
  setBufFootPrint B_1P
  ```

Related Information

- `checkFootPrint`

  - Using the Footprintless Flow

setDelayFootPrint

```
setDelayFootPrint
[-help]
[-library libName]
names
```

Specifies the delay cell footprint. This footprint name is usually assigned during design import. The delay cells from the cell footprint name are used for inserting delays when you run timing optimization to fix hold-time violations.

Parameters

`-help`	Prints a brief description that includes type and default information for each `setDelayFootPrint` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setDelayFootPrint`
`-library libName`	Specifies the library name from where the cells will be picked up.
names	Specifies the delay cell footprint name or a delay cell name. When you specify a delay cell name, the Innovus software automatically finds the cell footprint name.

Example

The following command sets the delay footprint name to `DEL_1P`:

```
setDelayFootPrint DEL_1P
```

  - Using Cell Footprints in Timing Optimization

setDontUse

```
setDontUse
[-help]{{cellName value} | {-reset}}
[-hinst hinstName [-reset]]
```

Sets a dont_use attribute on a cell, prohibiting timing optimization commands from using this cell during optimization. Optionally, you can specify a library that contains the cell. Using this command overrides the library and/or timing constraints. The dont_use attribute you set remains persistent through save and restore operations.

If you set the dont_use attribute on a cell whose dont_use attribute is already set, the software issues a warning message, for example:

```
setDontUse buff1 true
Setting BUFF1 as a don't use cell
setDontUse buff1 true
Warning: Cell BUFF1 already has a dont_use attribute
```

Parameters

`-help`	Outputs a brief description that includes type and default information for each `setDontUse` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setDontUse`
`cellName`	Specifies the cell to constrain. To choose a cell in a specific library, specify *`libName/cellName`*. You can use wildcards to specify cell names.
`-hinst` *`hinstName`*	

	Specifies the hierarchical module instance names on which the “don’t use” setting should be applied. This parameter is specified with the *cellName* and the *value* parameters.
	`setDontUse -hinst cellName value`
	The following scenarios are applicable to the use of this parameter:
	• The hinst setting overrides the non-instance specific settings. For example:
	`setDontUse -hinst Inst1 BUFX1 false`
	Where `Inst1` is the instance name, `BUFX1` is the cell name, and the value is set to `false`
	`setDontUse BUFX1 true`
	Where `BUFX1` is the cell name and the value is set to `true`
	In the above example, the first command will override the second command and so the cell, BUFX1 is usable within the instance, Inst1, but not elsewhere within the design.
	• The more specific definition always takes precedence irrespective of the sequence of commands. For example:
	Setting 1
	`setDontUse -hinst Inst1/Inst2 BUFX1 true`
	`setDontUse -hinst Inst1 BUFX1 false`
	In `Inst1/Inst2`, the dont_use attribute of `BUFX1` is `true`
	Setting 2
	`setDontUse -hinst Inst1 BUFX1 false`
	`setDontUse -hinst Inst1/Inst2 BUFX1 true`
	In `Inst1/Inst2`, the dont_use attribute of `BUFX1` is also `true`
	So, the above two settings are equivalent.
	• When using this parameter, complete instance names should be specified. Wildcards are not supported.
	• The `true` or `false` value specified for cells using the `setDontUse` command can be reset by using the `-reset` parameter alongwith the `-hinst` parameter.

`-reset`	This parameter is used with the `-hinst` parameter. When specified, it removes all dont_use constraints attached to the specified hierarchical module instance.
	`setDontUse -hinst A BUF1 true`
	`setDontUse -hinst A -reset`
	The above command resets the dont_use attribute on cell `BUF1` in `hinst A`.
	Note: The `setDontUse -hinst hinstName -reset` command clears the "don't use" settings for the specified hierarchical instances but does not clear the "don't use" settings for any sub-hierarchical instances inside the specified hierarchical instances. For example:
	`setDontUse -hinst A BUF1 true`
	`setDontUse -hinst A/B BUF2 true`
	`setDontUse -hinst A -reset`
	The above sequence of commands resets the dont_use constraint on BUF1 but does not reset the dont_use constaint on BUF2.
	Note: The standard design-wide dont_use constraints from SDC, .lib, and the `setDontUse` command without the `-hinst` parameter will still apply.

value	Specifies whether to set or unset the dont_use attribute: `true` sets the dont_use attribute on the specified cell, and `false` unsets it.

Command Order

Use this command before you run `optDesign`.

Examples

- The following commands set buff1 and buff2 as "don't use" cells:

```
setDontUse buff1 true
Setting BUFF1 as a don't use cell
setDontUse buff2 true
Setting BUFF2 as a don't use cell
```

- The following command sets AND2 in library libSlow as "don't use" cells:

```
setDontUse libSlow/AND2 true
Setting libSlow/AND2 as a don't use cell
```

Related Information

- The following topic in the *Innovus User Guide*
  - Using the Footprintless Flow

setInvFootPrint

```
setInvFootPrint
[-help]
[-library libName]
invCellOrFootprintNames
```

Specifies the inverter cell footprints. The footprint names are usually assigned during design import. The Innovus software uses these inverter footprint names during timing optimization and top-level inverter insertion in a partition design.

Parameters

`-help`	Prints a brief description that includes type and default information for each `setInvFootPrint` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setInvFootPrint`
`invCellOrFootprintNames`	Specifies the inverter cell footprint names or inverter cell names. When you specify an inverter cell name, the Innovus software automatically finds the cell footprint name.
`-library` *`libName`*	Specifies the library name from where the cells will be picked up.

setLatencyFile

```
setLatencyFile
[-help]
latencyFileName
```

Specifies the latency file that the timing engine must load when the timing analysis mode is set to `-usefulSkew`.

To see the current settings for the `setLatencyFile` command, see `getLatencyFile`.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `setLatencyFile` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setLatencyFile`
`latencyFileName`	Specifies the latency file to load.

Command Order

Use this command after setting analysis mode to `-usefulSkew`. For more information, see the Timing Analysis chapter in the *Innovus User Guide*.

Example

The following example sets the latency filename to `latency1`.

```
setLatencyFile latency1
```

Related Information

- `getLatencyFile`

  - Performing Optimization Before CTS

setMaxCapPerFreq

```
setMaxCapPerFreq
[-help]
[-lib libName]
[-force]
-freq {freq1 freq2 …}
-cap {cap1 cap2 …}
-pins {cell pin}
```

Adds a maximum capacitance per frequency table to the existing `max_capacitance` statement in the timing library. Timing analysis uses this table to detect violations, and `optDesign` attempts to repair violations.

The timing engine derives the frequency of an instance from the clock domain to which it is connected (the fastest clock domain, if there is more than one). If the instance is a clock instance (that is, part of the clock tree), the actual clock frequency is used. If the instance is part of the combinational logic (that is, a flip-flop, or the logic connected to the output of a flip-flop), the frequency used equals one-half of the associated clock domain frequency because a flip-flop output can only toggle at one-half the rate of the input clock. For example, a clock of 1.0 Mhz has 1,000,000 rise and fall transitions per second; however the output of a flip-flop connected to a 1.0 Mhz clock can only have 500,000 rise and fall transitions per second.

Timing analysis computes the frequency directly from the timing graph. Use the `dbSetNetFrequency` command to write the effective frequency onto the associated net in the database. You can then use the `dbNetFrequency` database command to check a given net's frequency value. The frequency values are stored in Hertz in the database. Modifying this value with the `dbSetNetFrequency` database command only affects `verifyACLimit`.

Note: This command supports MMMC and performs DRV computation as per view frequency. This feature is enabled by setting the below global variable to `true`.

```
set_global timing_report_drv_enable_frequency_per_view true
```

For detailed description of the variable, see the Timing Global Variables chapter.

You can use this command any time after loading the timing library files (that is, after importing or restoring the design).

Parameters

`-help`	Outputs a brief description that includes type and default information for each `setMaxCapPerFreq` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setMaxCapPerFreq`
`-cap {`*`cap1 cap2 …`*`}`	
	Specifies a list of capacitance values that must be greater than or equal to 0. You must specify the same number of -freq and -cap values. The software derives the maximum capacitance from a linear interpolation (or extrapolation) for a given frequency value using two frequency values in the table. For interpolation, the software uses the closest value above the frequency, and the closest value below the frequency. For extrapolation, the software uses the two closest values to the frequency. *Type:* Float, specified in units of pF
`-force`	Computes the maximum capacitance from the interpolated `-freq` and `-cap` values only, and ignores any previously defined `max_capacitance` values for these pins in the library. *Default:* Computes the maximum capacitance using the worst case (minimum value) between the library `max_capacitance` values and the interpolated `-cap` values.
`-freq {`*`freq1 freq2 …`*`}`	
	Specifies a list of at least two frequency values that must be greater than or equal to 0. You must specify the same number of -freq and -cap values, and the frequency values must be specified in ascending order. *Type:* Float, specified in units of Hz
`-lib` *`libName`*	
	Modifies only the matching cell-pins in the specified library. *Default:* Modifies the matching cell-pins in all libraries
`-pins {`*`cellpin`*`}`	
	Adds the new capacitance constraints to the specified set of cells and pins. You can specify output or inout pins. The asterisk (*) wildcard character can be used in a cell or pin name. If a table associated with the pin already exists, it is replaced with the new table. For analysis and optimization, the software uses the most restrictive (the lowest capacitance) value from either the table or the .lib max_capacitance. If you also specify the -force parameter, the max_capacitance value is ignored. The final value can be further modified using .sdc set_max_capacitance statements.

Examples

Assume all output pins of a library have a `max_capacitance` of 3.5 pF from the library file.

- The following command sets the frequency dependent `max_capacitance` to 3.0 pF at a frequency of 100 Mhz, and to 1.5 pF at a frequency of 200 Mhz, for all output or inout pins for all cells in the library named `fast`:

  ```
  setMaxCapPerFreq -lib fast -freq {100e6 200e6} -cap {3.0 1.5} -pins {* *}
  ```

  As a result, for a net at 300 Mhz, an and2 cell output pin has an extrapolated `max_capacitance` value of 0 pF (which means the cell cannot be used at that frequency). An extrapolation to 50 Mhz results in a `max_capacitance` value of 3.75 pF. However, the 3.75 pF value is greater than the existing `.lib max_capacitance` limit of 3.5 pF; therefore timing analysis uses the 3.5 pF value.

- The following command applies the same constraints to all libraries with cell names matching `dff*` that have a pin named `Qbar`:

```
setMaxCapPerFreq -force -freq {100e6 200e6} -cap {3.0 1.5} -pins {dff* Qbar}
```

Note: The original `.libmax_capacitance` limit is ignored because the `-force` parameter is specified; therefore extrapolation to 50 Mhz results in a final `max_capacitance` constraint value of 3.75 pF.

Related Information

- `dbNetFrequency`
- `dbSetNetFrequency`
- `optDesign`
- `verifyACLimit`
- `timing_report_drv_enable_frequency_per_view`

setMaxCapPerFreqTran

```
setMaxCapPerFreqTran
[-help]
-freq {freq1 freq2 freq3…}
-tran {tran1 tran2 tran3…}
-cap {{cap11 cap12 cap13…} {{cap21 cap22 cap23…}} {{cap31 cap32 cap33…}}}
-pins {cell outputpin}
[-lib libName]
[-force]
[-inputpin inputpin]
```

Sets the maximum capacitance of a pin in the design. Considers both the input transition time and the output frequency. If the maximum capacitance exceeds this value, the `reportCapViolation` command displays a capacitance violation.

You can use this command any time after loading the timing library files (that is, after importing or restoring the design).

Parameters

`-help`	Outputs a brief description that includes type and default information for each `setMaxCapPerFreqTran` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setMaxCapPerFreqTran`
`-cap {{cap11 cap12 cap13…} {{cap21 cap22 cap23…}} {{cap31 cap32 cap33…}}}`	
	Specifies a table of capacitance values with the maximum output pin capacitances associated with `-freq` and `-tran` values. The total number of `-cap` values must be the total number `-freq` values times the total number of `-tran` values. The `-freq` and `-tran` values must be specified before `-cap`. The capacitance values are floats in units of pico farad and all values must be greater than or equal to zero. The capacitance table uses frequency as the first index and the input transition as the second index. For example, `cap11`, `cap12`, and `cap13` are for `freq1`, while `c12`, `c22`, and `c32` correspond to the input transition `tran2`. The maximum capacitance is derived from a linear interpolation (or extrapolation) for a given frequency value and a transition value using two frequency values and two transition values n the table (closest above and below for interpolation, the two closest for extrapolation. *Type:* Float, specified in units of pF
`-force`	Computes the maximum capacitance from the interpolated `-freq`, `-tran`, and `-cap` values only, and ignores any previously defined `max_capacitance` values for these pins in the library. *Default:* (`-force` not specified) Computes the maximum capacitance using the worst case (minimum value) between the library `max_capacitance` values and the interpolated `-cap` values.
`-freq {freq1 freq2 freq3…}`	
	Specifies a list of at least two frequency values with the toggle frequencies at the output pin. Frequency values must be increasing, and the total number of frequency values cannot exceed 255. *Type:* Float, specified in units of Hz. All values must be equal to or greater than `0`.
`-inputpin inputpin`	
	Specifies the input pin name corresponding to the input transition values in `-tran`. If `-inputpin` is not given, `-tran` values correspond to all input pins.

`-lib` *libName*	Specifies the library name from inside a `.lib` file to update the cell-pins. *Default:* If a library name is not specified, modifies the matching cell-pins in all libraries
`-pins {`*cell* output*pin*`}`	
	Adds the new capacitance constraints to the specified set of cells and pins. You can specify output or inout pins; input pins are ignored. The asterisk (`*`) wildcard character can be used in a cell or pin name. If there is already a table associated with the same input-output pair (input pins are specified using `-inputpin`), it is replaced with the new constraints; otherwise, it is added to the output maximum capacitance table list. For analysis and optimization, the software uses the most restrictive (the lowest capacitance) value from either the table or the `.lib max_capacitance`. If you also specify the `-force` parameter, the `max_capacitance` value is ignored. The final value can be further modified using `.sdc set_max_capacitance` statements.
`-tran {`*tran1 tran2 tran3…*`}`	
	Specifies a list of at least two transition values with the input transition times. Transition times must be increasing in value, and the total number of transition times cannot exceed 255. *Type:* Float, specified in units of nanoseconds, and all values must be equal to or greater than `0`.

Example

The following command establishes a maximum capacitance table for all pins on all cells in all libraries.

```
setMaxCapPerFreqTran -force -pins {* *} -freq {1e8 1.25e8 1.5e8} -tran {450 475 500} -cap {{0.022 0.017 0.012} {0.02 0.014 0.01} {0.018 0.013 0.008}}
```

The table is shown below:

```
          450         475         500
1e8       0.022       0.017       0.012
1.25e8    0.02        0.014       0.01
1.5e8     0.018       0.013       0.008
```

Related Commands

setMaxTranPerFreq

```
setMaxTranPerFreq
[-help]
[-lib libName]
[-force]
-freq {freq1 freq2 freq3…}
-tran {tran1 tran2 tran3…}
-pins {cell pin}
```

Adds a maximum transition per frequency table to the existing `max_transition` statement in the timing library. Timing analysis uses this table to detect violations, and `optDesign` attempts to repair violations.

Use this command any time after loading the timing library files (that is, after importing or restoring the design).

The timing engine derives the frequency of an instance from the clock domain to which it is connected (the fastest clock domain, if there is more than one). If the instance is a clock instance (that is, part of the clock tree), the actual clock frequency is used. If the instance is part of the combinational logic (that is, a flip-flop, or the logic connected to the output of a flip-flop), the frequency used equals one-half of the associated clock domain frequency because a flip-flop output can only toggle at one-half the rate of the input clock. For example, a clock of 1.0 Mhz has 1,000,000 rise and fall transitions per second; however the output of a flip-flop connected to a 1.0 Mhz clock can only have 500,000 rise and fall transitions per second.

Timing analysis computes the frequency directly from the timing graph. Use the `dbSetNetFrequency` command to write the effective frequency onto the associated net in the database. Use the `dbNetFrequency` database command to check any given net's frequency value. The frequency values are stored in Hertz in the database. Modifying this value with the `dbSetNetFrequency` database command only affects `verifyACLimit`.

Note: This command supports MMMC and performs DRV computation as per view frequency. This feature is enabled by setting the below global variable to `true`.

```
set_global timing_report_drv_enable_frequency_per_view true
```

For detailed description of the variable, see the Timing Global Variables chapter.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `setMaxTranPerFreq` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setMaxTranPerFreq`
`-force`	Computes the maximum transition from the interpolated `-freq` and `-tran` values only and ignores any previously defined `max_transition` values for these pins in the library. *Default:* Uses the worst case (minimum value) between the `.lib max_transition` values and the interpolated `-tran` values.
`-freq {`*`freq1 freq2 freq3…`*`}`	
	Specifies a list of at least two frequency values that must be greater than or equal to 0. You must specify the same number of `-freq` and `-tran` values, and the frequency values must be specified in ascending order. *Type:* Float, specified in units of Hz
`-lib` *`libName`*	
	Modifies only the matching cell-pins in the specified library. *Default:* Modifies the matching cell-pins in all libraries.
`-pins {`*`cell pin`*`}`	
	Adds the new transition constraints to the specified set of cells and pins. You can specify input, output, or inout pins. The asterisk (`*`) wildcard character can be used in a cell or pin name. If a table associated with the pin already exists, it is replaced with the new table. For analysis and optimization, the software uses the most restrictive (the lowest transition) value from either the table or the `.lib max_transition`. If you also specify the -force parameter, the `max_transition` value is ignored. The final value can be further modified using `.sdc set_max_transition` statements.
`-tran {`*`tran1 tran2 tran3…`*`}`	
	Specifies a list of transition values that must be greater than or equal to 0. You must specify the same number of `-freq` and `-tran` values. The software derives the maximum transition limit from a linear interpolation (or extrapolation) for a given frequency value using two frequency values in the table. For interpolation, the software uses the closest value above the frequency, and the closest value below the frequency. For extrapolation, the software uses the two closest values to the frequency. *Type:* Float, specified in units of ns

Examples

Assume all output pins of a library have a `max_transition` value of 0.9 ns from the library file.

- The following command sets the frequency dependent `max_transition` to 1.0 ns at a frequency of 100 Mhz, and to 0.7 ns at a frequency of 200 Mhz, for pins matching `in*` of cells matching `*` (that is, all cells) in the library named `slow`:

  ```
  setMaxTranPerFreq -lib slow -freq {100e6 200e6} -tran {1.0 0.7} -pins {* in*}
  ```

  As a result, at 300 Mhz, an `and2` cell input pin named `in1` has an extrapolated `max_transition` value of 0.4ns. An extrapolation to 50 Mhz results in a `max_transition` value of 1.15 ns. However, the 1.15 ns value is greater than the existing `.lib max_transition` value of 0.9 ns; therefore timing analysis uses the 0.9 value.
- The following command applies the same constraints to all libraries with cell names matching `dff*` that have a pin named `clk`:

  ```
  setMaxTranPerFreq -force -freq {100e6 200e6} -tran {1.0 0.7} -pins {dff* clk}
  ```

Note: The original `.libmax_transition` value is ignored because the `-force` parameter is specified; therefore an extrapolation to 50 Mhz results in a final `max_transition` limit of 1.15 ns.

Sets global parameters for timing optimization. Parameters that you specify with `setOptMode` are then used automatically when you run timing optimization by invoking the `optDesign` command or by using the Optimize Design form in the ECO Menu.

To see the current settings for the `setOptMode` command, see `getOptMode`.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `setOptMode` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setOptMode`

`-opt_activity_refresh_args "`*`list_of_arguments`*`"`	Specifies the list of simulation options to be passed for Joules Xreplay. The parameter accepts all arguments of the `xreplay_stimulus` command.
	The following arguments can be specified using this option:
	• `[-xrun_path]` Specify xrun binary path to run Xcelium for replay simulation.
	• `[-rtl_stim]` Specify the input RTL stimulus file.
	• `[-stim_format]` Suboption of `-rtl_stim`, provides format of rtl stimulus.
	• `[-dut_instance]` Suboption of `-rtl_stim`, provides dut hierarchy in rtl stimulus.
	• `[-start]` Specify start time to run replay for particular stimulation time duration, for example 24ns. Default is simulation start time.
	• `[-end]` Specify end time to run replay for stimulation time duration, for example 100ns. Default is simulation end time.
	• `[-verilog_model_files]` Specify list of library verilog models
	• `[-stim_annotation]` Honor stim annotation of only the specified objects.
	• `[-pre_script]` Specify the Tcl file to be sourced before xreplay.
	• `[-out]` Specify the output replayed gate-level stimulus file. Default is joulesWorkDir/replayed_stim.shm
	• `[-reset_activity_before_readback]` Will reset the previous activity before reading the xreplayed activity file.
	• `[-delay_mode none | zero | unit | punit | delay | pdelay] (default: none)`
	For setting the arguments, use:
	`setOptMode -activity_refresh_args "<args>"`
	For querying the arguments, use:
	`getOptMode -activity_refresh_args`
	Default:`""`

`-opt_add_always_on_feed_through_buffers {true | false}`	

	Used by `optDesign` and PD-aware `addRepeaterByRule`. When this parameter is set to true, optDesign will use always-on buffers in both pre-route and post-route for all the optimization steps; and `addRepeaterByRule` will use always-on buffer for repeater insertion. It should be used for aggressive always-on buffering during optimization. The default optDesign behavior is to use always-on buffers only during pre-route DRV fixing. *Default:* `false`
`-opt_add_insts {true | false}`	Controls whether timing optimization can add instances. *Default:* `true`
`-opt_add_ports {true | false}`	Controls whether timing optimization adds ports to the lower-level hierarchies of the design. Prohibiting the software from adding ports (when this parameter is set to `false`) might not be optimal because buffers are not allowed to be added exactly where needed; however, this preserves hierarchical boundaries of the design so that generated test vectors are still valid, and module-by-module verification is possible. *Default:* `true`
`-opt_add_repeater_report_failure_reason {true | false}`	

When set to `true`, enables the printing of detailed failure reasons for each net for the `addRepeaterByRule` command. By default, the report will be generated in the `timingReports` directory. If the directory is not available, it will be created. For example,

```
<run_dir>/timingReports/ARRFailureReason/ARRRpt.preRoute.1
```

Use Model

```
setOptMode -opt_add_repeater_report_failure_reason true

addRepeaterByRule -selNet ./net.list -rule $scr/rule -preRoute
-reportIgnoredNets ignore_nets
```

Note the following:

- The ignored nets report is appended at the beginning of the failure reason report file. If "`-reportIgnoredNets IGNORE_NET_REPORT_NET_FILE_NAME`" is specified, then the ignored nets report is also saved to the file "`IGNORE_NET_REPORT_NET_FILE_NAME`".
- For multiple calls of ARR with different set of nets and constraints, equal number of failure reports will be generated under the `ARRFailureReason` directory. A suffix, "`_<n>`" will be added, with n being the n^{th} call of ARR. For example, three calls of ARR will lead to the generation of the following three files:
  `<run_dir>/timingReports/ARRFailureReason/ARRRpt.preRoute.1`
  `<run_dir>/timingReports/ARRFailureReason/ARRRpt.preRoute.2`
  `<run_dir>/timingReports/ARRFailureReason/ARRRpt.preRoute.3`
- The default mode of ARR reporting is preRoute. If you specify `-postRoute` or `-alongRoute`, the following will be appended in the report names:`<run_dir>/timingReports/ARRFailureReason/ARRRpt.postRoute.1`
  `<run_dir>/timingReports/ARRFailureReason/ARRRpt.alongRoute.1`

Note: The behavior of the parameter, `-reportIgnoredNets`, remains unchanged. It writes the reports with user-specified file name under the run directory.

Default: `false`

`-opt_all_end_points {true | false}`	Runs total negative slack optimization in addition to the worst negative slack optimization and does so on all end points to ensure a high quality timing result. This feature is automatically activated while running either of the `setDesignMode -flowEffort standard | extreme` timing-closure flows. So, despite the default being `false` it is overwritten by the `setDesignMode` command. **Note:** When this parameter is set to `false`, there may still be some fast TNS optimization done during `preRoute` optimization but there is no effect on the `postRoute` setup optimization. It also has no effect on hold optimization, which means that regardless of this setting, all hold violating paths will always be optimized. *Default:* `false`
`-opt_allow_only_cell_swapping {true | false}`	
	Forces the postRoute optimization to perform only same-size Vth swapping for timing improvements. This option works best on multi-Vth library designs. **Note:** Use this option for reoptimizing the timing in specific cases where routing should remain unchanged. *Default:* `false`
`-opt_allow_multi_bit_on_flop_with_sdc {true | false | mergeOnly | splitOnly}`	
	When this parameter is set to `true`, or by default, the software will not honor the SDC constraints while merging or splitting of flops in the multi-bit flip flop flow. Set this parameter to `false` to honor SDC constraints while merging or splitting of flops. Use `mergeOnly` to ignore the SDC constraints while merging but honor for splitting. Use `splitOnly` to ignore the SDC constraints while splitting but honor for merging. *Default*: `true` **Note**: When this parameter is set to `true`, the software will do merge/split even if there is SDC on D/Q pins and the SDC will be copied to the corresponding D/Q pins in the new flop. But if there are SDC constraints on SE/SI pin, the merging becomes more complicated. For example, a single flop A and flop B have 1 SE pin and D/Q pin. When merging is done, the SDC on D/Q pin will be copied to the new D0/Q0 and D1/Q1, and the SDC information will not be lost. But in the new 2-bit flop, there will be only one SE pin. This raises the issue of which SDC should be copied into the new flop. In this case, the software will check the SE pin SDC in flop A and flop B. If they are compatible, then it will do merging. Otherwise, the merging will not be done, even if the parameter is set to `true`.
`-opt_area_recovery {true |false | default}`	

	Controls whether timing optimization creates additional space by downsizing gates or deleting buffers, while maintaining worst slack and total negative slack. This parameter can be used in three modes: `default, true,` and `false`. • `default`: By default, area reduction is always called after global optimation and after the second TNS optimization. During the rest of `optDesign`, area reduction is called depending on the density level of the current design. • `true`: When this parameter is set to `true`, area reduction is always called before the global optimization stage, after the global optimization stage, and after the second TNS optimization. During the rest of optDesign, area reduction is called depending on the density level of the current design. • `false`: No area reduction is performed during `optDesign`. *Default:* `default` **Note**: This parameter is used to reclaim area during `preRoute` optimization. For reclaiming area during `postRoute` optimization, use the `-opt_post_route_area_reclaim` parameter of this command.
`-opt_area_recovery_setup_target_slack` *slack*	
	Specifies a user-defined target slack for area reclaim vs timing. When a slack value is specified, the software prevents area reclaim optimization from creating or working on near critical paths. Typically, you can set `setOptMode -opt_area_recovery_setup_target_slack 0.1` with `setOptMode -opt_setup_target_slack` at the default value of 0.0. This implies that the area reclaim will not work on any paths less than 0.1ns. Note that the value for `-opt_setup_target_slack` takes higher priority. For example, if `setOptMode -opt_area_recovery_setup_target_slack` is set to -0.1 and `setOptMode -opt_setup_target_slack` is at 0.0 then setup timing will not be allowed to degrade past 0ps and a warning will be issued. Similarly, if say `setOptMode -opt_area_recovery_setup_target_slack` is at +0.1 and `setOptMode -opt_setup_target_slack` is set to +0.2 then timing will target +0.2 and a warning will be issued. You need to set this parameter before any area reclaim is done. *Default*: `0ns`
`-opt_consider_routing_congestion {auto | false | true}`	

	Checks the routing congestion at the PostRoute stage during optimization of setup, hold, drv, or glitch. The option also impacts postCTS hold fixing. This option helps improve NR DRC's as well as Timing jumps caused by routing detours on congested designs. By default, this parameter is set in the following ways: • `auto` – turned “off” for postCTS hold fixing and “on” for postRoute setup and hold fixing • `false` – turned “off” for postCTS hold fixing and postRoute setup and hold fixing • `true` – turned “on” for both postCTS hold fixing and postRoute setup and hold fixing *Default:* `auto`
`-opt_constant_inputs {true | false}`	When set to `true`, forces optimization of instances with constant inputs, even if it worsens the objective gain - in terms of area, power, and delay. *Default:* `false`
`-opt_constant_nets {true | false}`	Controls whether timing optimization optimizes constant nets. This parameter affects only postRoute optimization. *Default:* `true`
`-opt_concatenate_default_and_user_prefixes {true | false}`	

	Controls whether to combine the default prefix for cells and nets added by timing optimization with the prefix specified by `-opt_new_net_prefix` and `-opt_new_inst_prefix`. By default, the software combines the specified prefixes with the default prefix. Specify false for this parameter to ignore the default prefix and use only the prefix specified by `-opt_new_net_prefix` and `-opt_new_inst_prefix`.
	
	For example, if the default prefix is `PSN_000234` and you type the following command:
	`setOptMode -opt_concatenate_default_and_user_prefixes true -opt_new_net_prefix POSTROUTE_N -opt_new_inst_prefix POSTROUTE_C`
	
	The software uses the following prefixes:
	• For cells added by optimization: `POSTROUTE_C_PSN_00234`
	• For nets added by optimization: `POSTROUTE_N_PSN_00234`
	
	If the default prefix is `PSN_000234` and you type the following command:
	`setOptMode -opt_concatenate_default_and_user_prefixes false -opt_new_net_prefix POSTROUTE_N -opt_new_inst_prefix POSTROUTE_C`
	
	The software uses the following prefixes:
	• For cells added by optimization: POSTROUTE_C
	• For nets added by optimization: POSTROUTE_N
	
	Note: If you specify false for this parameter, you must also specify `-opt_new_inst_prefix` and `-opt_new_net_prefix`. In addition, you must specify a different prefix for instances and nets.
	
	Default: `true`

`-opt_delete_insts {true | false}`	Controls whether timing optimization can delete instances. *Default:* `true`
`-opt_detail_drv_failure_reason {true | false}`	
	When set to `true`, enables the printing of detailed DRV failure reason report file that contains the failure summary with the net name. The log file contains a simple version of failure summary without the net name. In addition, the top number(default 50) of violating nets are printed in separate files along with the violation reasons. By default, this parameter is set to false, which means that only a simple version of failure summary without the net name is printed in the log file and no other files are created. **Note**: If there is no DRV failure during the optimization flow, the failure reason report file will not be generated even when this parameter is set to `true`. *Default*: `false`
`-opt_detail_drv_failure_reason_max_num_nets` *value*	

	Specifies the number of violating nets for which the DRV failure reasons are to be printed in the report files. The default value is 50, which means failure reasons for top 50 violating nets are printed by default. The minimum value that can be specified is 1. The maximum value that can be specified is 9999. If this value is specified, failure reasons for all the violating nets are printed. For example, if you set this option to 100, then the top 100 max tran violating nets, if present, will be printed in file, "`xx.maxTran`" and the top 100 max cap violating nets, if present, will be printed in file, "`xx.maxCap`". Also, a file, "`xx.maxFanout`" may also be generated. For each file that is generated, the first printed net has the worst violation value. The file is sorted based on violation values while printing. *Default*: `50`
`-opt_down_size_insts {true | false}`	Controls whether timing optimization can downsize instances. *Default:* `true`
`-opt_drv {true | false}`	Repairs all nets that are constrained for maximum capacitance violations and maximum transition violations. The capacitance and transition constraint values are specified in the timing constraint file or in the library. If you specify false for this parameter, the software repairs only the paths with timing violations. *Default:* `true`
`-opt_drv_margin` *margin*	Scales the maxCap and maxTran constraints according to the *margin* decimal value specified. For example, specifying a value of 0.2 for this parameter tightens the margin (makes it more pessimistic) by 20 percent during optimization and specifying a value of -0.2 relaxes the margin (makes it more optimistic) by 20 percent. Introducing a pessimistic margin improves correlation between the number of DRC violations before and after routing. Value range: `-0.7 ~ 0.7` *Default:* `0`
`-opt_drv_with_miller_cap {true | false}`	When set to `true`, enables ECSM/CCS miller capacitance DRV reporting and fixing for `timeDesign` and `optDesign`. However, the `timing_report_use_receiver_model_capacitance` varibale must also be set to `true`. By default , this parameter is set to `false`, which means that miller cap DRV reporting and fixing is disabled. *Default*: `false`
`-opt_duplicate_cte_constrained_hport {true | false}`	When set to `true`, allows buffering to duplicate hports with CTE constraints to fix DRVs and setup violations. *Default*: `false`
`-opt_enable_data_to_data_checks {true | false}`	

	Enables data to data checks during optimization. During optimization the data to data timing checks are set to off by default to ensure that the engine focuses on other paths. To allow checks to be visible during optimization you can set this option to `true`. *Default*: `false`
`-opt_enable_podv2_clock_opt_flow {true | false}`	When set to `false`, enables the `place_opt_design` and `ccopt_design` flow. By default it is set to `true`, which means the place_opt_design V2 (PODV2 or pod_turbo) and `clock_opt_design` flow is enabled. *Default*: `true`
`-opt_enable_restructure {true | false}`	Controls whether timing optimization swaps pins and restructures the netlist. *Default:* `true` **Note:** This parameter is not enabled when `setDesignMode -flowEffort express` is set.
`-opt_fix_fanout_load {true | false}`	Forces timing optimization to correct fanout load violations, which can be maximum load or maximum fanout count violations, depending on the libraries. *Default:* `false`
`-opt_flop_pins_report {false | true}`	Set this parameter to true for printing out full hierarchical pin names used in the incoming netlist for flops deleted during simplifyNetlist. The output file name format is `<userPrefix>_simplified_flops_pins.rpt`. *Default*: `false` You can choose to write both files with pins or without pins (`-opt_flops_report`) in same session .
`-opt_flops_report {false | true}`	Set this parameter to true for printing full hierarchical flop names used in the incoming netlist for flops deleted during simplifyNetlist. The output file name format is `<userPrefix>_simplified_flops.rpt`. *Default*: `false` You can choose to write both files with pins (`-opt_flop_pins_report`) or without pins in same session.
`-opt_high_effort_cells` *list_of_cells*	Specifies the list of cells to be used for high-effort optimization. This parameter is applicable in both pre-route and post-route setup optimization. **Note**: If the `dont_touch` constraint is set to `true` for the specified cells, then these cells will not be used for high-effort optimization. *Default:* `"" (empty string)`

`-opt_hold_allow_overlap {auto | true | false}`	Allows hold-fixing algorithm to insert buffers with overlap when large enough empty space locations are not available. The placement will then be legalized before ECO routing. Activating this option allows to the tool to fix hold violations, but might have some negative impact on setup timing. • `auto`: Hold fixing will be running in the allow overlapping mode in postCTS and not in the postRoute stage. • `true`: Hold fixing will be running in the allow overlapping mode in both postCTS and the postRoute stage. • `false`: Hold fixing will not be running in allow overlapping mode in both postCTS and the postRoute stage. *Default:* `auto`
`-opt_hold_allow_resize {true | false}`	
	Controls the resizing capability inside hold optimization. When set to `true` or `false`, resizing is turned on or off in both postCTS and postRoute hold optimization. *Default:* `true`
`-opt_hold_allow_setup_tns_degradation {true | false}`	
	Controls whether the software allows total negative slack to degrade during hold fixing operations. By default, the software allows the slack to degrade in order to fix more hold violations. To override the default behavior and ensure that the setup total negative slack is maintained during hold fixing, specify `false` for this parameter. *Default*: `true`
`-opt_hold_cells` *`list_of_buffers`*	Allows you to force the usage of only a specific list of buffer and delay cells. The *`list_of_buffers`* contains regular buffers and delay buffer cells. When this list contains at least one cell, use only the specified cells. *Default*: An empty list. This will trigger the default flow. **Note:** This parameter does not support wildcards. The *`list_of_buffers`* must contain only exact cell name. **Note:** `optDesign` disables automatic cell filtering when this list is specified which could impact the runtime/QOR/leakage of optDesign. **Note:** `optDesign` uses the specified cells without honoring `dont_use` attribute.
`-opt_hold_on_excluded_clock_nets {true | false}`	Controls whether hold fixing will be performed on excluded clock nets or not. This parameter is applicable for both postCTS and postRoute Hold optimization. *Default*: `false`

`-opt_hold_slack_threshold` *slack*	Allows you to provide a hold slack threshold value beyond which the hold timing violations will not be fixed. This is used to avoid fixing out of bound violations at an early stage when the timing constraints and design environment might not be mature enough. The slack value is specified in nano seconds (ns). **Note**: When the hold slack threshold value is specified using this parameter, the hold fixing timing table excludes the violations with slack worse than the specified value. **Note**: The threshold value specified is for hold WNS. *Default:* `-1000ns`
`-opt_hold_target_slack` *holdTargetSlack*	Specifies a target slack value in nanoseconds to use for hold analysis only. During setup violation repair, the setup target slack is *setupTargetSlack* and the hold target slack value is 0. Generally, you use both `-opt_setup_target_slack` and `-opt_hold_target_slack` for hold analysis. If you specify `-opt_hold_target_slack` only, the `-opt_setup_target_slack` value is 0. *Default:* `0`
`-opt_honor_density_screen {true | false}`	Controls whether or not density screens (partial placement blockages used to control congestion) are honored while optimizing timing. By default, this parameter is set to `false`, which means that the density screens are not honored. *Default:* `false`
`-opt_honor_fences {true | false}`	Specifies that the timing optimization takes fences or region constraints into account. This option is honored by each `optDesign` step. If you optimize design with the parameter set to true, the placement is legal. This feature is useful for hierarchical designs. Because this parameter adds constraints to timing optimization, enable it only when needed. *Default*: `false` **Note**: For Multi Supply Voltage (MSV) designs, this parameter is set to `true` by default. **Note:** `optDesign` will not honor very small fences when this parameter is set to true if it would cause fence utilization to be greater than 100 percent.
`-opt_hold_ignore_path_groups {`*groupAgroupB* `...}`	
	Specifies which clock domains or path groups should be excluded from hold timing optimization. This option impacts only `optDesign -postCTS/-postRoute -hold`. *Default:* `""` **Note:** To reset this option, apply an empty list. **Note:** If a violated path is in two path groups and only one of those paths is specified using the `-opt_hold_ignore_path_groups` parameter, this path is still fixed during hold fixing.

`-opt_leakage_to_dynamic_ratio` *ratio*	Controls the priority of the power-driven optimization. You can set any value between 0 and 1. Use this parameter along with the `-opt_power_effort` parameter. *Default:* `1` Some examples of what the value of this parameter indicates are provided below: • `setOptMode -opt_leakage_to_dynamic_ratio 1` This is the default value and implies that timing optimization will be purely leakage-power driven optimization. • `setOptMode -opt_leakage_to_dynamic_ratio 0` This implies that timing optimization will be purely dynamic power-driven optimization. • `setOptMode -opt_leakage_to_dynamic_ratio 0.5` This implies that timing optimization will be both dynamic and leakage power-driven and trade-offs may need to be done to get a balance between the leakage and dynamic power optimization. • `setOptMode -opt_leakage_to_dynamic_ratio 0.1` This implies that timing optimization will be both dynamic and leakage power-driven but dynamic power optimization will be favored. • `setOptMode -opt_leakage_to_dynamic_ratio 0.9` This implies that timing optimization will be both dynamic and leakage power-driven but leakage power optimization will be favored.
`-opt_max_density` *density*	Specifies the maximum value for density (area utilization). The `optDesign` command does not grow the netlist above this value. When reaching a density close to the value specified by this parameter, `optDesign` has limited optimization capability. *Default:* `0.95`

`-opt_max_length` *length*	Specifies that `optDesign` honors the maxLength rule as any other DRV rule (`max_cap/max_tran/max_fanout`). The `optDesign` command will fix all the nets that are violating this rule and will ensure to not create any long nets that violate it. The value is specified in micrometer. **Note:** This parameter implies that more buffers gets inserted in the netlist. *Default:* `-1` *min*=`-1`, *max*=`2147483647` This parameter is disabled by default. **Note:** During the pre-route stage, some maxLength violations might still exist after running `optDesign` due to routing topology changes taking place during the flow.
`-opt_move_insts {true | false}`	Allows cells in the critical path to move when the software repairs setup violations or optimizes timing along the critical path, if allowing them to move improves timing. *Default:* `true`
`-opt_multi_bit_combinational_mode {auto | power | area}`	
	Enables the user-specific multi-bit combinational cell (MBCC) merging and splitting based on area and power. • `auto`: Enables merging or splitting of MBCCs based on area (if power effort is none), otherwise based on power. • `power`: Enables merging or splitting of MBCCs based on power. • `area`: Enables merging or splitting of MBCCs based on area. *Default*: `auto`
`-opt_multi_bit_combinational_opt {false | true | mergeOnly | splitOnly}`	
	Enables and disables the multi-bit combinational flow. This flow is called as a part of the preCTS optimization stage. The following settings are available: • `true`: enables both merging and splitting of combinational cells • `false`: disables the flow • `mergeOnly`: only merges the combinational cells. • `splitOnly`: only splits the combinational cells. *Default:* `splitOnly`
`-opt_multi_bit_combinational_merge_timing_effort {none | low | medium | high}`	

	Specifies the timing effort-level for multi-bit combinational merging. • If the parameter is set to `high`, the software merges the combinational cell to maintain or improve the timing. • If the parameter is set to `low`, the software merges the combinational cell with allowing timing degradation. • If the parameter is set to `medium`, the software allows merging without/minimal degradation in timing. *Default:* `medium`
`-opt_multi_bit_combinational_split_timing_effort {none | low | medium | high}`	
	Specifies the timing effort-level for multi-bit combinational splitting. • If the parameter is set to `low`, the software allows splitting to critical paths only. • If the parameter is set to `medium`, the splitting happen to critical paths to improve timing. • If the parameter is set to `high`, the software performs aggressive splitting to improve timing. *Default:* `low`
`-opt_multi_bit_flop_merge_bank_label_inference {true | false}`	
	When set to `true`, this parameter enables soft merging of flops with the same bank label. By default, this parameter is set to `false`, which means hard merging is done. *Default*: `false`
`-opt_multi_bit_flop_merge_timing_effort {low | medium | high}`	
	Specifies the timing effort level for MBFF merging. • `low` effort setting allows degrading in timing to achieve merging. • `medium` effort means that merging happens either without or with minimal degradation of timing after merging. • `high` effort setting does not allow any degradation and does merging only if it either maintain or improves timing. *Default*: `medium`
`-opt_multi_bit_flop_name_prefix` *`prefix_name`*	
	Specifies the MBFF name prefix. When single-bit flip-flops are merged into a multi-bit flip-flop, you can use this parameter to specify the prefix for the new merged flip-flop. If no prefix is specified, the name of the merged flip-flop starts with the default name, `CDN_MBIT_`. *Default*: `CDN_MBIT_`
`-opt_multi_bit_flop_name_suffix` *`_user_suffix`*	

	Specifies the MBFF name suffix. When this parameter is set, the software adds the user-specified suffix at the end of the multi-bit cell instance name along with the bit-width of the multi-bit cell.
	For example, the below command is used to specify `_FTREG` as suffix:
	`setOptMode -opt_multi_bit_flop_name_suffix _FTREG`
	`CDN_MBIT_bit1_MB_bit2_FTREG2 for a 2-bit multibit cell CDN_MBIT_bit1_MB_bit2_MB_bit3_MB_bit4_FTREG4 for a 4-bit multibit cell`
	Default: `""`

`-opt_multi_bit_flop_name_separator` *separator_name*	
	Specifies the flip-flop merge and split name separator. The separator is used while splitting and merging flip-flops. The default separator is `_MB_` . The use model is detailed below. **Scenario1**: When two or more SBFFs are merged, the separators are used between names of single bit flip-flops. The MBFF is named as; `prefix_bit1_separator_bit2_separator_bit3..._separator_bit#`. **Scenario2**: When an MBFF is split into smaller bits, then each smaller bit is named as; `prefix_bit1_separator_bit2`. **Scenario3**: When an MBFF is split into the original number of single-bit flip-flops, then each SBFF reverts to its original name, which is without prefix and separator such as; `bit1, bit2`... Consider the example below to understand the above scenarios: There are four SBFFs: `bit1, bit2, bit3`, and `bit4`. • With default settings, when they are merged, the following MBFF is generated: **CDN_MBIT**_bit1_**MB**_bit2_**MB**_bit3_**MB**_bit4 This MBFF has the default prefix and the default separator. • When the above MBFF is split into two-bit MBFFs, the following is generated: **CDN_MBIT**_bit1_**MB**_bit2, and **CND_MBIT**_bit3_**MB**_bit4 • When the MBFF is split into the original SBFFs, the names of the SBFFs revert to the original names: `bit1, bit2, bit3`, and `bit4` *Default*: `_MB_`
`-opt_multi_bit_flop_opt {true | false | mergeOnly | splitOnly}`	

	Enables and disables the multi-bit flip flop flow. This flow is called as a part of the preCTS optimization stage. Set this parameter to `true` to enable both merging and splitting of flops. Set it to `false` to disable the flow. Set it to `mergeOnly` to only merge flops. By default, the parameter is set to `splitOnly`, which means the flow is enabled for splitting MBFFs. **Note**: • This option is independent of `-opt_enable_restructure`, `-opt_resize_flip_flops`, and `-opt_preserve_all_sequential` options. • To ensure sufficient multi-bit conversion ratio, allow more usable multi-bit flop cells from the libraries. Use the command, `reportMultibit -equiv` to write out the corresponding multi-bit flop cells to the single-bit flop cells. • To reduce long runtime in flop merge steps, ensure that the scan enable signal nets connecting to the flops are buffered, which means without max-fanout violations. *Default:* `splitOnly`
`-opt_multi_bit_flop_reorder_bits {false | true | timing | power}`	
	Enables swap MBFF bits to take advantage of mixed-drive strength (MDS) multi-bit cells. The following settings are possible: • `false`: the software does not identify the MDS cells and no bit-reordering is done • `timing`: software identifies and uses the MDS cells for timing optimization • `power`: software identifies and uses the MDS cells for power optimization • `true`: software identifies and uses the MDS cells for both timing and power optimization **Note**: When this parameter is set to `true`, `power`, or `timing`, a "Bit-strength (strong to weak)" column will be added in the report generated using the `reportMultibit -cell` parameter. *Default*: `false`
`-opt_multi_bit_flop_split_report_failure_reason {true|false}`	
	When set to `false`, disables the printing of MBFF split failure reasons. By default this parameter is set to `true`, which means the reasons for MBFF instances not splitting are printed. This is the default behavior. *Default*:`true`
`-opt_multi_bit_flop_split_timing_effort {low | medium | high}`	

	Specifies the timing effort level for MBFF splitting. • `low` effort setting means splitting will be done only when absolutely necessary for critical paths. • `medium` effort setting means splitting happens for more critical paths to improve timing and remove critical timing bottlenecks . • `high` effort setting does aggressive splitting and try to improve timing . *Default*: `low`
`-opt_multi_bit_unused_bit_count` *integer*	Specifies the maximum number of unused bits to be allowed in each multi-bit cell. *Default*: `0` *Min*: `1` *Max*: `32` **Note**: To use this parameter, set the `-opt_multi_bit_unused_bits` parameter to `true`.
`-opt_multi_bit_unused_bits {false | true | prePlace | preCTS}`	
	Specifies whether a mapped multi-bit instance can have one or more unused bits. By default, at prePlace stage Innovus tries to merge the single-bit registers to multi-bit instances without unused bits. If during merging, the software is unable to find a suitable multi-bit lib_cell with a width that matches the left-over bits of a bus, it chooses the closest matching width, which leaves the minimum unused bits and, therefore, increases the multi-bit merging coverage. When set to `false`, any merging that results in unused (undriven/unloaded) bits is prevented. When set to `true`, the software tries to merge the single-bit register to multi-bit instances with unused bits at both, prePlace and preCTS stages. When set to `preCTS`, the software merges the single-bit register to multi-bit instances with unused bits at the preCTS stage. *Default*: `prePlace`
`-opt_new_inst_prefix` *prefix*	Specifies a prefix string to add to instances created by timing optimization. For example, if a default prefix is OFC_000234, when you use the command `setOptMode -opt_new_inst_prefix POSTROUTE_`, the combined prefix added to the instance name is `POSTROUTE_OFC_00234`. *Default:* `""` **Note:** To ignore the default prefix, use the following parameter: `-opt_concatenate_default_and_user_prefixes false`.

`-opt_new_net_prefix` *prefix*	Specifies a prefix string to add when timing optimization creates nets. For example, if a default prefix is PSN_000234, when you use the command `setOptMode -opt_new_inst_prefix POSTROUTE_`, the combined prefix added to the net name is `POSTROUTE_PSN_00234`. *Default:* `""` **Note:** To ignore the default prefix, use the following parameter: `-opt_concatenate_default_and_user_prefixes false`.
`-opt_one_pass_lec {true | false}`	When set to `true`, enables the one pass Logical Equivalence Check (LEC) flow. In one pass LEC, you can do a Register Transfer Level (RTL) to netlist comparison between RTL and postRoute optimization (PRO) netlist - any place and route (PnR) stage netlist - in a single step. *Default*: `false`
`-opt_podv2_flow_effort {auto | standard | extreme}`	Specifies the effort level for the place_opt_design V2 (PODV2) flow. See `clock_opt_design`. The following settings are available: • `auto`: The software follows the `setDesignMode -flowEffort` setting to perform optimization. • `standard`: The software performs a fast prects optimization and runtime is less. This option is recommended in the early design stage or in simple designs for PPA estimation. • `extreme`: The software performs a deep optimization to chase the best PPA. Runtime is high. *Default*: `auto`
`-opt_pin_swapping {true | false}`	Controls whether timing optimization allows pin swapping. *Default:* `true` **Note:** This parameter is not enabled when `setDesignMode -flowEffort express` is set.
`-opt_post_route_allow_overlap {true | false}`	Controls whether timing optimization allows overlap during `optDesign -postRoute`. *Default:* `true`
`-opt_post_route_area_reclaim {none | setupAware | holdAndSetupAware}`	

	This parameter can be used after routing to reclaim area during `optDesign -postRoute`. It safely reclaims area while not impacting the timing and DRV violations. You can use the following options: • `none`: No area reclaim is done. This is the default setting. • `setupAware`: Reclaim is done but is not hold aware. This may degrade hold timing significantly but will maintain the setup timing while giving the best possible reclaim results. • `holdAndSetupAware`: Reclaim is done but is both hold and setup aware. It will not give as good reclaim results as setupAware alone. But it will mean both setup and hold Timing will be maintained. *Default:* `none`
`-opt_post_route_art_flow {true | false}`	Ensures that timing optimization applies to ART-based flow. In the ART-based flow, it partially activates the design at the top-level and at the interface path of partition blocks so that there is a reduction in memory usage and run time if the design is large. This parameter marks the core logic inside the partition as `dont_touch`, so the logic is not optimized. *Default:* `false` **Note:** This parameter requires partition definition information and applies to the post-route mode only.
`-opt_post_route_check_antenna_rules {true | false}`	
	Allows optimization to check/ignore antenna rules for LEF-safe swaps. The default behavior is to check the antenna rules, in order to avoid antenna violations caused by the cell swappings. LEF files have certain antenna rules defined in them. By default, when doing LEF-safe swaps for leakage power optimization and for LEF-safe timing recovery, it is ensured that the cells have the same antenna rules. If cells don't have the same antenna rules, they are not swapped. However, if this parameter is set to `false`, in postRoute mode, antenna rules will not be considered when doing LEF-safe swaps. Therefore, setting this option to `false` improves timing and leakage but it can potentially lead to routing having antenna violations, which will require a call to the `ecoRoute` command for cleanup. *Default*: `true`
`-opt_post_route_drv_recovery {false | auto | true}`	

	Controls the DRV/glitch recovery step performed when `optDesign -postRoute -setup -hold` and `optDesign -postRoute -hold` commands have been specified. You can specify the following options: • `false`: Disables DRV/glitch recovery. • auto: Allows the software to determine when to trigger DRV/glitch recovery. Here recovery will be triggered if any of the DRV's or glitches degrade beyond a certain margin. • true: Always triggers DRV/glitch recovery if there are any left in the design. *Default*: `auto`
`-opt_post_route_fix_clock_drv {true | false}`	
	Controls whether `ccopt_pro` is called or not at the start of postRoute optimization. By default this parameter is set `true`, which means that `ccopt_pro` is called to repair clock tree design rule violations (DRVs) that have occurred in the clock tree after routing. These DRVs are most commonly the user-set clock transTime violations. To disable the fixing of DRVs, set the parameter to `false`. *Default*: `true`
`-opt_post_route_fix_glitch {true | false}`	Determines whether to fix glitch violations during SI optimization. To disable fixing of glitch violations, set this parameter to false. *Default*: `true` **Note**: For SI glitch fixing, you must set the `setSIMode -enable_glitch_report` parameter to `true`. If `setOptMode -opt_post_route_fix_glitch` is set to `true` but `setSIMode -enable_glitch_report` is set to `false`, the software will issue a warning during glitch fixing.
`-opt_post_route_fix_si_transitions {true | false}`	
	Enables fixing SI induced slew violations in postRoute optimization. **Note**: The transition values will be used for maximum transition violation fixing only and will not affect the timing calculation in EDI's timing engine. This is because the transition effect is considered by the internal SI engine during delay pushout calculation. *Default*: `false`
`-opt_post_route_hold_recovery {false | auto | true}`	

	Controls the Hold Recovery step performed when `optDesign -postRoute -setup -hold` and `optDesign -postRoute -hold` commands have been specified. You can specify the following options: • `false`: Disables hold recovery. • `auto`: Allows the software to determine when to trigger hold recovery. Here recovery will be triggered if WNS or TNS degrade beyond a certain margin. • `true`: Always triggers hold recovery if timing is not met, irrespective of the gain/degradation in post route timing. *Default*: `false`
`-opt_post_route_setup_recovery {false | auto | true}`	
	Controls the Setup Recovery step performed when `optDesign -postRoute -setup -hold` and `optDesign -postRoute -hold` commands have been specified. You can specify the following options: • `false`: Disables setup recovery. • `auto`: Allows the software to determine when to trigger setup recovery. Here recovery will be triggered if WNS or TNS degrade beyond a certain margin. • `true`: Always triggers setup recovery if timing is not met, irrespective of the gain/degradation in post route timing. *Default*: `auto`
`-opt_power_effort {none | low | high}`	Specifies the power-driven optimization functionality in Innovus. This parameter provides the effort level for optimizing leakage power and dynamic power in the design. Use the `-opt_power_effort` parameter along with the `-opt_leakage_to_dynamic_ratio` parameter to give a superior QOR and to trigger power-driven optimization. Power-driven optimization implies that the `optDesign` command now performs Power, Performance, and Area (PPA) trade-offs at the transform level at every step of timing optimization. You can specify any one of the following options: `none`: Specifies that no power optimization is to be performed. `low`: Specify this parameter when power optimization is not the highest priority. Using the low effort level option indicates the following: • Power optimization is performed only at certain stages of the `optDesign` flow, which is dependent on the value of the `-opt_leakage_to_dynamic_ratio` parameter. When the `-opt_leakage_to_dynamic_ratio` is 1.0, `optDesign` will optimize leakage power after each timing optimization step and no high leakage cells are inserted during hold fixing. When `-opt_leakage_to_dynamic_ratio` is 0.0, `optDesign` will optimize dynamic power at the preCTS stage. For all values of `-opt_leakage_to_dynamic_ratio` between 0.0 and 1.0, both of the above are done.

- Timing optimization is power-aware but uses only low-effort techniques when choosing the best timing optimization fixes to implement.
- Timing closure remains the first priority and the worst negative slack achieved is the same as that in effort mode “none”.
- On an average, the CPU full flow runtime impact is +26% for a -opt_leakage_to_dynamic_ratio of 0.5 as compared to that in effort mode “none”. This can vary depending on both the ratio being used and on the design.
- On an average, the MEM full flow impact is +5%.
- Utilization remains roughly at par with effort level “none” results.
- On an average, the overall standard cell dynamic power saving is -30% and can go up to -69% as compared to that achieved in effort mode “none”. On an average, the overall standard cell leakage power saving is -41% and can go up to -90% on some designs. This is achieved with a -opt_leakage_to_dynamic_ratio of 0.5 and will vary if this ratio is changed.

  Note: The above numbers are estimates and are completely dependent on the type of design.Therefore, they may be very different from the averages given above.

high: Use the high effort level option when having low power is the highest priority. Using the high effort level option indicates the following:

- Power optimization is performed during all calls to optDesign, which is dependent on the value of the -opt_leakage_to_dynamic_ratio parameter. Timing Optimization is power aware and uses high-effort techniques when choosing the best timing optimization fixes to implement.
- Timing closure should still be achievable, if it was previously, and in the majority of cases the same worst negative slack is reached as effort mode "none".
- CPU full flow runtime impact is on an average +63% for a -opt_leakage_to_dynamic_ratio 0.5 compared to effort "none". This can vary depending on both the ratio being used and on the design.
- MEM full flow impact is on an average +11%.
- Utilization is generally improved by -1.3% on average compared to effort level "none" results.
- On an average, the overall standard cell dynamic power saving is -32% and can go up to -70% as compared to that achieved in effort mode “none”. On an average, the overall standard cell leakage power saving is -54% and can go up to -98% on some designs. This is achieved with a -opt_leakage_to_dynamic_ratio of 0.5 and will vary if this ratio is changed.
  Note: The above numbers are estimates and are completely

	dependent on the type of design.Therefore, they may be very different from the averages given above. *Default*: `none` Before power optimization is performed, it is required that the correct power view is specified using the `set_analysis_view -leakage or -dynamic` *`view_name`* command. Both, leakage and dynamic optimization need to target the view that is most important in the design and then use it when optimizing the leakage, internal, and switching power. If dynamic optimization is being done (when a `-opt_leakage_to_dynamic_ratio` is anything other than the default of 1) then it is also required that the switching activity is specified. This can be done by using the `read_activity_file -format {VCD | TCF | SAF}` *`file name`*. In the absence of a switching file, it is recommended to specify the following: `set_default_switching_activity -input_activity 0.2 -seq_activity 0.2.` This will ensure both predictability and consistency throughout the flow.
`-opt_pre_route_ndr_aware` *`list`*	Enables NDR-based optimization by providing a list of NDR names. Using NDR-based optimization, GigaOpt assigns NDR on timing critical nets in order to improve timing. GigaOpt will automatically assess the list of NDRs provided and choose the one that can help timing. It is not recommended to use many NDRs for TAT point of view. *Default*: `""`
`-opt_preserve_all_sequential {true | false}`	
	Preserves sequential elements when netlists are optimized. When the `setOptMode -opt_remove_redundant_insts` parameter is set to `true`, the command removes unobservable or useless logic. However, you can retain sequential elements by setting `-opt_preserve_all_sequential` parameter to `true`. *Default*: `false`
`-opt_preserve_hpin_function {true | false}`	
	Determines whether to preserve logical functions at hierarchical module ports. When set to `false`, only the hierarchical module ports that have a timing assertion applied on them will be preserved (not deleted, duplicated, or polarity changed). This is the recommended setting since it allows more freedom for timing optimization while not impacting the netlist functionality or the timing constraints. When set the `true`, every port of every hierarchical mode will be preserved (not deleted, duplicated, or polarity changed). This is very constraining. *Default*: `false`

`-opt_remove_redundant_insts {true | false}`	Controls whether timing optimization simplifies the netlist. The software recovers area, decreases congestion, and improves runtime by simplifying the netlist in the following ways: • Removing dangling output instances • Propagating constants • Removing unobservable logic • Remapping useless logic The software respects the `set_dont_touch` constraint, so it does not remove the constrained flip-flops, and does not touch non-uniquified modules. *Default:* `true` **Note:** This parameter is not enabled when `setDesignMode -flowEffort express` is set.. **Note**: If a netlist contains spare cells, ensure that you define them using the `specifySpareGate` command else they might be removed by the `-opt_remove_redundant_insts` parameter.
`-opt_report_multi_bit_unmerged_reasons {true | false}`	When this parameter is set to `true`, the reasons for unmerged multibit flops/latches are printed in the MBFF summary. For details of the use model, see Reporting Unmerged Reasons for MBFFs. *Default:* `false`
`-opt_resize_flip_flops {true | false}`	Controls whether timing optimization upsizes or downsizes flip-flops. *Default:* `true`
`-opt_resize_level_shifter_and_iso_insts {true | false}`	
	Controls whether timing optimization resizes shifters and isolation instances. In default mode (false), shifters and isolations are considered "don't-touch" instances and are not changed during timing optimization. When this parameter is set to true, the shifters and isolation cells are resized for timing optimization by using `optDesign`. **Note:** When this parameter is set to true, all the shifters and isolation cells can be resized even if they are marked as dont_touch. *Default:* `false`
`-opt_resize_power_switch_insts {true | false}`	When set to `true`, enables resizing of power switch instances during optimization. By default, this parameter is set to `false`, which means the power switch instances are not resized during optimization. *Default*: `false`
`-opt_sequential_genus_restructure_report_failure_reason {true | false}`	

	When set to `true`, the sequential critical region resynthesis (CRR) failure reasons are reported in the `SeqCrrFailReasons.rpt` file. The report includes the instance name and the corresponding failure reason. **Note**: When CRR is enabled, Innovus uses Genus to restructure portions of the design to improve timing/area/power during setup optimization. *Default:* `false`
`-opt_setup_target_slack` *`setupTargetSlack`*	
	Specifies a target slack value in nanoseconds for setup analysis. During setup violation repair, the setup target slack is *`setupTargetSlack`* and the hold target slack is set to 0. Generally, you use both `-opt_setup_target_slack` and `-opt_hold_target_slack` for hold analysis. If you specify `-opt_hold_target_slack` only, the `-opt_setup_target_slack` value is 0. *Default:* `0ns`
`-opt_skew {true | false}`	Controls whether timing optimization runs the `skewClock` command. This parameter produces scheduling and latency files before CTS runs, or adds buffers and inverters after CTS, just as `skewClock` does. Useful skew optimization is run iteratively within `optDesign`, so you do not need to specify this parameter more than once. **Note**: The `setAnalysisMode -opt_skew` parameter gets set to `true` after `optDesign -preCTS`, which generates the latency file. When the `-opt_skew` parameter is set to `false`, it disables all useful skew everywhere, regardless of other `setOptMode -opt_skew*` settings such as those specified using the `-opt_skew_ccopt`, `-opt_skew_post_route`, and `-opt_skew_pre_cts` parameters. *Default:* `true` **Note:** This parameter is not enabled when `setDesignMode -flowEffort express` is set.

`-opt_skew_ccopt {none | standard | extreme}`	Specifies the effort for useful skew in both CTS and post-CTS flow. It replaces the earlier parameters, `-opt_skew_pre_cts` and `-opt_skew_post_route`. This parameter setting is only respected by `ccopt_design` and `optDesign -postCTS`. • `none`: low effort `ccopt_design` with no skewing • `standard`: low effort `ccopt_design`. This is the default setting. • `extreme`: high effort `ccopt_design` **Note**: To achieve the best possible timing result, the `extreme` setting will significantly increase the execution time of the `ccopt_design` command. Also, for best results the extreme setting should be used with `setDesignMode -flowEffort extreme`. The obsoleted options/commands and the corresponding values set by this parameter are detailed below: • `setOptMode -opt_skew_pre_cts false` corresponds to `setOptMode -opt_skew_ccopt standard` • `setOptMode -opt_skew_post_route true` corresponds to `setOptMode -opt_skew_ccopt` standard if `setDesignMode -flowEffort` is not set to `extreme` • `setOptMode -opt_skew_post_route false` corresponds to `setOptMode -opt_skew_ccopt none` if `setDesignMode -flowEffort` is not set to `extreme` *Default*: `standard`
`-opt_skew_post_route {true | false}`	When set to `false`, it disables useful skew in postRoute optimization. *Default*: `true`
`-opt_skew_pre_cts {true | false}`	When set to `false`, it disables useful skew in preCTS optimization. *Default*: `true`

`-opt_target_based_opt_file` *filename*	Specifies the file containing information that target-based optimization (TBOpt) will use to do fine grain target-based optimization using the `optDesign -postRoute -targeted` command.
	
	The format of the TBOpt file is as follows:
	`NETS : {net1} {net2} {netN}`
	`FROMTOS : {fromTerm1 toTerm1} {fromTerm2 toTerm2} {fromTermN toTermN}`
	`INSTS : {inst1} {inst2} {instN}`
	`PATHS : {endpoint1} {endpoint2} {endpointN}`
	`END_POINT_ADJ : {endpoint1} {slack_adj: value in ps}`
	`AREA_RECLAIM : {ModuleName} {x1 y1 x2 y2}`
	`PWR_RECLAIM : {ModuleName} {x1 y1 x2 y2}`
	`SI_GLITCH : {netName or netNameList} {value: e.g. 0.1}`
	`DRVS : {netName1} {netName2} {max_tran: e.g. 100}`
	
	Note: For more information about the file syntax and what is possible with respect to node specification and end point adjustment, area, power, max transition, and SI glitch optimization see Generating the Target File and Using a Target File for Target-Based Optimization in the *Innovus User Guide*.
	
	An example of a TBOpt file is provided below:
	`NETS : {mod_i/mod_sub_i/reset_l_sync_3}`
	`{mod_i/mod_sub_i/FE_OCPN210_reset_l_sync_3}`
	`INSTS : {mod_i/mod_sub_i/reset_l_sync_reg_15}`
	`{mod_i/mod_sub_i/FE_OCPC210_reset_l_sync_16}`
	`PATHS : {mod_i/mod_sub_i/ser_en/data_d1_reg_32/D}`
	
	Default: `""`

`-opt_target_based_opt_file_only {true | false}`	
	This parameter is used along with the `-opt_target_based_opt_file` parameter. By default, this parameter is set to `true`. So, by default, TBOpt only optimizes the nodes contained within the file specified using the `-opt_target_based_opt_file` parameter. When set to `false`, the TBOpt optimizes other nodes in addition to those specified in the file, if the software considers them to be critical. *Default*: `true`
`-opt_target_based_opt_hold_file` *hold_file_name*	

	Specifies the file containing information that TBOpt will use to perform hold optimization.
	
	`setOptMode -opt_target_based_opt_hold_file` *hold_file_name*
	
	`optDesign -postRoute -targeted -hold`
	
	Note: You can launch setup optimization followed by hold optimization using the following command:
	
	`optDesign -postRoute -targeted -setup -hold`
	
	Hold optimization is only called in the `-opt_target_based_opt_file_only` mode.
	
	Default: `""`

`-opt_tied_inputs {true | false}`	When set to `true`, forces optimization of instances with inputs tied together, even if it worsens the objective gain - in terms of area, power, and delay. *Default:* `false` **Note**: This parameter does not need to be specified when the `ecoRemoveTiedInputs` command is run. In that case this parameter is automatically set to `true` and instances with inputs tied together are optimized. After the command has been run, the parameter reverts to the value before executing the command.
`-opt_time_design_compress_reports {true | false}`	
	When set to `true`, this parameter forces `timeDesign` and `optDesign` to output timing reports in a compressed format. *Default*: `true`
`-opt_time_design_expanded_view {true | false}`	
	When set to `true`, this will force `timeDesign` or `optDesign` to print summary timing reports as per the view in the log file. **Note**: This parameter does not have any effect when the auto view pruning flow is ON for `optDesign`. This is the default flow, starting from the 15.1 release version of the software. Therefore, to output view-specific timing reports in this flow, run `timeDesign -expandedViews` after performing optimization. *Default*: `false`
`-opt_time_design_num_paths number`	Allows you to select the number of paths that should be reported per path group during `timeDesign` or `optDesign` final summary reports. *Default*: `50`
`-opt_time_design_report_net {true | false}`	
	When set to `true`, it forces `timeDesign` or `optDesign` to print timing reports with the net section. *Default*: `true`
`-opt_time_design_vertical_timing_summary {true|false}`	When set to `true`, prints vertical timing summary after `timeDesign` and final summary report. *Default*: `false`
`-opt_unfix_clock_insts {true | false}`	

	Controls whether the software is allowed to resize fixed sequential elements and to move them during placement legalization. optDesign temporarily removes the fixed attribute of each sequential element at the beginning of this step and sets it back to its original value at the end. This option does not remove the routed wires of the clock tree. It minimizes the movement of sequential elements as much as possible. This option impacts only `optDesign -postCts` and `optDesign -postRoute`. • When `true`, the software is allowed to resize and move fixed registers. • When `false`, the software is not allowed to resize or move fixed registers. *Default:* `true` **Note:** If you specify `true` for this parameter, Cadence recommends you use the `routeDesign` command for routing your design.
`-opt_verbose {true | false}`	Controls the amount of information timing optimization outputs to the log file. Specify true to output additional information to use to debug design issues. When you set this parameter to true, the various reasons for not fixing hold violations are listed in the log file. *Default:* `false` For more information, see the "Reasons for Hold Violations to Remain Unfixed" section below.
`-reset`	Resets parameters to their default values. The `-reset` parameter *must* be the first parameter specified. If you specify `-reset` by itself, the software resets all `setOptMode` parameters to their default values. If you specify parameters after `-reset`, the software resets only those parameters to their default values. Any values that do not already match the default value and are reset will be reported.

Examples

- The following command resets all `setOptMode` parameters to their default values:

  ```
  setOptMode -reset
  ```

- The following commands specify target slack values for setup and hold times and optimize timing in the design based on those values:

  ```
  setOptMode -opt_setup_target_slack 0.1 -opt_hold_target_slack 0.15
  optDesign -postCTS
  ```

- The following commands optimize leakage power in addition to optimizing timing and area, and fixing design rule violations:

  ```
  setOptMode -opt_power_effort high -opt_leakage_to_dynamic_ratio 1.0
  optDesign -preCts
  optDesign -postCts
  optDesign -postRoute
  optDesign -postRoute -hold
  ```

- The following commands allow the software to move clock instances during post-CTS timing optimization, and then run timing optimization:

  ```
  timeDesign -postCts
  ```

```
setOptMode -opt_unfix_clock_insts true
optDesgin -postCts
```

- The following command forces hold fixing to use the four cells specified in the list:
  ```
  setOptMode -opt_hold_cells {BUFFX8 BUFFX12 DELAY2 DELAY3}
  optDesign -postCts/-postRoute -hold
  ```
- The following command force `optDesign` to buffer all the nets that have a wirelength larger than `900um` and also not to generate any new long net that would violate this rule:
  ```
  setOptMode -opt_max_length 900
  optDesign -preCts | -postCts | -postRoute
  ```
- The following command forces `optDesign` to work towards positive slack for hold instead of zero:
  ```
  setOptMode -opt_hold_target_slack 0.5
  ```
- The following command will fix all the hold timing violations down to `0ns` slack except the violations that are initialy violated by more than `-3ns`. Those ones would be left untouched.
  ```
  setOptMode -opt_hold_slack_threshold -3 -opt_hold_target_slack 0
  ```
- The following commands will perform a fine grain target-based optimization at the postRoute stage on the nodes provided by the TBOpt file, `tb_opt.txt` as well as any other nodes that are identified as being critical:
  ```
  setOptMode -opt_target_based_opt_file tb_opt.txt
  optDesign -postRoute -targeted
  ```
- The following commands will perform a fine grain target-based optimization at the postRoute stage on the nodes provided by the TBOpt file, `tb_opt.txt` only:
  ```
  setOptMode -opt_target_based_opt_file tb_opt.txt -opt_target_based_opt_file_only true
  optDesign -postRoute -targeted
  ```

Reasons for Hold Violations to Remain Unfixed

The following table lists the various reasons for hold violations to remain unfixed:

Reason	Description
No legal location	There are no valid locations to insert buffers on those violated nets. Limit the local placement congestion and use instance/cell padding during initial placement. In parallel, to allow the tool to insert buffers at non-legal location, set the following parameter: `setOptMode -opt_hold_allow_overlap true`.
Degradation in setup register-to-register WNS	The nets are violated in hold but they are also a part of the register-to-register setup timing-critical paths. So inserting a buffer would degrade the setup register-to-register WNS. To fix these nets at the cost of register-to-register setup degradation, set a negative setup target slack using `setOptMode -opt_setup_target_slack` *`setupTargetSlack`*.
Degradation in setup TNS	The nets are violated in hold but they are also timing critical during setup. So, inserting a buffer would increase the setup TNS. To fix these nets at the cost of setup TNS degradation, set the following parameter: `setOptMode -opt_hold_allow_setup_tns_degradation true`
Degradation in setup WNS	The nets are violated in hold but they are also setup timing critical. So inserting a buffer would degrade the setup WNS. To fix these nets at the cost of setup degradation, set a negative setup target slack using `setOptMode -opt_setup_target_slack` *`setupTargetSlack`*.

Degradation in hold	The nets are violated in hold but inserting a buffer would further degrade hold timing. Check the topology of those nets and probably enlarge the list of available buffer/delay cells that are allowed to be used.
Degradation in maximum capacitance violation	The nets are violated in hold but inserting a buffer would create a new setup maximum capacitance violation. To fix these nets at the cost of DRV degradation, set the following parameter: `setOptMode -opt_drv false`
Degradation in maximum transition violation	The nets are violated in hold but inserting a buffer would create a new setup maximum transition violation. To fix these nets at the cost of DRV degradation, set the following parameter: `setOptMode -opt_drv false`
DRV violations	The nets are violated in hold but also in setup DRV, so they are skipped. To fix these nets at the cost of DRV degradation, set the following parameter: `setOptMode -opt_drv false`
Nets are set as `dont_touch`	To allow hold fixing on these nets, remove the `dont_touch` attribute.
Nets are routed incorrectly	Verify the routing wires for those nets.
Nets are clock nets	No buffers can be inserted on clock nets. You should check your timing constraint file.
None of the always-on-buffers are usable	Verify the environment to allow the use of always-on-buffers.
None of the valid mode is found on a net	The tool is not able to insert a buffer on such a net. This could be related to specific design cases.
Any internal failure	The tool was not able to find a solution for fixing the violation of those nets. This could be related to libraries or specific design cases.

setPathGroupOptions

```
setPathGroupOptions
[-help]
pathgroupName
[-early]
[-effortLevel {low | high}]
[-late]
[-skewingSlackConstraint value_in_ns]
[-slackAdjustment float]
[-slackAdjustmentPriority integer]
[-targetSlack float]
[-view view_names]
[-weight  integer]
```

Specifies options to guide timing optimization and timing analysis when path groups are used. To reset parameters to their default value, use `resetPathGroupOptions`.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `setPathGroupOptions` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setPathGroupOptions`

`-early`	Specifies early mode.
	This parameter is used with the `-slackAdjustment` option when you wish to adjust a path group's slack in Hold timing mode only.
	Note the following:
	• If you do not specify either `-early` or `-late`, then `-late` is implied.
	• If you specify `-early`, then `-early` is used.
	• If you specify `-late`, then `-late` is used.
	• If you specify both `-early` and `-late`, then both `-early` and `-late` are used, which means the same value of `-early` and `-late` are set at the same time.
	For example,
	`setPathGroupOptions reg2reg -slackAdjustment -0.3 -early -late`
	`Slack adjustment of -0.3 applied on reg2reg path_group`
	`**INFO: Setting reg2reg as high effort level since it has a negative slack adjustment.`
	`[DEV]innovus 25> reportPathGroupOptions`
	`---------------------------------------------------------------------------------------------`
	`| Path Group|Effort|Adjustment(early/late)|Target Slack|weight|SkewingSlackCons|view|`
	`---------------------------------------------------------------------------------------------`
	`| reg2reg  | high |  -0.3 /  -0.3  |  0  | 2  |  300  |setup_view9|`

`-effortLevel {low | high}`	Specifies the effort applied to close timing on a specific path group. This parameter is honored by timing optimization (`optDesign`). Select one of the following options: `low`: Specifies that this path group is optimized together with other path groups for best overall slack. low is the default effort value for all user-created path groups. **Note**: Cadence recommends you specify low effort for all path groups except that ones that the tool should focus on most strongly. `high`: Specifies that this path group is optimized separately from the low-effort path groups in order to achieve the best possible WNS for this path group. *Default*: low
pathgroupName	Specifies the path group for which to set options.
`-late`	Specifies late mode. This parameter is used with the `-slackAdjustment` option when you wish to adjust a path group's slack in Setup timing mode only. For usage details, see the description of the `-early` parameter.
`-skewingSlackConstraint` *value_in_ns*	When set, applies the specified skewing slack constraint to the path group. The value specified is in nanoseconds. If not set, no skewing slack constraint is applied to the path group. This parameter provides the ability to control the I/O slack during skewing without degrading the core slack value. The skewing engine skews in a way not to make any already -ve slack path more -ve or not introduce a new -ve slack path. **Examples**: If the following is specified: `setPathGroupOptions R2O -skewingSlackConstraint 0` *Before skewing*: FF's D slack is `-100 ps`(R2R), Q slack is `-20ps` (R2O) *After skewing*: D slack is `-100ps`, Q slack is `-20ps` *Before skewing*: FF's D slack is `-100 ps`(R2R), Q slack is `30ps` (R2O) *After skewing*: D slack is `-70ps`, Q slack is `0ps` **Note**: • This option can control CCOpt useful skew. If you are running ECF (early clock flow), preCTS will use CCOpt useful skew engine to do skewing. in this scenario, this option will take effect. • This option can control postCTS `skewClock` behavior • This option does not impact timing analysis
`-slackAdjustment` *float*	Specifies a positive or negative value used to modify path constraints on all paths that are part of a specific path group. The value is in nanoseconds. To relax the path constraints computed by the timing engine, specify a positive value. To tighten the timing constraints, specify a negative value. This parameter is honored by timing optimization (`optDesign`) and timing analysis (`report_timing`). This means that that the -`slackAdjustment` parameter setting impacts the timing analysis result and all optimization is then performed based on this timing. Using this parameter might have an impact on run time during timing optimization. **Note**: Path groups with negative slack adjustment will be automatically set to high effort, unless the `-effortLevel` option is explicitly set to "'`low`". For positive slack adjustment, the effort level will remain the same. This means if the effort is low before setting a positive slack adjustment, the new effort will be low; if the effort is high before setting a positive slack adjustment, the new effort will be high. **Tip**: Use this parameter together with the `-effort` parameter to direct timing optimization focus.

`-slackAdjustmentPriority` *integer*	
	Provides priority to a path group for the slack adjustment feature. The paths that are a part of overlapping path groups get slack adjustment from the path group that has a higher priority value. If the number is higher, the priority is higher. In case of multiple overlapping path groups with different slack adjustment values, the most constraining slack adjustment is applied. *Default*: 0 **Note**: The `-slackAdjustmentPriority` parameter is ignored if `-slackAdjustment` is not specified.
`-targetSlack` *float*	
	Specifies a target value for setup slack, in nanoseconds, for all paths that are part of a specific path group. The value can be positive or negative. This parameter is honored by timing optimization (`optDesign`). Using this parameter might have an impact on run time during timing optimization. **Note**: Setting this parameter does not impact the timing analysis results, and only setup optimization considers the target slack as the goal of optimization. The path group target slack (`setPathGroupOptions -targetSlack`) and the global setup target slack (`setOptMode -opt_setup_target_slack`) are cumulative. When both are set, global setup target slack adds on top of what is specified using the `setPathGroupOptions -targetSlack` parameter. The effective number depends upon whether path group target slack number is positive or negative. The global setup target slack is the timing closure target for timing optimization. **Note**: When both, `-slackAdjustment` and `-targetSlack` parameters are set, the setup optimization considers the target slack based on slack adjustment timing.
`-view` *view_names*	Specifies the view names. This parameter is used when you want to specify different effort levels of the path group for different views. *Default*: `{}` **Note**: When this parameter is used, only the specified views are active for timing analysis on the path group. Any timing reporting on this path group with inactive views will result in an error.
`-weight` *integer*	Defines the optimization priority. For the default path groups, the software assigns weights in the following manner: • For high-effort path groups: the software assigns a weight of "1" to reg2cgate and "2" to reg2reg. • All low-effort path groups are assigned a default weight of "0". You can assign any value to this parameter (0 to INT_MAX). There is no upper limit. The software looks at the relative priority of the weights for each path group -- the higher the number, the higher the weight. For example, if there are 10 path groups with weights ranging from 1 to 10 and they are all high-effort path groups, the high-effort optimization for all these ten path groups will be started simultaneously. If, however, the optimization is stuck at the path group with the weight 6, the software drops all the path groups that have weights ranging from 1 to 6 and continues to work on the remaining four path groups. **Note**: Use this parameter to control optimization and not `slackAdjustmentPriority`, which only controls the slackAdjustment.

Examples

- To change the timing measured for all setup paths in `PATH_GROUP_A` by relaxing the required time by 2 nanoseconds, specify:
  ```
  setPathGroupOptions PATH_GROUP_A -slackAdjustment 2
  ```

- To change the timing measured for all setup paths in `PATH_GROUP_B` by tightening the required time by 0.2 nanoseconds, specify:
  ```
  setPathGroupOptions PATH_GROUP_B -slackAdjustment -0.2
  ```
- To direct the `optDesign` command to optimize paths in `PATH_GROUP_C` until the worst setup slack in that path group is better than 2 nanoseconds, specify:
  ```
  setPathGroupOptions PATH_GROUP_C -targetSlack 2
  optDesign
  ```

  When these commands run, the software internally subtracts 2 nanoseconds from the required time for all paths of `PATH_GROUP_C`. Note that the `optDesign` command stops optimization when it no longer thinks that it can make progress, regardless of the slack target.
- To change the timing measured for all hold paths in `PATH_GROUP_D` by relaxing the required time by 0.2 nanoseconds, specify:
  ```
  setPathGroupOptions PATH_GROUP_D -slackAdjustment +0.2 -early
  ```
- The following commands are used to set the effort level, skewing slack constraint, weight, and views of the two path groups, and generate a report using these parameters:
  ```
  setPathGroupOptions reg2reg -effortLevel low -skewingSlackConstraint 0.3 -view AV_HL_FUNC_MIN_RC1
  setPathGroupOptions reg2cgate -effortLevel high-skewingSlackConstraint 0.5 -view AV_HL_FUNC_MAX_RC1
  reportPathGroupOptions
  The software prints the following report:
  ```

```
-------------------------------------------------------------------------------------------------
|Path Group|Effort|Adjustment(early/late)|Target Slack|weight|SkewingSlackCons|view               |
-------------------------------------------------------------------------------------------------
|reg2reg   |low   | 0.1/     0.2         | 0          |   2  |    0.3         |AV_HL_FUNC_MIN_RC1 |
|reg2cgate |high  | 0.2/     0           | 0          |   1  |    0.5         |AV_HL_FUNC_MAX_RC1 |
```

The description of the columns headings and the corresponding parameters to which they map is provided below.

Column Heading	Parameter and Description
Path Group	*pathgroupName:* Name of the path group for which the options are being set.
Effort	`-effortLevel`: Specifies the effort applied to close timing on a specific path group. `low`: Specifies that this path group is optimized together with other path groups for best overall slack. low is the default effort value for all user-created path groups. `high`: Specifies that this path group is optimized separately from the low-effort path groups in order to achieve the best possible WNS for this path group.
Adjustment (early/ late)	`-slackAdjustment`: Specifies a positive or negative value used to modify path constraints on all paths that are part of a specific path group. The value is in nanoseconds.
Target Slack	`-targetSlack`: Specifies a target value for setup slack, in nanoseconds, for all paths that are part of a specific path group. The value can be positive or negative. **Note**: This column only displays the latest setting, either early or late.
weight	`-weight`: Defines the optimization priority. For the default path groups, the software assigns weights in the following manner: • For high-effort path groups: the software assigns a weight of "1" to reg2cgate and "2" to reg2reg. • All low-effort path groups are assigned a default weight of "0".
SkewingSlackCons	`-skewingSlackConstraint`: Specifies the skewing slack constraint for the path group. If no constraint is applied to a path group, the column is empty.

view	`-view`: Specifies the view name. It allows you to specify different effort levels of the path group for different views.

Related Commands

- `createBasicPathGroups`
- `resetPathGroupOptions`
- `reportPathGroupOptions`

setSchedulingFile

```
setSchedulingFile
[-help]
schedulingFileName
```

Specifies the name of the scheduling file. The file is not taken into account by CTS, but `skewClock` must have access to the file if it runs several times consecutively.

To see the current setting for the `setSchedulingFile` command, use `getSchedulingFile`.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `setSchedulingFile` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setSchedulingFile`
`schedulingFileName`	Specifies the name of the scheduling file.

Example

The following command sets the name of the scheduling file to `scheduling_file.cts`:

```
setSchedulingFile scheduling_file.cts
```

[-verbose {true | false}]
```

Applies non-default settings for `signoffTimeDesign` and `signoffOptDesign` super commands.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `setSignoffOptMode` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setSignoffOptMode`
`-reset`	Resets all or specified options to default value. The `-reset` parameter *must* be the first parameter specified. If you specify `-reset` by itself, the software resets all `setSignoffOptMode` parameters to their default values. If you specify parameters after `-reset` , the software resets only those parameters to their default values. Any values that do not already match the default value and are reset will be reported.

`-addInst {true|false}`	Specifies whether Setup/Hold/DRV optimizer is allowed to add buffer/delay/swap cell instances. *Default:* `true` **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-addLoad {true|false}`	Specifies whether Hold optimizer is allowed to add dummy cell instances. *Default* : `false` **Note:** If set, this parameter must be applied before `signoffOptDesign`.

`-allowSkewing {true | false}`	Allows clock skewing to be done during Setup timing optimization to further improve Setup slack. When set to true, `signoffOptDesign -setup` works on the last level of the clock tree to modify the clock skew in order to improve Setup timing closure. Modification on the clock tree can be either resizing of the last level of the clock tree or buffering to pad endpoint clock pin.
	Default: `false`
	Note:
	• If set, this parameter must be applied before signoffOptDesign.
	• When `-allowSkewing` is active, `signoffOptDesign` will automatically unfix all clock tree instances/nets but it does not honor any CCOpt property that is set using the `set_ccopt_property` command. This is also performed when implementing the ECOs.
	• As for data path optimization, skewing is not allowed to create new Hold violated paths.
	Example:
	The following commands perform clock skewing during setup fixing.
	Only `CKBUFX1` and `CKBUFX4` can be added to the clock tree.
	`setSignoffOptMode -clockCellList {CKBUFX1 CKBUFX4}`
	`setSignoffOptMode -allowSkewing true`
	`signoffOptDesign -setup`

`-alongRouteBuffering {true | false}`	
	When set to `true`, the software uses node location provided through the parasitic data in order to insert buffers along the routing topology not only at the start or end of the net. This helps to better balance the slew or the load for long nets, which is typically needed for setup timing optimization or DRV fixing. *Default*: `false` **Note:** • A prerequisite of this parameter is that parasitic with the node location is provided to `signoffOptDesign`. In addition, the node location parasitic should be read using the `-starN` parameter. For example: `spefIn -starN`. • If set, this parameter must be applied before `signoffOptDesign`.

`-bufferCellList` *cell_list*	Specifies a list of buffer/delay cells that can be used for the timing optimizer, regardless of whether those cells have a dontUse attribute. When the list is empty, the software will automatically identify the list of usable buffer/delay cells. *Default:* `" "` (empty string) **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-checkDrvFromHoldViews {true | false}`	
	Enables optimization of DRV violations (max_capacitance/max_transition) in hold views as well in setup views during DRV optimization. Also, when enabled, this parameter ensures that timing/area/power optimization will not create any new DRV violation in hold and setup views. *Default*: `false` **Note:** If set, this parameter must be applied before `signoffTimeDesign` and `signoffOptDesign`.
`-checkType {early | late | both}`	
	Specifies the type of ECO Timing DB to be generated in PBA mode. The `early` argument specifies hold ECO Timing DB and `late` specifies setup ECO Timing DB. When set to `both`, the ECO Timing DB generation will be done in PBA for both Setup and Hold timing. *Default:* `both` **Note:** • This parameter is only active when the `-retime` option is being set. • If set, this parameter must be applied before `signoffTimeDesign`.
`-clockCellList` *cell_list*	Restricts the list of buffers that are allowed to be used by ECO on the clock tree. *Default*: `""` (empty string) **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-clockMaxLevel` *INT*	Specifies the maximum levels in clock skewing thus limiting the amount of clock tree levels and avoiding the creation of an unbalanced clock tree. This parameter sets an upper boundary when adding a buffer or pair of inverters to the clock nets. The software counts the number of levels in the clock tree branch that is being modified to ensure that the maximum level will be equal to or less than the value set by this parameter. *Default*: `0` **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-deleteInst {true | false}`	Enables buffer deletion when doing timing, power, or area reduction. This option is not honored by the `-leakage` parameter of `signoffOptDesign` since it performs only swapping. *Default*: `true` **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-disableGeometryChecks {true | false}`	

	Performs Vth swapping without checking the pins and geometry of a design. You can relax/stop/avoid the geometry checks during Vth swapping so that the tool just checks the cell size while performing Vth swapping. This will lead to more Vth swaps. The counterpart to this is that ecoRouting will be needed once the ECOs are applied since pin geometries might always match between old and new cells. *Default*: `false` **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-drvMargin` *float*	Specifies the ratio by which DRV check would be relaxed or tightened. It scales the maximum capacitance and maximum transition constraints according to the margin decimal value specified. For example, specifying a value of 0.2 for this parameter tightens the margin (makes it more pessimistic) by 20 percent during optimization and specifying a value of -0.2 relaxes the margin (makes it more optimistic) by 20 percent. This margin is honored for DRV optimization. **Note**: The software only accepts values from -0.7 to +0.7. A positive value indicates tighter constraints. *Default*: `0` **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-ecoFilePrefix` *string*	Specifies the prefix name for the ECO files generated. *Default:* `""` (empty string) **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-emType {all | avg | rms | peak}`	Specifies the current waveform calculation method when doing EM fixing. *Default*: `all`
`-fixCellEm {true | false}`	When set to `true`, fixes the cell-level signal electromigration violations during DRV fixing using resizing and additional transforming techniques. *Default*: `false` **Note:** • If set, this parameter must be applied before `signoffOptDesign -drv`. • If set during DRV fixing, the software will fix only the cell EM violations. This means that fixing of max_transition/max_capacitance/SI glitch/SI Xtalk/IR drop will be disabled.
`-fixClockDrv {true | false}`	Fixes maxCap/maxTran violations on the clock networks. This is performed only when the `signoffOptDesign -drv` command is run. *Default*: `false` **Note**: • For clock network DRV fixing, only the cells listed in the clock cell list (specified using the `setSignoffOptMode -clockCellList` parameter), is used. The DRV fixing is not performed if a cell list is not provided. • If set, this parameter must be applied before `signoffOptDesign`.

`-fixDataDrv {true | false}`	Fixes maxCap/maxTran violations on data nets. This is performed only when the `signoffOptDesign -drv` command is run. *Default*: `true`
`-fixGlitch {true | false}`	Performs SI glitch fixing during DRV fixing using resizing and buffering techniques. *Default*: `false` **Notes:** • If set, this parameter must be applied before `signoffTimeDesign`. • The glitch fixing is done before max_tran/max_cap fixing.
`-fixHoldAllowSetupDegrade {none | low | medium}`	
	This parameter guides the Hold fixing engine to determine what effort it has to put into resolving timing violations and how much flexibility it has to impact the Setup timing. When set to `low`, Hold optimization engine will buffer sink pins that have large Setup positive slack even though the net Setup slack is barely meeting timing. When set to `medium`, Hold optimization engine will behave the same as in the `low` mode but will also allow Setup TNS to degrade, if required. **Note:** • This parameter is honored by Hold optimization engine. • If set, this parameter must be applied before `signoffOptDesign`. • When the `-fixHoldAllowSetupDegrade` parameter is set to `low`, `medium`, or `none`, the `-fixHoldAllowSetupTnsDegrade` parameter is ignored. *Default*: `none`
`-fixHoldAllowSetupOptimization {true | false}`	
	When set to `true`, incremental Setup fixing is performed during Hold fixing in order to create more Setup margins on Hold violated nodes that could not be fixed earlier due to Setup timing conflict. *Default*: `false` **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-fixHoldAllowSetupTnsDegrade {true | false}`	
	When active, the Setup Total Negative Slack can be degraded during Hold time violations fixing while still maintaining the Setup Worst Negative Slack in every Setup active views. *Default*: `false` **Note:** If set, this parameter must be applied before `signoffOptDesign`.

`-fixHoldVariationAware {true | false}`	When set to `true`, more sizing and Vth swapping is performed during Hold fixing to reduce the cost of buffer insertion. This is particularly effective when Hold timing paths have incremental delay due to SI or large SOCV impacted instances. **Note**: • This parameter is only honored by `signoffOptDesign -hold`. • If set, this parameter must be applied before `signoffOptDesign`. *Default*: `false`
`-fixHoldWithMargin float`	Specifies a slack margin value in nanoseconds for Hold time violations fixing. The purpose is to overfix any Hold violations by the amount of the margin value. This margin is not applied on nets that are already meeting the Hold target slack. *Default*: `0` **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-fixIrDrop {true|false}`	Fixes the IR drop voltages for all instances in the design. *Default*: `false` **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-fixMaxCap {true | false}`	Specifies that nets with max_cap violations should be fixed. *Default*: `true` **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-fixMaxTran {true | false}`	Specifies that nets with max_tran violations should be fixed. *Default*: `true` **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-fixOsusGlitch {true | false}`	When set to `true`, fixes nets with overshoot and undershoot glitches during DRV optimization. *Default*: `false`
`-fixSlackInRangeLowerLimit value_in_ns`	Sets the lower slack limit for a violated path to be considered during timing closure. The value is specified in ns. *Default*: `-1.00000001504747e+30`
`-fixSlackInRangeUpperLimit value_in_ns`	Sets the upper slack limit for a violated path to be considered during timing closure.The value is specified in ns. *Default*: `1.00000001504747e+30`
`-fixSiSlew {true | false}`	Reports SI slews violations and fixed during DRV optimization. This is run as the first step of optimization before proceeding for any other incremental optimization. When this parameter is set to `true`, it automatically sets the value of the `-fixMaxTran` parameter to `true`. *Default* : `false` **Note:** If set, this parameter must be applied before `signoffTimeDesign` and `signoffOptDesign`.

`-fixXtalk {true | false}`	Reduces the crosstalk on nets that have xtalk delta delays greater than the specified threshold value. *Default*: `false` **Note:** If set, this parameter must be applied before `signoffTimeDesign` and `signoffOptDesign`.
`-fixXtalkPreserveHold {true | false}`	When this parameter is set to `true`, the Xtalk fixing engine is not allowed to degrade Hold timing. *Default*: `false` **Note**: • This parameter is only honored by `signoffOptDesign -drv` when Xtalk fixing is enabled. • If set, this parameter must be applied before `signoffOptDesign`.
`-fixXtalkPreserveSetup {true | false}`	When this parameter is set to `true`, the Xtalk fixing engine is not allowed to degrade Setup timing. *Default*: `false` **Note**: • This parameter is only honored by `signoffOptDesign -drv` when Xtalk fixing is enabled. • If set, this parameter must be applied before `signoffOptDesign`.
`-holdTargetSlack` *float*	Specifies a target slack value in nanoseconds for hold timing optimize. *Default*: `0` **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-holdTargetSlackPerView {viewName1 slack1 viewName2 slack2 …}`	When enabled, this parameter forces a specific hold target slack per view. If a given Hold active view is not listed in this parameter, the software uses the global Hold target slack set by the `-holdTargetSlack` parameter for that view. *Default*: `""` (empty string) **Note**: • This parameter is honored by Setup, Hold, Area, Power, and Leakage optimization engines. • If set, this parameter must be applied before `signoffOptDesign`.
`-holdXtalkDeltaThreshold` *value_in_ns*	Fixes the nets with the crosstalk delta delay value equal to or greater than the specified threshold value for hold views. The threshold value is specified in `ns`. *Default*: `0.3 ns` **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-holdXtalkSlackThreshold` *value_in_ns*	Fixes nets with the slack threshold value equal to or less than a specified threshold value for hold views. The threshold value is specified in `ns`. *Default*: `1000 ns` **Note:** If set, this parameter must be applied before `signoffOptDesign`.

`-ignoreDrvChecks {true | false}`	Specifies that DRV checks should be ignored in setup/hold/area/leakage/dynamic optimization. *Default*: `false` **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-keepTempfiles {true | false}`	Keeps all the temporary files generated by the distributed multi-mode multi-corner (DMMMC) and Tempus clients for debugging purposes. *Default*: `false` **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-legalOnly {true | false}`	
	Enables the tool to use the physical data to search for legal location while doing any buffer insertion or instance movement. This ensures that there is no instance overlap at the end of the ECO fixing stage, and after sourcing the ECO file in the implementation tool, you can directly run ECO routing. When this parameter is set to `false`, `signoffOptDesign` will not check for legal location although physical data is provided. In this mode, `signoffOptDesign` behaves in a Logical mode flow, which means that physical data will be ignored and this might create an instance overlap and will not check local density while inserting buffers. So it is recommended that you first run ECO fixing in the legal-only mode (which is the default mode) and then, depending on the requirement, you may perform an incremental run by setting `-legalOnly` to `false`. *Default*: `true` **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-loadCellList` *cell_list*	Specifies the list of load cells to be inserted during Hold fixing, regardless of whether those cells have a dontUse attribute. *Default*: `""`(empty string) **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-loadEcoOptDb` *dir_name*	Specifies the path of the directory where previously generated ECO Timing DB files are kept. If not specified, the ECO Timing DB files will be generated. *Default:* `""` (empty string) **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-loadIrdropDb` *dir_name*	Specifies the path of directory where previously generated IR drop database files are stored. *Default:* `""` (empty string) **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-maxCapMargin` *cap_margin_value*	Specifies the ratio by which the max_cap check should be relaxed or tightened. *Default*: `0` *Minimum value*: -10.000000 *Maximum value*: 0.990000 **Note:** If set, this parameter must be applied before `signoffOptDesign`.

`-maxLocalDensity` *threshold_value*	This parameter lets you set a local placement density threshold that the software will honor during timing optimization. When the local density for a given area exceeds the threshold, the software stops adding or moving more instances in that local area. The default value for this option is -1, which means the software will not do any local placement density checks because, by default, it is running with `-legalOnly true` parameter. This parameter accepts values between 0 and 1. For example, to allow a maximum local placement density of 98%, set the value to 0.98. *Default*: `-1` **Note**: • This parameter is honored by DRV, Setup, and Hold optimization engines. • If set, this parameter must be applied before `signoffOptDesign`.
`-maxOptRunTime` *INT*	Specifies the time out period for only the timing/power optimization phase after which `signoffOptDesign` will exit the session. *Default:* `0` **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-maxPaths` *INT*	Specifies the worst path found for each endpoint up to the number specified by the -maxPaths parameter during ECO Timing DB generation. By default, the tool will automatically set a value for `-maxPaths` that would lead to good PBA coverage of the design within reasonable run time. You can overwrite this by setting a specific `-maxPaths` value, but it is recommended to keep it larger than 1 million. In any case, you must ensure that `-maxPaths` value is superior or equal than the `-nworst` value multiplied by the number of GBA violated endpoints. *Default*: `-1` **Note**: • This parameter is only active when the `-retime` parameter is set. • If set, this parameter must be applied before `signoffTimeDesign`.
`-maxRunTime` *INT*	Specifies the time out period, in minutes, after which `signoffOptDesign` will exit the session. *Default*: `0` **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-maxSlack` *float*	Specifies the maximum slack value to be used during ECO Timing DB generation when using PBA. Setting a positive -maxSlack value forces the software to retime positive GBA slack paths so that ECO optimization engine can benefit from an extra PBA Setup slack credit when doing Hold fixing or Power recovery. A positive -maxSlack value implies larger runtime during ECO Timing DB generation, but the software will retime only as many paths as what is specified through the `-maxPaths` parameter. *Default*: `0` **Note**: • This parameter is only active when the `-retime` parameter is set. • If set, this parameter must be applied before `signoffTimeDesign`.

`-maxTranMargin` *`tran_margin_value`*	Specifies the ratio by which the max_tran check should be relaxed or tightened. *Default*: `0` *Minimum value*: -10.000000 *Maximum value*: 0.990000 **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-numReportPaths` *`INT`*	Specifies the number of paths printed after signoff timing analysis per view. *Default*: `50` **Note:** If set, this parameter must be applied before `signoffTimeDesign`.
`-nworst` *`INT`*	Specifies the nworst control for path-based analysis. *Default*: `-1` **Note**: • This parameter is only active when the `-retime` parameter is set. • If set, this parameter must be applied before `signoffTimeDesign`.
`-optimizeCoreOnly {true | false}`	Performs only reg2reg optimization, when set to `true`. *Default*: `false` **Note**: • This parameter is not applicable for DRV optimization. • If set, this parameter must be applied before `signoffOptDesign`.
`-optimizeReplicatedModules {true | false}`	
	Allows the software to perform timing optimization inside replicated hierarchies while generating only one ECO file per sets of clones. The cell name of the replicated hierarchies have to be listed in a file pointed by the `-partitionListFile` option. *Default*: `false` **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-optimizeSequentialCells {true | false}`	
	Allows the software to perform timing optimization for sequential cells. *Default*: `true` **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-partitionListFile` *`string`*	Specifies the file containing list of partitions in the design. *Default:* `""` (empty string) **Note:** If set, this parameter must be applied before `signoffOptDesign`.

`-pbaEffort {medium | high}`	When high effort mode is specified, all the optimization engines perform more aggressive timing closure or area/power recovery with respect to path-based (PBA) timing and the expectation is to get better quality of results. In some cases, when large amount of ECOs are done in this mode, the final timing signoff might show some setup timing degradation, which can be recovered by running a second ECO loop doing only setup timing recovery with the `-setupRecovery parameter` set to `true`. *Default*: `medium` **Note:** If set, this parameter must be applied before `signoffTimeDesign` and `signoffOptDesign`.
`-pbaEcoRoute {true|false}`	When set to `true`, enables `ecoRoute` to use accurate path-based analysis (PBA) timing during the ECO signoff timing/power closure flow. This parameter should be specified at the start of the `signoffOptDesign`/`signoffTimeDesign` flow. *Default*: `false`

`-postMask {true | false}`	Enables the timing closure engine to perform the following netlist changes without touching the base layer mask:
	• Inserts the Gate Array buffers or an inverter pair in place of existing Gate Array filler cells.
	• Resizes regular cells to Gate Array cells. It also resizes Gate Array cells to Gate Array cells.
	• Deletes a regular cell.
	The software automatically identifies the Gate Array cells by checking which library instances have the same SITE name as the Gate Array filler cells specified by the user. Here, empty spaces are filled up by the Gate Array filler cells to ensure 100% placement density.
	Note:
	• This is supported by DRV, Setup, and Hold fixing.
	• When `setTieHiLoMode -cell {{tieLo_name tieHi_name}}` setting is used, the Metal ECO flow will insert the TieLo cells to connect dangling input pins, in case the existing TieLo cells in the floorplan are extremely far or too overloaded.
	Example:
	The following command enables Hold fixing in the metal ECO mode by allowing the listed Gate Array filler cells to be deleted or inserted during the ECO process.
	`setSignoffOptMode -postMask true`
	`setSignoffOptMode -useGaFillerList {GFILL1BWP GFILL2BWP GFILL4BWP GFILL10BWP}`
	`signoffOptDesign -hold`
	Default: `false`

`-postStaTcl FILE`	Specifies the file containing the TCL code that will be executed immediately after signoff timing analysis per view. *Default:* `""` (empty string) **Note**: • These TCL codes should follow Tempus syntax. • If set, this parameter must be applied before `signoffTimeDesign`.

`-powerAware {true | false}`	Enables power awareness in all optimizers and transforms. Tempus ECO provides the ability to take power as part of the overall cost function when doing timing closure. When this parameter is enabled before the start of an optimization session, the current optimization and any subsequent optimizations (if running in incremental mode) checks for power changes for all optimizers and transforms during any changes in the design. In any case, the first priority remains getting the best final timing but enabling this option will get there with possibly slighter ECO although resulting in lesser final power. For example, during to fix a Setup timing path violation, by default the tool would potentially choose to size one instance to a high leakage cell, while with `-powerAware` mode, the tool would try to get to same timing by doing multiple sizing to non-high leakage cells. **Note** • This feature requires power activity to be annotated on the netlist with `report_power` command, either through external activity file (recommended) or using propagated activity based on some default toggling rate. • This feature honors the `-powerOptFocus` option, which means that the user can decide to force the tool in reducing more total or leakage or dynamic power increase. *Default*: `false`
`-powerOptFocus total | leakage | dynamic | leakageOnly | dynamicOnly`	
	Specifies whether a given netlist should be optimized only for leakage or dynamic power reduction, or more for leakage or dynamic power while still reducing the overall total power during total power optimization. The following options are available: • `total`: The power optimization engine focuses on getting the optimal total power in the design. • `leakage`: The power optimization engine optimizes total power but focuses more on leakage power reduction than on dynamic power reduction. • `dynamic`: The power optimization engine optimizes total power but focuses more on dynamic power reduction than on leakage power reduction. • `leakageOnly`: The power optimization engine focuses only on leakage power reduction. • `dynamicOnly`: The power optimization engine focuses only on dynamic power reduction. *Default*: `total` **Note**: • This parameter is honored by `signoffOptDesign -power` and also by `signoffOptDesign -drv/-setup/-hold` when the `-powerAware` parameter is set to `true`. • If set, this parameter must be applied before `signoffOptDesign`.
`-prefixName` *string*	Specifies the prefix to be assigned to the new instances inserted. *Default:* `ESO` **Note:** If set, this parameter must be applied before `signoffOptDesign`.

`-preserveFiller {true | false}`	When set to `true`, saves and restores filler states during signoff timing optimization. This helps improve the runtime as it saves the time taken to re-insert all the fillers. *Default*: `true`
`-preStaTcl` *FILE*	Specifies a file containing the TCL code that will be executed immediately prior to signoff timing analysis per view. *Default:* `""` (empty string) **Note**: • These TCL codes should follow Tempus syntax. • If set, this parameter must be applied before `signoffTimeDesign`.
`-resizeInst {true | false}`	Enables/disables resizing transform. *Default*: `true` **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-retime {none | aocv | path_slew_propagation | aocv_path_slew_propagation}`	
	Selects the retime mode for path-based analysis. *Default*: `none` **Note:** If set, this parameter must be applied before `signoffTimeDesign` and `signoffOptDesign`.
`-retimeDepth {default | infinite}`	
	Retimes depth for exhaustive path based analysis. *Default*: `default`
`-retimeDepthEarly {default | infinite}`	
	Retimes depth for exhaustive path based early analysis. *Default*: `default`
`-retimeMode {none | path | exhaustive}`	
	Retimes mode for path based analysis. *Default*: `path`
`-routingCongestionAware {true | false}`	
	Checks routing congestion before doing any netlist change. *Default*: `false` **Note:** If set, this parameter must be applied before `signoffOptDesign`.

`-routeCongestionThreshold` *`threshold_value`*	This parameter allows you to change the threshold at which the software considers a local area to be too routing congested to allow any ECO change. The default value is 0.7. To tighten the routing congestion checks, apply a value between 0 and 0.7. To relax the routing congestion checks, apply a value between 0.7 and 1. *Default*: `0.7` *Min value*: `0` *Max value*: `1` **Note**: • This parameter is honored by Drv, Setup, Hold, Area, and Power optimization engines. • If set, this parameter must be applied before `signoffOptDesign`.
`-saveEcoOptDb` *`dir_name`*	Specifies a path of directory where generated database files are kept. *Default*: `ecoTimingDB` **Note:** If set, this parameter must be applied before `signoffTimeDesign`.
`-selectHoldEndpoints` *`file_name`*	Specifies a file containing the list of selected endpoints for hold fixing. **Note**: • When including endpoints, the `-optimizeCoreOnly` option must be set to `false`. • This parameter is set during ECO optimization. *Default:* `""` (empty string) For details about the file syntax, see Path Group Support in Timing Optimization in the *Innovus User Guide*.
`-selectDrvNetFile` *`file_name`*	Specifies a file containing the list of nets to be optimized during DRV fixing. The fixing of max_transition and max_capacitance violations occurs only on the specified nets and the other violating nets are ignored. The file specified includes one net per line. **Note**: Wild cards and regular expressions are not supported in this file. *Default*: `""` (empty string) **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-selectDrvPinFile` *`file_name`*	Specifies a file containing the list of instance pins to be optimized during DRV fixing. The fixing occurs only on the specified instance pins and the other violating pins are ignored. The file specified includes one pin per line. **Note**: Wild cards and regular expressions are not supported in this file. *Default*: `" "` (empty string) **Note:** If set, this parameter must be applied before `signoffOptDesign`.

`-selectSetupEndpoints` *file_name*	Specifies a file containing the list of selected endpoints for setup fixing. **Note**: • When including endpoints, the `-optimizeCoreOnly` option must be set to `false`. • If set, this parameter must be applied before `signoffOptDesign`. *Default:* `""` (empty string) For details about the file syntax, see Path Group Support in Timing Optimization in the *Innovus User Guide*.
`-setupRecovery {true | false}`	Specifies power-aware setup recovery for setup fixing. *Default*: `false` **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-setupTargetSlack float`	Specifies a target slack value in nanoseconds for setup timing optimization. *Default*: `0` **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-setupTargetSlackPerView {viewName1 slack1 viewName2 slack2 …}`	When enabled, this parameter forces a specific setup target slack per view. If a given Setup active view is not listed in this parameter, the software will use the global Setup target slack set by the `-setupTargetSlack` parameter for that view. *Default*: `""` (empty string) **Note**: • This parameter is honored by Setup, Hold, Area, Power, and Leakage optimization engines. • If set, this parameter must be applied before `signoffOptDesign`.
`-setupXtalkDeltaThreshold` *value_in_ns*	Fixes the nets that have a crosstalk delta delay value equal to or greater than a specified threshold value for setup views. The threshold value is specified in `ns`. *Default*: `0.3 ns` **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-setupXtalkSlackThreshold` *value_in_ns*	Fixes the nets with the slack threshold value equal to or less than a specified threshold value for setup views. The threshold value is specified in `ns`. *Default*: `1000 ns` **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-skewCoreOnly {true | false}`	When this parameter is set to `true`, the skewing engine is not allowed to skew sequential elements that are part of an IO boundary timing path. *Default* : `false` **Note**: • This parameter is only honored by `signoffOptDesign -setup`. • If set, this parameter must be applied before `signoffOptDesign`.

`-skipDrvNetfile` *file_name*	Specifies a file containing the list of nets to be excluded during DRV fixing. The fixing of max_transition and max_capacitance violations occurs on nets other than specified nets. The file specified includes one net per line. **Note**: Wild cards and regular expressions are not supported in this file. *Default:* `""` (empty string) **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-specifyHoldEndpointsMargin` *string*	
	Specifies endpoint-specific margin for Hold fixing. *Default:* `""` (empty string) For details about the file syntax, see Path Group Support in Timing Optimization in the *Innovus User Guide*. **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-specifySetupEndpointsMargin` *string*	
	Specifies endpoint-specific margin for Setup fixing. *Default:* `""` (empty string) For details about the file syntax, see Path Group Support in Timing Optimization in the *Innovus User Guide*. **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-swapInst {true | false}`	Enables/disables VT swap resizing. The setup/leakage optimizers do not honor this option and always perform VT-swapping. *Default*: `true` **Note:** If set, this parameter must be applied before `signoffOptDesign`.
`-upsizeInPowerOpt {true | false}`	When this parameter is set to `true`, it allows the power optimization engine to perform cell upsizing in order to recover more power. *Default*: `false` **Note**: • This parameter is only honored by `signoffOptDesign -power`. • If set, this parameter must be applied before `signoffOptDesign`.
`-useGaFillerList` *list_of_Gate_Array_filler_cells_name*	
	Enables the software to list all the Gate Array filler cells that can be deleted or inserted back. **Note**: This parameter is applicable in the Metal ECO mode only. *Default*: `""`
`-usePfcDecapList` *list_of_decap_cells*	
	Lists all the programmable decap cells that are allowed to be removed in post-mask mode. *Default*: `{}`
`-usePfcFillerList` *list_of_filler_cells*	

	Lists all the programmable filler cells that are allowed to be removed/reinserted in post-mask mode. *Default*: `{}`
`-usePfcRegularList` *list_of_regular_cells*	

	Lists all the programmable regular logic/ECO cells that are allowed to be inserted in place of filler/decap cells during optimization in post-mask mode.
	Default: `{}`
	Example:
	The following set of commands will allow Hold timing closure in post-mask mode using programmable filler cells.
	`setSignoffOptMode -postMask true`
	`setSignoffOptMode -usePfcFillerList {ln10_ecofiller40x … ln10_ecofiller4x}`
	`setSignoffOptMode -usePfcDecapList {ln10_ecofillsgcap40x … ln10_ecofillsgcap4x}`
	`setSignoffOptMode -usePfcRegularList {ln10_ecodlybt01 ln10_ecobuft04 … ln10_ecoand02 … ln10_ecoinv04 …}`
	`signoffOptDesign -hold`

`-verbose {true | false}`	Specifies whether the command should output log file reporting with verbosity or not. *Default*: `false` **Note:** If set, this parameter must be applied before `signoffOptDesign`.

setTieHiLoMode

```
setTieHiLoMode
[-help]
[-reset]
[-cell {{tieHi1 tieLo1} {tieHi2 tieLo2} ...}]
[-createHierPort {true | false}]
[-honorDontTouch {true | false}]
[-honorDontUse {true|false}]
[-maxDistance distanceValue]
[-maxFanout fanOutValue]
[-modulePrevention {true | false}]
[-prefix prefixName]
[-reportHierPort {true | false}]
```

Controls certain aspects of how the software adds or deletes tie-high and tie-low cells.

See `getTieHiLoMode` to query current settings for the `setTieHiLoMode` command.

The parameters of the `setTieHiLoMode` command affect the behavior of the following commands:

- `addTieHiLo`
- `deleteTieHiLo`

  Note: Parameters specified by `addTieHiLo` and `deleteTieHighLo` supersede those specified by the `setTieHiLoMode` command.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `setTieHiLoMode` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setTieHiLoMode`
`-cell {{tieHi1 tieLo1} {tieHi2 tieLo2} ...}`	Specifies the pairs of tie cells to be used by the `addTieHiLo` command. You can specify a maximum of two tie-cells in a cell list, where one cell must be a tie-high driver, and the other a tie-low driver. A single cell with both tie connections, high and low, can be specified as below. `setTieHiLoMode -cell {{TieHiLo1} {TieHiLo2} {TieHiLo3} ….}` The software selects the nearest cell pair to make new tie connections during the postMask flow. *Default:* `""` (empty string)
`-createHierPort {true | false}`	Allows the added tie cells to connect to tie pins across hierarchical boundaries if other constraints, such as maximum fanout and maximum distance, allow it. *Default:* `false`
`-honorDontTouch {true | false}`	Allows both `addTieHiLo` and `deleteTieHiLo` commands to honor the `dont_touch` property set on instances, nets, cells, and modules. *Default:* `false`
`-honorDontUse {true|false}`	Honors `dont_use` attribute on cells. *Default:* `false`
`-maxFanout` *`fanOutValue`*	Specifies the number of tie-pins a tie-net can drive. A value of `0` implies no fanout constraint. *Default*: `0`
`-maxDistance` *`distanceValue`*	Specifies the maximum Manhattan distance, in microns, between the tie-cell driver and the tie-pins. A value of `0` implies no distance constraint. *Default*: `0`
`-modulePrevention {true|false}`	When this parameter is set to `true`, the `addTieHiLo` command adds tie-cells for module instantiation port. Tie-cells may also be added inside the module to tie the output port of the module so that module function can be prevented. *Default*: `false`
`-prefix` *`prefixName`*	Specifies a prefix for the added tie-cell instances. *Default*: `""`
`-reportHierPort {true | false}`	When the value of `-createHierPort` is `true`, reports created port connections to a file named `tiehilo.rpt`. *Default:* `false`
`-reset`	Resets parameters to their default values. The `-reset` parameter *must* be the first parameter specified. If you specify `-reset` by itself, the software resets all `setTieHiLoMode` parameters to their default values. If you specify parameters after `-reset`, the software resets only those parameters to their default values. Any values that do not already match the default value and are reset will be reported.

Example

- The following command sets `TIEHI` and `TIELO` cells a maximum distance of 20 microns between the tie-cell pin and the tie-off input pins and a tie-net can drive up to 10 tie-pins:
  ```
  setTieHiLoMode -maxFanout 10 -maxDistance 20 -cell "TIEHI TIELO"
  ```
- The following command resets the `-maxDistance` parameter to its default value:
  ```
  setTieHiLoMode -reset -maxDistance
  ```
- The following command resets all `setTieHiLoMode` parameters to their default values:
  ```
  setTieHiLoMode -reset
  ```

setUsefulSkewMode

```
setUsefulSkewMode
[-help]
[-opt_skew_apply_delay_limits_to_full_flow {true|false}]
[-opt_skew_delay_pre_cts {true|false}]
[-opt_skew_macro_only {true | false}]
[-opt_skew_max_allowed_delay delay]
[-opt_skew_min_allowed_delay delay]
[-opt_skew_no_boundary {true | false}]
[-reset]
```

Sets global parameters for the `skewClock` command.

Use the `getUsefulSkewMode` to return the current settings for the `setUsefulSkewMode` command.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `setUsefulSkewMode` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setUsefulSkewMode`
`-opt_skew_apply_delay_limits_to_full_flow {true | false}`	
	When set to `true`, specifies that the useful skew limit is to be applied to the whole flow. With this setting, the Early Clock Flow is modified so that pre-existing tool-generated useful skews count towards the limit imposed by the `-opt_skew_max_allowed_delay` parameter. The tool-generated useful skew comprises any pin insertion delay (PID) of category useful_skew or global_skew. PIDs of other categories are not considered. By default, this parameter is set to `false`, which means the pre-existing skews are not considered while calculating the limit imposed by using the `-opt_skew_max_allowed_delay` parameter. *Default*: `false`
`-opt_skew_delay_pre_cts {true |false}`	Specifies that the useful skew feature is allowed to delay sequential elements in preCTS stage, in addition to just advancing them. This enables a more aggressive algorithm which is recommended when timing closure is gated by optimal skewing. *Default:* `true`
`-opt_skew_macro_only {true | false}`	Allows you to limit skewing only for macro cells. When enabled, regular sequential elements (such as flip-flops) will not be skewed. *Default*: `false`

`-opt_skew_max_allowed_delay` *delay*	Limits the amount of slack (in nanoseconds) that the software can borrow from neighboring flip-flops when performing useful skew operations. The Innovus delay calculation and RC extraction methods might differ from those of sign-off tools, so other setup violations might occur if the software borrows too much slack. By having control over slack borrowing, you can prevent these setup violations. Limiting borrowed skew also limits the clock tree skew to avoid large hold violations. *Value Range: min*=`0` *max*=`1000` *Default:* `1ns` **Note**: • This parameter is not honored in the postCTS mode of `skewClock`. • In the non-early clock flow, when `skewClock` is triggered inside `optDesign`, and this parameter is set to its default value, the default value of this parameter will change from 1 to become a certain percentage of clock cycle. This is determined by the software on the basis of internal calculations.
`-opt_skew_min_allowed_delay` *delay*	Allows the tool to skip any skewing that would be smaller than the minimum delay that is set. The purpose is to avoid creating very small delay macro models which would not be correctly honored during CTS stage but also to reduce the amount of macro models generated. *Value Range*: *min*=`0` *max*=`1000` *Default*: `0` **Note:** • This is supported in both standalone `skewClock` command and for `-usefulSkew` called within `optDesign`. • Enable the `-usefulSkew` parameter in `optDesign` by setting `setOptMode -opt_skew true`
`-opt_skew_no_boundary {true |false}`	Excludes or includes boundary sequential cells in addition to ordinary sequential elements in useful skew calculations. *Default:* `false`
`-reset`	Resets parameters to their default values. The `-reset` parameter *must* be the first parameter specified. If you specify only `-reset`, the software resets all `setUsefulSkewMode` parameters to their default values. If you specify parameters after `-reset`, the software resets only those parameters to their default values. Any values that do not already match the default value and are reset will be reported.

Examples

- The following command resets the `-delayPreCts` parameter to its default value:
  ```
  setUsefulSkewMode -reset -opt_skew_delay_pre_cts
  ```
- The following command resets all `setUsefulSkewMode` parameters to their default values:
  ```
  setUsefulSkewMode -reset
  ```
- The following command forces the tool to skew at minimum by `30ps` any elements that can be skewed to improve the setup timing slack:
  ```
  setUsefulSkewMode -opt_skew_min_allowed_delay 0.03
  skewClock /optDesign -preCts
  ```

- The following command allows the user to limit skewing only for macro cells:

  ```
  setUsefulSkewMode -opt_skew_macro_only true
  skewClock or optDesign -preCts/-postCts
  ```

  - Optimizing Timing using Useful Skew

signoffOptDesign

```
signoffOptDesign
[-help]
[-all]
[-area]
[-drv]
[-dynamic]
[-hold]
[-leakage]
[-noEcoRoute]
[-outDir dir_name]
[-reportFullClockPath]
[-power]
[-prefix prefix_name]
[-setup]
```

Runs timing, area, DRV, dynamic or leakage optimization on signoff timing.

This command must be run on a design that has gone through the implementation flow. It allows you to fix timing violations or to improve area and power visible in signoff STA mode while staying in the implementation tool.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `signoffOptDesign` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man signoffOptDesign`
`-all`	Performs DRV, Setup, Hold, and Power optimization in the path-based analysis (PBA) mode. It also includes embedded calls to ecoRoute, parasitic extraction and signoff timing analysis. **Note**: The all-in-one mode does not replace all customized fine-tuned flows. It provides the Innovus users easy access to Tempus ECO technology. The existing Tempus ECO flow using individual optimization steps within Innovus is still supported and can sometimes be more efficient than the all-in-one mode.
`-area`	Reclaims area on the netlist without causing any DRV/Setup/Hold degradation.
`-drv`	Optimizes DRV (maximum capacitance and maximum transition) violations. DRV optimization supports buffer addition and resizing.
`-dynamic`	Prints initial and final power numbers. It optimizes the dynamic power to reduce the total power consumption. Dynamic power optimization supports buffer deletion ,resizing, and swapping.
`-hold`	Triggers hold fixing in signoff timing mode.
`-leakage`	Optimizes leakage power. Leakage optimization supports VT swapping.
`-noEcoRoute`	Allows `signoffOptDesign` command to skip ECO routing and final signoff STA.
`-outDir` *dir_name*	Specifies the directory in which the reports will be saved. **Note**: In case `signoffOptDesign` is reusing ECO timing DB generated earlier by `signoffTimeDesign` or when the `-noEcoRoute` parameter is applied, no timing reports are saved.
`-power`	Optimizes total power in the design. During total power optimization, the software performs swapping and sizing on both the combinational and the sequential cells, and also removes buffers. This reduces leakage, internal, and switching power in the design.
`-prefix` *prefix_name*	Specifies the prefix for the timing report file names.
`-reportFullClockPath`	When this parameter is specified, the detailed timing report that is generated contains the full clock path.
`-setup`	Optimizes setup timing violations. Setup optimization supports buffer addition, VT swapping and resizing.

Examples

- Use the following commands to perform setup optimization followed by a leakage power optimization. The setup optimization is with no -ecoRoute, while the leakage power optimization calls the -ecoRoute along with final signoff STA results.

  ```
  signoffOptDesign -setup -noEcoRoute
  signoffOptDesign -leakage
  ```

- Use the following commands to perform an area reclaim optimization that is based on external spef files:

  ```
  spefIn -rc_corner rc_max rc_max.spef.gz
  spefIn -rc_corner rc_min rc_min.spef.gz
  signoffTimeDesign -reportOnly
  signoffOptDesign -area
  ```

- Use the following command to dump out the final STA results in a folder named "RPT". The timing report files inside the "RPT" folder will be named "SIGNOFF_ECO_*".

  ```
  signoffOptDesign -hold -outDir RPT -prefix SIGNOFF_ECO
  ```

- Use the following set of commands to reclaim total power in the design:

  ```
  report_power
  setSignoffOptMode -deleteInst true -optimizeSequentialCells true
  signoffOptDesign -power
  ```

- Use the following set of commands to perform DRV, Setup, Hold, and Power optimization in the PBA mode:

  ```
  setMultiCpuUsage -localCpu 16 -remoteHost 4 -cpuPerRemoteHost 4
  setSignoffOptMode -allowSkewing true -clockCellList {.....}
  signoffOptDesign -all
  ```

  Innovus will run Tempus ECO for PBA-based DRV, timing and power closure. The Setup fixing will be done using useful skew technology. Signoff timing analysis will use 4 remote hosts each using 4 CPUs while ECO fixing, ECO routing, and parasitic extraction will use 16 CPUs.

skewClock

```
skewClock
[-help]
[-hold]
[-postCTS]
[-postRoute]
```

Modifies the clock arrival time on sequential elements in order to improve the data path timing between two sequential elements. The `skewClock` command outputs depend on whether the clock tree is built or not.

- In preCTS mode, `skewClock` generates two files: a scheduling file and a latency file.
- In postCTS and postRoute mode, `skewClock` inserts buffers and/or inverters in an existing clock tree. In addition, resizing of buffers and/or inverters can also be committed.

> Cadence recommends using `setOptMode -opt_skew` and `optDesign -preCTS`, `-postCTS`, or `-postRoute` to run useful skew optimization during timing optimization. For information on how to use `optDesign`, see Optimizing Timing in the *Innovus User Guide*.

PreCTS Mode

The `skewClock` command identifies elements that can be advanced or delayed, and computes target delay for each. An advancable element is a sequential gate on which the clock signal can be safely made to arrive early without worsening the slack on the critical path. In general, this is true for sequential elements where the slack on the output pin (SQ) is negative (SQ < 0) and is worse than the slack on the input pin (SD) : (SQ < SD).

The `skewClock` command generates the following files:

- **Scheduling file**: The CTS scheduling file lists the delays to consider on sequential elements by the clock tree synthesis tool. When loaded in CTS, the scheduling file constrains CTS to build a tree that fulfills the targets computed by `skewClock`.
  The scheduling file must be loaded in addition to the original clock tree specification file (see "Examples" section below).
  The syntax of the scheduling file is as follows:
  `Macromodel pin lefPinName maxRiseDelay minRiseDelay maxFallDelay minFallDelay inputCap`
  An entry in the configuration file is available to specify the scheduling file:
  `Set rda_input ui_scheduling_file scheduling_file.cts`
  When the design is saved, the scheduling file is copied in the design directory, and the line above is added to the configuration file of the saved design.
- **Latency file**: This file lists the delays to be considered on sequential elements by the timing analysis tool. These delays are computed by `skewClock`.
  The file syntax is as follows:
  `set_clock_latency rise delaypinName`
  The timing engine takes the latency file into account when the following parameter is specified:
  `setAnalysisMode -usefulSkew true`
  When building the timing graph, the Innovus software first loads the timing constraints, and then the latency file, as specified in the configuration file, for example
  `set_rda_input (ui_latency_file) latency_file.sdc`
  When the design is saved, the latency file is copied to the design directory, and the line above is added to the configuration file of the saved design.

PostCTS and PostRoute Mode

The `skewClock` command identifies delayable elements and delays the clock for each element. A delayable element is a sequential element on which the clock signal can be safely delayed without worsening the slack on the critical path. In general, this is true for each sequential element where the slack on the data pin (SD) is negative (SD<0) and is worse than the slack on the output pin (SQ) : (SD < SQ). The `skewClock` command inserts and/or resizes buffers and/or inverters on an existing clock tree.

- The skewClock net name prefix is `FE_%sN`
- The skewClock instance name prefix is `FE_%sC`
- The default instance name added during useful skew optimization is `FE_USKC`
- The default net name added during useful skew optimization is `FE_USKN`

If SD > SQ, the elements before the D pin can be advanced, and skewClock can do resizing on the buffers and/or inverters to compensate the timing on Q pin.

Note: To control the buffer and inverter cells used by `skewClock`, use `set_ccopt_property buffer_cells` and `set_ccopt_property inverter_cells`.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `skewClock` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man skewClock`
`-hold`	Allows optimization for hold timing.

`-postCTS`	The `skewClock` command allows the use of an algorithm in the postCTS mode. When this parameter is specified, only setup timing optimization is performed. When it is specified along with the `-hold` parameter, only hold timing optimization is performed.
	This means,
	• The `skewClock -postCTS` command will only optimize setup timing.
	• The `skewClock -postCTS -hold` command will only optimize hold timing, without degrading setup timing.
	To optimize both setup and hold violations, run the following commands:
	`skewClock -postCTS`
	`skewClock -postCTS -hold`

`-postRoute`	The `skewClock` command allows the use of an algorithm in the PostRoute mode. It forces the command to end with ECO routing for the modified clock nets. An `ecoRoute` is followed by clock skewing. The difference between PostCTS mode and PostRoute mode is that the former is not limited to be legal only, while the latter is in a legal only mode.
	When this parameter is specified, only setup timing optimization is performed. When it is specified along with the `-hold` parameter, only hold timing optimization is performed.
	This means,
	• The `skewClock -postRoute` command will only optimize setup timing.
	• The `skewClock -postRoute -hold` command will only optimize hold timing, without degrading setup timing.
	To optimize both setup and hold violations, run the following commands:
	`skewClock -postRoute`
	`skewClock -postRoute -hold`

Examples

- The following commands show how to use `skewClock` in preCTS flow without using `optDesign`:

  ```
  setAnalysisMode -usefulSkew true
  timeDesign -preCTS
  skewClock
  timeDesign -preCTS
  ccopt_design
  timeDesign -postCTS
  ```

  Note: The recommended method for useful skew in preCTS mode is as follows:

  ```
  setOptMode -opt_skew true
  optDesign -preCTS
  ```

- The following example shows how to use `skewClock` in postCTS mode as an incremental fixing after normal postCTS optimization:

  ```
  ccopt_design
  skewClock -postCTS
  timeDesign -postCTS
  ```

add_obj_on_bump

```
add_obj_on_bump
[-help]
{{-cell bump_cell_name | -selected | -feedthru } {-relative_pin_layer pin_layer_name |
-rect {x1 y1 x2 y2} | -polygon {{x1 y1} {x2 y2}...}}}
[-check_only bump_name | -write_script filename]
{[-shape layer+] [-placement_blockage] [-routing_blockage layer+] [-physical_pin
layer+]}
[-shape layer+ [-check_only bump_name] [-incremental][-shape_keep_net ]]
[-feedthru [-cdl_map_file cdl_map_file_name]]
```

Adds shapes on the TSV bumps. You can use this command to add shapes on all the specified TSV bumps or the specified bump. The shape size could be user-defined or same as bump pin on the specified layer.

Parameters

`-help`	Prints a brief description of the `add_obj_on_bump` command usage. For a detailed description of the command, use the `man` command: `man add_obj_on_bump`
`-cdl_map_file` *`cdl_map_file_name`*	
	Specifies the output cdl map file for LVS.
`-cell` *`bump_cell_name`*	Specifies the name of the bump cell on which the shape is to be added.
`-check_only` *`bump_name`*	Checks if there is a shape on the specified bump and outputs a report file. The `-check_only` option cannot be used with `-write_script`. ⚠ The `-check_only` option can be used only when `-shape` is specified.
`-feedthru`	Adds shapes on the bump that contains the TSV layer and whose net is a feedthrough net.

`-incremental`	Adds shapes in the incremental mode. It deletes the shapes without a bump, and adds new shapes on the bumps without shapes. The -incremental parameter only checks the shapes on the same layer.
	In the following sequence of commands, the first command is `add_obj_on_bump -shape M1` and the second command is `add_obj_on_bump -shape M2 -incremental`. In these commands, the layers specified are different. Therefore, `add_obj_on_bump` will not delete previously added shapes on `M1`. Also, the result of the command `add_obj_on_bump -shape M2 -incremental` is the same as `add_obj_on_bump -shape M2`.
	`>add_obj_on_bump -shape M1`
	`>add_obj_on_bump -shape M2 -incremental`
	⚠ The `-incremental` option can be used only when `-shape` is specified.

`-shape` *layer+*	Specifies the layer(s) on which new shapes are to be added. Polygons with non-45-degree edges are supported.
`-placement_blockage`	Adds a placement blockage on bumps. Only orthogonal polygons are supported.
`-physical_pin` *layer+*	Specifies the layer(s) on which to add physical pins. For a single-pin bump, the name of the physical pin is same as that of the target bump. For a multiple-pin bump, the name of the physical pin is same as that of the bump pin on the same layer. If no bump pin exists on the layer specified for adding the physical pin, the tool chooses the name of any of the pins on the target bump as the pin name of the physical pin. Polygons with non-45-degree edges are supported.
`-polygon {{x1 y1} {x2 y2}...`	
	Specifies the point list of the polygon to add shapes. The center of the specified polygon bounding box aligns with the center of the specified bump cell.

`-rect {x1 y1 x2 y2}`	Specifies the rectangle to add shapes. The center of specified rectangle aligns with the center of the specified bump cell.
`-relative_pin_layer` *pin_layer_name*	
	Specifies the pin layer of the pin shape of the specified bump. Adds shapes based on the specified pin shape of the bump. If the `-relative_pin_layer` option is specified while adding objects, the shape of the added object is same as the shape of the relative pin.
`-routing_blockage` *layer+*	
	Specifies the layer(s) on which to add routing blockages on bumps. Only orthogonal polygons are supported.
`-selected`	Adds shapes on the selected bump.
`-shape_keep_net`	Keeps the net when adding the layer shape. When you specify the `-incremental` option, the tool adds shape with net name if there is no shape with this net on the bump.
`-write_script` *filename*	
	Specifies the file name to dump a Tcl script for adding objects on bumps. If this option is specified, the tool will not add objects on bumps directly. The `-write_script` option cannot be used with `-check_only`.

Example

- The following command adds a shape on layer M1 at the position of the TSV bump whose net is a feedthrough net. The shape on layer M1 is the same as the bump pin shape on layer TSV.

```
add_obj_on_bump -shape M1 -feedthru -relative_pin_layer TSV
```

addTSV

```
addTSV
[-help]
[-noRouteBlkg]
{[-frontBump bumpCellName] [-backBump bumpCellName] [-tsvViaName viaName]}
[-frontBump bumpCellName [-loc_type {geometry_center|cell_center} -prefix prefixName]
[-stackViaUnderBump stackViaName]]
[-backBump bumpCellName  [-loc_type {geometry_center|cell_center} -prefix prefixName]]
[-tsvViaName viaName [-noPlaceBlkg  | -spacing s]
    [[[-tsvFeedthru {x y} [-stackViaTopLayer layer]] | [-stripeNet pgnetName
    -stripeLayer layerNum]] | [-stackViaName stackViaName [-stackViaMarkerLayer
markerLayerName][-stack_via_array {x y} -stack_via_pitch {x y}]]]]
{-lowerLeftLoc {x y}}
 [-relative_bump_cell bumpCell | -relative_selected_bump ]} {[-pitchxy {x y}] [-
relative_bump_cell bumpCell | -relative_selected_bump ]}
{[-upperRightLoc {x y} | -numxy {x y}] [-relative_bump_cell bumpCell | -
relative_selected_bump ]}}
[{-relative_bump_cell bumpCell | -relative_selected_bump } [-relative_min_pitch
<float>] [-relative_offset {x y}] [-relative_bump_type {signal power ground}]]
[-perim n]
[-stagger]
```

Adds TSVs, front-side bumps, and backside bumps under specified conditions. Use this command to create TSVs and bumps after the initial floorplan is loaded.

Parameters

`-tsvViaName viaName`

	Specifies the name for TSV via defined in the LEF file. If this option is not specified, no TSV will be created. The following arguments are used only with `tsvViaName`: • `noPlaceBlkg` • `spacing` • `tsvFeedthru` • `stackViaTopLayer` • `stripeNet` • `stripeLayer`
`-frontBump` *`bumpCellName`*	
	Specifies the name for the front-side bump cell. If this option is not specified, no front-side bump will be created.
`-backBump` *`bumpCellName`*	
	Specifies the name for the backside bump cell. If this option is not specified, no backside bump will be created.
`-loc_type {geometry_center|cell_center}`	
	Specifies the location type for bump creation. • `geometry_center`: Specifies to use bump pin geometry to create bump • `cell_center`: Specifies to use bump bounding box to create bump This option is used with the `-frontBump` and `-backBump` options.
`-lowerLeftLoc x y`	
	Specifies (in microns) the lower left coordinate of the box in which TSV/Bumps will be created.

`-numxy` x y	Specifies (in microns) the count of the TSV/bump in the horizontal and vertical direction.

`-perim` *n*	Creates TSV, front-side bumps, and backside bumps along the rings on the perimeter.
	If `-perim` is specified, *n* defines the number of rings. Then you can create TSV in the following ways:
	• Define the lower left and upper right location of the ring by `-lowerLeftLoc` and `-upperRightLoc`, and then the pitch value of x and y direction by `-pitchxy`. For example, the following command creates TSV in which the lower-left is at `{x1 y1}` and the upper-right is at `{x2 y2}`
	`addTSV -lowerLeftLoc {x1 y1} -upperRightLoc {x2 y2} -pitchxy {px py} -stagger -perim 1`
	`*********`
	`*  *`
	`*  *`
	`*  *`
	`*  *`
	`*********`
	• Define the lower left location of the ring by `-lowerLeftLoc`, and then specify the number and pitch value of tsv in x and y directions by `-numxy` and `-pitchxy`, respectively. For example, the following command creates TSV in which the lower left is at {x1 y1}
	`-lowerLeftLoc {x1 y1} -numxy {12 8} -pitchxy {px py} -perim 2`
	`************`
	`************`
	`**  **`

`-prefix` *prefixName*	
	Adds a prefix name for a bump during bump creation and bump mapping. The prefix name is not added to the TSV.
`-relative_bump_cell` *bumpCell*	Creates TSV or bumps by default at the geometry center of bumps with specified bump cell.
`-relative_bump_type {signal power ground}`	Creates the relative bump type, TSV, or bumps by default at the geometry center of bumps with the specified bump type.
`-relative_min_pitch` *minPitch*	Specifies the minimum pitch between the created bumps/TSVs. The pitch between all the created bumps/TSV should be larger than specified min pitch. The `-relative_min_pitch` option is optional and can be used only if `-relative_bump_cell/-relative_selected_bump` is specified.
`-relative_offset {x y}`	Specifies the offset of created bump/TSV location compared with the relative bump. The geometry center of the created bump/TSV is the geometry center of the relative bumps plus the offset. `-relative_offset` is optional and can be used only if `-relative_bump_cell/-relative_selected_bump` is specified.
`-relative_selected_bump`	Creates TSV or bumps by default at the geometry center of the selected bumps.
`-upperRightLoc x y`	
	Specifies (in microns) the upper right coordinate of the box in which TSV/Bumps will be created.
`-pitchxy` *x y*	Specifies (in microns) the distance between TSV centers in the x and y direction.

`-stagger`	Staggers (offsets) the TSV/bump array. For example:
	without `-stagger` with `-stagger`
	`*****` `*****`
	`*****` `****`
	`*****` `*****`
	`*****` `****`
	`*****` `*****`

`-noPlaceBlkg`	The placement blockage overlapped with TSV cut will be added as default if `-noPlaceBlkg` is not specified.
`-noRouteBlkg`	The routing blockage for each crossing layer will be added if `-noRouteBlkg` is not specified.
`-tsvFeedthru` *`sizex sizey`*	
	Creates the feedthru. `sizeX` and `sizeY` are the dimensions, in microns, for the stack vias aligned with the TSV. **Note:** Feedtrhu is a collection of components including TSV, the stacked via (from the first metal to the top metal) aligned with the TSV, and two bumps on the frontside and backside.
`-stackViaMarkerLayer` *`markerLayerName`*	Specifies the mark layer name. Mark cut layer of stack via as specified mark layer.
`-stackViaName` *`stackViaName`*	Specifies the stack via cell name. The tool automatically adds the specified via cell stacking to the top layer of long TSV.
`-stackViaTopLayer` *`layer`*	

	Defines the top layer that the TSV structure should connect to. For example, if you specify M5 for this parameter, Innovus will create a structure like `TSV+VIA12+M2+VIA23+M3+…..+M5`. This parameter must be used with `-tsvFeedthru`.
`-stackViaUnderBump` *stackViaName*	
	Specifies the stack via name under the front bump. The tool automatically adds the specified via cell stacking to the bottom layer of front-side bump.
`-stripeNet` *pgnetName*	
	Declares that the TSV will be added beneath the power stripe, a stack via will be generated to touch the power stripe, and the new added TSV will be assigned by the power or ground net of the power stripe. **Note:** This options should be used along with the `-stripeLayer` option.
`-stack_via_array {x y}`	Specifies the number of columns and rows for the stack via array. The `-stack_via_array` and `-stack_via_pitch` options can only be specified when –stackViaName is specified. `-stack_via_array` and `-stack_via_pitch` are specified at the same time. The value of `-stack_via_pitch` should be larger than stack via size. Otherwise, the stack via will overlap each other and cause DRC.
`-stack_via_pitch {x y}`	Specifies the pitch_x and pitch_y of the stack via. The `-stack_via_array` and `-stack_via_pitch` options can only be specified when –stackViaName is specified. `-stack_via_array` and `-stack_via_pitch` are specified at the same time. The value of `-stack_via_pitch` should be larger than stack via size. Otherwise, the stack via will overlap each other and cause DRC.
`-stripeLayer` *layerNum*	

	Specifies the layer number or layer name for the stripe net when adding TSV under stripe net. **Note:** This option should be used along with `-stripeNet` option.
`-spacing s`	Specifies the placement blockage size. Blockage size = TSV cut size + 2*s. If this option is not specified, "s" will be with the value defined in LAYER TSV session in LEF file.

⚠ At least one option of the following arguments is required for the `addTSV` command:

- `tsvViaName`
- `frontBump`
- `backBump`

Examples

- The following command creates a 10 x 10 TSV array with a pitch of 40 microns and the lower left at (300 300):
  ```
  addTSV -lowerLeftLoc 300 300 -numxy 10 10 -pitchxy 40 40 - tsvViaName TSVVIA
  ```
- The following command creates a backside array in box (300 300 700 700) with a pitch of 40 microns:
  ```
  addTSV -lowerLeftLoc 300 300 -upperRightLoc 700 700 -pitchxy 40 40 -backBump
  BUMPCELL
  ```

Related Information

- `assignTSV`
- `deleteTSV`

assignTSV

```
assignTSV
[-help]
[-write_down_level_bump]
[-selected netName | [[-signal | -pgpad ] [-feedthru | -nonFeedthru ] [-net netlist | -exclude_net excludeNetList] [-area llx lly urx ury ...] [-exclude_region llx lly urx ury ...] [-tsvViaName tsvViaCellName] [-interposer ] ] ]
[{[-backBump ] [-frontBump ]} [-force_current_die ]]
```

Assigns nets to TSVs and/or frontside and backside bumps, and/or feedthrus. The command considers all dies in the 3D IC System by using the die abstract files, and optimizes bump assignment for the global nets which connect these dies. If you run the `readDieAbstract` command to import die abstract files of other chips inside the 3D IC System before running the `assignTSV` command, `assignTSV` will optimize TSV/bump assignment by considering the whole system.

Note: Use this command after the TSVs and bumps are created and the instances connected with the IO pins are placed.

Parameters

`-help`	Print out the command usage.
`-backBump`	Declares that the back side bumps and the TSVs will be assigned automatically.
`-force_current_die`	Assigns all IO pins to backside bumps or frontside bump directly without checking the XML file and the top level netlist. You can use `-force_current_die` only if `-backBump` or `-frontBump` is specified.
`-frontBump`	Declares that the front side bumps will be assigned with the IO pins automatically.
`-tsvViaName` *tsvViaCellName*	
	If this option is specified, only the TSV with the VIA cell `tsvViaCellName` will be assigned. Others will be ignored.
`-selected` *netName*	

	Assigns the selected TSVs and bumps with a specified net. **Note:** If the selected TSV belongs to a feedthru, the whole feedthru will be assigned with the net. This option is used for manual assignment and is exclusive to any other options for auto assignment.
`-signal`	Declares that only signal will be assigned.
`-pgpad`	Declares that only power/ground net will be assigned.
`-feedthru`	Declares that the command assigns only the feedthru net.
`-nonFeedthru`	Declares that the command assigns only the nonfeedthru signal or power/ground net.
`-net` *`netlist`*	Assigns the specified nets to the near TSV/bumps.
`-exclude_net` *`excludenetlist`*	
	Excludes the nets in the specified boxes.
`-area {`*`llx lly urx ury ...`*`}`	
	Assigns the TSV/bump within the box only.
`-exclude_region {`*`llx lly urx ury ...`*`}`	
	Excludes the TSV/bumps in the specified boxes.
`-interposer`	Declares that the assignment is done in silicon interposer without any instance.
`-write_down_level_bump`	Writes down the level bump file for each hierarchical instance.

Notes:

- If neither `-signal` nor `-pgpad` is specified, both signal and pgpad will be assigned.
- If neither `-feedthru` nor `-nonFeedthru` is specified, both feedthru and non-feedthru net will be assigned.
- If neither `-frontBump` nor `-backBump` is selected, none of the bumps will be assigned. However, the TSV will still be assigned.

Examples

- The following command assigns the signal IO pins to the frontside bump:
  ```
  assignTSV -frontBump -signal
  ```
- The following command assigns the selected TSV with net VDD:
  ```
  addTSV -selected VDD
  ```

create_stress_rule

```
create_stress_rule
[-help]
{ {-layer layerName -spacing_table spacing_table [-chip_name chipName]} | [-reset ] }
```

Defines a spacing table for spacing rules. Since the spacing rule varies with the location of the keep out zone in the chip, user can define different spacing tables for different spacing rule. These spacing tables are used by the tool to identify different scenarios and select the correct spacing constraint for a scenario.

Parameters

`-help`	Prints a brief description of the `create_stress_rule` command usage. For a detailed description of the command, use the `man` command: `man create_stress_rule`
`-chip_name chipName`	Specifies the name of the chip for which the spacing table is used for checking violation. If this option is not specified, the tool applies the spacing rule for all the chips above, below, and current based on the masterslice layer definition in the LEF file
`-layer layerName`	Specifies the name of the stress layer for which the spacing table is used for checking violation.
`-reset`	Resets all stress rules.
`-spacing_table spacing_table`	Specifies the spacing table definition, {x1 y1} {x2 y2}.

createTSVNoLoadSPEF

```
createTSVNoLoadSPEF
fileName
```

Creates a top-level spef that describes the connectivity between dies. The RC is `0` in this SPEF file, but only inter-die connectivity is written. This spef file, together with the spef for each die, is the input of Tempus for static timing analysis.

This command is used after reading the stacked die config file (XML) using `readTSVConfig` as the die configuration is required to detect the connectivity between dies.

Parameters

fileName	Specifies the file name.

Examples

- The following command creates a `0` load top-level spef file:

  ```
  createTSVNoLoadSPEF top.spef
  ```

Related Information

- `readTSVConfig`

deleteTSV

```
deleteTSV
{-all | -selected| -unassigned}
```

Deletes the specified TSVs. If the TSV belongs to a feedthru, the entire feedthru will also be deleted.

Parameters

`-all`	Deletes all the TSVs.
`-selected`	Deletes the selected TSVs.
`-unassigned`	Deletes the unassigned TSVs.

Examples

- The following command deletes all the TSVs:
  ```
  deleteTSV -all
  ```

Related Information

- `addTSV`

read_codesign_die_abstract

```
read_codesign_die_abstract
[-help]
DIEABSTRACTFILE
[-check_only]
[-no_diff]
```

Reads the die abstract directly to update Innovus. The command provides flexibility in terms of what is read and the elimination of the I/O Update file and TCL code.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `read_codesign_die_abstract` parameter. For a detailed description of the command and all of its parameters, use the man command: `man read_codesign_die_abstract`
`DIEABSTRACTFILE`	Specifies the name of the die abstract file.
`-check_only`	This is only valid with the `-no_diff` option. If these two options are given, then the difference viewer will not be used, and the Innovus db will not be updated.
`-no_diff`	When the `-no_diff` option is used, the difference viewer will not be utilized. The die abstract will be read and the Innovus db will be updated with all the changes unless the `-check_only` option is provided.

Related Information

- `readDieAbstract`
- `write_codesign_die_abstract`

read_design_stack_config

```
read_design_stack_config
[-help]
[-avoid_floorplan_change]
[-chipName NameOfChip]
[-manufacturing_grid grid]
[-power_config_file PowerConnectionFile]
[-topNetlist VerilogFileName]
[-xml StackedDieFileName]
```

Loads the die stacking config file (*.xml) for Innovus to understand the 3D-IC top-level structure.

You can use this command before or after the `init_design` command. When you use `read_design_stack_config` before `init_design`, in addition to loading the die stacking information into the memory, it patches up the virtual techLEF of the 3DIC top cell and the Verilog netlist if the `init_lef_file` and `init_verilog` variables are not set before `init_design`. If you use `read_design_stack_config` after `init_design`, when the top design (Netlist, tech LEF) has already been loaded into Innovus, but without XML. Without the XML, Innovus does not know that the top cell is the top of a 3DIC design. Therefore, XML is required to let Innovus know the vertical position and face up/down information of the dies for the GUI display and the contact layer mapping relationship.

When the top-level netlist is missing, read_design_stack_config can help generate a virtual netlist, but the pins are floating so that you can still load the 3D-IC design into Innovus with iHDB. Only top is in the virtual netlist. `read_design_stack_config` internally calls addInst to add other dies.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `read_design_stack_config` parameter. For a detailed description of the command and all of its parameters, use the man command: `man read_design_stack_config`
`-avoid_floorplan_change`	When you specify this option, the floorplan and die instances will not be created.
`-chipName` *`NameOfChip`*	Specifies the name to be used when the current die is instantiated.
`-manufacturing_grid` *`grid`*	Specifies the manufacturing grid. However, if the manufacturing grid is set by TLEF, `read_design_stack_config` does not update the manufacturing grid and prints an error.
`-power_config_file` *`PowerConnectionFile`*	Specifies the file name of the power connection.
`-topNetlist` *`VerilogFileName`*	Specifies the file name of the top-level netlist verilog.
`-xml` *`StackedDieFileName`*	Specifies the file name of the stacked die.

Related Information

- `init_design`
- `init_lef_file`
- `init_verilog`

readBumpLocation

```
  readBumpLocation
[-help]
fileName
[-allow_overlap_control {keep_all keep_existing_bumps keep_new_bumps}]
[-die_box]
[-ignore_route_blockages]
[-force_current_die]
{[-frontBump bumpCellName] [-backBump backBumpCellName] [-bump_cell_from_bump_file ]}
[{-backBump backBumpCellName | -bump_cell_from_bump_file } [-rotate_bump  -
prefix prefixName]]
[{-frontBump bumpCellName | -bump_cell_from_bump_file }[-rotate_bump  -
prefix prefixName] [-stackViaUnderBump stackViaName]]
[-prefix prefixName | -bump_name_from_bump_file {true | false}]
[-checkAlignment ]
[-nonFeedthru ]
[-feedthru ]
[-tsvViaName viaCellName [-feedthruSize sizex sizey] [-offset {x y}]]
```

The command creates or assigns objects on the current die according to the bumps on the adjacent die. In a TSV design, the micro bumps on the adjacent die should be aligned, and the aligned micro bumps should be with the same signal. Specify this command to sync-up the micro bump between dies. Firstly, the command tries to find the front side bump/back side bump/TSV at the location aligned to the bump on the adjacent dies. If all the specified bumps/TSVs are found on the current die, the command will assign the found bump/TSV with the same signal as the bump on the adjacent die; if none of the specified bumps/TSV are found, the command will create the specified bump/TSV with the same signal at the aligned position.

This command supports the combo bump and embedded bump flows.

Use this command after reading the stacked die config file (XML), by using `readTSVConfig`, as the die configuration is required for the bump alignment.

Note: A combo bump is a group of bumps that are treated as one bump, which means all bumps in the same combo bump will be created, assigned, unassigned, and manipulated at the same time. This command synchronizes the combo bump information between adjacent chips automatically. All bumps belonging to the same combo bump will be treated as one unit. Embedded bump is the bump at the block-level, and the information of these bumps can be exchanged between chips at the top-level.

Parameters

`-allow_overlap_control {keep_all keep_existing_bumps keep_new_bumps}`	Specifies the overlap control type. The allowed values for the `-allow_overlap_control` parameter are: • `keep_all`: Keeps all overlapping bumps. • `keep_existing_bumps`: Keeps the existing bumps before calling `readBumpLocation` if there is an overlap. If this option is specified, `readBumpLocation` keeps creating a bump if there is an overlap and continues creating the remaining bumps. A warning message is displayed when bump creation is skipped to avoid overlap. • `keep_new_bumps`: Removes the existing bumps before calling `readBumpLocation`, places the newly created bump if there is overlap, and then continues creating the remaining bumps. A warning message is displayed when deleting the existing bumps to avoid overlap. If the status of the existing bumps to be deleted is covered or fixed, a warning is displayed and the new bumps overlapping with the covered or fixed old bump are not kept.
`-backBump` *`bumpCellName`*	Creates or assigns the backside bumps at the location aligned with the bumps on the adjacent die.
`-checkAlignment`	Use this parameter to check the alignment between current die and the adjacent dies. It also checks the overlap between the OBS layer and bumps (both front and back bumps). When this parameter is specified, all other parameters are ineffective.
`-bump_cell_from_bump_file`	Creates bumps with the same bump cell defined in the bump file.
`-bump_name_from_bump_file {true | false}`	Creates bumps with the same bump name defined in bump file.

`-die_box`	Draws the die bounding box based on the DieBox value in the bump file.
`-force_current_die`	Specifies to consider the bump file as the current die bump file. Skip to check if the specified bump file is for current die or adjacent die or a block.
`fileName`	Specifies the name of the bump location file of the adjacent die.
`-frontBump` *`bumpCellName`*	Creates or assigns the frontside bumps at the location aligned with the bumps on the adjacent die.
`-feedthru`	Creates or assigns the bump with feedthru net only. If `-feedthruSize` and `-tsvViaName` are specified, the TSV and the stacked via of the feedthru will also be created.
`-feedthruSize` *`sizex sizey`*	Specifies the size for feedthru. This option is exclusive with the `-nonFeedthru` option.
`-ignore_route_blockages`	Allows creation of bumps on route blockages. When this option is specified, the tool ignores checking route blockages when creating bumps.
`-nonFeedthru`	Creates or assigns the bump with normal net only.
`-offset x y`	Specifies the offset from the TSV to the corresponding bump. **Note:** You can also specify the offset in the bump file by appending `-offset x y` to the line. The offset in the bump file has higher priority than the offset specified in the command line. If `-offset` is specified at both command line and bump file, the program will follow the offset specified in the bump file.

`-prefix` *`prefixName`*	Adds prefix name for a bump during bump creation and bump mapping. The default name of bumps are `frontBump_*` or `backBump_*` with serial numbers. If `-prefix` *`prefixName`* is applied, created bump names are `prefixName_frontBump_*` or `prefixName_backBump_*`. **Note**: Single underscore (_) is automatically added between the *`prefixName`* and the default bump name.
`-rotate_bump`	Rotates bumps during bump mapping according to the chip and bump orientation information of the adjacent die.
`-stackViaUnderBump` *`stackViaName`*	Specifies the stack via name under the front bump. The tool automatically adds the specified via cell stacking to the bottom layer of front-side bump.
`-tsvViaName` *`viaCellName`*	
	Creates or assigns the TSV at the location aligned (or with offset if `-offset` is specified) to the bumps on the adjacent die.

Note: If neither `-feedthru` nor `-nonFeedthru` is specified, the bump/TSV with both feedthru net and non-feedthru net will be created and assigned.

Examples

- The following command reads a bump file and creates the corresponding frontside bump on current die:

  ```
  readBumpLocation bumpfile -frontBump front_bump_cell
  ```

- The following command reads a bump file and creates the corresponding backside bump and TSV current die:

  ```
  readBumpLocation bumpfile -backBump back_bump_cell -tsvViaName tsv_via
  ```

Related Information

- writeBumpLocation
- readTSVConfig

readDieAbstract

```
readDieAbstract
DIEABSTRACTFILE
```

Reads the die abstract of the adjacent die. With this command, the abstract of the adjacent die is imported and displayed overlapped with the current design.

This command supports the embedded bump flow for hierarchical designs.

The `readDieAbstract` command is used after reading the stacked die config file (XML) by using `readTSVConfig` because the die configuration is required for die alignment. You can turn off the import adjacent die objects by changing the visibility of abs* layers in the *Custom* tab of the *Color Preferences* form.

Parameters

DIEABSTRACTFILE	Specifies the name of the die abstract file.

Examples

- The following command reads a die abstract file `die1.abs`:

  ```
  readDieAbstract die1.abs
  ```

Related Information

- `readTSVConfig`
- `writeDieAbstract`
- The *Color Preferences* section of the The Main Window chapter in *Innovus Menu Reference*.

readTSVConfig

```
readTSVConfig
{[-stackedDieFile filename] [-powerFile filename]}
[-chipName chipName]
[-topNetlist]
```

Imports 3D IC configuration files of the whole design, including the stack die configuration file, power net configuration file and top-level netlist.

Parameters

-stackedDieFile filename	
	Reads the stack die configuration file.
-powerFile *filename*	
	Imports the power net configuration file.

-chipName *chipName*	Specifies the hierarchical instance name (chip) name of the current design in the top-level netlist.
	For example, if the current design is `ramextra` and the top-level netlist is below it, then you can specify the chip name, `i_ramextra`, as follows:
	`module top (...) ;`
	`asic_entity i_asic_entity (.pin1(), .pin2(), ...);`
	`ramextra i_ramextra (.pin1(), .pin2(), ...);`
	`end module`

-topNetlist	Imports the top-level netlist to support 3D IC design in OA mode. **Note:** You can import the top-level netlist in the non-OA mode in case the top-level netlist is not loaded during the design import.

Examples

- The following command reads the stacked die configuration file and power configuration file and specifies that the current design is named `i_ramextra`:

  ```
  readTSVConfig -stackedDieFile stacked_die.xml -powerFile power.side -
  chipName i_ramextra
  ```

- Below is the example of a stack die configuration file:

```
<StackChip>
  <TopDesign name="top" />
  <Tier number=1>
    <Chip name="i_asic_entity" orientation="R0" faceUp="Yes" llx=0 lly=0
sizeX=6000.0 sizeY=6000.0 scaleFactor=1 />
  </Tier>
  <Tier number=2>
    <Chip name="i_ramextra" orientation="R0" faceUp="Yes" llx=1500.0 lly=1250.0
sizeX=3500.0 sizeY=3000.0 scaleFactor=1 />
  </Tier>
</StackChip>
```

- Below is the example of a power net configuration file:

```
VDD i_asic_entity   sharable
VDD i_ramextra      backside
VSS i_asic_entity   sharable
VSS i_ramextra      backside
Alias:
i_asic_entity/VDD i_ramextra/VDD
i_asic_entity/VSS i_ramextra/VSS
```

unassignTSV

```
unassignTSV
{-netName netname| -all |-signal | -power | -ground | -selected}
```

Unassigns the specified TSV. This command is used for manual operating on TSV or iteration between TSV assignment and instance placement.

Parameters

`-netName` *netname*	Unassigns the specified net from TSVs.
`-all`	Unassigns all the TSVs.
`-signal`	Unassigns the signal net from TSVs.
`-power`	Unassigns the power net from TSVs.
`-ground`	Unassigns the ground net from TSVs.
`-selected`	Unassigns selected TSVs.

Examples

- The following command reads unassign all the TSVs with power net:
  ```
  unassignTSV -power
  ```

Related Information

- addTSV
- assignTSV
- deleteTSV
- readDieAbstract

verify_stacked_die

```
verify_stacked_die
[-help]
[-check_type type_name]
[-chip_name {chip1 chip2 ...}]
```

Checks die edge violation between adjacent dies. Once you define an OBS layer inside a macro, the adjacent die edge should not overlap this OBS area. If there is any violation between macro OBS and adjacent die edge, it will be marked in the GUI window.

This command must be used after `readDieAbstract` to input adjacent die's die abstract file.

Parameters

`-help`	Prints a brief description of the `verify_stacked_die` command usage. For a detailed description of the command, use the `man` command: `man verify_stacked_die`
`-check_type type_name`	Specifies the check constrain types. Currently, only the `die_edge` and `bump_keepout` zone checking are supported.
`-chip_name {chip1 chip2 ...}`	Specifies the name of the adjacent chip whose edge is to be checked for violation. In a 3D-IC design, there could be more than one top die (in interposer design), so you can specify the chip that needs to be checked. Using this parameter, you can check one or more chips at the same time.

Examples

- The following command checks die edge violation between the macro's keep-out area and adjacent die `mother_die`:

  ```
  verify_stacked_die -chip_name {mother_die}
  ```

write_codesign_die_abstract

```
write_codesign_die_abstract
[-help]
DIEABSTRACTFILE

[-scribe_west distance_in_microns]
[-sealring_all distance_in_microns]
[-sealring_east distance_in_microns]
[-sealring_north distance_in_microns]
[-sealring_south distance_in_microns]
[-sealring_west distance_in_microns]
[-version {4.0}]
```

Writes the abstract of current die to a file. It also writes the OBS for die edge checking to the die abstract file. Specify this command after the initial floorplan is loaded. The file will be imported by the adjacent die and therefore the current design will be honored by the adjacent die. The `write_codesign_die_abstract` command is similar to the `writeDieAbstract` except that the `write_codesign_die_abstract` command provides options for filtering portions of the abstract which may not be required for some flows. It also provides the option to write out a third-party die abstract for ICs that do not have TSVs.

This command supports the embedded bump flow for hierarchical designs.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `write_codesign_die_abstract` parameter. For a detailed description of the command and all of its parameters, use the man command: `man write_codesign_die_abstract`
DIEABSTRACTFILE	Specifies the name of the die abstract file.
`-block_pin_layer_bottom` *layer_name*	Specifies the name of the legal routing layer for block macros. If specified, the layers below the mentioned layer should not be the output to the die abstract. If not specified, the default value is the next layer down from the top routing layer.
`-block_pin_layer_top` *layer_name*	Specifies the name of the legal routing layer for block macros. If given, the layers above the mentioned layer should not be the output to the die abstract.
`-block_pin_minimum_size` *x y*	Defines the minimum size of the pin that will be output to the die abstract.
`-block_pin_name_includes` *pin_name*	Specifies that only pins that contain the mentioned value will be in the output.
`-bump_pin_layer_bottom` *layer_name*	Specifies the legal routing layers name for bump macros. If given, the layers below the specified layer are not to be output to the die abstract

`-bump_pin_layer_top` *layer_name*	Specifies the legal routing layer name; used for bump macros. If given, the layers above the specified layer are not to be output to the die abstract.
`-constraints` *file_name*	Specifies the name of the file that lists the constraints. This file will be read and the constraints will be applied to the design.
`-die_shrink_by` *num*	Specifies the percentage by which the die should be shrunk. A typical shrink value is 10 (for a 10% optical shrink). *Default*: `0` The default value, `0`, indicates no shrink.
`-die_thickness` *num*	Specifies the die thickness. *Default*: `0`
`-include_macro_obstructions`	Specifies to give LEF macro OBS shapes in the output to the die abstract. By default, OBS obstructions are not included.
`-io_macros` *macro_names*	Identifies the I/O macros that are to be written to the die abstract. If a macro is not specified, co-design is done at the bump level.
`-io_pin_layer_bottom` *layer_name*	Specifies the legal routing layer name; used for I/O macros. If given, the layers below is not to be output to the die abstract.
`-io_pin_layer_top` *layer_name*	Specifies the legal routing layers' name; used for I/O macros. If given, the layers above is not to be output to the die abstract.
`-io_pin_minimum_size` *pin_size*	This parameter defines the minimum size of pin that will be output to the die abstract. The pin's x and y dimensions must be at least this value.
`-io_pin_name_includes` *pin_name*	This string indicates that only pins that contain the string value will be output.
`-layer_details`	When given, indicates that the layer_details is to be output to the die.

`-macro_obstructions_layer_bottom` *layer_name*	If specified, identifies the bottom layer for which OBS shapes are exported to the die abstract. The default value for this option is the top metal layer.
`-macro_obstructions_layer_top` *layer_name*	If specified, identifies the top layer for which OBS shapes are exported to the die abstract.
`-no_block_macros`	Indicates that block macros should not be the output to the die abstract.
`-no_blockages`	Indicates that blockages should not be the output to the die abstract.
`-no_rdl_routing`	Indicates that the rdl routing should not be the output to the die abstract.
`-power_routing`	Indicates that the power routing should not be the output to the die abstract.
`-power_routing_layer_bottom` *layer_name*	Specifies the names of the legal routing layers for power routing. If given, the layers below are not to be output to the die abstract.
`-power_routing_layer_top` *layer_name*	Specifies the names of legal routing layers for power routing. If given, the layers above are not output to the die abstract.
`-rdl_routing_layer_bottom` *layer_name*	Specifies the names of legal routing layers for rdl routing. If given, the layers below are not to be output to the die abstract.
`-rdl_routing_layer_top` *layer_name*	Specifies the names of legal routing layers for rdl routing. If given, the layers above are not to be output to the die abstract.
`-scribe_all` *distance_in_microns*	Specifies the distance in microns from the die boundary to the edge of the silicon after being cut from the wafer from all sides.
`-scribe_east` *distance_in_microns*	Specifies the distance in microns from the die boundary to the edge of the silicon after being cut from the wafer from the East side.

`-scribe_north` *`distance_in_microns`*	Specifies the distance in microns from the die boundary to the edge of the silicon after being cut from the wafer from the North side.
`-scribe_south` *`distance_in_microns`*	Specifies the distance in microns from the die boundary to the edge of the silicon after being cut from the wafer from the South side.
`-scribe_west` *`distance_in_microns`*	Specifies the distance in microns from the die boundary to the edge of the silicon after being cut from the wafer from the West side.
`-sealring_all` *`distance_in_microns`*	Species the distance of the seal ring from the die boundary on all sides. Seal ring is a border around the die boundary that is put in pre-shrink.
`-sealring_east` *`distance_in_microns`*	Species the distance of the seal ring from the die boundary from the East side.
`-sealring_north` *`distance_in_microns`*	Species the distance of the seal ring from the die boundary from the North side.
`-sealring_south` *`distance_in_microns`*	Species the distance of the seal ring from the die boundary from the South side.
`-sealring_west` *`distance_in_microns`*	Species the distance of the seal ring from the die boundary from the West side.
`-version {4.0}`	Specifies the version number of die abstract.

write_design_stack_config

```
write_design_stack_config
[-help]
{[-xml StackedDieFileName] [-power_config_file PowerConnectionFile]}
```

Saves the xml file and power config file in the specified path.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `write_design_stack_config` parameter. For a detailed description of the command and all of its parameters, use the man command: `man write_design_stack_config`
`-power_config_file` *`PowerConnectionFile`*	Specifies the file name of the power connection.
`-xml` *`StackedDieFileName`*	Specifies the file name of the stacked die.

Related Information

- `read_design_stack_config`

writeBumpLocation

```
writeBumpLocation
fileName
[-selected]
```

Writes the bump information to a file. It also writes the bump keep-out area information to the bump file. Specify this command after the bumps are created and/or assigned.

This command supports the combo bump and embedded bump flows.

Parameters

fileName	Specifies the file name.
-selected	Specifies to output information related to selected bumps to the bump file. Select the required bumps in the GUI or on the command line, and specify this parameter to output the bump information. You can use this parameter when you want to output bump information that is related to a specific block in hierarchical designs.

Examples

- The following command create a bump information file `die1.bump`:
  ```
  writeBumpLocation die1.bump
  ```

  The below example shows a sample a bump information file:

  ```
  === die1.bump ===

        ChipName: ramextra

        DieBox: 0.000000 0.000000 3500.000000 2999.910000

        OBS: BumpKOZ -poly 2593.970 1952.465 2593.970 2899.910 3400.000 2899.910
  ```

```
3400.000 1952.465 -spacing 0.000 -backSide
      Bump: backBump_499 backUBump_40 3450.000 2850.000 -backside
      Bump: backBump_498 backUBump_40 3450.000 2650.000 -backside
      Bump: backBump_497 backUBump_40 3450.000 2450.000 VSS -ground -backside
      ...
      Bump: backBump_438 backUBump_40 50.000 250.000 VSS -ground -backside
      Bump: backBump_437 backUBump_40 50.000 50.000 VDD -power -backside
      Bump: backBump_436 backUBump_40 3400.000 1800.000 qa_3[31] -backside
      Bump: backBump_435 backUBump_40 3400.000 1700.000 qb_3[31] -backside
      ...
      Note: backUBump_40 is the backBump cell name.
      The design "ramextra" origin is the coordinate original of bump information
file.
```

- The following command creates the bump information file, `die2.bump`, for a multiple-pin feedthrough bump:

  ```
  writeBumpLocation die2.bump
  ```

  The below example shows a sample a bump information file for a multiple-pin feedthrough bump：

  ```
  === die1.bump ===

  ................................
  ................................
  ................................
  ................................
  Bump: Bump_1 uBUMP 200 200 PIN_1 CLK_IN PIN_1 CLK_OUT PIN2
  Bump: Bump_2 uBUMP 200 400 VSS -ground
  ................................
  ................................
  ................................
  ................................
  ................................
  ................................
  ................................
  ................................
  ```

Related Information

- readBumpLocation

writeDieAbstract

```
writeDieAbstract
DIEABSTRACTFILE
[-noFilter]
```

Writes the abstract of current die to a file. It also writes the OBS for die edge checking to the die abstract file. Specify this command after the initial floorplan is loaded. The file will be imported by the adjacent die and therefore the current design will be honored by the adjacent die.

This command supports the embedded bump flow for hierarchical designs.

Note: By default, the proposed behavior for `writeDieAbstract` is:

- For MACRO pin geometries, output ports on top metal layer in all MACROS of all classes.
- For routing, output routing for all top level Verilog ports, and for power and ground, output only those wires with a SHAPE of IOWIRE.

Parameters

DIEABSTRACTFILE	Specifies the file name.
-noFilter	Turn off to filter the die abstract contents.

Examples

- The following command creates a die abstract file `die1.abs`:

  ```
  writeDieAbstract die1.abs
  ```

Related Information

- readDieAbstract
- readTSVConfig

writeMicroBumpMappingFile

```
writeMicroBumpMappingFile
[-help]
fileName
[-mergeWith {filename1 filename2 ...}]
```

Writes the micro bump mapping file for Quantus and Voltus use. Use this command after the aligned bump pair is created by `readBumpLocation` command. This command supports the embedded bump flow for hierarchical designs.

Parameters

`-help`	Prints a brief description of the `writeMicroBumpMappingFile` command usage. For a detailed description of the command, use the `man` command: `man writeMicroBumpMappingFile`
`-mergeWith`	If there are more than two dies in the design, this command may be called more than one time. This option should be specified at the last time to merge the previously generated files.
`fileName`	Specifies the file name.

Example

- The following command creates a bump mapping file:
  ```
  writeMicroBumpMappingFile tier2.map2 -mergeWith tier1.map
  ```

  Here is an example of a bump mapping file, `tier2.map2`:

  ```

```

Related Information

- readBumpLocation

writeVSMappingFile

```
writeVSMappingFile
fileName
```

Writes out a bump mapping file for Voltage Storm use. Use this command after the aligned power bump pairs are created by the `readBumpLocation` command.

Parameters

fileName	Specifies the file name.

Examples

- The following command creates a power bump mapping file:
  ```
  writeVSMappingFile powerBump.mapping
  ```

Related Information

- `readBumpLocation`

Unified Safety Format Commands

Midas Unified Safety Format (USF) Physical is loaded at startup. To enable USF in Innovus, you must set `safety_midas_enable` to `physical`.

```
set safety_midas_enable physical
```

You will see a message like this:

```
Cadence Midas USF - Physical
Copyright 2022 Cadence Design Systems, Inc. All rights reserved worldwide.
Cadence and the Cadence logo are registered trademarks of Cadence Design Systems Inc.
in the United States and other countries.
Midas USF - Physical Version: 22.03.001
physical
```

ⓘ Once USF Physical is loaded, it is not possible to disable or reload it in the current session.

- USF File Commands
- USF Support Commands

USF File Commands

- apply_safety_mechanism
- create_esubpart
- create_failure_mode
- create_safety_mechanism
- set_safety_mechanism_rules_dcls
- set_safety_mechanism_rules_tmr

apply_safety_mechanism

```
apply_safety_mechanism
[-help]
safety_mechanism
[-generated]
-to failure_mode
```

Maps a safety mechanism to one or more failure modes.

This command should be applied only via a USF file that is read in using `read_usf`.

Parameters

`-help`	Prints a brief description of the `apply_safety_mechanism` command. For a detailed description of the command, use the `man` command: `man apply_safety_mechanism`.
`safety_mechanism`	Specifies the safety mechanism identifier.
`-generated`	Specifies that the additional logic required to create this safety mechanism has already been inserted into the design.
`-to` *`failure_mode`*	Specifies the failure mode identifier to which the specified safety mechanism should be associated. **Note**: One safety mechanism can be mapped to multiple failure modes.

Example

- The following command applies the `SM_TMR` safety mechanism to the `FM_22` failure mode:

  ```
  apply_safety_mechanism SM_TMR -to FM_22
  ```

Related Information

- check_safety_mechanism

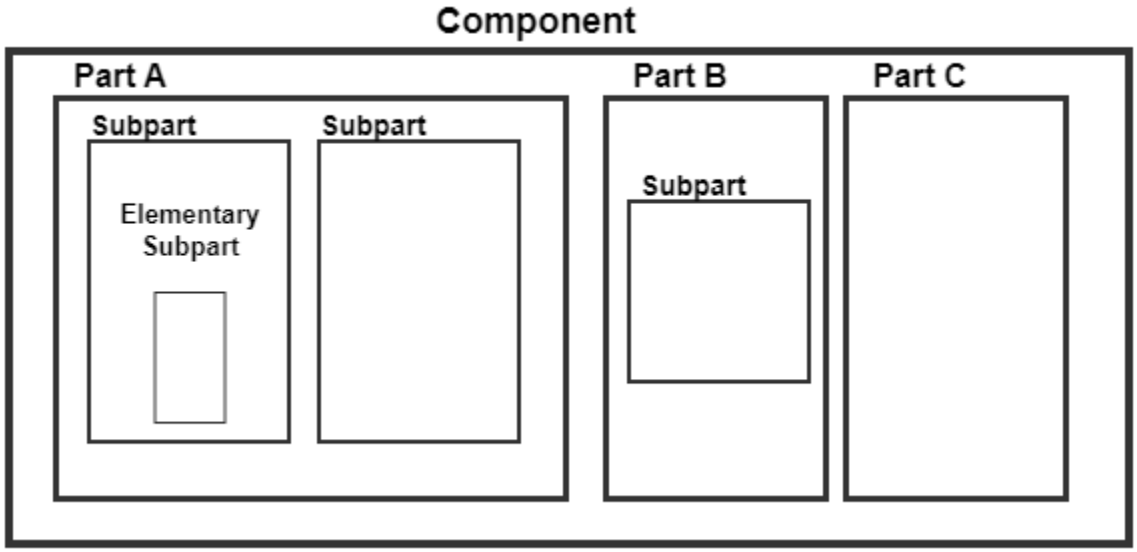
- set_safety_mechanism_rules_tmr

create_esubpart

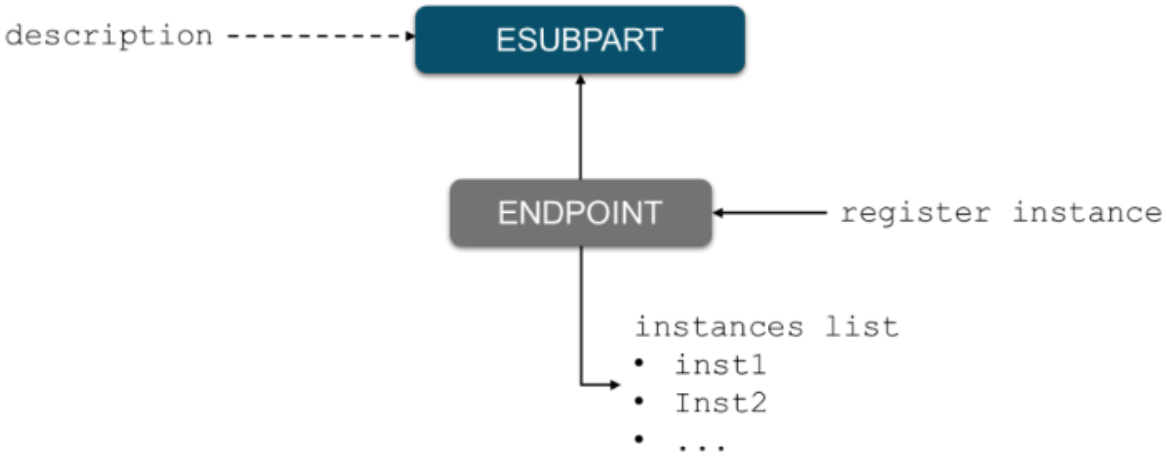
```
create_esubpart
[-help]
esp
[-description description]
-inst string
-register_endpoint string
```

Creates an elementary subpart, which is the smallest hardware subpart considered in safety analysis.

The diagram below represents a component with its parts, subparts, and elementary subparts.



An elementary subpart is a group of instances identified with a descriptor. The instances are associated to reference an endpoint. In the current implementation, the endpoint can only be a register.



The `create_esubpart` command should be applied only via a USF file that is read in using `read_usf`.

Parameters

`-help`	Prints a brief description of the `create_esubpart` command. For a detailed description of the command, use the `man` command: `man create_esubpart`.
esp	Specifies the identifier to be associated with the elementary subpart being created.
`-description` *description*	
	Specifies a textual description for the elementary subpart being created.
`-inst` *string*	Specifies the instances to be mapped to the elementary subpart.
`-register_endpoint` *string*	
	Specifies a reference instance for the endpoint.

Example

- The following command creates an elementary subpart named with the specified description, endpoint, and instances:

```
create_esbupart ESP_VOT_0 -description "automatically generated elementary subpart"
 -register_endpoint { xsv_fpga_top/or1200_top/or1200_cpu/or1200_fpu/s_exp_diff_reg\[5\] }
 -inst { xsv_fpga_top/or1200_top/or1200_cpu/or1200_fpu/s_exp_diff_reg\[5\]_tv_an1
         xsv_fpga_top/or1200_top/or1200_cpu/or1200_fpu/s_exp_diff_reg\[5\]_tv_an2
         xsv_fpga_top/or1200_top/or1200_cpu/or1200_fpu/s_exp_diff_reg\[5\]_tv_or1
         xsv_fpga_top/or1200_top/or1200_cpu/or1200_fpu/s_exp_diff_reg\[5\]_tv_or2
 }
```

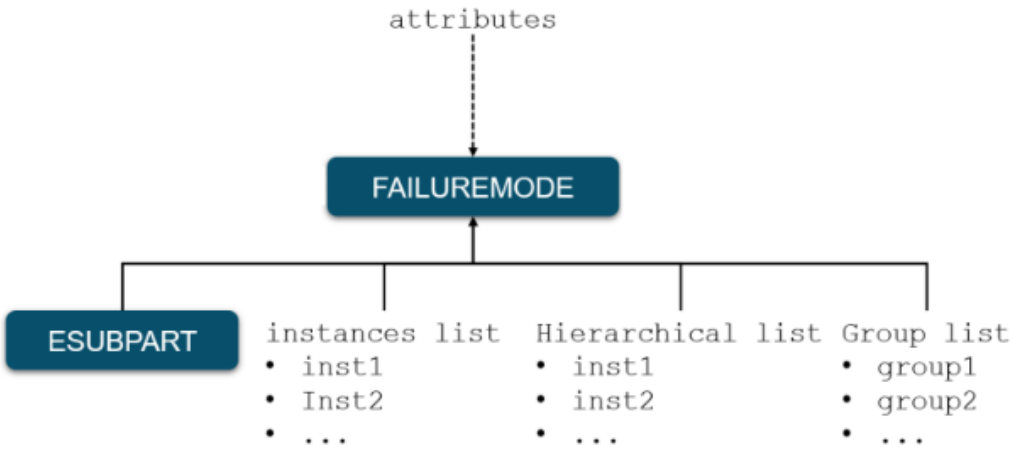
Related Information

- apply_safety_mechanism
- check_safety_mechanism
- create_failure_mode
- create_safety_mechanism
- read_usf
- set_safety_mechanism_rules_dcls
- set_safety_mechanism_rules_tmr

create_failure_mode

```
create_failure_mode
[-help]
FailureMode
[-attributes string]
[-description description]
{-hinst string | -inst string | -esubpart string | -group string}
```

Defines a failure mode. The failure mode groups a given set of logic that is relevant from the safety point of view. For example, it could be the logic that needs to be protected by one or more safety mechanisms or the logic that is describing a safety mechanism that has already been implemented.



The `create_failure_mode` command should be applied only via a USF file that is read in using `read_usf`.

Parameters

`-help`	Prints a brief description of the `create_failure_mode` command. For a detailed description of the command, use the `man` command: `man create_failure_mode`.
`FailureMode`	Specifies the identifier to be associated to the failure mode being created.
`-attributes` *`string`*	Specifies the optional attributes attached to the failure mode.
`-description` *`description`*	Specifies a textual description for the failure mode being created.
`-esubpart` *`string`*	Specifies a list of elementary subparts.
`-group` *`string`*	Specifies the groups to be mapped to the failure mode.
`-hinst` *`string`*	Specifies the hierarchical instance(s) to be mapped to the failure mode.
`-inst` *`string`*	Specifies the instances to be mapped to the failure mode.

Example

- The following command creates a failure mode named `FM_22` with the specified description and hierarchical instance:

```
create_failure_mode FM_22 -description "FPU Adder produces incorrect data due to
fault into the FPU prenorm addsubtracter"
     -hinst
xsv_fpga_top/or1200_top/or1200_cpu/or1200_fpu/fpu_arith/fpu_prenorm_addsub
```

Related Information

- apply_safety_mechanism
- check_safety_mechanism
- create_esubpart

create_safety_mechanism

```
create_safety_mechanism
[-help]
safety_mechanism
[-class {aou hw sw aou_hw aou_sw}]
[-description description]
[-type {tmr dcls}]
```

Defines a new safety mechanism. A safety mechanism is extra hardware inserted into your design to bypass, detect, or correct faults.

This command should be applied only via a USF file that is read in using `read_usf`.

Parameters

`-help`	Prints a brief description of the `create_safety_mechanism` command. For a detailed description of the command, use the `man` command: `man create_safety_mechanism`.
`safety_mechanism`	Specifies a name for the safety mechanism being defined.
`-class {aou hw sw aou_hw aou_sw}`	Specifies the supported safety mechanism classes. The possible values are: • `aou`: assumption of use • `hw`: hardware • `sw`: software • `aou_hw`: assumption of use hardware • `aou_sw`: assumption of use software *Default*: `hw`
`-description` *`description`*	Specifies a description for the safety mechanism being defined.
`-type {tmr dcls}`	Specifies the type of the safety mechanism being defined. The options are: • `tmr` - triple modular redundancy • `dcls` - dual-core lockstep *Default*: `tmr`

Example

- The following command creates a safety mechanism named, `SM_TMR`, of the specified class and type:
  ```
  create_safety_mechanism SM_TMR -description "Triple Modular Redundant Flip Flops" -type tmr -class hw
  ```

Related Information

- apply_safety_mechanism
- create_esubpart
- create_failure_mode
- read_usf
- set_safety_mechanism_rules_dcls
- set_safety_mechanism_rules_tmr

set_safety_mechanism_rules_dcls

```
set_safety_mechanism_rules_dcls
[-help]
[-exclusive_groups {{group_A1 {group_A2 group_A3 ...}} {group_B1 group_B2
group_B3 ...} ... }]
[-isolate_clock {* | group_A1 group_A2 ...}]
[-spacing d]
```

Defines the separation rules to be applied to the dual core lockstep (DCLS) groups in the design.

Each time the `set_safety_mechansim_rules_dcls` command is issued, the tool clears any previously set DCLS-associated attributes across all groups prior to setting them in the way the latest command dictates. Therefore, this command cannot be used multiple times to accumulate a set of rules.

This `set_safety_mechansim_rules_dcls` command may be interactively applied at the command line. That is, it is not restricted to be read in as part of a USF file using `read_usf`. However, if the command is not in a USF file that is being read, it must be applied only after DCLS-related USF information has been read because it depends on this information to function correctly.

Attempting to use this command before a design is loaded or before the groups listed in arguments are defined will cause an error to be issued. In addition, any groups mentioned in this command must already be defined as DCLS groups using a combination of the `create_failure_mode`, `create_safety_mechanism` (with type `dcls`), and `apply_safety_mechanism` commands.

Parameters

`-help`	Prints a brief description of the `set_safety_mechanism_rules_dcls` command. For a detailed description of the command, use the `man` command: `man set_safety_mechanism_rules_dcls`.
`-exclusive_groups {{group_A1 {group_A2 group_A3 ...}} {group_B1 group_B2 group_B3 ...} ... }`	

	Specifies a list of mutually exclusive DCLS group lists. This parameter is mandatory if the `-spacing` parameter is being used. Wildcards are not allowed in the `-exclusive_groups` arguments. If a group is referenced more than once in the `-exclusive_groups` arguments, an error will be issued. In the argument example above, `{group_A1 {group_A2 group_A3 ...}` is a master/checker arrangement, where `group_A1` is the "master" group and `group_A2` and `group_A3` are the "checker" groups. This means that the checker groups must be separated from the master group by a distance of at least `d` as specified with the `-spacing` parameter. However, a checker group may overlap other checker groups. When a master/checker arrangement is specified, there can be only one master and there must be at least two checkers. In the `{group_B1 group_B2 group_B3 ...}` part of the argument, `group_B1`, `group_B2`, and `group_B3` are all mutually exclusive. This means that they must all be separated from one another by a distance of at least `d` specified with the `-spacing` parameter. Each list of mutually exclusive groups must have at least two members or else an error will be issued.
`-isolate_clock {* | group_A1 group_A2 ...}`	

	Specifies a list of groups where clock isolation is required. This argument is optional. Clock isolation is specific to each listed group. If specified for a group, it isolates that group from the rest of the clock network in the design. Clock isolation is not just about separating two groups. For example, in the diagram below, the path shown in red will not occur for the groups with isolated clocking.  If * is specified, clock isolation is enacted for all the DCLS groups in the design.
`-spacing` *d*	Defines in microns the minimum spacing between exclusive DCLS groups. This parameter is mandatory if the `-exclusive_groups` parameter is used. The distance `d` here is expected to be a positive rational number. The specified distance is rounded to the nearest 0.001 value. If the distance specified is a negative number, a warning is issued and the setting is changed to `0`.

Examples

- The following command specifies that groups `A` and `B` are mutually exclusive to one another. The group boundaries must be at least 5 microns apart:
  ```
  set_safety_mechanism_rules_dcls -exclusive_groups { {A B} } -spacing 5
  ```
- The following command specifies that groups `A`, `B`, and `C` are mutually exclusive. These groups must be at least 10 microns apart:
  ```
  set_safety_mechanism_rules_dcls -exclusive_groups { {A B C} } -spacing 10
  ```
- The following command specifies that group `W` must be at least 5 microns from groups `X`, `Y`, and `Z`. However, `X`, `Y`, and `Z` may overlap one another:
  ```
  set_safety_mechanism_rules_dcls -exclusive_groups { {W {X Y Z}} } -spacing 5
  ```
- The following command specifies that groups `A`, `B`, and `C` must be at least 5 microns apart from one another and group `W` must be at least 5 microns from groups `X`, `Y`, and `Z`. However, `X`, `Y`, and `Z` may overlap one another. In addition, groups `A`, `B`,`C`, `W`, `X`, `Y`, and `Z` are to have isolated clocks:
  ```
  set_safety_mechanism_rules_dcls -exclusive_groups { {A B C} {W {X Y Z}} } -spacing 5
  -isolate_clock { * }
  ```

Related Information

- apply_safety_mechanism
- check_safety_mechanism
- create_esubpart
- create_failure_mode
- create_safety_mechanism
- read_usf
- set_safety_mechanism_rules_tmr

set_safety_mechanism_rules_tmr

```
set_safety_mechanism_rules_tmr
[-help]
{[-spacing float] [-spacing_x dx] [-spacing_y dy] [-isolate_clock {none unique_driver}] }
[-spacing float | -spacing_x dx]
[-spacing float | -spacing_y dy]
```

Defines the triple modular redundancy (TMR) safety-mechanism rules that need to be enforced during implementation.

The rules concern the physical spacing between TMR flip-flops and clock isolation of TMR flip-flops. The `set_safety_mechanism_rules_tmr` command may be applied interactively at the command line. That is, it is not restricted to be read in as part of a USF file using `read_usf`.

Each time the `set_safety_mechansim_rules_tmr` command is issued, the tool first clears any previously set TMR rules. This means that the `set_safety_mechansim_rules_tmr` command cannot be used multiple times to accumulate a set of rules.

One of the following parameters must be specified with the command:

- `-spacing`
- `-spacing_x` and/or `-spacing_y`
- `-isolate_clock`

Additionally, the `-spacing` parameter is mutually exclusive to the `-spacing_x` and `-spacing_y` parameters.

Parameters

`-help`	Prints a brief description of the `set_safety_mechanism_rules_tmr` command. For a detailed description of the command, use the `man` command: `man set_safety_mechanism_rules_tmr`.
`-isolate_clock {none unique_driver}`	

	Controls whether or not the three flops in a TMR group may share the same leaf clock buffer. Supported values are: • `none` - Specifies that the three flops in a TMR group may also share the same leaf clock buffer. • `unique_driver` - Specifies that the clock pin of every TMR flop should be directly driven by its own unique clock cell with fanout equal to `1`. *Default*: `none`
`-spacing` *float*	Specifies the minimum radial spacing in µm between a group of TMR flip-flops sharing the same parent. This parameter is mutually exclusive to the `-spacing_x` and `-spacing_y` parameters. The spacing is expected to be a positive rational number. The specified value is rounded to the nearest 0.001. If a negative number is given, a warning is issued and the `spacing` value is set as `0`.
`-spacing_x` *dx*	Specifies the minimum spacing in the X dimension in µm between a group of TMR flip-flops sharing the same parent. This parameter is mutually exclusive to the `-spacing` parameter. The specified value is rounded to the nearest 0.001. If a negative number is given, a warning is issued and the `-spacing_x` value is set as `0`.
`-spacing_y` *dy*	Specifies the minimum spacing in the Y dimension in µm between a group of TMR flip-flops sharing the same parent. This parameter is mutually exclusive to the `-spacing` parameter. The specified value is rounded to the nearest 0.001. If a negative number is given, a warning is issued and the `-spacing_y` value is set as `0`.

Example

- The following command specifies a 5µm radial spacing between TMR flip-flops and requires isolation of clock pins.

```
set_safety_mechansim_rules_tmr -spacing 5 -isolate_clock unique_driver
```

- read_usf
- reset_usf
- usf_version
- write_usf

check_safety_mechanism

```
check_safety_mechanism
[-help]
[-out_file file_name]
```

Checks all the safety mechanisms and prints a report, optionally writing it to the specified file as well.

The report contains a list of:

- All the safety mechanisms
- The safety mechanism violations found for each safety mechanism, grouped by type

See Report Content for details.

Parameters

`-help`	Prints a brief description of the `check_safety_mechanism` command. For a detailed description of the command, use the `man` command: `man check_safety_mechanism`.
`-out_file` *file_name*	Writes the report to the specified file. If omitted, no report file is generated.

Report Content

The report contains one section per safety mechanism, listing all violations (if any) of that safety mechanism, grouped by type.

Safety mechanisms of type `dcls` (dual-core lockstep) have the following violation types:

- dcls group overlap violations: Two exclusive dcls groups overlap.
- dcls group spacing violations: Two exclusive dcls groups are closer than permitted.
- dcls inst placement violations: An inst belonging to a dcls group is placed outside of that group's boundary.
- dcls internal net routing violations: A net connected only to the insts inside a single dcls group is routed outside that group's boundary.
- dcls interface net routing violations: A net connected to insts both inside and outside a dcls group is routed inside the boundary of an exclusive group.
- dcls clock isolation violations: A clock net connected to a dcls group is driving loads outside that group.

Safety mechanisms of type `tmr` (triple modular redundancy) have the following violation types:

- tmr spacing violations: Two tmr insts from the same safety mechanism are placed closer than permitted.
- tmr clock isolation violations: A clock net driving a tmr inst is also driving other insts.

Example

- The following command checks all the safety mechanisms and writes the report to the `safety_report.rpt` file:

  ```
  check_safety_mechanism -out_file safety_report.rpt
  ```

Related Information

- read_safety_tmr
- read_usf
- reset_usf

- write_usf

read_safety_tmr

```
read_safety_tmr
[-help]
tmr_info_file
-failure_mode failure_mode_name
-safety_mechanism safety_mechanism_name
```

Reads the triple modular redundancy (TMR) information file. For designs with TMR logic already inserted, either in the register-transfer level (RTL) or with third party tools, this command identifies the existing TMR logic and assimilates it into the Unified Safety Format (USF).

You can issue the `read_safety_tmr` command multiple times to build up information in cases where there are multiple different safety mechanism names or failure mode names. However, this may be done only for new safety mechanism and failure mode names. You cannot accumulate TMR information by reusing a safety mechanism or failure mode name that has been already read in with the `read_safety_tmr` command.

Parameters

`-help`	Prints a brief description of the `read_safety_tmr` command. For a detailed description of the command, use the `man` command: `man read_safety_tmr`.

tmr_info_file	Specifies the name of the TMR information file. This is a text file listing each flip-flop and its accompanying cloned flip-flops where TMR has already been applied. Optionally, the file may also list the names of the voter cells that are used.
	
	The TMR information file has the following format:
	
	`<parent_FF1> <clone_FF1A> <clone_FF1B> <voter1A> <voter1B>`
	`...`
	`<parent_FF2> <clone_FF2A> <clone_FF2B> <voter2A> <voter2B>`
	`...`
	`...`
	
	The instance names may be supplied with the full path including the design name at the root. If the design name is not given at the root of the instance path for a given instance, that instance is assumed to be in the current design. The instance names are separated by white space.
	
	Comments are allowed in this file and must be preceded by #.
	
	Blank lines are also allowed.

`-failure_mode` *failure_mode_name*	
	Specifies the name of the failure mode for parent flops. The failure mode for clone flops will be *<failure_mode_name>*`_clones`. The failure mode for voter cells will be *<failure_mode_name>*`_voters`.
`-safety_mechanism` *safety_mechanism_name*	
	Specifies the name of the safety mechanism for the TMR logic.

Related Information

- check_safety_mechanism
- read_usf
- reset_usf
- usf_version
- write_usf

read_usf

```
read_usf
[-help]
USF_file
```

Reads in a Unified Safety Format (USF) file specifying the safety intent of your design.

Parameters

`-help`	Prints a brief description of the `read_usf` command. For a detailed description of the command, use the `man` command: `man read_usf`.
`USF_file`	Specifies the name of the USF file to be read.

Example

- The following command reads in the USF file named `myFile.usf`:

  ```
  read_usf myFile.usf
  ```

Related Information

- `check_safety_mechanism`
- `read_safety_tmr`
- `reset_usf`
- `usf_version`
- `write_usf`

reset_usf

```
reset_usf
[-help]
```

Resets the Unified Safety Format (USF) Physical safety information and related database attributes completely.

Parameters

`-help`	Prints a brief description of the `reset_usf` command. For a detailed description of the command, use the `man` command: `man reset_usf`.

Related Information

- `check_safety_mechanism`
- `read_safety_tmr`
- `read_usf`
- `usf_version`
- `write_usf`

usf_version

```
usf_version
[-help]
```

Retrieves the version of the USF Physical being used to interpret the USF commands.

Parameters

`-help`	Prints a brief description of the `usf_version` command. For a detailed description of the command, use the `man` command: `man usf_version`.

Related Information

- `check_safety_mechanism`
- `read_safety_tmr`
- `read_usf`
- `reset_usf`
- `write_usf`

write_usf

```
write_usf
[-help]
USF_file
```

Writes the safety intent of your design to the specified Unified Safety Format (USF) file.

Parameters

`-help`	Prints a brief description of the `write_usf` command. For a detailed description of the command, use the `man` command: `man write_usf`.
`USF_file`	Specifies the name of the USF file to be saved.

Example

- The following command saves the USF information in the `myFile.usf` file.

  ```
  write_usf myFile.usf
  ```

Related Information

- `check_safety_mechanism`
- `read_safety_tmr`
- `read_usf`
- `reset_usf`
- `usf_version`

```

Launches an Innovus™ Implementation System session. The `innovus` command starts one of the

following products:

- Innovus Implementation System
- Innovus Implementation System Basic
- Virtuoso® Digital Implementation
- Virtuoso® Digital Implementation XL
- First Encounter® L
- First Encounter® XL

For an overview of the products and product licensing, see Product and Licensing Information chapter in the *Innovus User Guide.*

To start an Innovus session, type the `innovus` command with the appropriate parameters on the UNIX/Linux command line. If you type the command without parameters, the software starts in GUI mode and creates a log file and a command file. The system attempts to check out the license with the most functionality, then the license with the next most functionality, and so on.

Parameters

`-help`	Writes out the usage and options with brief descriptions.
`-abort_on_error`	Exits if an error is detected at any point. If any Tcl command returns `TCL_ERROR` to the top level, or any `Error (XXX): ...` message occurs, the process will exit.
`-batch`	Runs without interactive prompt. After all the options, including `-execute` and `-files`, are processed, the job exits.
`-cds_lib_file` *`in_file`*	
	Loads the specified file instead of the default `cds.lib` file in the current directory to obtain the names and locations of OpenAccess libraries. The `cds.lib` file is used to list the OpenAccess library names, and their physical locations.

`-cpus` *value*	Specifies the number of CPUs to be used for multi-threading on current host. This calls the appropriate Tcl command to set the local cpu count. This happens before any `-execute` or `-files` commands are processed. This may require extra multi-CPU licenses to be checked out (see `-lic_multi_cpu`).
`-db` *dir*	Specifies the DB directory to be read. This option calls `restoreDesign` internally. Example: innovus -db *path*/*dbName.enc.dat* The specified DB directory is read before `-execute` or `-files` is invoked. **Note**: The database being restored with `-db` should not be an Integrated Hierarchical Database (iHDB). If you want to restore an iHDB database, use `-ihdb` *dir* instead. The `-db` and `-ihdb` options cannot be used together.
`-disable_user_startup`	Reads only the init file in the installation hierarchy. Does not read init files in the home or current directory. This option suppresses the default loading from the home and current directory, which can be used to guarantee there are no local over-rides to various project settings. See the "*Initialization Files*" section for the init files that are loaded by default.
`-execute` *list_of_Tcl_commands*	
	Specifies the Tcl commands to be executed at startup, as a quoted string.
`-files` *in_file_list*	Specifies one or more Tcl files to be sourced at startup, after `-execute` commands are processed.

`-ihdb` *`dir`*	Specifies that the Integrated Hierarchical Database (iHDB) directory is to be read, such as `xxx/my_design/placed`. This option calls `restore_module_model` internally. Example: `innovus -ihdb` *`iHDB_path/cell/tag`* The specified iHDB directory is read before `-execute` or `-files` is invoked. The specified iHDB should already have been created with `create_module_model`. To learn more about the iHDB flow, refer to the "*Integrated Hierarchical Database*" section in the Hierarchical and Prototyping Flow chapter of the *Innovus User Guide*. **Note**: If you want to restore a non-iHDB database, use the `-db` *`dir`* option instead. The `-db` and `-ihdb` options cannot be used together.
`-lic_multi_cpu` *`lic_list`*	
	Controls which licenses are to be used for higher multi-CPU usage in priority order from left to right. The allowed license names are: `invs_cpu`: Innovus CPU Accelerator Option `invs` - Innovus Implementation System `invsb` - Innovus Implementation System Basic `fel`: First Encounter® L `fexl`: First Encounter® XL For example, `-lic_multi_cpu "fel fexl"` will try to check out `fel` first, and then `fexl`. The licenses will not be checked out until a Tcl command tries to use extra cpus that require more licenses.
`-lic_options` *`lic_list`*	
	Specifies the order for dynamic checkout of extra option licenses when needed by a specific command. In some cases, more than one option license can be used to enable a given feature. You can control which options are allowed to be checked out, and in what priority (from left to right) when required during the run. For example, `-lic_options "encan encng enccco"` will only allow those three options to be

checked-out dynamically, and in that priority order.

The allowed license option names are:

`invs_hier` – Innovus Hierarchical Design Option

`invs_ms` - Innovus Mixed Signal Option

`invs_3d_ic` - Innovus 3D-IC Option

`invs_2nmGAA` - Innovus 2nm GAA Option

`invs_3nmGAA` - Innovus 3nm GAA Option

`invs_3nm` - Innovus 3nm Option

`invs_5nm` - Innovus 5nm Option

`invs_7nm` - Innovus 7nm Option

`invs_10nm` - Innovus 10nm Option

`invs_20nm` - Innovus 20nm Option

`invs_hfr` - Innovus HFR Option

`invs_gigaplace` - Innovus GigaPlace XL Option

`invs_gigaplace_gxl` - Innovus GigaPlace GXL Option

`qrcaa` - Quantus Advanced Analysis GXL Option

`enclp` - Encounter Low Power GXL Option

`encan` - Encounter Advanced Node GXL Option

`enccco` - Encounter Clock Concurrent Opt GXL Option

`encng` - Encounter Next Generation (This license is used to enable beta features.)

`vdixl_capacity` - VDI-XL Block Capacity Option

`invs_vi` - Innovus Voltus InsightAI Option

`invs_ml` - Innovus Machine Learning Implementation Option

`invs_ehfs` - Innovus Early Hierarchical Floorplan Synthesis Option

`invs_dfm` - Innovus DFM Option

`invs_sc` - Innovus Superconducting Option

	`invs_automotive` - Innovus Automotive Option `tpsxl` - Tempus Timing Signoff Solution XL `tpsl` - Tempus Timing Signoff Solution L `vtsxl` - Voltus IC Power Integrity Solution XL `vtsl` - Voltus IC Power Integrity Solution L `vtsxm` - Voltus IC Power Integrity Solution - XM `vtsesd` - Voltus IC Power Integrity Solution - ESD `vtsaa` - Voltus IC Power Integrity Solution Advanced Analysis GXL Option Option licenses can be checked out dynamically when a specific Tcl command requires it. This may cause the Tcl script to stall and wait for a license, or to exit if the wait period expires.
`-lic_startup` *`lic_list`*	
	Requests one of these licenses at startup in priority order from left to right. The supported licenses are: `invs` - Innovus Implementation System `invsb` - Innovus Implementation System Basic `fexl` - First Encounter® XL `vdixl` - Virtuoso® Digital Implementation XL. `vdi` - Virtuoso® Digital Implementation `fel`: First Encounter® L For example, `-lic_startup "fexl fel"` will try to check out `fexl` first, and then `fel`. The checkouts will be attempted repeatedly until one succeeds or the `-wait` period expires.
`-lic_startup_options` *`lic_list`*	
	Specifies additional option licenses needed at startup. If not provided, they will be checked out when needed during the run. The allowed license names are: `invs_hier` – Innovus Hierarchical Design Option

`invs_ms` - Innovus Mixed Signal Option

`invs_3d_ic` - Innovus 3D-IC Option

`invs_2nmGAA` - Innovus 2nm GAA Option

`invs_3nmGAA` - Innovus 3nm GAA Option

`invs_3nm` - Innovus 3nm Option

`invs_5nm` - Innovus 5nm Option

`invs_7nm` - Innovus 7nm Option

`invs_10nm` - Innovus 10nm Option

`invs_20nm` - Innovus 20nm Option

`invs_hfr` - Innovus HFR Option

`invs_gigaplace` - Innovus GigaPlace XL Option

`invs_gigaplace_gxl` - Innovus GigaPlace GXL Option

`qrcaa` - Quantus Advanced Analysis GXL Option

`enclp` - Encounter Low Power GXL Option

`encan` - Encounter Advanced Node GXL Option

`enccco` - Encounter Clock Concurrent Opt GXL Option

`encng` - Encounter Next Generation (This license is used to enable beta features.)

`vdixl_capacity` - VDI-XL Block Capacity Option

`invs_vi` - Innovus Voltus InsightAI Option

`invs_ml` - Innovus Machine Learning Implementation Option

`invs_ehfs` - Innovus Early Hierarchical Floorplan Synthesis Option

`invs_dfm` - Innovus DFM Option

`invs_sc` - Innovus Superconducting Option

`invs_automotive` - Innovus Automotive Option

`tpsxl` - Tempus Timing Signoff Solution XL

`tpsl` - Tempus Timing Signoff Solution L

	`vtsxl` - Voltus IC Power Integrity Solution XL `vtsl` - Voltus IC Power Integrity Solution L `vtsxm` - Voltus IC Power Integrity Solution - XM `vtsesd` - Voltus IC Power Integrity Solution - ESD `vtsaa` - Voltus IC Power Integrity Solution Advanced Analysis GXL Option For example, `-lic_startup_options "enccco encan"` will try to check out both `enccco and encan` when Innovus starts up. The checkouts will be attempted repeatedly until it succeeds or the `-wait` period expires.
`-lic_stack {1 | 2}`	Specifies the number of licenses to stack for stackable licenses. Some startup licenses that have limited instance counts can be stacked so that multiple licenses can be checked-out to increase the instance limit. Innovus allows stacking of two `vdi` or `vdixl` licenses to increase the instance limit from 50,000 to 100,000. For example, `-lic_stack 2` combined with `-lic_startup vdi` would check out two vdi licenses to allow 100,000 instances. *Default*: `1`
`-log` *`prefix`*	Specifies the prefix for the `.log`, `.cmd`, and `.logv` files. If three arguments are given, such as `-log "a b c"`, then the three names are used exactly without any extension added. So, `-log "mylog mycmd mylogv"` will result in `mylog mycmd mylogv` files. The default for *`prefix`* is `innovus`. So if `-log` is not specified, `innovus.log`, `innovus.cmd`, and `innovus.logv` files will be created. If you specify `-log test`, the tool creates `test.log`, `test.cmd` and `test.logv` files. The `.log` file contains the normal logging output, the `.cmd` file contains the Tcl commands that were executed, and the `.logv` file contains a super-set of the .log output plus "verbose" debugging output that is

	needed only for detailed debugging. If the `.log` file already exists, an integer is added to the end of all the files to make them unique. This means if `-log test` is specified, the tool will create `test.log test.cmd test.logv` for the first run, `test.log1 test.cmd1 test.logv1` for the next run, and so on. Only the existence of .log is checked, the existence of the .cmd or .logv files is not checked. The `-overwrite` option can be used to disable this behavior and overwrite an existing .log file. If the *`prefix`* value has a period in it, the last extension is stripped off for the `.cmd` and `.logv` usage. For example, `-log out.log` will result in `out.log out.cmd out.logv` files, and `-log out.a.log` will result in `out.a.log out.a.cmd out.a.logv` files. However, if the last extension in the *`prefix`* value is `.gz`, it will be retained. For example, if you specify `-log test.gz`, the tool will create `test.log.gz`, `test.cmd.gz`, and `test.logv.gz` files. If you specify `-log "test.log.gz test.cmd test.logv.gz"`, the tool will not gzip all files but will create files exactly as specified: `test.log.gz`, `test.cmd`, and `test.logv.gz`. If `test.log` or `test.log.gz` already exists, an integer is added to make the new files unique: `test.log1.gz`, `test.cmd1`, and `test.logv1.gz`. If there is an additional extension before `.gz` , it is stripped off. You can disable any given file by using `/dev/null`. For example, `-log "my.log /dev/null /dev/null"` will only create `my.log`. *Default*: `innovus.log` **Note**: If you provide the log file name under a directory path and the directory path does not exist, Innovus will create the directory path and save the log file under the directory.
`-no_cmd`	Specifies that the `.cmd` file should not be created.
`-no_gui`	Disables GUI and Tk support. GUI will not be available later in the session.
`-no_logv`	Specifies that the verbose log file should not be created.
`-overwrite`	Overwrites an existing .log file (and associated `.cmd` and `.logv` files) instead of adding an integer to make the files unique.

`-stylus`	Launches the Innovus Stylus Common UI interface. This changes the Tcl commands to the Stylus Common UI interface described in the Innovus Stylus Common UI Text Reference Manual and the Stylus Common UI Database Object Information manuals. See the Innovus Stylus Common UI Migration Guide for a summary of the changes.
`-version`	Returns the program version information.
`-wait` *minutes*	Specifies the number of minutes the system waits for a license to become available before exiting. *Default:* 0 (no wait time) *Value range:* 0 to 10,000

Initialization Files

By default, various initialization files are loaded at startup, if they exist. They can be used to configure the GUI, load utility Tcl files, or configure Innovus settings. The initialization files are read in the following sequence:

1. `~/.cadence/innovus/{gui.pref.tcl, gui.color.tcl, workspaces}` in the home directory if the GUI is enabled. These files are intended to be created by *View -> Set Preference* and V*iew -> All Colors -> Save* options for a specific user.
2. `.cadence/innovus/{gui.pref.tcl, gui.color.tcl, workspaces/}` in the current directory if the GUI is enabled. These files are intended to be created by *View -> Set Preference* and V*iew -> All Colors -> Save* options for any user working in this directory.
3. `<install_dir>/etc/innovus/enc.tcl` in the installation directory. This is intended for CAD teams that want to set Tcl parameters, customize the GUI, or add user-defined Tcl commands that affect all users of this release.
4. `~/enc.tcl` in the home directory. This is intended for user-specific setting that should affect only one user.
5. `./enc.tcl` in the current directory. This is intended for design-specific setting that should affect only designs in this directory.

Note: The GUI files are not loaded in the non-GUI mode.

If the `-stylus` parameter is specified, the initialization files are loaded in the following order instead:

1. `~/.cadence/innovus/{gui.pref.tcl, gui.color.tcl, workspaces}` in the home directory if

the GUI is enabled.

2. `.cadence/innovus/{gui.pref.tcl, gui.color.tcl, workspaces/}` in the current directory if the GUI is enabled.
3. `<install_dir>/etc/innovus/innovus.tcl` in the installation directory.
4. `~/.cadence/innovus/innovus.tcl` in the home directory.
5. `./.cadence/innovus/innovus.tcl` in the current directory.
6. `./innovus_startup.tcl` in the current directory.

Note: The `-stylus` usage sets the `source_verbose` root attribute to `true` at startup. The GUI preference init files (1 and 2 above) ignore this setting, but the non-GUI preference initialization files above (3, 4, 5, and 6) will use verbose logging by default. If the shell envar `CDS_STYLUS_SOURCE_VERBOSE` exists and has a boolean value, then the `source_verbose` attribute will be set to the envar value at startup. So you can turn off verbose logging at startup by using the following command:

```
setenv CDS_STYLUS_SOURCE_VERBOSE 0
```

Setting Up the Run-Time Environment

If *install_dir* is the location of your Innovus installation, you should set up your run-time environment like this:

- Add the *install_dir*`/bin` directory to your path. The `bin` directory has links to all the public executables in the install hierarchy.
- If you want the legacy Innovus man pages to be available from the Unix `man` command, you can add *install_dir*`/share/innovus/man` to your `MANPATH` envar.
- If you want the Tcl man pages to be available from the Unix `man` command, you can add *install_dir*`/share/tcltools/man` to your `MANPATH` envar.

For example, you might add this to your startup shell script:

```
set install_dir = /tools/innovus16.2/lnx86

set path = ($install_dir/bin $path)

setenv MANPATH $install_dir/share/innovus/man:$install_dir/share/tcltools/man:$MANPATH
```

Note: When Innovus launches, it automatically adds either the legacy or the Innovus Stylus Common UI man pages (depending on the `-stylus` option) and the Tcl man pages to the beginning

of the current `MANPATH` inside Innovus. Therefore, from within Innovus, the `man` command will see both sets of man pages before any other man pages.

Temporary File Locations

Each Innovus session creates its own temporary directory to store temporary files at the beginning of the run.

If you have the write permission, the tool creates `tmp_dir` under the current directory (.). If not, `tmp_dir` is created in `/tmp`. If the Unix envar `TMPDIR` is set, then the `tmp_dir` directory is created inside `$TMPDIR`.

The name of the `tmp_dir` directory will look like:

```
innovus_temp_[pid]_[hostname]_[user]_xxxxxx
```

Where `_xxxxxx` is a string added to make the directory unique. For example:

```
innovus_temp_10233_farm254_bob_nfp9ez
```

The temporary directory is automatically removed on exit or if the run terminated with a catchable signal (e.g. `SIGSEGV`).

The LEF to OpenAccess translator can be used to convert LEF files into equivalent OpenAccess

data. It supports three main styles of use:

1. Converting the technology information, such as layers, DRC rules, via rules, vias, and so on, into an OA tech file. This OA techfile is sufficient for Innovus use but is not really usable for Virtuoso because it does not contain information about custom layers below `metal1`, pcells, and so on. This techfile can be read by `techLoadDump` to create an ASCII techfile and then users can cut-and-paste the necessary information, such as DRC rules, into a Virtuoso OA PDK ASCII techfile to create a merged OA techfile.
2. Creating an incremental techfile using the `-pnrLibDataOnly` option that only has technology data that is dependent on the standard cell library, such as default routing rule (`LEFDefaultRouteSpec)`, non-default rules (NDRs), sites, and so on.
3. Converting the LEF macros into OA abstract cellviews.

Innovus uses a Cadence version of the LEF to OpenAccess translator that does more than the public domain `lef2oa` executable. The main difference is that many DRC rules that are expressed as properties that begin with `LEF58_` (for example, `PROPERTY LEF58_SPACING "..." ;`) are understood and mapped directly to the correct OA foundry constraints. In general, the rules needed for 28nm nodes and older are supported, while newer rules for 20nm and smaller are not supported. If you have any unsupported LEF property rules, they can be translated using Innovus commands instead. To do so, read the LEF into Innovus and use the `write_oa_techfile` Innovus command.

Parameters

`-commentChar` *`char`*	Identifies the comment character. *Default*: `#`
`-compress`	Allows libraries to be compressed.
`-compressLevel` *`zLevel`*	Defines the compression level to be used. *Default*: 1
`-createFixedViaDefs`	Allows the creation of fixed via definitions.
`-dataModel` *`version`*	

	Specifies a data model value of 0, 1, 2, or 3, which determines the data model for the OpenAccess database and determines how properties are mapped to the database. If this option is omitted, the default data model value of 4 is used unless the OA_DATAMODEL environment variable is set or a file named OA.DATAMODEL is found in the data directory of your OpenAccess installation hierarchy. *Default*: `4`
`-defaultRuleName` *name*	
	Specifies the name of the constraint group (default: `LEFDefaultRouteSpec`) to generate in the technology database. If a constraint group named `LEFDefaultRouteSpec` already exists in a technology database being modified, the translation fails unless the `-overwrite` option is used. *Default*: `LEFDefaultRouteSpec`
`-DMAttributes` *attributeList*	
	Specifies a list of design management (DM) attributes that are associated with every library that this application creates. Attributes are specified as `name=value` pairs. There must be no space on either side of the equal sign, two or more pairs must be space-separated, and the list must be enclosed in quotes.
`-DMSystem` *sysName*	Specifies the DM system to be used for the library, which can be any DM plug-in available to the user. The DM plug-ins included with OpenAccess are `oaDMTurbo` or `oaDMFileSys`. The default DM system is `oaDMSystem`, which automatically selects between `oaDMTurbo` or `oaDMFileSys`. Use of the `oaDMTurbo` plug-in is not recommended.

`-h	-help`	Displays usage information.
`-layerMap` *`filelist`*	Specifies a quoted, space-separated list of one or more layer mapping files to be used during translation. You must specify the complete path for each layer map file.
`-layoutView` *`viewName`*	Specifies the view name used for FOREIGN container views. *Default:* `layout`
`-lef` *`file`*	Specifies the LEF file to import into the OpenAccess database.
`-lib` *`library`*	Specifies the name of the destination library. If the library exists, the library must contain a technology database or refer to a library with a technology database. If the specified library exists, new designs are created for macro definitions. If you redefine a macro in the file, a new design is created by overwriting the existing design. If the library does not exist, a library is created in the current working directory and will contain a technology database.
`-libDefFile` *`fileList`*	
	Specifies the library definitions (`lib.defs`) file to load. The path to the `lib.defs` file can be a full or relative path. If this option is omitted, the default search mechanism of the DM system is used to find and load the `lib.defs` file.
`-libPath` *`path`*	Specifies the path to the output library.
`-logFile` *`file`*	Specifies the log filename. If this option is omitted, the log filename defaults to `lef2oaCDS.log`.

`-lockColors`	Specifies that all shapes created from `PORT` and `PIN` definitions that have a `MASK` construct associated with them will have their locked state set to `true` in addition to having their color set.
`-mapConflicts`	Maps certain conflicts between incremental and base technologies to constraints and constraint parameter definitions.
`-noInfo` *`msgIds`*	Suppresses the specified INFO messages. *`msgIds`* is a quoted, space separated list of numbers. Each number in the list represents the numerical portion of the ID for the message you want to suppress. None of the numbers in the list may be zero. Suppressed messages do not appear on the terminal or in the log file.
`-noWarning` *`msgIds`*	Suppresses the specified WARNING messages. *`msgIds`* is a quoted, space separated list of numbers. Each number in the list represents the numerical portion of the ID for the message you want to suppress. None of the numbers in the list may be zero. Suppressed messages do not appear on the terminal or in the log file and are not included in the total of WARNING messages displayed in the summary.
`-overwrite`	Replaces MACROS in an existing design with the translated data. If this option is omitted, the default behavior is to update the existing library. This option does not affect the DBU value in an existing technology database.
`-pinLabels`	Creates pin labels in designs by using OpenAccess `oaAttrDisplay` objects on `oaTerms`. Labels are added on the `oaTerm` for each pin figure of the terminal at the location of the pin figure. See also the `-textLayer` and `-textHeight` options.

`-pnrLibDataOnly`	Maps only library-specific place and route information to an incremental tech, ignoring foundry rules. Recommended for converting a LEF file to an incremental technology database that references a technology database that has complete foundry information. LEF constructs `DIRECTION` and `PITCH`, along with `WIDTH`, `OFFSET`, and `WIREEXTENSION` (if specified) are mapped to constraints in the `LEFDefaultRouteSpec` type constraint group. `VIAS` and `VIARULES` defined are added to the `validRoutingVias` constraint in the `LDRS`. `NONDEFAULTRULES` are mapped to OA constraint groups, `SITES` are mapped to `oaSiteDefs`, and `MACROS` are mapped to abstract `oaDesigns`.
`-shared`	Allows other applications to access the output library while this application is running.
`-suffix` *string*	Adds the specified suffix to the constraint group definition names.
`-techDMAttributes` *attrList*	Specifies a list of DM attributes to be associated with every technology library created.
`-techDMSystem` *sysName*	Specifies the DM system to be used for the technology library, which is either `oaDMTurbo` or `oaDMFileSys`. The default is `oaDMTurbo`.
`-techLib` *library*	Specifies the name of a technology library to use when creating a new cell library. If the specified technology library does not exist, the library is created using the technology information in the LEF file.
`-techLibPath` *path*	Specifies the path to be used for creating a technology library specified by the `-techLib` argument. The is only used when the library specified by the `-techLib` argument does not exist.

`-techRefs` *libList*	Specifies the list of libraries that contain the master technology databases.
`-templateFile` *file*	Specifies a file containing arguments to `lef2oa`. You can specify a template file instead of entering a string of arguments on the command line.
`-textHeight` *value*	Specifies an integer value for the pin label text height in database units (DBU). The DBU value is set by `lef2oa` by using the DATABASE UNITS value in LEF. If `-pinLabels` is used, and this option is omitted, the pin label text height defaults to the DBU value in the technology database for maskLayout views.
`-textLayer` *value*	Specifies the layer used for pin label text. If `-pinLabels` is used, and this option is not specified, the pin label text layer defaults to text. If the specified layer does not exist in the technology database, it is added.
`-useFoundryInnovus`	Specifies that the LEF LAYER LEF58 properties constraints will be placed into the `foundry_innovus` constraint group. This option is required only when creating Rapid MSOA tech files for use by the mixed signal flow. For more information on Rapid MSOA PDKs, refer to the Technology Data Preparation chapter in the *Mixed Signal Interoperability Guide*.
`-view` *viewName*	Specifies the output view name. The default view name is `abstract`.
`-v`	Prints tool, format and library version information
`-version`	Prints tool and format version information

nagelfar

```
nagelfar
[<nagelfar.tcl options>]
[file1.tcl file2.tcl …]
```

Does the “lint type” checking of Innovus Tcl script files.

It finds many common Tcl errors, such as misspelled commands, using a Tcl variable before setting it.

The check-syntax command is a wrapper around the public-domain Tcl linter named nagelfar. Nagelfar automatically loads the Innovus syntax and plugin files and is therefore aware of Innovus commands and options. Nagelfar is available from http://sourceforge.net/projects/nagelfar. A recent version of nagelfar is included in the installation hierarchy at: `<install_dir>/share/nagelfar`.

Nagelfar is a wrapper around `<install_dir>/share/nagelfar/nagelfar.tcl`

The wrapper automatically loads the correct Innovus nagelfar syntax file and plugin file so that Innovus commands and options are understood by nagelfar. The files are loaded from:

```
<install_dir>/share/fe/nagelfar/innovus.syntaxdb.tcl
<install_dir>/share/fe/nagelfar/innovus.plugin.tcl
```

You can check the nagelfar documentation in the installation directory for details about its options, the checks it performs, and the steps to turn on or off various checks.

To run this command, you should have tclsh in your search path.

You can type `nagelfar -help` to see all the nagelfar.tcl options.

Options	Description
`-encoding <enc>`	Reads script with this encoding.
`-exitcode`	Returns status code 2 for any error or 1 for warning.
`-filter <p>`	Specifies to suppress any message that matches the global pattern.
`-glob <pattern>`	Adds matching files to scriptfiles to check.
`-gui`	Starts with GUI even when files are specified.
`-H`	Specifies a prefix each error line with file name.

`header <file>`	Creates a "header" file with syntax info for scriptfiles.
`-html`	Generates html-output.
`-instrument`	Instruments source file for code coverage.
`-markup`	Markup source file with code coverage result.
`-novar`	Disables variable checking.
`-prefix <pref>`	Specifies the prefix for line anchors (html output)
`-quiet`	Suppresses non-syntax output.
`-s <dbfile>`	Includes a database file. You can include more than one database file. If <dbfile> is "_", it adds the default database.
`-severity <level>`	Sets severity level filter to N/W/E (default N).
`-strictappend`	Enforces having an initialized variable in (l)append.
`-tab <size>`	Specifies the Tab size, default is 8.
`-WelseN`	Enforces else keyword. Default 1.
`-WexprN`	Sets expression warning level to N.
`-WsubN`	Sets subcommand warning level to N.
`1`	Does not warn on single commands. "if [apa] {...}" is ok.
`1 (def)`	Warns about shortened subcommands.
`2 (def)`	Warns about any unbraced expression.

Example

- The following example show the usage of `nagelfar` for file `a.tcl`:

```
innovus> nagelfar a.tcl
Checking file a.tcl
Line 2: W Unknown command "typo_in_cmd_name"
Line 3: E Unknown variable "abc"
```

Related Information

- `check_syntax` is the corresponding Tcl command that can be used directly inside Innovus.

oa2lef

```
oa2lef
-lef file
-lib library
[-cell cells]
[-h | -help]
[-libDefFile filename]
[-lockedColorsOnly]
[-logFile file]
[-noInfo msgIds]
[-noTech]
[-noWarning msgIds]
[-templateFile file]
[-useFoundryInnovus]
[-views viewName]
[-v]
[-ver version]
[-version]
```

This translator can be used to convert OpenAccess data into equivalent LEF data.

Innovus uses a Cadence version of `oa2lef` that does more than the public domain `oa2lef` executable. The main difference is that many DRC rules that are expressed as properties that begin with `LEF58_` (for example, `PROPERTY LEF58_SPACING "..." ;`) are understood and mapped to the correct LEF syntax. In general, the rules needed for 28nm nodes and older are supported, while newer rules for 20nm and smaller are not supported. If you have any unsupported LEF property rules, they can be translated into LEF using Innovus commands instead. To do so, read the OA techfile into Innovus, and use the Innovus `write_lef_library` command.

Parameters

`-cell cells`	Specifies a space-separated list of cells to translate.
`-help or -h`	Displays usage information.
`-lef file`	Specifies the output LEF file name.
`-lib library`	Specifies the name of the source library, containing a technology database.

`-libDefFile` *`filename`*	Specifies the `lib.defs` file to load. The path to the `lib.defs` file can be a full or relative path. If this option is omitted, the default search mechanism of the DM system is used to find and load the `lib.defs` file.
`-lockedColorsOnly`	Prints the colors of only the shapes with a locked state of `true` when mapping the oaFigs or oaVias belonging to oaPins to the LEF PINs and PORTs.
`-logFile` *`file`*	Specifies the log filename. If this option is omitted, the log filename defaults to `oa2lef.log`.
`-noInfo` *`msgIds`*	Suppresses the specified INFO messages. msgIds is a quoted, space-separated list of numbers. Each number in the list represents the numerical portion of the ID for the message you want to suppress. None of the numbers in the list may be zero. Suppressed messages do not appear on the terminal or in the log file.
`-noTech`	Specifies that the technology information is not output.
`-noWarning` *`msgIds`*	Suppresses the specified WARNING messages. *`msgIds`* is a quoted, space-separated list of numbers. Each number in the list represents the numerical portion of the ID for the message you want to suppress. None of the numbers in the list may be zero. Suppressed messages do not appear on the terminal or in the log file and are not included in the total of WARNING messages displayed in the summary.
`-templateFile` *`file`*	Specifies a file containing arguments to `oa2lef`. You can specify a template file instead of entering a string of arguments on the command line.
`-useFoundryInnovus`	Prints the `foundry_innovus` constraint group as LEF LAYER LEF58 properties. These constraints are found only in Rapid MSOA tech files that are used for the Cadence mixed signal implementation solution. For more information on Rapid MSOA PDKs, refer to the Technology Data Preparation chapter in the *Mixed Signal Interoperability Guide*.
`-v`	Prints tool, format, and library version information.
`-ver` *`version`*	Specifies the LEF version to write, which can be 5.3, 5.4, 5.5, 5.6, 5.7 or 5.8. The default version is 5.7.
`-version`	Prints tool and format version information

`-views` *viewName*	Specifies a space-separated list of views to translate. Only the first view name for a particular cell is used; all others are ignored.

clearDrc

```
clearDrc [-help]
```

Clears all design rule checking (DRC) markers in your design.

Note: Do not use the `clearDrc` command before using `ecoRoute` or any other routing command. This is because NanoRoute works only on the existing DRC/violation markers. The routing commands will not necessarily perform DRC checks in the routing halo regions if the violation markers are already cleared.

Parameters

`-help`	Prints a brief description of the `clearDrc` command usage. For a detailed description of the command, use the `man` command: `man clearDrc`

Related Information

- `verify_drc`
- The Identifying and Viewing Violations chapter of *User Guide*.

createMarker

```
createMarker
[-help]
[-bbox { x1 y1 x2 y2 } | -poly { x1 y1 x2 y2 ...}]
[-desc description]
[-layer {layerName | layerNumber}]
[-rulemap]
[-subtype subtypeName]
[-tool toolName]
[-type typeName]
```

Creates markers for violations in the database. Use this command to create a specific marker that has been created by a third party tool. The created markers can be saved and restored by `saveDesign`/`restoreDesign`.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `createMarker` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man createMarker`
`-bbox` *`x1 y1 x2 y2`*	Specifies the area of the bounding box of the marker. For example, `createMarker -bbox 100 100 100.5 100.5`. *Type:* Real
`-desc` *`description`*	Describes the marker. For example, `createMarker -desc "the user mark is non default rule spacing check"`. *Default:* `""` *Type:* String
`-layer {layerName | layerNumber}`	Specifies the layer. Following are few examples: • `createMarker -layer METAL2` creates a marker on layer METAL2. • `createMarker -layer VIA3` creates a marker on cut layer VIA3. • `createMarker -layer 4` creates a marker on layer METAL4. *Type:* String
`-poly {`*`x1 y1 x2 y2...`*`}`	Specifies the area of the bounding polygon of the marker.
`-rulemap`	Specifies if the marker needs to be created through `ruleMap`.
`-subtype` *`subtypeName`*	Specifies the marker subtype. For example, `createMarker -subtype user_spacing`. *Default:* `Other` *Type:* String
`-tool` *`toolName`*	Specifies the source software application. For example, `createMarker -tool Calibre`. *Default:* `Other` *Type:* String
`-type` *`typeName`*	Specifies the marker type. For example, `createMarker -type user_verify`. *Default:* `Other` *Type:* String

Example

- The following command generates a marker for tool named `Calibre` with type `METAL1` and subtype `S.1`:

  ```
  createMarker -bbox { 1 2 1 2 } -tool Calibre -type METAL1 -subtype S.1
  ```

  The violation browser displays the marker in the above example as follows:

  ```
  + Calibre
      + METAL1
          + S.1
              ...
  ```

- Suppose the cadence LPA tool has created the following marker on layer `METAL3`:

  ```
  CDNLitho;SPACING; Severity: 3; MARKER_INFO: "CD = 45.39"
  bbox = (468.248, 63.511) (468.310, 63.599)
  ```

  The following command creates a corresponding marker in the Innovus design:

  ```
  createMarker -bbox {468.248 63.511 468.310 63.599} -layer metal3 \
               -type CDNLitho -subtype Spacing
  ```

- The following command generates a polygon shape marker with the user description:

  ```
  createMarker -poly {100.0 100.0 194.0 100.0 194.0 238.0 168.0 238.0 168.0 288.0 100.0 288.0} \
  -tool User -desc "congested area"
  ```

get_signoff_verify_design_config

```
  get_signoff_verify_design_config
[-help]
[-abort_on_layout_error]
[-abort_on_missing_rulecheck]
[-area]
[-attach_instance_name]
[-attach_net_name]
[-attach_net_prop]
[-auto_merge_base_class]
[-config_file]
[-control_file
[-core_license]
[-die_area_as_boundary]
[-dp]
[-dp_timeout]
[-error_limit]
[-extra_options]
[-format]
[-ignore_blockage]
[-ignore_fill]
[-keep_data]
[-layer_map_file]
[-layer_range]
[-layers]
[-layout_path]
[-lib_name]
[-license_dp_continue]
[-license_stacking]
[-license_timeout]
[-merge]
[-merge_path]
[-mode]
[-mp]
[-mt]
[-net_map_file]
[-nets]
[-no_structure_name]
[-offset]
[-output_macros]
[-pegasus_bin]
[-process_node]
[-pvs_fill]
[-report_file]
[-rule_file_drc]
[-rule_file_smart_verify_lvs]
[-rule_selection_options]
[-run_name]
[-selected_inst]
```

```
[-skip_auto_load_results]
[-stripes]
[-structure_name]
[-transform_to_inst_master]
[-ui_data]
[-uniquify_cell_names]
[-units]
[-working_dir]
```

Prints parameters for the `signoff_verify_design` command. It also prints `rule_selection_options` for a given process node that can be combined with `all {} | beol {} | feol {}`.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `get_signoff_verify_design_config` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man get_signoff_verify_design_config`
`parameter_names`	Displays information for the specified parameters. You can specify one or more parameters. See `set_signoff_verify_design_config` for descriptions of the parameters you can specify.

Examples

- The following command displays the current setting of the `-stripes` parameter:
  `get_signoff_verify_design_config -stripes`
- The following command displays the current settings for all the `signoff_verify_design` parameters:
  `get_signoff_verify_design_config`

Related Information

- `set_signoff_verify_design_config`
- `signoff_verify_design`

get_verify_drc_mode

```
  get_verify_drc_mode
[-help]
[-area]
[-check_illegal_trim_shapes]
[-check_ndr_spacing]
[-check_only]
[-check_reverse]
[-check_routing_halo]
[-check_routing_halo_corner]
[-check_same_via_cell]
[-check_short_only]
[-check_trim_length]
[-check_uncolored]
[-disable_rules]
[-enable_post_passive_fill_check]
[-exclude_pg_net]
[-ignore_cell_blockage]
[-ignore_fill_wire]
[-ignore_non_rectangle_shapes]
[-ignore_trial_route]
[-layer_range]
[-limit]
[-max_wrong_way_halo]
[-nonDefault]
[-report]
[-use_min_spacing_on_block_obs]
[-quiet]
```

Displays the following information about a `set_verify_drc_mode` parameter in the Innovus console.

- Parameter name
- Current value
- Type (Boolean, string, and so on)
- Default value
- Whether the current value was set by user

Use this command when you want to retrieve current values of all or specified `set_verify_drc_mode` settings. If you do not specify any parameter, `get_verify_drc_mode` returns information on all the `set_verify_drc_mode` parameters.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `get_verify_drc_mode` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man get_verify_drc_mode`
`parameter_names`	Displays information for the specified parameters. You can specify one or more parameters. See `set_verify_drc_mode` for descriptions of the parameters you can specify.
`-quiet`	Displays the current settings for the specified parameters in Tcl list format only. If you specify `-quiet` without any parameters, the software displays the current settings of all `set_verify_drc_mode` parameters in Tcl list format.

Examples

- The following command displays the current setting of the `-limit` parameter:
  ```
  get_verify_drc_mode -limit
  ```
  The software displays the following information:
  ```
  -limit 1000 # int, default=1000
  1000
  ```
- The following command displays the current settings for all `set_verify_drc_mode` parameters:
  ```
  get_verify_drc_mode
  ```

Related Information

- The Identifying and Viewing Violations chapter of *User Guide*.
- `verify_drc`
- `set_verify_drc_mode`

loadDrc

```
loadDrc
[-help]
fileName
[-incremental]
[-orient {r0 | r90 | r180 | r270 | mx | mx90 | my | my90}]
[-origin x y]
```

Loads the specified Design Rule Checking (DRC) violation marker file. Use this command to load DRC markers, which are saved in DB format, into Innovus design. The `loadDrc` command is useful in situations when you want to load DRC violation markers without having to load an entire design.

For example, if during an Engineering Change Order (ECO), you find that only 25 of the 300 reported violations are actual violations that need to be corrected immediately, you can:

1. Delete the other 275 violations.
2. Save the 25 actual violations in a marker file using the `saveDrc` command.
3. Clear the violations from the design window.
4. Load the marker file containing the saved violation markers using the `loadDrc` command.

You can also use the `loadDrc` command in situations where, when correcting violations, the ECO editor didn't make changes in the way that you want. Because the editor removed the marker when it made the change, you cannot find the original violation in the design. You can use the `loadDrc` command to load the original marker file, then click on the violation, and zoom to the area in which you are working on.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `loadDrc` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man loadDrc`
`fileName`	Specifies the name of the marker file to be loaded.
`-incremental`	Loads the markers stored in the specified file incrementally. This means that the markers that are already loaded in memory will not be removed before new ones are loaded from the specified file.
`-orient {r0 | r90 | r180 | r270 | mx | mx90 | my | my90}`	
	Rotates all the DRCs available in the violation marker file with the specified orientation.
`-origin` *`x y`*	Specifies the origin coordinate of the DRC available in the violation marker file.

Example

The following command loads markers that were previously saved to the `VG.drc` file using `saveDrc`:

```
loadDrc VG.drc
```

Related Information

- The following sections in the Identifying and Viewing Violations chapter of the *User Guide*:
  - Viewing Violations With the Violation Browser
  - Clearing Violations

loadViolationReport

```
loadViolationReport
[-help]
-filename fileName
[-orient {r0 r90 ...}]
[-rulemap mapName ]
-type {Assura | Calibre | PVS | Hercules | ICV | CDNLitho | CDNCMP | inShapeLitho | CalibreLitho | DRV |
ClockTran | CLP | VerifyPower}
[-xoffset value ]
[-yoffset value]
```

Loads a violation marker file or a hotspot interface format (HIF) file in one of the following formats and creates markers that the Innovus software can interpret. Use this command to load third-party markers into Innovus:

- Assura™
- Calibre
- PVS
- Hercules
- ICV
- Chemical and Mechanical Polishing (CMP) HIF
- Transition violation report
- Low power violation reports
- Cadence litho hotspot
- NanoRoute litho
- inShapeLitho
- Calibre litho hotspot

After you load the file, you can view the markers in the Violation Browser. By cross-probing between Violation Browser and the design area, you can analyze the violations and take steps to resolve them. The Innovus Auto Query feature displays the rule names for the markers.

Note: The `route_fix_signoff_drc` command can be used to call NanoRoute, to attempt and fix the violations based on the markers from the external DRC tool.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `loadViolaltionReport` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man loadViolaltionReport`
`-filename` *`fileName`*	Specifies the marker file to load. Assura files must have a `.err` extension. Calibre files must have a `.db` extension.
`-orient {`*`r0 r90 ...`*`}`	Supports advanced orientation transforms for loading rotated DRC violation markers before loading. This helps in overlaying the design to the top of the layout.

`-rulemap` *`mapName`*	Specifies the rule map file for a PVS or Calibre Litho report. The rule map file provides the layer/error type information.
	
	`loadViolationReport` saves this information to the database. When the markers are created, the layer, error type, and object information can be identified on the GUI in the Violation Browser. NR could fix the converted drc markers, the supported drc types: `spacing`, `mincut`, `colorLoop`, `area`, `minhole`, `maxstackedvia`, `enclosure`, `width`, and `minstep`. For the unsupported types, it can be mapped with "other". The rule map file should be a txt file with 3 columns:
	
	`Rule_name Innovus_error_type layer_name`
	
	Below is an example:
	`M1.W_4.5 width metal1`
	`M1.A_0.048 minhole metal1`
	`M1.M_1 minstep metal1`

`-type {Assura | Calibre | PVS | Hercules | ICV | CDNLitho | CDNCMP | inShapeLitho | CalibreLitho | DRV | ClockTran | CLP | VerifyPower}`	

	Specifies the file type. The following file types contain violation markers: • Assura - For Assura violations • Calibre - For Calibre violations • PVS - For PVS violations • Hercules - For Hercules violations • ICV - For ICValidator report violations • CDNCMP - For Cadence CMP Predictor (CCP) violations • DRV - For transition violations (reportTranViolation) • ClockTran, CLP, and VerifyPower - For low power violations The following file types contain hotspot markers, which are used to identify areas susceptible to lithography problems: • CDNLitho (LPA as well as NanoRoute litho HIF) • inShapeLitho • CalibreLitho
`-xoffset` *value*	Specifies the X offset. When you specify the X and Y offsets, Violation Browser displays the violations at the correct coordinates after accounting for the offsets.
`-yoffset` *value*	Specifies the Y offset, which Violation Browser takes into account to displays violations at the correct coordinates.

Examples

- The following command loads a CDN Litho marker file named `LPA.hif`:

```
loadViolationReport -type CDNLitho -xoffset 0.05 -yoffset 0.05 -filename LPA.hif
```

- The following command loads a NanoRoute litho repair file named `NR.hif`:

```
loadViolationReport -type CDNLitho -filename NR.hif
```

- The following command loads a Calibre litho file named `litho.rdb`:

```
loadViolationReport -type CalibreLitho -filename litho.rdb -rulemap rule.map
Contents of rule map
====================
M1.W_4.5 width metal1
```

[-save]
[-selection string]
[-streamOutOptions string]
[-techFile string]
[-verify_function string]
```

Runs LPA on the selected design to flag Litho hotspots. It helps in creating, extracting, finding, and fixing patterns. This command uses squish and TVL patterns to find locations within a layout. Once a is pattern defined, you can use it for a variety of operations. Patterns can be extended to define via replacement, landing pad extensions, polygon insertions, and routing blockages. Patterns are commonly used to define markers for DRC or Litho hotspots.

Parameters

`-help`	Outputs a brief description that includes the type and default information for the `optimizePattern` parameters. For a detailed description of the command, use the man command: `man optimizePattern`
`-backout` *string*	Reverts the fixing on the nets.
`-check_locally`	Applies fixing with the local DRC check.
`-config string`	Specifies the name and path of the LPA custom configuration file. This file, if specified, controls all the run options of LPA.
`-create`	Streams out the Innovus design into a GDS file and loads it in `design_review` or `k2_viewer`. ⚠ Specify the stream out map file with `-mapFile`.
`-deck string`	Specifies the pattern deck to be used for LPA hotspot detection. ⚠ • The configuration variable, `lpaTechFile`, needs to be specified in the configuration file. • The LPA layer map needs to contain all the layers mentioned in the deck file.
`-dir string`	Specifies the LPA output directory. This directory contains individual subdirectories for each layer.

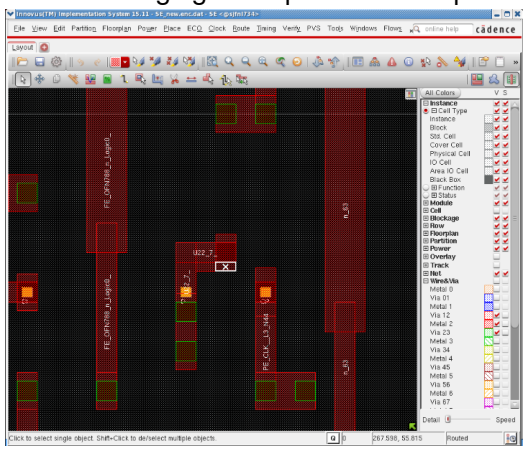
`-envLayers string`	Specifies the list of extra layers to be included in `streamOut` GDS/OASIS. ⚠ The layer number and data type of these extra layers need to be included in the LPA layer map.
`-exclude string`	Specifies the list of nets that need not be used while fixing hotspots.
`-excludeHalo string`	Specifies an extra halo around the marker to check the exclude nets. ⚠ This parameter works with `-exclude`.
`-extractSquish`	Produces squish patterns as opposed to TVL patterns, for extraction.
`-find`	Detects and fixes LPA hotspots at the time of run.
`-findLimit string`	Specifies the number of hotspots to be detected.
`-fix`	Helps LPA in applying the hints to fix hotspots.
`-fixLimit string`	Specifies the number of hotspots to be fixed.
`-gdsList string`	Specifies the name and path of the text file containing the list of GDS files for LEF abstracts.
`-hintsOnly`	Specifies LPA to turn off fixing of hotspots after detection. ⚠ The default behavior of the `-find` parameter is to find and fix hotspots.
`-include string`	Specifies the list of nets to be used while fixing hotspots.

`-incrCheck string`	Specifies the name and path of the HIF file to be used for incremental validation. This HIF file includes the locations that identify the areas affected by each hotspot fix. LPA reads these locations and performs incremental checking only in these areas. This reduces the time required for validation.
`-input string`	Specifies the path of a GDS. It opens design review with the given file.
`-layerMapFile string`	Specifies the path of LPA layer map. ⚠ It can also be specified by including the following string in the configuration file: `setConf layerMapFile`
`-layers string`	Specifies the list of layers to run on LPA. ⚠ It can also be specified by including the following string in the configuration file: `setConf layerOrder`
`-load`	Loads guideline fixing from the database.
`-mapFile string`	Specifies the name and path of the Stream Out Map file created by Innovus to map the GDS stream to the layers in the Innovus database. If the GDS List file and Stream Out Map file are specified, LPA runs on the potential IP blocks defined in these files.
`-markerLayers string`	Specifies the layers to be extracted in pattern extraction. ⚠ This parameter works along with `-markers`.
`-markers string`	Specifies the path to a marker file in the HIF/RDB format for pattern extraction.
`-noCompress`	Inputs GDS instead of `gds.gz`.

`-noViolationBrowser`	Prevents LPA from loading the detected hotspots to the Innovus Violation Browser.
`-oasis`	Ensures that the stream out process uses OASIS output format.
`-oasisList`	Specifies the name and path of the text file containing the list of OASIS files for LEF abstracts.
`-save`	Saves guideline fixing from the database.
`-selection`	Specifies a list of hotspot type and severity to be extracted in the following format: `[list <type1>:<level1> <type2>: <level2> …]`
`-streamOutOptions`	Enables additional `streamOut` command options.
`-techFile`	Specifies the path of non-default LPA Mx technology file.
`-verify_function`	Specifies the DRC function.

Examples

- The following command presents how to use `optimizePattern` to find the hotspots:
  ```
  optimizePattern -find -deck deck.cpaHook.xml -mapFile streamOut.map -streamOutOptions { -outputMacros } -dir Find_hook -layers "M2"
  ```
- The following command presents how to fix the patterns with the `hinsts` created:
  ```
  optimizePattern -find -deck deck.cpaHook.xml -mapFile streamOut.map -streamOutOptions { -outputMacros } -dir Find_hook -fix -layers "M2"
  ```
  The following figure depicts an example of a fixed location:



- The following command applies double via patterns:
  ```
  optimizePattern -find -deck deck.cpaDoubleVia.xml -dir Find_via -mapFile streamOut.map -streamOutOptions { -outputMacros } -layers "M2"
  ```
- The following command finds the double via patterns and fixes 200 of those:
  ```
  optimizePattern -find -deck deck.cpaDoubleVia.xml -dir Find_via -mapFile streamOut.map -streamOutOptions { -outputMacros } -layers "M2" -fix -findLimit 200
  ```

reportFreqViolation

```
reportFreqViolation
[-help]
[-outfile fileName]
[-selInstFile selInstFileName]
[-em_type {avg | peak | rms | all}]
[-excInstFile excInstFileName]
[-tableScale float]
[-detailed]
[-slew {min | max}]
[-sort {name | freq | minDiff | maxDiff | minFreq | maxFreq}]
[-reportFormat integer]
[-view viewName]
```

Runs electromigration (EM) analysis based on the frequency table defined in the Liberty library and generates a frequency violation report.

You must run the following commands prior to setting the `reportFreqViolation` command:

- `write_tcf` *activityFile*
- `read_activity_file -format TCF` *activityFile*
- `propagate_activity`
- `read_activity_file -set_net_freq true -format TCF activityFile`
- `set_analysis_view -setup default_view_setup -hold default_view_hold`
- `setAnalysisMode -checkType hold`

Note: If activity files are not defined, then the frequency can also be calculated on a pin by the clock period. There will also be a default frequency of 500M (toggle count 1e+9) if there is no clock phase on this pin.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `reportFreqViolation` parameter. For a detailed description of the command and all its parameters, use the man command: `man reportFreqViolation`
`-detailed`	Generates a detailed report containing information for instances with violations.
`-em_type {avg | peak | rms | all}`	Specifies the electromigration type. *Default:* `avg`

`-excInstFile` *excInstFileName*	Specifies an instance file that lists the names of instances to be excluded from the frequency violation report. **Note:** The instance file is a text file that contains a list of instances. Each instance name appears in one line in the file. The comments begin with "#". Leading or ending spaces in instance names are ignored.
`-outfile` *fileName*	Specifies the report file for the violation data.
`-reportFormat` *integer*	Specifies a format for the violation report. The report details vary according to the selected report format. You can specify report formats 0, 1, or 2. For more information on the report formats, see *Report Format* section below. *Default*: 0
`-selInstFile` *selInstFileName*	Specifies a file that lists the names of instances to be included in the frequency violation report. **Note:** The instance file is a text file that contains a list of instances. Each instance name appears in one line in the file. The comments begin with "#". Leading or ending spaces in instance names are ignored.
`-slew {min | max}`	Specifies the minimum or maximum slew value. *Default*: *min*
`-sort {name | freq | minDiff | maxDiff | minFreq | maxFreq}`	Sorts the instance-based frequency data by name, freq, minDiff, maxDiff, minFreq, and maxFreq. By default, the violation report is not sorted. You can use one of the following options: ◦ `name`: Name of a pin or arc. ◦ `freq`: Frequency value of a pin or arc. ◦ `minDiff`: Difference between freq and minFreq of a pin or arc. ◦ `maxDiff`: Difference between freq and maxFreq of a pin or arc. ◦ `minFreq`: Minimum frequency value of a pin or arc as defined in the frequency table. ◦ `maxFreq`: Maximum frequency value of a pin or arc as defined in the frequency table.
`-tableScale` *float*	Specifies the scale factor for EM table value. *Default:* `1.0`
`-view` *viewName*	Specifies the view for which to generate the frequency violation report. Use this parameter when working with multi-mode multi-corner (MMMC) designs.

Example

The following command reports instances that violate frequency constraints and lists them in the `freqViol.rpt` report file:

```
reportFreqViolation -outfile freqViol.rpt
```

Report Format

The report formats are described below.

- Format `0`
  The following command generates a report providing details of `minFreq`, `Freq`, `Tran`, `Cap`, `Remark`, and `Arc/Pin` and directs the output to report file `summaryViol.rpt`:

  ```
  reportFreqViolation -outfile summaryViol.rpt -reportFormat 0
  ```

  For example:

  ```
  minFreq    Freq    Tran     Cap         Remark    Arc/Pin
  5.985      1.009   0.0356   0.003103              tt0/data/r3/add_27/U1_1_6/Y
  ```

- Format `1`
  When `reportFreqViolation -reportFormat` is set to `1`, the report provides details as shown in the following example:

  ```
  Status   Remark   freq   minFreq   maxFreq   Arc/Pin
  [P]      *        1.009  5.985     5.995     tt0/data/r3/add_27/U1_1_6/Y
  ```

- Format `2`
  A detailed report is generated when `reportFreqViolation -reportFormat` is set to `2`, as shown in the following example:

  ```
  Status  Remark  freq   minFreq  maxFreq    minTran    maxTran    minCap         maxCap     Arc/Pin
  [P]     *       1.009  5.985    5.995      3.560e-02  3.790e-02  3.103e-03      3.103e-
  03  tt0/data/r3/add_27/U1_1_6/Y
  ```

  Where:

`Status`	Arc or pin status - `F` (fail), `V` (violation), `P` (pass), or `?` (unknown)
`Remark`	Indicates whether the pin is a clock
`freq`	Working frequency of the arc or pin
`minFreq`	Minimum frequency value taken from the frequency table
`maxFreq`	Maximum frequency value taken from the frequency table

`minTran`	Minimum slew value
`maxTran`	Maximum slew value
`minCap`	Minimum capacitance load
`maxCap`	Maximum capacitance load
`Arc/Pin`	Name of the arc or pin

run_pegasus_drc

```
run_pegasus_drc
[-help]
pvlFile
[-area {x1 y1 x2 y2}]
[-dp N]
[-error integer]
[-gds_file fileName | -oasis_file fileName]
-mapfile fileName
[-merge list_files]
[-noclean]
[-oa_view view_name]
[-output fileName]
[-repRoutingOnly]
[-report string]
[-stream_out]
[-units integer]
[-version]
[-work_directory working_directory]
```

Calls the Cadence Pegasus application to check DRC rules with a sign-off Pegasus rule deck.

This command is loaded only if you have a Pegasus installation and the Pegasus bin directory is in your Linux search path (e.g. the command pegasus can be run).

It is possible there are different options than described here depending on the version of Pegasus that you have installed. Use `run_pegasus_drc -help` to view the exact command syntax for your current Pegasus installation.

`run_pegasus_drc` will assemble the necessary files, call pegasus, and then read back the Pegasus violations so they are visible in the Innovus violation browser. The call to pegasus requires the appropriate Pegasus licenses in order to run.

The `run_pegasus_drc` command takes as input:

- A GDSII/OASIS layout file (normally created by `streamOut` command in Innovus)
- A layer map file
- A PVL (Physical Verification Language) rule file that contains the DRC rules to check
- The name of the output Pegasus results database file to be created
- Other optional arguments, such as distributed processing, area to check, number of errors to output, and so on.

Details about the various file formats can be found in the Pegasus documentation.

This command returns a status of `0 (tcl_OK)` or `1 (tcl_ERROR)`. Error messages or warnings are written to the Innovus log file.

Parameters

`-help`	Prints out the command usage.

pvlFile	Specifies the Pegasus rule file. Pegasus supports the same PVL rule deck, which is used by PVS.
-area {*x1 y1 x2 y2*}	
	Defines the area to be checked. The default is the entire chip window.
-dp *N*	Specifies the number of local cores to use. The default is 1.
-error *integer*	Specifies the maximum number of errors to output. The default is 1000000.
-gds_file *fileName*	Specifies a GDSII file to be read by Pegasus. If this parameter is specified, then the -mapfile parameter is ignored and streamOut is not run.
-mapfile fileName	Specifies a stream map file. In the usual case, the Innovus map file used by the Innovus streamOut command is specified. If this parameter is specified but the parameters -gds_file or -oasis_file is not specified, then the streamOut command is automatically run before Pegasus starts. The streamOut command is: streamOut .pegasus_xxx/*topcell*.gds.gz -mapFile *mapfile* -libName designLib -outputMacro -mode ALL [-units *integer*] Here, *topcell* is the top cell name of the design and *mapfile* is the file name specified with the -mapfile parameter. The optional -units *integer* is taken from the run_pegasus_drc -units value (if given). If not given, Innovus streamOut uses the Innovus DB unit value. Refer to the Innovus streamOut command for more details. For information on the map file format, see "About the GDSII or OASIS Map File" in the Importing and Exporting Designs chapter of the *Innovus User Guide*. **Note:** The -mapfile parameter is currently mandatory, even if it is not used due to the presence of -gds_file or -oasis_file. It will become optional in future release.
-merge *list_files*	Specifies the list of external stream files for streamOut.
-noclean	Specifies that the working directory, which is created while the run_pegasus_drc command is running, should not be removed after the run. The working directory name begins with .pegasus.
-oa_view *view_name*	Specifies the temporary OA view.
-oasis_file *fileName*	
	Specifies an Oasis file to be read by Pegasus. If this parameter is specified, then the -mapfile parameter is ignored and streamOut is not run.
-output *fileName*	Specifies the error markers result database in ASCII format. If not specified, *topCellName*.ascii is used.

`-repRoutingOnly`	Ignores standard cell violations. This parameter is equivalent to setting `"abort_on_layout_error no"` in Pegasus rule deck. The `abort_on_layout_error` checks for problems such as missing cell masters and duplicate cell references. If `-repRoutingOnly` is specified, Pegasus does not abort even if any of these errors happen. For more information, refer to the *Cadence Pegasus Developers Guide*.
`-report` *`fileName`*	Specifies the name of the Pegasus DRC summary report file to be created. When a relative path has been specified, the report file is created relative to the Innovus invocation directory. The default is no report file.
`-stream_out`	Uses the `streamOut` command for GDS in the OA flow.
`-units` *`integer`*	Specifies the user-defined DB unit value used for `streamOut` (see `-mapfile` above). This value should be consistent with the DB unit value in PVL rules.
`-version`	Prints the Pegasus version.
`-work_directory` *`working_directory`*	Specifies the current working directory.

Examples

- The following command runs sign-off DRC check with the gds file from Innovus, using the Pegasus rule file `28nm.pvl`. The gds file will be streamed out with the specified map file, `gds.map`, and the gds unit will be 1000 as specified:

  ```
  run_pegasus_drc 28nm.pvl -mapfile gds.map -units 1000
  ```

- The following command runs sign-off DRC check on routing layers within the specified area {0 0 100 100} using 8 local CPUs. The command will report only up to 1000 DRC issues:

  ```
  run_pegasus_drc 28nm.pvl -area {0 0 100 100} -dp 8 -error 1000 -mapfile gds.map
  ```

- The following command runs sign-off DRC check on the existing gds file `ios.gds`, and writes the report file to `pegasus.signoff.db`:

  ```
  run_pegasus_drc 28nm.pvl -report pegasus.signoff.db -gds_file ios.gds
  ```

Related Information

saveDrc

```
saveDrc
[-help]
fileName
[-force]
[-selected]
```

Saves DRC violation markers in the specified file. The `saveDrc` command is useful for situations where you want to save DRC violation markers without having to save the entire design.

For example, if during ECO you find that only 25 of the 500 reported violations are actual violations that need to be corrected immediately, you can:

1. Delete the other 475 violations.
2. Save the 25 violations in a marker file using the `saveDrc` command.
3. Clear the violations from the design window.
4. Load the marker file containing the saved violation markers using the `loadDrc` command.

Use the `saveDrc` command after markers have been flagged by any of the following commands:

- `verify_drc`
- `verifyMetalDensity`

You can also use this command to save Calibre violation markers after a Calibre file has been loaded using the `loadViolationReport` command.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `saveDrc` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man saveDrc`
`fileName`	Saves the DRC violation markers in a file with the specified name.
`-force`	Creates drc file with a 0 drc count. **Note:** When there is no drc in the design, drc file is not generated (Default).
`-selected`	Saves only the selected DRC violation markers.

Examples

The following command saves markers to the `VG.drc` file:

```
saveDrc VG.drc
```

```

Sets the global parameters for the `signoff_verify_design` command. Parameters specified with the `set_signoff_verify_design_config` command are used automatically whenever `signoff_verify_design` is being run. The settings are saved in the design database and will be restored after reloading a database saved earlier.

Use the `get_signoff_verify_design_config` command to return the current values of the `set_signoff_verify_design_config` parameters.

Parameters

`-help`	Prints a brief description of the `set_signoff_verify_design_config` command usage. For a detailed description of the command, use the `man` command: `man set_signoff_verify_design_config`
`-abort_on_layout_error {yes | no}`	Optional keyword to specify whether to continue processing of the design in case of layout error or exit.
`-abort_on_missing_rulecheck {yes | no}`	Optional keyword to specify whether to continue processing of the design in case of missed rule name.
`-area {x1 y1 x2 y2}]`	Optional keyword to specify a set of coordinates within which to trim metal fill.
`-attach_instance_name attribute_number`	Optional keyword to specify the instance name to attach.
`-attach_net_name attribute_number`	Optional keyword to specify the net name to attach.
`-attach_net_prop {{prop_name attr_num} ... }`	Optional keyword to specify the net property to attach.
`-auto_merge_base_class string`	Optional keyword to specify the list of cell base classes to auto merge. It must be one or combination of block, core, corner, cover, none, and pad.
`-config_file file_name`	Optional keyword to specify the Pegasus configuration file.

`-control_file` *file_name*	Optional keyword to specify PVL control file.
`-core_license` *license_combination*	Optional keyword to set exact combination of licenses to use.
`-die_area_as_boundary`	Optional keyword to write the die area as a polygon, that is, a boundary. Otherwise, the `streamOut` command writes the die area as a rectangle, that is, a box.
`-dp` *n*	Optional keyword to run Pegasus in multi-processor mode, n is number of processors. By default, it gets data from Innovus multi CPU usage option.
`-dp_timeout` *seconds*	Optional keyword to specify how long to wait for the worker processes to start.
`-erc_checks`	Optional keyword to enable ERC checks to run (also requires `-connect_all` option).
`-error_limit` *n*	Optional keyword to limit the number of output errors.
`-extra_options` *string*	Optional keyword to specify to run Pegasus with additional set of parameters defined in the command string.
`-format {stream | oasis}`	Optional keyword to specify the format of the flow.
`-ignore_blockage`	Optional keyword to ignore design blockage objects.
`-ignore_fill`	Optional keyword to ignore design fill objects.
`-keep_data` *key_file*	Keeps debugging data for R&D (requires a key file).
`-layer_map_file` *streamOut_map_file*	Optional keyword to specify `streamOut` layer map file.
`-layer_range {top_layer | bottom_layer}`	Optional keyword to specify top layer name and bottom layer name for selected range.
`-layers` *layer_names*	Optional keyword to specify that only rules that use selected layers will be processed.
`-layout_path` *string*	Optional keyword to specify path to layout file to use for the run instead of streaming out.
`-lib_name` *library name*	Optional keyword to specify library name.
`-license_dp_continue`	Optional keyword to specify that in DP if required number of licenses cannot be obtained, continue with fewer CPUs based on the number of licenses obtained.

`-license_stacking {larger_license | same_license}`	Optional keyword to specify license borrowing behavior.
`-license_timeout` *`number_of_seconds`*	Optional keyword to specify how long to wait (in seconds) if a license is not immediately available when the run starts. The default is 300 seconds.
`-light`	Enables rule selection preset for the light check.
`-merge` *`string`*	Optional keyword to specify the list of external stream files.
`-merge_path` *`string`*	Optional keyword to specify the list of directories with external stream files.
`-mode {ALL | FILLONLY | NOFILL | NOINSTANCES}`	Optional keyword to specify the mode. It identifies the layers to write.
`-mp` *`n`*	Optional keyword to specify number of workers.
`-mt` *`n`*	Optional keyword to specify number of threads per worker. The default is 1.
`-net_map_file` *`string`*	Optional keyword to specify the path to file containing net name mapping information.
`-nets` *`string`*	Specifies the list of net names to check in the `SmartVerify` LVS runs.
`-no_query`	Disables queries to get cell names and types from the Innovus database.
`-no_structure_name`	Optional keyword to merge GDSII file without loading an Innovus database when the `-merge` parameter is also specified.
`-offset {`*`x y`*`}`	Optional keyword to specify, in microns, the location of the design in the GDSII output file.
`-output_macros`	Optional keyword to write LEF abstract information such as LEF pin geometries and obstructions for macros.
`-process_node` *`foundary_node`*	Optional keyword to specify process node of used rule deck.
`-pvs_fill`	Optional keyword to merge the PVS fill data attached to the current database into the output GDSII/OASIS.
`-report_file`	Optional keyword to output cell name changed to the file.

`-rule_file_drc` *file_name*	Optional keyword to specify rule file for DRC run.
`-rule_file_smart_verify_lvs` *file_name*	Optional keyword to specify rule file for the `smart_verify_lvs` run.
`-run_name` *directory_name*	Optional keyword to specify name of run directory.
`-selected_inst`	Runs only the selected instance.
`-skip_auto_load_results`	Optional keyword to specify not to run Pegasus RV after successful run.
`-stripes` *number*	Optional keyword to specify the number of stripes that divide the design. The default is 1.
`-structure_name` *structure_name*	Optional keyword to specify the superstructure that consists of all geometries that the map file writes out.
`-transform_to_inst_master`	Transforms data to the selected instances master coordinate space.
`-ui_data`	Optional keyword to save data required for LVS/`smart_verify_lvs` probing and debugging.
`-uniquify_cell_names`	Optional keyword to create unique cell names if there are name collisions when the software merges files.
`-units {100 | 200 | 400 | 800 | 1000 | 2000 | 4000 | 8000 | 10000 | 20000}`	
	Optional keyword to specify the resolution for values in the GDSII/OASIS file.
`-working_dir` *working_directory*	Optional keyword to specify working directory.

Examples

Following are few examples of the set_signoff_verify_design_config command for defining other options required for the run:

- ```
  set_signoff_verify_design_config \
  -output_macros -die_area_as_boundary \
  -rule_file_drc $drcDeck\
  -layer_map_file $gdsOutMap \
  -control_file $drcCtrl \
  -units 2000 \
  -mp 4 -mt 4
  source merge.txt
  ```
  ```

- ```
  set_signoff_verify_design_config \
  -format stream \
  -merge $merge
  ```
- ```
  set_signoff_verify_design_config
  -process_node EXAMPLE_NODE \
  -process_node_data "./RULE/my_custom_template"
  ```

```

Sets the global parameters for the `verify_drc` command. Parameters specified with the `set_verify_drc_mode` command are used automatically whenever `verify_drc` is being run. The settings are saved in the design database and will be restored after reloading a database saved earlier.

Use the `get_verify_drc_mode` command to return the current values of the `set_verify_drc_mode` parameters.

`set_verify_drc_mode` is pre-configured with a set of default parameter values. The `-reset` parameter can be used to reset all or certain parameters to the default values.

Parameters

`-help`	Prints a brief description of each `set_verify_drc_mode` parameter, including type and default value. For a detailed description of the command and all its parameters, use the man command: man `set_verify_drc_mode`
`-area {x1 y1 x2 y2}`	
	Specifies the coordinates of the area to be verified. If the area specified is bigger than the chip boundary, all the objects inside and outside the die will be verified. If the `-area` parameter is not specified, the objects within the chip boundary are verified against the design rules. *Default:* `{0 0 0 0}`
`-check_illegal_trim_shapes {true | false}`	
	Checks the missing trim shapes for a fulfilled design.
`-check_ndr_spacing {true | false | auto}`	
	Checks non-default rule spacing as a hard rule. Following are the parameter values: • `true`: Checks all non-default rules. • `false`: Skips checking any non-default rule. • `auto`: Checks only the non-default rules with `hard_spacing`. *Default:* `auto` **Note:** When the `setNanoRouteMode -route_enforce_route_rule_on_special_net_wire` parameter is set to `true`, the non-default rule for special net is also checked.
`-check_only {all | regular | special | selected_net | selected | cell | default}`	

	Specifies which types of shapes are checked against the design rules. Following are the various values of this parameter: • `all`: Reports the violations between all routing shapes (regular and special) and all other shapes, including routing blockages and cell pin/obs shapes. • `regular`: Reports only the violations between regular routing shapes (normally created by NanoRoute) and all other shapes. It does not report violations between special routes, routing blockages and cell shapes. This is useful to find violations caused only by NanoRoute. • `special`: Reports only the violations between the special routes and all other shapes. It does not report violations between the regular routes, routing blockages, and cell shapes. This is useful while checking the power routing or pre-routed special routes with isolating these errors from other violations. • `selected_net`: Reports only the violations between the objects on the selected nets. Before running `verify_drc`, the nets need to be selected with the `selectNet` command. • `selected`: Reports only the violations on special wire objects/vias of the secondary PG nets with the specified user class. • `cell`: Reports only the violations between the shapes of cells including the objects inside the same cell and different cells. • `default`: This value is equivalent to specifying the `regular` and `special` at the same time. *Default:* `default`
`-check_reverse`	Reports the `CONVEXCORNER REVERSE` violation in the flow. *Default:* `false`
`-check_routing_halo {true | false}`	
	Checks for routing violations in the routing halo area. It also creates the DRV markers on any routing wire parallel to the block boundary or design boundary. *Default*: `false`
`-check_routing_halo_corner {true | false}`	
	Checks for routing violations in the halo corner. It also creates the DRV markers on all the routing wires in the halo corner. *Default*: `false`
`-check_same_via_cell {true | false}`	
	Checks the DRC issues in the same via cell. *Default*: `false`

`-check_short_only {true | false}`	
	Excludes checking all other DRCs except the short ones.
`-check_trim_length {true|false}`	
	Checks for the maximum length on the trim shape layer.
`-check_uncolored {true | false}`	
	Reports the color change violation when the DPT layer shapes have no color.
`-disable_rules {jog2jog_spacing | eol_spacing | cut_spacing | min_cut | enclosure | color | min_step | protrusion | min_area | out_of_die | off_manufacturing_grid | off_routing_track}`	

	Disables checking of the specified design rules. The supported values for the rule list are: `jog2jog_spacing`, `eol_spacing`, `cut_spacing`, `min_cut`, `enclosure`, `color`, `min_step`, `protrusion`, `min_area`, `out_of_die`, `off_manufacturing_grid`, and `off_routing_track`
	Use this parameter to make only specific checks with `verify_drc` and to skip checking certain design rules.
	Examples:
	The following set of commands disables the `eol_spacing` check and runs `verify_drc`. In other words, all other rules are checked by `verify_drc`, except `eol_spacing`.
	`set_verify_drc_mode -disable_rules {eol_spacing}`
	`verify_drc`
	Default: "" This means no rules are disabled.

`-enable_post_passive_fill_check {true | false}`	
	Checks if the track is fully filled for the `full_fill` trim layer.
`-exclude_pg_net {true | false}`	
	Disables the design rule checking on power and ground nets. *Default*: `false`
`-ignore_cell_blockage {true | false}`	
	Ignores geometries of cell blockages inside cell. *Default:* `false`
`-ignore_fill_wire {true | false}`	
	Ignores metal fill wires while checking DRCs.
`-ignore_non_rectangle_shapes {true | false}`	

	When set to `true`, this parameter ignores checking DRC markers for the objects with the non-rectangular shapes. When set to `false`, it checks DRC markers for the objects of all shapes. *Default*: `true`
`-ignore_trial_route {true | false}`	
	Ignores early global route objects while checking design rules. *Default*: `false`
`-layer_range {`*`layer1`* `[`*`layer2`*`]}`	
	Checks all the metal and cut layers between the specified bottom and top layers. You can use the full layer name, or abbreviations such as 1 for the routing layer number, etc. For example, `-layer_range {M1 M3}` will check all the metal and cut layers between `M1` and `M3` (including `M1` and `M3`). If *`layer2`* is not specified, it only checks design rules on *`layer1`*.
`-limit` *`value`*	Specifies the maximum number of errors to be reported. *Default:* 1000
`-report` *`filename`*	Specifies the name of the output report file, which will contain the detailed violation report. If the `-report` parameter is not specified, no external report will be saved. **Note:** The output file will be overwritten each time `verify_drc` is run, if the filename is not changed in the meantime. *Default:* `""`
`-max_wrong_way_halo` *`haloLength`*	
	Specifies the length up to which short jog shapes in halo area can be ignored. Routing halos are used to avoid cross-coupling between top-level and inside-the-block routes, and short jogs do not affect cross-coupling much. Normally, it is better to have some short jogs rather than more vias. When this option is specified, any segment with length less than *`haloLength`* is ignored for wrong way check, even if it overlaps with the halo region. `verify_drc` reports violations only for jog shapes with lengths greater than *`haloLength`*. *Default:* If you do not specify the `-max_wrong_way_halo` option, `verify_drc` uses 4* *`pitch`* as the default value, where *`pitch`* is the METAL2 routing pitch.
`-reset`	Resets all, or a list of specified parameters. If no parameter(s) are specified, this parameter resets all the parameters. Any values, that do not already match the default value, are reset and reported. Values, that already match the default value for a particular parameter, will not be reported. Example: `set_verify_drc_mode -reset -report -limit`
`-use_min_spacing_on_block_obs {true | false | auto}`	

	Performs as below with various parameter values: • `true`: Checks the Macro OBS with `minSpacing`. If the OBS SPACING was specified in the LEF file, it honors the SPACING from LEF. • `false`: Considers the Macro OBS as real metal to check the spacing rules. If the OBS SPACING was specified in the LEF file, it honors the SPACING from LEF. • `auto`: Considers the Macro OBS as real metal, if the OBS width is lesser than or equal to `maxWidth`. It also checks the Macro OBS with `minSpacing` if the OBS width is greater than `maxWidth`. If the OBS SPACING was specified in the `LEF` file, it honors the SPACING from LEF. *Default*: `auto`

setIsolatedCutRule

```
setIsolatedCutRule
[-help]
-spacing spacing1
[-cornerSpacing spacing2]
[-layer {cutLayer_list}]
```

Specifies spacing rules for isolated cut layers. Use this command before running the `verifyIsolatedCut` command to set the spacing rules against which `verifyIsolatedCut` should check isolated cuts.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `setIsolatedCutRule` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man setIsolatedCutRule`
`-cornerSpacing` *spacing2*	Specifies the maximum distance *spacing2* for the corner check. If all corners of the cut being validated have another cut within *spacing2* in the quadrant, the cut being checked is not a violation. **Note:** `-connerSpacing` is ignored if *spacing2* is smaller than `-spacing` *spacing1*.
`-layer` `{`*cutLayer_list*`}`	Sets the spacing rule for specified cut layers. If this parameter is not specified, the rule is applied for all cut layers.
`-spacing` *spacing1*	Specifies the maximum distance between the cut being validated to its nearest cut. If the actual distance is less than or equal to *spacing1*, `verifyIsolatedCut` does not report a violation. If the actual distance between the cut being validated and its nearest cut is greater than *spacing1*, `verifyIsolatedCut` reports a violation.

Examples

- The following command specifies that the maximum distance between the cut being validated and the nearest cut should be `0.5`:

  ```
  setIsolatedCutRule -spacing 0.5
  ```

- The following set of command specifies that the maximum distance between the cut being validated and the nearest cut should be `0.1`. In addition, the maximum distance for the corner check should be `0.5`. All cuts that violate these spacing rules are marked:

  ```
  setIsolatedCutRule -spacing 0.1 -cornerSpacing 0.5
  verifyIsolatedCut
  ```

setSnapGrid

```
setSnapGrid
[-help]
-layer {layer_list}
[-pitch x y]
```

Creates a global snapping grid for wiring (including metal fill shapes and via cuts). The grid defines the snap pitch, which is finer than the LEF `PITCH` for the specified layer. The grid is a multiple of the manufacturing grid. You can specify pitch value to check/set routing/metal fill segment's corner edges on the snap grid.

When you specify this command, the wires, metal fill shapes, and via cuts are snapped to this grid, and the edges of the shapes (for example, wires and vias) lie on the manufacturing grid. The `verify_drc` command can check that the shapes are on-grid.

> The snap grid is not saved in the Innovus database. To use the snap grid, you must run this command each time you load a design.

Verify geometry, power planning and routing, metal fill, and wire editing share the grid setting. Before running commands related to these areas, use `setSnapGrid` to define the grid as additional constraints.

For more information, see the commands `add_metal_fill_signoff`, `addViaFill`, or `verify_drc`.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `setSnapGrid` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man setSnapGrid`
`-layer {layer_list}`	Specifies the layers for the snap grid. You can specify metal layers as METAL1, METAL2, and so on, and cut layers as VIA12, VIA23, and so on.
`-pitch x y`	Specifies the pitch for the snap grid. The LEF `PITCH` must be a multiple (for example, 2x, 4x, 8x) of the snap grid for the specified layer. For example, if the LEF `PITCH` is 0.2 µ, you can specify a snap grid pitch for both x and y of `0.1` µ.

Example

The following commands set snap grid settings that are used while verifying geometry:

```
setSnapGrid -layer {1 2 V12 V23} -pitch 0.02 0.02
```

```

Enables configurable signoff checking at every design stage. It integrates Pegasus Signoff and Pegasus SmartVerify™ with Innovus. These checks help you maintain your designs DRC and LVS clean through the design cycle, and help achieve zero DRC and zero shorts out of Innovus. Running signoff checks late in the design involves long iterative runtimes, debug, fixing, and validation cycles. This impacts time to tapeout. This command allows you to run the signoff checks simultaneously without interrupting Innovus.

Parameters

`-help`	Prints a brief description of the `signoff_verify_design` command usage. For a detailed description of the command, use the `man` command: `man signoff_verify_design`
`-abort_on_layout_error {yes | no}`	Optional keyword to specify whether to continue processing of the design in case of layout error or exit.
`-abort_on_missing_rulecheck {yes | no}`	Optional keyword to specify whether to continue processing of the design in case of missed rule name.
`-area {x1 y1 x2 y2}`	Optional keyword to specify a set of coordinates within which to trim metal fill.
`-attach_instance_name attribute_number`	Optional keyword to specify the instance name to attach.
`-attach_net_name attribute_number`	Optional keyword to specify the net name to attach.
`-attach_net_prop {{prop_name attr_num} ... }`	Optional keyword to specify the net property to attach.
`-auto_merge_base_class string`	Optional keyword to specify the list of cell base classes to auto merge. It must be one or combination of block, core, corner, cover, none, and pad.

`-beol` *string*	Optional keyword to provide list of rule selection blocks for BEOL checks.
`-bg`	Optional keyword to run SVD job in background mode.
`-config_file` *file_name*]	Optional keyword to specify the Pegasus configuration file.
`-control_file` *file_name*	Optional keyword to specify PVL control file.
`-core_license` *license_combination*	Optional keyword to set exact combination of licenses to use.
`-die_area_as_boundary`	Optional keyword to write the die area as a polygon, that is, a boundary. Otherwise, the `streamOut` command writes the die area as a rectangle, that is, a box.
`-dp` *n*	Optional keyword to run Pegasus in multi-processor mode, n is number of processors. By default, it gets data from Innovus multi CPU usage option.
`-dp_timeout` *seconds*	Optional keyword to specify how long to wait for the worker processes to start.
`-drc`	Required keyword to run DRC check.
`-erc_checks`	Optional keyword to enable ERC checks to run (also requires `-connect_all` option).
`-error_limit` *n*	Optional keyword to limit the number of output errors.
`-extra_options` *string*	Optional keyword to specify to run Pegasus with additional set of parameters defined in the command string.
`-feol` *string*	Optional keyword to provide list of rule selection blocks for FEOL checks.
`-format {stream | oasis}`	Optional keyword to specify the format of the flow.
`-generate_context`	Generates context for an instance.
`-ignore_blockage`	Optional keyword to ignore design blockage objects.
`-ignore_fill`	Optional keyword to ignore design fill objects.
`-layer_map_file` *streamOut_map_file*	Optional keyword to specify `streamOut` layer map file.

`-layer_range {top_layer | bottom_layer}`	Optional keyword to specify top layer name and bottom layer name for selected range.
`-layers` *layer_names*	Optional keyword to specify that only rules that use selected layers will be processed.
`-layout_path` *string*	Optional keyword to specify path to layout file to use for the run instead of streaming out.
`-lib_name` *library name*	Optional keyword to specify library name.
`-license_dp_continue`	Optional keyword to specify that in DP if required number of licenses cannot be obtained, continue with fewer CPUs based on the number of licenses obtained.
`-license_stacking {larger_license | same_license}`	Optional keyword to specify license borrowing behavior.
`-license_timeout` *number_of_seconds*	Optional keyword to specify how long to wait (in seconds) if a license is not immediately available when the run starts. The default is 300 seconds.
`-light`	Enables rule selection preset for the light check.
`-load_results` *path_to_rundir*	Required keyword to run Pegasus RV with data from provided run directory.
`-lsf`	Optional keyword to specify to distribute the run to different machines using LSF.
`-merge` *string*	Optional keyword to specify the list of external stream files.
`-merge_library`	Generates single merged layout from the list of layouts to merge.
`-merge_path` *string*	Optional keyword to specify the list of directories with external stream files.
`-mode {ALL | FILLONLY | NOFILL | NOINSTANCES}`	Optional keyword to specify the mode. It identifies the layers to write.
`-mp` *n*	Optional keyword to specify number of workers.
`-mt` *n*	Optional keyword to specify number of threads per worker. The default is 1.
`-net_map_file` *string*	Optional keyword to specify the path to file containing net name mapping information.

`-nets` *string*	Specifies the list of net names to check in the `SmartVerify` LVS runs.
`-no_query`	Disables queries to get cell names and types from the Innovus database.
`-no_structure_name`	Optional keyword to merge GDSII file without loading an Innovus database when the `-merge` parameter is also specified.
`-offset {`*x y*`}`	Optional keyword to specify, in microns, the location of the design in the GDSII output file.
`-output_macros`	Optional keyword to write LEF abstract information such as LEF pin geometries and obstructions for macros.
`-process_node` *foundary_node*	Optional keyword to specify process node of used rule deck.
`-pvs_fill`	Optional keyword to merge the PVS fill data attached to the current database into the output GDSII/OASIS.
`-report_file`	Optional keyword to output cell name changed to the file.
`-rule_file_drc` *file_name*	Optional keyword to specify rule file for DRC run.
`-rule_file_smart_verify_lvs` *file_name*	Optional keyword to specify rule file for the `smart_verify_lvs` run.
`-run_name` *directory_name*	Optional keyword to specify name of run directory.
`-selected_inst`	Runs only the selected instance.
`-skip_auto_load_results`	Optional keyword to specify not to run Pegasus RV after successful run.
`-smartconnect`	Runs `smartconnect` check.
`-smart_verify_drc`	Required option to run `smart_verify_drc` check.
`-smart_verify_lvs`	Required option to run `smart_verify_lvs` check.
`-stripes` *number*	Optional keyword to specify the number of stripes that divide the design. The default is 1.
`-structure_name` *structure_name*	Optional keyword to specify the superstructure that consists of all geometries that the map file writes out.

`-transform_to_inst_master`	Transforms data to the selected instances master coordinate space.
`-ui_data`	Optional keyword to save data required for LVS/`smart_verify_lvs` probing and debugging.
`-uniquify_cell_names`	Optional keyword to create unique cell names if there are name collisions when the software merges files.
`-units {100 | 200 | 400 | 800 | 1000 | 2000 | 4000 | 8000 | 10000 | 20000}`	
	Optional keyword to specify the resolution for values in the GDSII/OASIS file.
`-working_dir` *`working_directory`*	Optional keyword to specify working directory.

Examples

- The following command prevents auto-loading of results in Results Viewer, after completion of the software run:
  `signoff_verify_design -drc -working_dir DRC_rundir3 -run_name DRCrun -skip_auto_load_results`
  This will not open the Results Viewer with results once the run completes. To load results from the run, use the `-load_results` parameter, as shown in the example usage below:
  `signoff_verify_design -load_results DRC_rundir3/drc/DRCrun`
- The following command runs DRC and cross probes the run results using the Design Review:
  `signoff_verify_design -drc -working_dir DRC_rundir4 -run_name DRCrun`
- The following command runs DRC checks on a specified area:
  `signoff_verify_design -drc -area {30 0 45 15} -working_dir DRC_rundir5 -run_name beolArea`
- The following command runs DRC checks on a specified layers:
  `signoff_verify_design -drc -layer_range {Metal4 Metal5} -working_dir DRC_rundir6 -run_name beolM4M5`
- The following command specifies a single layer to run checks:
  `signoff_verify_design -drc -layers {Metal4 Metal4} -working_dir DRC_rundir7 -run_name beolM4`
- Following is an example of using the `-beol`, `-layer_range`, `-working_dir`, and `-run_name` parameters together:
  `signoff_verify_design -drc -beol {all} -layer_range {Metal2 Metal4} -working_dir workdir_drc -run_name beol_M2M4`
- Following is an example of using the `-beol`, `-area`, `-working_dir`, and `-run_name` parameters together:
  `signoff_verify_design -drc -beol {all} -area {30 0 45 15} -working_dir workdir_drc -run_name beolArea`

Related Information

verify_antenna

```
verify_antenna
[-help]
[-detailed]
[-limit integer]
[-no_max_float_area]
[-nets {netNames} | -selected]
[-report filename]
[-use {all | signal | power | clock}]
```

Verifies the process antenna effect (PAE) in multi-thread mode with geometry-based check through the advanced NanoRoute antenna checker feature. It also supports advanced antenna rules, such as `LEF58_ANTENNADIFFGATEPWL` and `LEF58_ANTENNAMAXCUMAREA`. This command supports checking antenna rules on the backside metal areas for both PG and signal nets.

Note: Before running this command, ensure that the process antenna or maximum floating area keywords are specified in the LEF file and the signal nets are routed.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `verify_antenna` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man verify_antenna`
`-detailed`	Generates a report containing the PAE value for all layers of all the nets in a design, including those with no violations. If this parameter is not set, the report will include only those layers in the net that have violations. **Note:** To know the point of violation in the report, use the * mark.
`-limit integer`	Specifies the maximum number of error messages to report.
`-no_max_float_area`	Disables the verification of max floating area violation.
`-nets {netNames}`	Reports the specified named nets. If you specify one net name, you do not need the braces around the name.
`-report filename`	Specifies the name of the report file. The file contains the PAE violation information. *Default:* `design_name.antenna.rpt`
`-selected`	Reports the specified selected nets. Select nets using the `selectNet` command. If you specify one net name, you do not need the braces around the name.
`-use {all | signal | power | clock}`	Specifies the type of net to be checked.

Example

The following command verifies PAE violations in the routed design and generates a report file called `Test7.antenna.rpt`:

```
verify_antenna -report Test7.antenna.rpt
```

verify_drc

```
verify_drc
[-help]
[-area {{lx1 ly1 ux1 uy1} {lx2 ly2 ux2 uy2}...}]
[-check_illegal_trim_shapes]
[-check_ndr_spacing]
[-check_only {all | regular | special | selected_net | selected | cell | default}]
[-check_reverse]
[-check_routing_halo]
[-check_same_via_cell]
[-check_short_only]
[-check_trim_length]
[-check_uncolored]
[-enable_post_passive_fill_check]
[-exclude_pg_net]
[-ignore_fill_wire]
[-ignore_trial_route]
[-layer_range {layer1 [layer2]}]
[-limit max_error]
[-report filename]
[-view_window]
```

Checks for DRC violations and creates violation markers in the design database that can be seen on the GUI and browsed with the Violation Browser. Use the `set_verify_drc_mode` command to set global parameters for `verify_drc`. The parameters you specify with the `set_verify_drc_mode` command are then automatically used on running `verify_drc`. The settings are saved in the design so you need not set them each time you run `verify_drc`.

Use `get_verify_drc_mode` to return the current settings for the `set_verify_drc_mode` command. The `verify_drc` command also checks the DRC violations within the specified via. This helps in minimizing the DRC violations before the sign-off. In case the design has any DRC violation, the software flags DRC on all the via masters, such as PG via, regular via, via pillar, and via array. Use `set_verify_drc_mode -check_same_via_cell true` to check via cell violation.

Note: The `verify_drc` command checks only the placed instances. It skips checking the DRC for unplaced instances. This command adds the LEF rule in the description section of the *Violation Browser* to provide more information on the rule that is causing the DRC violation.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `verify_drc` parameter. For a detailed description of the command and all its parameters, use the man command: man `verify_drc`
`-area {{`*`lx1 ly1 ux1 uy1`*`} {`*`lx2 ly2 ux2 uy2`*`}...}`	Specifies the coordinates of one or more area regions to verify. It verifies the objects inside and outside the die, if the area regions are bigger than chip boundary. By default, objects within the chip boundary are verified against the DRC rules. For example, `verify_drc -area {0 0 100 100} {100 100 200 200}`.
`-check_illegal_trim_shapes`	Checks the missing trim shapes for a fulfilled design.
`-check_ndr_spacing`	Checks non-default rule spacing as a hard rule. **Note**: When the `setNanoRouteMode -route_enforce_route_rule_on_special_net_wire` parameter is set to `true`, the non-default rule for special net is also checked.

`-check_only {all | regular | special | selected_net | selected | cell | default}`	Specifies which types of shapes are checked against the DRC rules. Following are the various values of this parameter : • `all`: Reports the violations between all routing shapes (regular and special) and all other shapes, including routing blockages and cell pin/obs shapes. • `regular`: Reports only the violations between regular routing shapes (normally created by NanoRoute) and all other shapes. It does not report violations between special routes, routing blockages and cell shapes. This is useful to find violations caused only by NanoRoute. • `special`: Reports only the violations between the special routes and all other shapes. It does not report violations between the regular routes, routing blockages, and cell shapes. This is useful while checking the power routing or pre-routed special routes with isolating these errors from other violations. • `selected_net`: Reports only the violations between the objects on the selected nets. Before running `verify_drc`, the nets need to be selected with the `selectNet` command. • `selected`: Reports only the violations on special wire objects/vias of the secondary PG nets with the specified user class. • `cell`: Reports only the violations between the shapes of cells including the objects inside the same cell and different cells. • `default`: This value is equivalent to specifying the `regular` and `special` at the same time. *Default:* `default`
`-check_reverse`	Reports the `CONVEXCORNER REVERSE` violation in the flow. *Default:* `false`

`-check_routing_halo`	Checks for routing violations in the routing halo area. It also creates the DRC markers on any routing wire parallel to the block boundary or design boundary. Routing halos are used to avoid cross-coupling between top-level and inside-the-block routes. As short jogs do not affect cross-coupling much, they can be ignored even if they overlap with the halo region. Normally, it is better to have some short jogs instead of more vias. When the `-check_routing_halo` option is specified, any jog shape with length less than the value set for `set_verify_drc_mode -max_wrong_way_halo` is ignored for the wrong way check. `verify_drc` reports violations only for the jog shapes that have lengths greater than the `set_verify_drc_mode -max_wrong_way_halo` setting. *Default:* If the `set_verify_drc_mode -max_wrong_way_halo` option has not been set, `verify_drc` uses `4* pitch` as the default value for the routing halo, where `pitch` is the METAL2 routing pitch.
`-check_same_via_cell`	Checks the DRC issues in the same via cell.
`-check_short_only`	Excludes checking all other DRCs except the short ones.
`-check_trim_length`	Checks the maximum length on the trim shape layer.
`-check_uncolored`	Reports violations with no color and invalid mask color for the multi-pattern (MPT) layers.
`-enable_post_passive_fill_check`	Checks if the track is fully filled for the `full_fill` trim layer.
`-exclude_pg_net`	Excludes the checking of power and ground (P/G) nets. `verify_drc -exclude_pg_net` reports violations caused by routing (special and regular) except for a P/G net.
`-ignore_fill_wire`	Ignores metal fill wires while checking DRCs.
`-ignore_trial_route`	Ignores early global route while checking DRCs.
`-layer_range {layer1 [layer2]}`	Checks between the specified range of metal layers, including the cut layers. You can use the full layer name, or abbreviations like `1` for the first routing layer, etc. For example, `-layer_range {metal1 metal3}` will check all the layers between `metal1` to `metal3`. If `layer2` is not specified, it only checks DRC on `layer1`.

`-limit` *`max_error`*	Specifies the maximum number of errors to be reported. The *`max_error`* value can be any integer from 1 to 2147483646. ⚠ Set *`max_error`* to `0` to remove the limit and report all the DRCs in the design. However, this may impact memory and runtime, if the design has too many DRCs. *Default:* 1000
`-report` *`filename`*	Specifies the report file name, which contains the violation information.
`-view_window`	Checks for DRC violations in the current window.

Example

- Any one of the following commands checks for DRC violations between Metal2 and Metal3 layers:

```
verify_drc -layer_range {2 3}
```

```
verify_drc -layer_range {3 2}
```

- The following command checks for special wire related DRC violations, such as spacing violation between power/ground wire to cell blockage:

```
verify_drc -check_only special
```

Related Information

- The Identifying and Viewing Violations chapter of *User Guide*.
- `checkPlace`
- `clearDrc`
- `get_verify_drc_mode`
- `saveDrc`
- `set_verify_drc_mode`

verifyACLimit

```
verifyACLimit
[-help]
```

Checks for the following types of AC current violations on signal nets.

- Root-mean-square (RMS) current limit violations (I_{rms} violations)
- Peak current limit violations (I_{peak} violations)

In addition, verifyACLimit can be used for average current limit (I_{avg}) analysis.

AC current limit violations are sometimes also referred as wire self-heat violations. DRC manuals have these current limits to avoid over-heating a signal-net wire with too much AC current. To prevent wire self-heating or AC signal electromigration, signal interconnects should be analyzed for their AC current carrying capacity and measured against the AC current limits specified by foundry.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `verifyACLimit` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man verifyACLimit`

Related Information

- `set_signal_em_analysis_mode`

verifyCMP

```
verifyCMP
[-help]
[-ccp_setup_file string]
[-cpu integer]
[-end_level string]
[-gdsList string]
[-mapFile string]
[-output_dir string]
[-pvs_fill]
[-runMode string]
[-start_level string]
[-tsmc_vcmp string]
[-tsmc_proc string]
[-vmp_files string]
[-vmp_name string]
```

Runs Chemical and Mechanical Polishing (CMP) analysis at block level or chip level during the Sign-Off phase. You can use the verifyCMP command to run the CMP simulation using the Cadence flow.

Note: The `verifyCMP` command is available only if you have the appropriate license and the Manufacturability and Variability Sign-off (MVS) installation path set up. Refer to the "Before You Begin" section of the Integration with LPA and CCP chapter in the *Innovus User Guide*.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `verifyCMP` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man verifyCMP`
`-ccp_setup_file` *string*	Specifies the name and path of the CMP configuration file. This file controls all run options of the CMP simulation.
`-cpu` *integer*	Specifies the total number of CPUs available for the CMP run.
`-end_level` *string*	Specify the end metal level for the CMP simulation. You can use this parameter along with the `-start_level` parameter to control the number of layers for prediction.
`-gdsList` *string*	Specifies the name and path of the text file containing the list of GDS files for LEF abstracts. By default, CMP analysis runs on the interconnect layers in Sign-Off mode but if the GDS List file and Stream Out Map file are specified, CMP runs on the potential IP blocks defined in these files.
`-mapFile` *string*	Specifies the name and path of the Stream Out map file created by Innovus to map the GDS stream to the layers in the Innovus database. If the GDS List file and Stream Out Map file are specified, CMP runs on the potential IP blocks defined in these files.
`-output_dir` *string*	Specifies the output directory path. This directory contains the extraction and prediction results of the CMP run.
`-pvs_fill`	Sets the software to use the PVS fill.
`-runMode` *string*	Launches CCP in the specific run mode.
`-start_level` *string*	Specifies the starting metal level for the CMP simulation. You can use this parameter along with the `-end_level` parameter to control the number of layers for prediction.
`-tsmc_vcmp` *string*	Specifies the location and name of the VCMP engine.
`-tsmc_proc` *string*	Specifies the location and name of the VCMP process file.
`-vmp_files` *string*	Specifies the name and path of the `vmp.xml` file to be used for the CMP run. The extraction and prediction results of the CMP analysis are based on the specifications in your vmp file.
`-vmp_name` *string*	Specifies the name of the vmp process calibration from the `vmp.xml` file.

Related Information

Integration with LPA and CCP chapter of *User Guide*.

verifyConnectivity

```
verifyConnectivity
[-help]
[-allPGPinPort]
[-append]
[-connLoop | -geomLoop | -geomConnect]
[-dividePowerNet]
[-error integer]
[-ignorePGPin cell_name:pin_name]
[-markerOnHighestLayer]
[-net netNames | -selected]
[-noAntenna]
[-noFill]
[-noFloatingMetal]
[-noOpen]
[-noSoftPGConnect]
[-noUnConnPin]
[-noUnroutedNet]
[-noWeakConnect]
[-preferredTopLayer integer]
[-rawViolsMark]
[-removeOldOpenVio]
[-report filename ]
[-tsv abstractdiefilenames]
[-type {all | special | regular}]
[-useNewOpenVio]
[-useVirtualConnection]
[-warning value ]
```

Detects conditions such as opens, unconnected wires (geometric antennas), unconnected pins, loops, partial routing, and unrouted nets; generates violation markers in the design window; reports violations. Running this command does not impact database unless you save the design, which also saves the violation markers.

The Verify Connectivity feature can use `setMultiCpuUsage` and other multi-CPU commands for multi-threading.

For more information, see the Multiple-CPU Processing Commands chapter in the *Innovus Text Command Reference* document.

Parameters

`-help`	Outputs a brief description that includes the type and default information of each `verifyConnectivity` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man verifyConnectivity`
`-allPGPinPort`	Verifies all PG ports connection.
`-append`	Displays incremental results in the Violation Browser. By default, violation markers are over-written with new results during each `verifyConnectivity` run. When you specify this parameter, violation markers are appended to the violations of the previous `verifyConnectivity` run.
`-connLoop`	Checks for connectivity loops in regular wires. Detects connectivity loops based on the end points of the center line of a regular wire segment or the center of a via.
`-dividePowerNet`	Divides power nets into four subareas for connectivity verification. Use this parameter to decrease memory usage in 32-bit machines with limited memory. This parameter might increase or decrease the run time, depending on the design.
`-error` *integer*	Specifies the maximum number of errors to report. The command stops when the maximum value is reached. *Default:* `1000`
`-ignorePGPin` *cell_name*`:`*pin_name*	Specifies the cell containing the PG pin that can be ignored during connectivity check.
`-markerOnHighestLayer`	Reports the opening on the highest layer of the pin, which has more one shape.
`-geomConnect`	Checks for connectivity violations of regular wires. Uses a geometrical model instead of the center-line model. In other words, if the wires overlap at any point, they are considered to be connected--they do not have to connect at the center line. Use this parameter if you manually change the routing or use a third-party router that does not route using the centerline connection routing technique.
`-geomLoop`	Checks for loop violations of regular nets using a geometrical model. The nets do not have to overlap on the center line. When you specify this parameter, the Innovus software does not perform any other connectivity checks. Use this parameter if you use a third-party router that does not route using the centerline connection routing technique. In this case, the `-connLoop` parameter might not detect connectivity loop violations.

`-net` *netNames*	Specifies that connectivity should be verified for specified nets only. If you specify more than one net, separate the net names with space and surround the list of net names with braces or quotes. You can use wildcards (`*` and `?`) when you specify net names. **Note:** The `-net` and `-selected` parameters are mutually exclusive. *Default:* If you do not specify either the `-net` or the `-selected` parameter, `verifyConnectivity` verifies all nets.
`-noAntenna`	Ignores violations due to unconnected wires (also called geometrical antennas or dangling wires). A wire is called an antenna when the wire end to nearest via edge distance is more than ½ of the wire width as shown in the picture below: In this picture, the blue rectangle is the wire and the yellow squares are the vias.
`-noFill`	Ignores the metal fill.
`-noFloatingMetal`	Ignores floating metals. A wire is called floating methal, when both ends of the wire are not connected to pin shapes as shown in the picture below. In this picture, the blue rectangle is the wire and the green squares are pin shapes.
`-noOpen`	Ignores open violations. A wire is said to be open when one of its ends is connected to a pin shape but the other end is not connected to any pin as shown in the picture below.  In this picture, the blue rectangle is the wire and the green squares are pin shapes. **Note:** This parameter automatically turns on the `-noUnConnPin` parameter, because open and unconnected pin verification are performed together. A pin shape that is not connected to any wire is called an unconnected pin (`unConnPin`).

`-noUnConnPin`	Ignores violations due to pins that are not connected to any other objects. In the picture below, the pin on the right is an unconnected pin (`unConnPin`) as it is not connected to any wire.  **Note:** This parameter is specified automatically when you specify the `-noOpen` parameter.
`-noUnroutedNet`	Ignores nets that are not routed.
`-noWeakConnect`	Disables checking for routing to more than one port of the weakly connected pin ports.
`-noSoftPGConnect`	Disables checking of soft Power/Ground connects. By default, `verifyConnectivity` checks the connectivity on masterslice layers. If `-noSoftPGConnect` option is specified, connectivity on these layers is ignored.
`-preferredTopLayer` *`integer`*	Specifies the preferred top metal layer. When this parameter is used, verifyConnectivity does not check the specified top layer and above layers.
`-rawViolsMark`	Displays violation markers for opens as the bounding box of the island. By default, violation markers for opens are displayed as polygons that include all wires, pins, and vias that connect to the island.
`-removeOldOpenVio`	Removes old open violations.
`-report` *`filename`*	Specifies the report file for connectivity violation data.
`-selected`	Specifies that connectivity should be checked for selected nets or the nets connected to the pins of selected instances/macros. **Note:** The `-net` and `-selected` parameters are mutually exclusive. *Default:* If you do not specify either the `-net` or the `-selected` parameter, `verifyConnectivity` verifies all nets in the design.
`-tsv` *`abstractdiefilenames`*	Specifies the TSV abstract die files to be used to check the uBumps between the current die and the adjacent dies. Here, *`abstractdiefilenames`* specifies the names of abstract die files created using the command `writeDieAbstract`.

`-type {all | regular | special}`	Specifies the type of wires to verify. `verifyConnectivity` is only concerned with the type of the wire and via (special or regular), but not the type of the pin. Irrespective of the `type` specified, all unconnected terminals (special and regular) are always reported unless `-noUnConnPin` is on. *Default:* `all` **Note:** To check connectivity for whole nets, you do not need to specify the type. **Note:** A pin-open violation is listed under VC DRC type "Problem(s) (ENCVFC-92): Pieces of the net are not connected together". Such a violation means the isolated open island only includes some pins' shapes that come from at least two different ports or pins. Choose one of the following: `all`: Checks all wires, including those that have been previously verified. `regular`: Reports all unconnected pins and open islands that do not include any special wire and via. Does not check a net with no regular objects (wire, via, pin). `special`: Reports all unconnected pins and open islands that do not include any regular wire and via. Does not report isolated open islands that have any regular wire and via.
`-useNewOpenVio`	Uses an open violation marker to show unconnected objects.
`-useVirtualConnection`	Implies a virtual connection for all bumps and external I/O pins of the same net. Set this parameter to override default behavior of `verifyConnectivity`, in which bumps and external I/O pins of the same net are not considered to be interconnected. It is useful in flip chip designs, where the power bumps are connected outside the chip.
`-warning` *value*	Specifies the maximum number of warnings to report. *Default:* `50` *Range:* [`0, 1000000`] *Type:* Integer

Examples

- The following command verifies connectivity for all nets and generates a maximum of 50 errors and 50 warning messages:
  ```
  verifyConnectivity -type all -error 50 -warning 50
  ```
- The following command reports special unconnected pins and open islands that do not include any regular wire and via
  ```
  verifyConnectivity -type special -noAntenna -error 1000 -warning 50
  ```
- The following command reports the open only from 1 to 4 metal layers, and ignores all the open on 5 and the metal layers above 5:
  ```
  verifyConnectivity -preferredTopLayer 5
  ```
- The following command ignores the `VDD1` pin in the `NAND*` cell, and the `VSS1` pin in the `NOR*` cell during

connectivity check:

```
verifyConnectivity -ignorePGPin {NAND*:VDD1 NOR*:VSS1}
```

Related Information

The following sections in the Identifying and Viewing Violations chapter of *User Guide*:

- Verifying Connectivity

verifyCutDensity

```
verifyCutDensity
[-area {x1 y1 x2 y2}]
[-detailed]
[-globalDensity]
[-ignoreCellBlock]
[-layer layer_name_list]
[-oversize value]
[-report fileName]
```

Checks the density of specified cut layers or areas of cut layers, or the cut density of the whole chip.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `verifyCutDensity` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man verifyCutDensity`.
`-area {x1 y1 x2 y2}`	Specifies the coordinates of the area to verify. For example, `verifyCutDensity -area {0 0 100 100}`. *Default:* Entire area
`-detailed`	Generates a detailed cut density report.
`-globalDensity`	Checks the density across the entire design for the specified cut layers and writes the results to the report file.
`-ignoreCellBlock`	Disables checking of windows that are fully covered by block or pad obstructions.
`-layer layer_name_list`	Specifies the cut layers to verify. Use the following format to specify layer names: {Via12 Via23} For example, `verifyCutDensity -layer {Via12 Via23}`.
`-oversize value`	Specifies an offset value for the area to verify. The value is in user units (not in DBU), and can be positive or negative. A positive value adds to the area that is verified. For example, if the design covers the area from `(0,0)` to `(100,100)` and you specify `-oversize 10`, `verifyCutDensity` checks the area from `(-10,-10)` to `(110,110)`. *Default:* `0`
`-report fileName`	Specifies the report file for the cut density violation information. *Default:* *designName*`.cutdensity.rpt`

Example

The following command checks the density across the entire design for the layers `Via12` and `Via23` and generates a detailed report named `density.rpt`.

```
verifyCutDensity -layer {Via12 Via23} -report density.rpt -detailed -globalDensity
```

Related Information

- "Overview" in the Identifying and Viewing Violations chapter of *User Guide*.

verifyEndCap

```
verifyEndCap
[-help]
[-area {x1 y1 x2 y2}]
[-coreBoundaryOnly]
[-error integer]
[-ignore_macro SCLA,...]
[-powerDomain string]
[-report filename]
[-row string]
[-tripleWell]
[-wrongLocation]
```

Checks whether pre/post cap cells have been inserted correctly based on `setEndCapMode` settings. Use this command after running `addEndCap` to flag violations such as:

- Inserted end cap cell is of wrong type
- End cap cell is missing

If you use `verifyEndCap` with the `-wrongLocation` option, it also checks whether the end cap cells are inserted in the right location. Use the `-powerDomain` option to check end cap cells inserted for a specific power domain.

Additionally, you can use `verifyEndCap -tripleWell` to check triple well insertion. Triple well technology is used to isolate p-well from substrate using a deep n-well.

You can view the violation markers generated by `verifyEndCap` in Violation Browser.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `verifyEndCap` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man verifyEndCap`
`-area {x1 y1 x2 y2}`	Specifies the area in which endcaps are to be verified.
`-coreBoundaryOnly`	Checks endcaps only at the core-boundary and not abutting obstructions. **Note**: The `-coreBoundaryOnly` option does not support triple well cap insertion.
`-error integer`	Specifies the maximum number of errors to report.
`-ignore_macro SCLA,...`	Specifies the macro to be ignored.
`-powerDomain string`	Specifies the power domain to be checked. Use this option to check end cap cells inserted for the specified power domain.
`-report filename`	Specifies the file name for the `verifyEndCap` report.
`-row string`	Specifies the row to check.
`-tripleWell`	Checks triple well insertion. Only checks the cell lists specified in `setEndCapMode`.
`-wrongLocation`	Checks for cap cells that are not inserted in the right location. If you specify this option, `verifyEndCap` marks with a violation marker any cap cell that is not on the beginning/end of the row or not on the boundary of the design/ block design.

Examples

- The following set of commands verifies whether cap cell insertion is as per the `setEndCapMode` settings and generates a default report file in the active folder:

```
setEndCapMode -leftEdge EC_LE10 -rightEdge EC_RE10
verifyEndCap
```

- The following command verifies end cap insertion and generates a report named `endcap.rpt`:

```
setEndCapMode -leftEdge EC_LE10 -rightEdge EC_RE10
verifyEndCap -report endcap.rpt
```

- The following command verifies triple well insertion. It also checks the cap cells that are not inserted in the right location and reports up to `10000` errors:

```
setEndCapMode -leftEdge EC_LE10 -rightEdge EC_RE10 -bottomEdge EC_BE10 \
              -leftBottomCorner EC_LBC10 -leftTopCorner EC_LTC10 \
              -rightBottomCorner EC_RBC10 -rightTopCorner EC_RTC10 \
```

```
                -topEdge EC_TE10
verifyEndCap -tripleWell -wrongLocation -error 10000
```

Related Information

- "Verifying End Cap Violations" in the Identifying and Viewing Violations chapter of *User Guide*.
- "Adding End-Cap Cells" in the Placing the Design chapter of *User Guide*.

verifyIO2BumpConnectivity

```
verifyIO2BumpConnectivity
[-help]
[-error integer]
[-report string]
[-subclass string]
[-warning integer]
[-bump_connect_target | -class_bump ]
[-bumps string | -class_bump ]
[-bumps string | -nets string]
```

Verifies multiBump multiPad connectivity. The flip chip flow in Innovus supports multiple pads to multiple bumps connections. Use the `verifyIO2BumpConnectivity` command, instead of `verifyConnectivity` to verify such connections.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `verifyIO2BumpConnectivity` parameter. For a detailed description of the command and all its parameters, use the `man` command: man `verifyIO2BumpConnectivity`
`-bump_connect_target`	Checks only whether or not the routing matches the connection specified by `bump_connect_target` properties (`io:pin:port`) regardless of the class of the port.
`-bumps` *`string`*	Specifies the name of the bumps that are to be checked.
`-class_bump`	Checks only whether or not the ports of `CLASS BUMP` are routed to the bumps regardless of the `bump_connect_target` properties.
`-error` *`integer`*	Specifies the maximum number of errors to report.
`-nets` *`string`*	Specifies the names of the nets that are to be checked.
`-report` *`string`*	Specifies the name of the report file in which `verifyIO2BumpConnectivity` violation data is recorded. *Default:* `designname.io2bump.rpt`
`-subclass` *`string`*	Specifies the name of the subclasses of which the wires and vias are to be checked.
`-warning` *`integer`*	Specifies the maximum number of warnings to report.

verifyIsolatedCut

```
verifyIsolatedCut
[-help]
[-area {x1 y1 x2 y2}]
[-error integer]
[-layer {cutLayer_list}]
[-maxXY]
[-report filename]
```

Checks cuts in all or specified cut layers against the spacing rules set by `setIsolatedCutRule`. If you use the `-area` parameter, checks cuts within the specified area. Reports violations in the log file and in `verify.isoVia.rpt` or the specified report file.

Note: Violations can be viewed in the Violation Browser.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `verifyIsolatedCut` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man verifyIsolatedCut`
`-area {x1 y1 x2 y2}`	Specifies the coordinates of the area to verify. If you do not specify this parameter, the command checks the whole design. For example, `verifyIsolatedCut -area {0 0 100 100}`. *Default:* Entire area
`-error integer`	Specifies the maximum number of errors to report. *Default:* `1000`
`-layer {cutLayer_List}`	Specifies the cut layers to be checked. If you specify only one layer name, you do not need the braces around the name. For example, `verifyIsolatedCut -layer {Via1 Via2}`. *Default:* All cut layers
`-maxXY`	Specifies that the Square metric should be used for checking isolated cuts. By this metric, another cut should exist within a square window from a certain cut. The size of the square window depends on the spacing rules set by `setIsolatedCutRule`. **Note:** If this parameter is not specified, the Euclidean metric is used for checking isolated cuts.
`-report filename`	Specifies the report file for the isolated cut violation information. *Default:* `verify.isoVia.rpt`

Examples

- The following command checks isolated cuts on all layers and generates a report file named `test.isoCut.rpt`:

  ```
  verifyIsolatedCut -report test.isoCut.rpt
  ```

- The following command checks for isolated cuts in the area specified and generates a report named `verify_isoVia.rpt`:

  ```
  verifyIsolatedCut -area {0 0 1600 1600}
  ```

- The following set of commands check for isolated cuts on all layers using the Square metric. Any cut that does not have another cut within a 25um x 25um square window is reported:

  > setIsolatedCutRule -spacing 25

  > verifyIsolatedCut -maxXY

  In the following pattern, no isolated cut violation is reported as each cut has one or more cuts within a `25um x 25um` square window.

  
  In contrast, the following pattern is not okay because no other cut exists within a 25um x 25um square window:

verifyLitho

```
verifyLitho
[-help]
-apply {hotspot | ripandreroute | squishHints}
[-check_locally]
[-config string]
[-cpu integer]
-dir string
[-gdsList string]
[-guideline]
[-hints_to_apply string]
[-incrCheck string]
[-layerMapFile string]
[-mapFile string]
[-noCompress]
[-oasis]
[-oasisList string]
[-optionFile string]
[-previousDir string]
[-reportFile string]
{-routingLayersOnly | -signOff | -reportOnly | -loadBlockage}
[-runMode string]
[-streamOutOptions string]
-techFile string
[-verify_function string]
```

Runs LPA on the selected design to flag litho hotspots.

Note: The `verifyLitho` command is available only if you have the appropriate license and the MVS installation path set up. Refer to the 'Before You Begin' section in the Integration with LPA and CCP chapter of *Innovus User Guide*.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `verifyLitho` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man verifyLitho`

`-apply {hotspot | ripandreroute | squishHints}`	Instructs Innovus to perform specific operations based on the results of `verifyLitho`. The operation performed depends on the value you specify with `-apply`: • `hotspot`: Loads the resulting hotspots into violation browser and prepare for regular litho fixing. • `ripandreroute`: Sets up Innovus to fix hotspots using the router with sized and shifted locations from the hotspot marker. • `squishHints`: Applies the fill and via replace hints created by `verifyLitho` automatically if `verifyLitho` is being run using squish patterns.
`-check_locally`	Applies fixing with the local DRC.
`-config` *string*	Specifies the name and path of the LPA custom configuration file. This file, if specified, controls all run options of LPA. It can also specify different instructions for each layer.
`-cpu` *integer*	Specifies the total number of CPUs available for the LPA run.
`-dir` *string*	Specifies the LPA output directory. This directory contains one subdirectory for each layer. The individual subdirectories for each layer (POLY, 1, etc.) are created when LPA is run with the configuration file for that layer.
`-gdsList` *string*	Specifies the name and path of the text file containing the list of GDS files for LEF abstracts. By default, LPA runs on the interconnect layers in Sign-Off mode but if the GDS List file and Stream Out Map file are specified, LPA runs on the potential IP blocks defined in these files.
`-guideline`	Generates LPA guidelines.
`-hints_to_apply` *string*	Specifies the list of hint number to apply.
`-incrCheck` *string*	Specifies the name and path of the HIF file that you want to use for incremental validation. This HIF file includes the locations that identify the areas affected by each hotspot fix. LPA reads these locations and performs incremental checking only in these areas. This reduces the time for validation.
`-layerMapFile` *string*	Specifies the name of the layer map file.

`-loadBlockage`	Loads the blockage file. **Note**: This parameter cannot be used along with `-signOff`, `-routingLayersOnly`, or `-loadBlockage`.
`-mapFile` *string*	Specifies the name and path of the Stream Out Map file created by Innovus to map the GDS stream to the layers in the Innovus database. If the GDS List file and Stream Out Map file are specified, LPA runs on the potential IP blocks defined in these files.
`-noCompress`	Inputs `gds` instead of `gds.gz`.
`-oasis`	Streams out using oasis.
`-oasisList` *string*	Specifies the `oasisOut` oasis list files.
`-optionFile` *string*	Specifies a text file, which can be used to set variables used by the `-apply` operations.
`-previousDir` *string*	Specifies the path to the run directory of a previous Verify Litho run that you want to use for XOR-based incremental validation. When this parameter is specified, the previous run results are compared to the new design and LPA is run only in locations where the layout has changed and where hotspots previously existed, thereby reducing the overall validation run time. This flow is recommended when the design has been changed but no HIF file that identifies the changed areas is available.
`-reportFile` *string*	Specifies the netlist report file.
`-reportOnly`	Generates the netlist report. **Note**: This parameter cannot be used along with `-signOff`, `-routingLayersOnly`, or `-loadBlockage`.
`-routingLayersOnly`	Specifies that LPA is to be run in the Routing Layers Only mode. The Routing Layers Only mode is the fast mode of LPA to flag L1 hotspots in a design at the block level during the Implementation phase. In this mode, LPA runs about 100X faster than the Sign-Off mode and helps you identify and fix most hotspots as routing is completed. **Note**: This parameter cannot be used along with `-signOff`, `-reportOnly`, or `-loadBlockage`.
`-runMode` *string*	Launches LPA in back/foreground.

`-signOff`	Specifies that LPA is to be run in the Sign-Off mode. You run LPA in Sign-Off mode for Litho sign-off, as mandated by foundries. Unlike the Routing Layers Only mode, the Sign-Off mode requires you to provide the LPA configuration file containing the Techfile and other settings. You must run LPA Sign-Off mode before handing off the design to the top-level or tape-out. **Note**: This parameter cannot be used along with `-routingLayersOnly`, `-reportOnly`, or `-loadBlockage`.
`-streamOutOptions` *string*	Enables additional `streamOut` command options.
`-techFile` *string*	Specifies the path and name of the qualified LPA Mx technology file that includes process-specific LPA model, hotspot patterns, and hotspot checking options. The LPA model captures the GDSII-to-silicon flow of the targeted process, enabling LPA to predict the variations and hotspots due to lithography, directly from the design database. Hotspot patterns can also be included in the LPA techfile in replacement for the LPA model to support the DRC+ flow, or along the LPA model to enable fast mode. **Note:** The `-techFile` parameter is mandatory if you use the `-routingLayersOnly` option to run LPA.
`-verify_function` *string*	Specifies the DRC function to be checked.

Examples

Following is an example of the `verifyLitho` command usage:

```
verifyLitho -dir lpa -techFile lpa.tcl -layerMapFile lef_map.file -mapFile gds_map.file -
routingLayersOnly -streamOutOptions "-outputMacros -merge list_of_GDS_files"
```

Related Information

verifyMetalDensity

```
 verifyMetalDensity
[-help]
[-report filename ]
[-detailed]
[-ignoreLEFDensity]
[-layer layer_name_list ]
[-area { x1 y1 x2 y2 } ]
[-oversize value ]
```

Checks the metal density of each routing layer and of macros against values specified by `setMetalFill`, by LEF file, or against its own internal default values. Reports density information in the log file.

> The `setMetalFill` command is a user-override command that provides constraints at the run time for each session. These constraints have precedence over the LEF/database values. For example, if you specify `setMetalFill -iterationName default`, `verifyMetalDensity` checks against the `default` value.

If neither the LEF file nor `setMetalFill` specifies the window size or density, `verifyMetalDensity` uses internal default values.

`verifyMetalDensity` now supports multi-threading to improve Metal Fill runtime performance in multi-thread mode. `verifyMetalDensity` supports the new `setMultiCpuUsage` command use model. For more information, see the following documents:

- Multiple-CPU Processing Commands chapter of the *Innovus Text Command Reference*.
- Accelerating the Design Process by Using Multiple-CPU Processing chapter of *User Guide*.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `verifyMetalDensity` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man verifyMetalDensity`

`-area {x1 y1 x2 y2}`	Specifies the coordinates of the area to verify. For example, `verifyMetalDensity -area {0 0 100 100}`. *Default:* Entire area **Behavior of `verifyMetalDensity -area` with external metal density** When metal fill is added to a block design the external metal density provides a density assumption to `verifyMetalDensity`. The external density is used only for density calculation purposes and no fill shapes are added outside of the design area. When the `-area` parameter is not specified, the external density value is not used. In this case, the `verifyMetalDensity` window is pushed back if it extends outside the design area, as shown in the figure below.  If the `-area` parameter is specified and is larger than the design size then `verifyMetalFill` windows extend outside of the block area and use the external density value (see `setMetalFill` external density value specification) for that area.  If external density is less than the specified preferred density, it is more likely that shapes will be added to the area. If external density is greater than the preferred density it is less likely that shapes will be added (shapes are only added within the design boundary). **Note:** Windows outside the design boundary are ignored.
`-detailed`	Generates a detailed metal density report.

`-ignoreLEFDensity`	Ignores the MACRO `DENSITY` table in the LEF file and instead uses the default macro density calculation method. **Note:** If you do not specify this parameter, `verifyMetalDensity` uses the LEF MACRO density table for density calculations.
`-layer` *layer_name_list*	Specifies the LEF or Innovus layers to verify. If you specify only one layer name, you do not need the braces around the name. For example, `verifyMetalDensity -layer {METAL1 METAL2}`.
`-oversize` *value*	Specifies an offset value for the area to verify. The value is in user units (not in DBU), and can be positive or negative. A positive value adds to the area that is verified. For example, if the design covers the area from `(0,0)` to `(100,100)` and you specify `-oversize 10`, `verifyMetalDensity` checks the area from `(-10,-10)` to `(110,110)`. *Default:* `0`.
`-report` *filename*	Specifies the report file for the metal density violation information. *Default:* *designName*`.metaldensity.rpt`.

Examples

- The following command checks metal density of all layers and generates a report file named `Test7.density.rpt`:

  ```
  verifyMetalDensity -report Test7.density.rpt
  ```

- The following command checks metal density on layer *Metal1* in the area specified and generates a detailed report named `test_chip.density.rpt`:

  ```
  verifyMetalDensity -area {-200 -200 1600.0 1600.0} -layer {Metal1} -report test_chip.density.rpt -detailed
  ```

  In the example above, the layout size is 0 0 1400.0 1400.0. The command considers the density of the area outside of the design as `0`.

verifyPowerVia

```
verifyPowerVia
[-help]
[-append]
[-area {x1 y1 x2 y2}]
[-checkWirePinOverlap]
[-edgeToEdge]
[-error integer]
[-exclude_region_file check_file]
[-fill]
[-hookup_pitch pitch_value]
[-ignore_objects {drc_fill | io_wire}]
[-layerRange {bottomLayer topLayer}]
[-layer_rail layer_name]
[-layer_stripe layer_list]
[-net {netNames} | -selected]
[-nonOrthogonalCheck [-distance {x y}]]
[-pitch pitch_value]
[-report file]
[-search_range {x y}]
[-shielding]
[-stackedVia]
[-stripe_rule value]
[-viaUtil value]
[-what_if_report filename]
[-widthRange string]
```

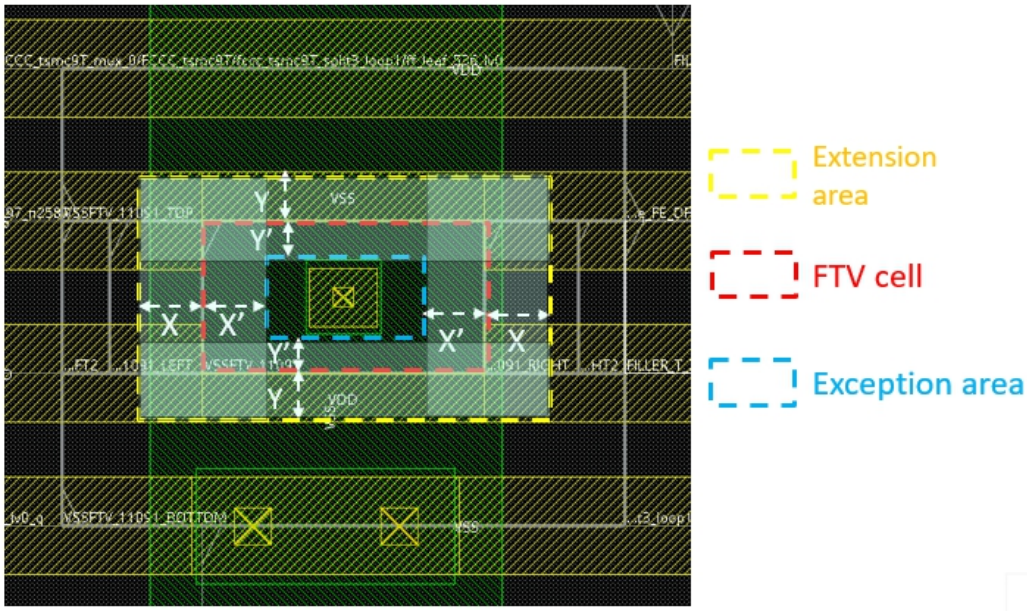
This command has a variety of power-rail overlap checks to look for missing power-grid vias. By default, it checks that orthogonal power-routes on adjacent routing layers have a via between them at every intersection. For example, there should be a via at the point where a Metal3 power stripe overlaps a Metal2 power stripe. By default, horizontal routes get checked only for overlaps with vertical routes. If the power shapes are polygon, the polygon is split into rectangles and the rectangles are used to decide the direction. Support for checking stacked vias between non-adjacent routing layers is optional. Violations are highlighted in the layout window, and a text report is generated with the location of the missing vias.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `verifyPowerVia` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man verifyPowerVia`
`-append`	Specifies that all previous `verifyPowerVia` settings will be kept.
`-area x1 y1 x2 y2`	Specifies the coordinates of the area to be checked.

`-checkWirePinOverlap`	Specifies that wire overlaps of pin shapes should also be checked. By default, only wire overlaps with wires are checked.
`-distance {x y}`	Specifies distances for finding missing via within a specified window for a non-orthogonal check, with `x` and `y` representing the distance in the horizontal and vertical directions, respectively. When the `x` or `y` distance is provided, `verifyPowerVia` checks if the wire is parallel with another wire. If yes, it checks: • The via center to via center spacing between parallel wires against the value *x (y)* • The via center to wire end distance against the value *x/2 (y/2)* If the actual distance is greater than the required distance in either case, it marks a violation. When the `x` or `y` distance is not provided or set to `0`, the via to via distances are not checked. **Note**: This parameter can only be specified with the `-nonOrthogonalCheck` parameter.
`-edgeToEdge`	Checks the non-orthogonal distance from edge to edge within a layer.
`-error integer`	Specifies the maximum number of errors to report.

`-exclude_region_file check_file`	Ignores missing VIA checks within the specified `check_file` regions for a cell extension area. The `check_file` format can be a set of the following values:
	• `cell`: Specifies the cell type.
	• `ext_layer_bottom`: Specifies the extension area bottom layer.
	• `ext_layer_top`: Specifies the extension area top layer.
	• `ext_x`: Specifies the extension length in the X direction.
	• `ext_y`: Specifies the extension length in the X direction.
	• `exc_x`: Specifies the exception length in the X direction.
	• `exc_y`: Specifies the exception length in the Y direction.
	Example 1:
	The following set of `check_file` formats ignores missing VIA check within the yellow rectangle (in the output), but checks missing VIA within the blue rectangle:
	`FTV_CELL, B_M0, B_M1, X, Y, X', Y'`
	`INV_D2, M0, M1, X2, Y2, X2', Y2'`
	Following is the output:

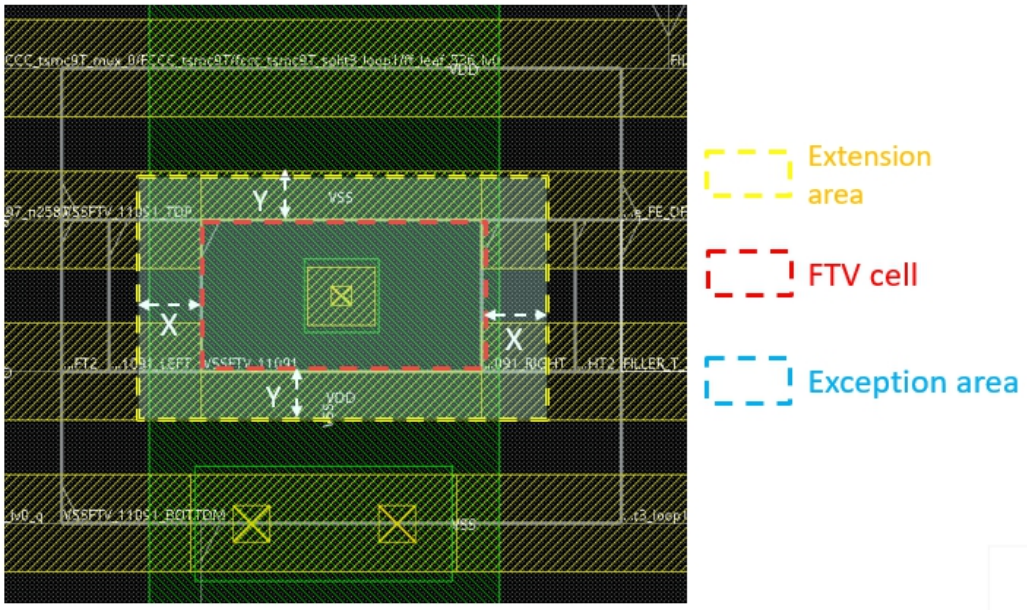


Example 2:

The following set of `check_file` formats ignores missing VIA check within the yellow rectangle (in the output):

```
FTV_CELL, B_M0, B_M1, X, Y
INV_D2, M0, M1, X2, Y2
```

Following is the output:



`-fill`	Specifies that tied-off metal fill should also be checked. Floating fill is still ignored. *Default*: Metal fill will be ignored.
`-hookup_pitch` *pitch_value*	Specifies the distance between two vias, which are on the filler instance and are greater than or equal to the given value.
`-ignore_objects {drc_fill | io_wire}`	Skips checking the power vias of the specified wire type.

`-layerRange` **{***bottomLayer topLayer***}**	Checks for the missing stacked vias between the bottom and top layers. It also checks for the missing vias between all the adjacent intermediate layers, but does not check for the stacked vias between the intermediate layers. While using this parameter, you can specify full layer names like `METAL1`, or abbreviations like `1`. For example, `verifyPowerVia -layerRange {2 5}` checks for missing stacked vias between overlapping `2` and `5`, and also missing adjacent vias for overlapping `2/3`, `3/4`, and `4/5`.
	This parameter checks the missing adjacent vias if `bottomLayer` is specified, but `topLayer` is not, with considering that `topLayer` is just one layer above. To review the missing stacked via or missing adjacent via DRC marker, use the `violationBrowser` command for filtering the DRC marker. For example:
	1. To display only the missing stacked via DRC markers, run:
	`violationBrowser -all -filter {stacked via} -search_desc -filter_mode AND`
	2. To display only the missing via DRC markers between the adjacent layers, run:
	`violationBrowser -all -filter {adjacent via} -search_desc -filter_mode AND`
	See `violationBrowser` for more information on the command usage.

`-layer_rail` *layer_name*	
	Specifies a single power rail layer for missing via (only the via above power rail) check. The check depends on the `-stripe_rule` option. When `-stripe_rule` is specified, the via to via distance should be less than or equal to the specified value. If a distance value is not specified with the `-stripe_rule` option, the check is ignored. See the examples below. The `-layer_rail` option is not controlled by `-layerRange`. You can specify a power rail layer other than that specified with `-layerRange` for checks against the `stripe_rule` and `search_range` rules.

`-layer_stripe` *layer_list*	Specifies the power stripe layers to be checked for a valid connection path from power rail to power stripe. The check depends on the `-search_range` option. If `-search_range` is specified, at least one valid connection path should be found from the power rail to power stripe in that search range. If a search range is not specified with the `-search_range` option, the check is ignored. You can specify the power rail layer with the `-layer_rail` option. By default, only the uppermost power rail layer is checked. See the examples below. The `-layer_stripe` option is not controlled by `-layerRange`. You can specify power stripe layers other than that specified with `-layerRange` for checks against the `search_range` rule.
`-net {`*netNames*`}`	Specifies the names of the power nets that will be checked. A single net or a list of nets enclosed in curly braces({}) or quotes (" ") can be specified. Wildcards (* and ?) are supported. For example, when you specify `verifyPowerVia -net {v*}`, all PG net names having initial letter as `v` are checked. **Note:** Currently, wildcards are supported for checking PG nets only. *Default*: All power grid nets.
`-nonOrthogonalCheck`	Checks the overlap area for non-orthogonal crossing wires (e.g. wires that are both in the same direction) in adjacent as well as non-adjacent layers. Checks for missing vias between two or more parallel wires. The via center-to-center distance between parallel wires should be less than or equal to the specified spacing If this parameter is not specified, horizontal wires get checked only against vertical wires. **Note**: You can use `-distance {x y}` parameter with `-nonOrthogonalCheck` to find missing vias within a specified window. When the `x` or `y` distance is provided, `verifyPowerVia` checks if the wire is parallel with another wire. If yes, it checks the via center-center spacing and via center-wire end distance between parallel wires. If the actual distance is greater than the required distance, it marks a violation.
`-pitch` *pitch_value*	Specifies the distance between two vias, which are not on the filler instance and are greater than or equal to the given value.
`-report file`	Specifies the name of the output file for the report. *Default:* `design_name.powervia.rpt`

`-search_range {x y}`	Specifies a rectangle area with `XY`. There should be one valid connection from power rail to power stripe in the specified area. By default, the valid connection would be searched from the uppermost power rail layer to all the power stripe layers. You can use the `-layer_rail` option to specify the power rail layer, and the `-layer_stripe` option to limit the power stripe layers. With the `-layer_rail` and `-layer_stripe` options, only the specified power rail and power stripes layers are used for valid connection check. The x and y values are floats in units of microns. Refer to the **Examples** section for search range examples.
`-selected`	Checks for the missing vias between the selected PG wires and other intersecting selected/unselected PG wires. When this parameter is used with the `-checkWirePinOverlap` parameter, it checks for the missing vias between the intersection of selected PG wires and pins of the selected instances. This parameter eliminates the requirement of running the command on the entire design, and hence improves the run time.
`-shielding`	Specifies that shielding wires should also be checked. By default, shielding wires are not checked.
`-stackedVia`	Checks for missing vias between all non-adjacent as well as adjacent layers.
`-stripe_rule` *value*	Specifies in microns the distance for power via. Only the power via above the power rail is checked. If the via to via center-to-center spacing is greater than the specified value, a violation marker is created. You can specify the power rail layer with `-layer_rail` for checking. By default, only the power via above the uppermost power rail is checked against the rule. Refer to the **Examples** section for stripe rule examples.
`-viaUtil` *value*	Checks if the cut area in the metal intersection area is sufficient. `viaUtil = Total cut area / Metal intersect area` If the actual ratio is less than specified ratio, `verifyPowerVia` marks it as violation. By default, the metal intersection area is the metal overlap area. If `setAddStripeMode -via_using_exact_crossover_size` is set to `false`, the partial overlapped metal will be extended to full width intersection area.
`-what_if_report` *filename*	
	Writes out `verifyPowerVia` violations data into a ECO file that can be used directly as input for whatIf rail analysis. When you specify this parameter, the missing via information generated can be used as input for what-if virtual wires.
`-widthRange` *string*	

	Specifies the metal width to be considered. `verifyPowerVia` uses the specified width range to filter wires. Only the bottom and top wires that fall in the range are checked. The *`string`* value takes the following format: `-widthRange {`*`minWidth`* `maxWidth [layerName …] [`*`minWidth maxWidth [layerName …]] … }` • If *`minWidth`* is 0, all wires with width less than specified *`maxWidth`* will be checked. • If *`maxWidth`* is 0, all wires with width greater than specified *`minWidth`* will be checked. • If *`layerName`* is specified in the string, `widthRange` is enabled only for the specified layer. • If no *`layerName`* is specified in the string, `widthRange` is enabled for all non-specified layers. Refer to the **Examples** section for width range examples. **Note:** Use braces or quotation marks to enclose the string value for `widthRange`.

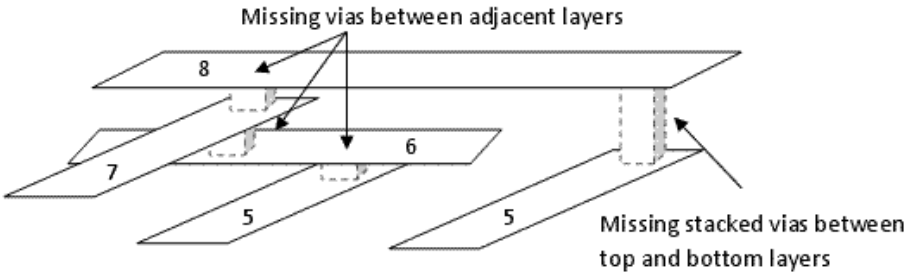
Examples

- The following command specifies that all vias for all powergrid nets will be checked, except for metal fill and shielding wires, and reports it to a file called `power_via.report`:

  ```
  verifyPowerVia -report power_via.report
  ```

- The following command checks for missing stacked vias between `METAL5` and `METAL8` layer intersections on the VSS net. In addition, it checks for missing vias between `METAL5-METAL6`, `METAL6-METAL7` and `METAL7-METAL8` layer intersections. The violations are reported in the `powerVia.rpt` file and highlighted in GUI.

  ```
  verifyPowerVia -layerRange {METAL5 METAL8} -net VSS -report powerVia.rpt
  ```



- The following command checks that the overlapping power routes on adjacent layers have vias that cover at least 70% of the overlap area..

  ```
  verifyPowerVia -viaUtil 0.7
  ```

- The following command checks that the overlapping power routes have vias that cover at least 70% of the overlap area for layers between `METAL3` and `METAL4`.

```
verifyPowerVia -viaUtil 0.7 -layerRange {METAL3 METAL4}
```

- The following command checks for wires overlaps for all pin shapes included, enclosed, or touched by the specified area:

  ```
  verifyPowerVia -area {100 100 1000 1000} -checkWirePinOverlap
  ```

- The following command checks wires with width greater than `0.032` and less than `0.096` for all layers:

  ```
  verifyPowerVia -widthRange {0.032 0.096}
  ```

- The following command checks wires with width in the `0.032` ~ `0.096` range for 1/2 and width `0.038~0.114` for 3/4. For other layers, there is no width control:

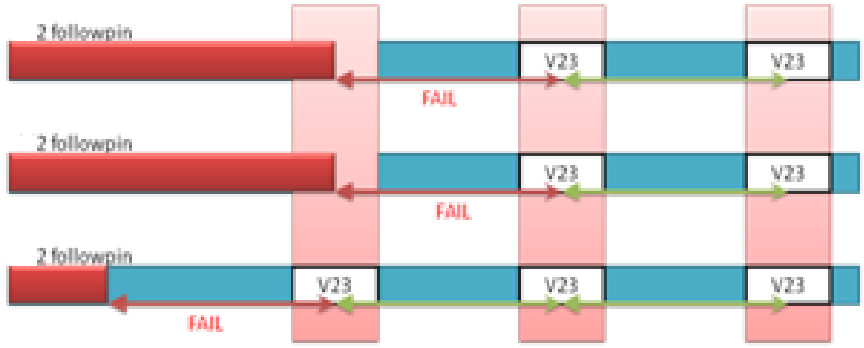
  ```
  verifyPowerVia -widthRange {0.032 0.096 1 2 0.038 0.114 metal3 metal4}
  ```

- The following command checks wires with width in the `0.032` ~ `0.096` range for 1/2. For other layers, it checks wires with width in the `0.038~0.114` range:

  ```
  verifyPowerVia -widthRange {0.032 0.096 1 2 0.038 0.114}
  ```

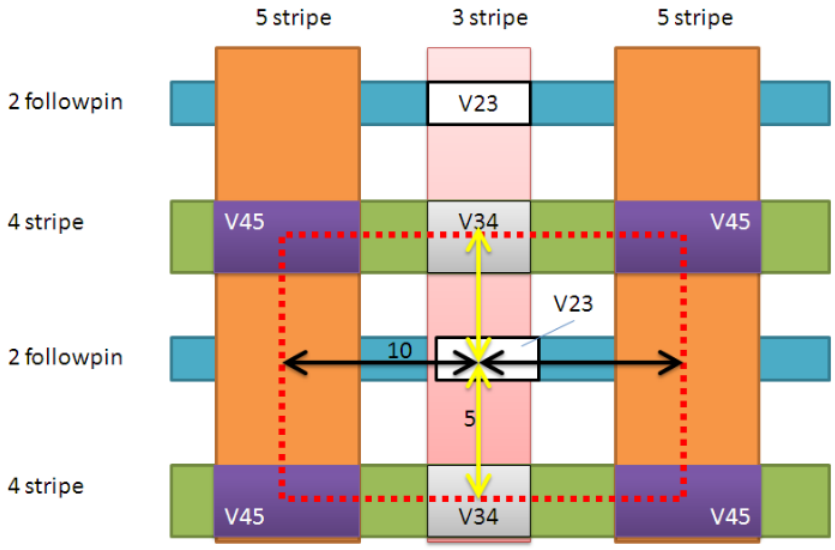
- The following command checks the via between power rail layer `2` and `3`. If the via's center-to-center distance is more than `17u`, the tool reports a violation and places a marker on the power rail wires.

  verifyPowerVia -stripe_rule 17 -layer_rail 2

- The following command checks the valid connection for `2` power rail to stripe layer `4` and `5` with the search rectangle area `10*5`. In the diagram below, there is no violation as the connection is built from `2` to `4`. If the `V34` vias are removed, then there is a violation as the connection cannot be built from `2` to `4`.

  verifyPowerVia -search_range {10 5} -layer_rail 2 -layer_stripe {4 5}



Related Information

- `editPowerVia`
- "Prior to Running Early Rail Analysis" in the Power and Rail Analysis chapter in the *Innovus User Guide*

verifyTieCell

```
verifyTieCell
[-help]
[-noTieCell filename]
[-powerDomain string]
[-report filename]
```

Checks tie cell connections. `verifyTieCell` honors the tie high/low cell list from `setTieHiLoMode -cell` and checks whether or not the tie high/low nets are connected to the tie high/low cells.

Use this command after using `addTieHiLo` to add instances of tie-off cells to the logical hierarchy of the design.

The expected flow is as follows:

1. Specify the tie cell names and other settings with the `setTieHiLoMode` command.
2. Add tie high/low cells with `addTieHiLo`.
3. Run `verifyTieCell` to check whether tie cell connections are correct.

Violations can be viewed in Violation Browser.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `verifyTieCell` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man verifyTieCell`
`-noTieCell` *`filename`*	Specifies a file containing exception list of instance/pin names. Use this parameter to specify the instance/pins that should not have any tie cell connections. The file should list instance and pin names in the following format: *`instance_name/pin_name`*
`-powerDomain` *`string`*	Specifies the power domain name to be checked.
`-report` *`filename`*	Specifies the report file for recording tie cell violations. By default, the report is saved as *`designName`*`.tie.rpt`.

Examples

- The following commands check the tie cell to assess if TIEH and TIEL are inserted for tie nets. If the `dontTouch` instance does not have a tie cell, violation will not be detected:

  ```
  setTieHiLoMode -cell {TIEH TIEL} -honorDontTouch true
  verifyTieCell -report vtc.rpt
  ```

- The following commands will check if `inst` or `pin` in `inst.list` has a tie cell. If it happens, a violation will be detected:

  ```
  setTieHiLoMode -cell {TIEH TIEL}
  verifyTieCell -noTieCell inst.list -report vtc.rpt
  ```

Related Information

- `addTieHiLo`
- `setTieHiLoMode`
- "Verifying Tie Cells" in the Identifying and Viewing Violations chapter of *User Guide*.

verifyWellAntenna

```
verifyWellAntenna
[-help]
[-needToProtect {cell_list}]
[-changeToProtect {cell_list}]
[-changeToNotProtect {cell_list}]
[-report filename [-detailed]]
```

Checks for any CORE rows that have well-process-antenna violations. Well-process-antenna violations are normally caused by rows with decap cells that do not have any protecting cells in the same row. This command marks with a violation marker any such CORE cell. You can then write a Tcl script to put in a well-antenna cell next to the violation marker.

Parameters

-help	Prints a brief description that includes the type and default information for each verifyWellAntenna parameter. For a detailed description of the command and all its parameters, use the man command: man verifyWellAntenna
-changeToNotProtect {*cell_list*}	Specifies the cell names that are to be marked as cells that do not protect rows. By default, the cells with LEF class CORE but without a subclass (e.g. normal BUF and AND2 cells) are assumed to have a well discharge path that protects a row from well-antenna violations. Use -changeToNotProtect option to override the default for any of these cells that do not protect a row. Pattern matching with * is allowed in cell names.
-changeToProtect {*cell_list*}	Specifies the cell names that are to be marked as protection cells. By default, cells with CLASS CORE and a subclass {FEEDTHRU | TIEHIGH | TIELOW | SPACER | ANTENNACELL | WELLTAP} or cells with class ENDCAP (with or without any subclass) do not have a well-discharge path to protect a row. Use the -changeToProtect option to override the default for any of these cells that do protect the row. Pattern matching with * is allowed.
-needToProtect {*cell_list*}	Specifies the cell names that need protection (typically decap cells). This option also indicates that the specified cells do not protect the row they are in. Pattern matching with * is allowed in cell names.
-report *filename*	Specifies the report file name. By default, the report includes information about only the cells that you specified with the options.
-detailed	If you specify -detailed, verifyWellAntenna reports every class CORE and ENDCAP cell with its subclass and protection status to the *filename* report.

Example

Normally, the decap cells are the only cells that need protection. However, if the standard-cell library in your design has one of the ENDCAP cells with a well-antenna protection device built-in, and the filler, well-tap, tie-high and tie-low cells are just class CORE rather than with the correct CORE sub-class, you can use the following command:

```
verifyWellAntenna -needToProtect decap* -changeToProtect wellAntEndCap -changeToNotProtect {filler*
welltap* tie*} -report wellant.rpt
```

Related Information

"Verifying Well-Process-Antenna Violations" in the Identifying and Viewing Violations chapter of *User Guide*.

verifyWellTap

```
verifyWellTap
[-help]
[-area x1 y1 x2 y2]
[-avoidAbutment]
[-check string]
[-cell list_of_well_tap_cells]
[-fromEdge]
[-layer layer_name]
[-powerDomain powerDomainName]
[-report filename]
[-rule distance]
[-siteOffset number_of_sites]
[-wellCutCell list_of_well_cut_cells]
```

Generates violation markers for missing well-tap cells and for well-tap cells that do not meet the rule specified for the distance between well-tap cells. Optionally, generates a well-tap violation report.

Honors the set_well_tap_mode settings for `-cell`, `-rule`, `-well_cut_cell`, `-bottom_tap_cell`, and `-top_tap_cell` options.

Marks violations in the area where well-tap placement violates the rule, covering the shared well of abutting rows. If there is no abutting row, marks the violation where it covers only one-half of a row with a violation.

Reports the actual distance between well-tap cells, as well as the rule distance. If there are no well-tap cells in a row and the row that abuts it, or no well-tap cells between the row end and the edge of a block, the software generates a message.

Does not check row areas that are covered by blocks and their halos, or by placement blockages.

The software places well-tap cells with the `addWellTap` command. You can delete well-tap cells with the `deleteFiller` command.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `verifyWellTap` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man verifyWellTap`
`-area x1 y1 x2 y2`	Specifies the area in which well-taps are to be verified.
`-avoidAbutment`	Checks that there is no abutted tap cell in the vertical and horizontal directions.
`-check string`	Checks the latchup rule violation for either Nwell or Pwell. The *`string`* can be either `power` (for Nwell check) or `ground` (for Pwell check).
`-cell list_of_well_tap_cells`	Specifies the well-tap cells. If not specified, uses cells defined as `CLASS CORE WELLTAP` in the Macro section of the LEF file.

`-fromEdge`	Checks the rule distance from the right and left edges of the well tap cells, instead of from the center line. Use this parameter when the design has well-tap cells of different widths. If this parameter is not specified, `verifyWellTap` checks the rule distance from the center line of the well-tap cells. `-layer` *`layer_name`*	Specifies the layer name to check the rule.
`-powerDomain` *`powerDomainName`*	Limits checking to the specified power domain. If you do not use this parameter, *`verifyWellTap`* checks the default domain with the designs of N3 or below nodes, and checks the entire design for the other nodes.
`-report` *`filename`*	Specifies the report name. *Default:* *`topCellName`*`.welltap.rpt`

`-rule` *distance*	Specifies the maximum distance between two well-tap cells. The spacing between two well-tap cells should be twice the `-rule` value when measured from center to center or edge to edge. The distance between tap and row end should be same as the `-rule` value. For example, `verifyWellTap -rule 50`. `-siteOffset` *number_of_sites*	Checks the offset value in number of sites that vertical taps need to be aware of. *Minimum*: `1` *Maximum*: `INT_MAX`
`-wellCutCell` *list_of_well_cut_cells*	Specifies the list of cells with the well cuts. Use this option to flag latch-up violations due to well cut cells.

Example

The following command displays violations due to well cut cells:

```
verifyWellTap -rule 30 -wellCutCell {EP32_VDDI_DSWITCH_50n_NOBUF EP32_VDDI_DSWITCH_50n_BUF} -cell
{EP8T32_VDDI_GNDS_CDM EP8T32_VDDI_VDDS_CDM}
```

verifyWireGap

```
verifyWireGap
[-help]
[-append]
[-area {x1 y1 x2 y2}]
[-layers layer_names]
[-net power_nets]
[-report filename]
[-wireToBoundary [-chip {v1 v2}] [-core {v1 v2}] [-block {v1 v2}] [-powerdomain {v1 v2}]]
[-wireToShape [-ring value]]
[-wireToWire value]
```

Verifies the continuity of follow pin and stripes. Use this command to identify power strap failures due to broken power wires in the power planning stage. The `verifyWireGap` command gives you the flexibility to check for breaks in a specific area and for specific layers or power nets.

Additionally, you can use this command to ensure that wires do not stop short of the expected distance from the chip, core, or block boundary.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `verifyWireGap` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man verifyWireGap`
`-append`	Specifies that all previous `verifyWireGap` settings will be kept.
`-area {x1 y1 x2 y2}`	Specifies the area to be checked.
`-block {v1 v2}`	Specifies the wire-to-block gap distance. Here: • *v1*: Specifies the threshold value or acceptable distance from the block boundary to the wire. • *v2*: Specifies how far to look from the block boundary to find wires that should be considered for the check. Use this check to ensure that vertical straps cover the horizontal straps underneath them near a block edge. For example, if you specify `verifyWireGap -wireToBounday -block {0 0.3}`, any wire that is at a distance less than 0.3um from the block boundary is reported as a violation. Wires that are at a greater distance than 0.3um are not flagged as violations as such breaks are assumed to be intentional.

`-chip {v1 v2}`	Specifies the wire-to-chip boundary gap distance. Here: • `v1`: Specifies the threshold value or acceptable distance from the chip boundary to the wire. • `v2`: Specifies how far to look from the chip boundary to find wires that should be considered for the check. For example, if you specify `verifyWireGap -wireToBounday -chip {0 0.3}`, any wire that is at a distance less than 0.3um from the chip boundary is reported as a violation. Wires that are at a greater distance than 0.3um are not flagged as violations as such breaks are assumed to be intentional.
`-core {v1 v2}`	Specifies the wire-to-core boundary gap distance. Here: • `v1`: Specifies the threshold value or acceptable distance from the core boundary to the wire. • `v2`: Specifies how far to look from the core boundary to find wires that should be considered for the check. For example, if you specify `verifyWireGap -wireToBounday -core {0 0.3}`, any wire that is at a distance less than 0.3um from the core boundary is reported as a violation. Wires that are at a greater distance than 0.3um are not flagged as violations as such breaks are assumed to be intentional.
`-layers layer_names`	Specifies the metal layers to be considered.
`-net power_nets`	Specifies the name of the power nets that will be checked.
`-powerdomain {v1 v2}`	Specifies the wire-to-power-domain gap distance. Here: • `v1`: Specifies the threshold value or acceptable distance from the power domain to the wire. • `v2`: Specifies how far to look from the power domain to find wires that should be considered for the check.
`-report filename`	Specifies the report file for `verifyWireGap` violations data.
`-ring value`	Specifies the wire-to-ring gap distance.
`-wireToBoundary`	Checks the wire to boundary gap. You must specify one of the following sub-options with `-wireToBoundary`: • `-block` to check the gap between wire and block boundary. • `-chip` to check the gap between wire and chip boundary. • `-core` to check the gap between wire and core boundary. • `-powerdomain` to check the gap between wire and power domain.
`-wireToShape`	Checks the gap between the wire and some specific shapes.

`-wireToWire` *value*	Specifies the wire-to-wire gap distance. Use this check to ensure that wires do not stop short of another wire of the same net or layer. For instance, you can use this check to ensure that wires connect properly to a power ring. If the wire-to-wire gap in the same net is less than the specified threshold value, `verifyWireGap` flags it as a violation. If the wire-to-wire is greater than the threshold value, the break is assumed to be intentional. 
Example

The following command checks wire-to-wire gap and flags wires in the same net that are closer than 0.2um:

```
verifyWireGap -wireToWire 0.2
```

violationBrowser

```
violationBrowser
[-help]
[-aclimit]
[-all]
[-area {x1 y1 x2 y2}]
[-connectivity]
[-density]
[-displayByLayer]
[-geometry]
[-max_error_per_type value]
[-no_display_false]
[-overlap]
[-process_antenna]
[-search_desc]
[-short]
[-filter_query LO_formula | {-filter filterString -filter_mode {AND | OR | NOT}}]
```

Displays a list of violations in the design database. The software generates markers for the violations after you use one or more verification commands.

Geometry or Metal Density Violations

Updates geometry and metal density violation markers incrementally during an Innovus session--that is, it displays the markers generated the first time you run the `verify_drc` or `verifyMetalDensity` command and adds new markers, or deletes markers, on subsequent runs during the same session. If the software finds violations during a subsequent run that were already found previously, the browser display does not change, as there is no incremental update.

The browser can make incremental changes because `verify_drc` and `verifyMetalDensity` can check a small area of the design and update the database. As a result of this behavior, the Innovus software saves the information from the first verification run.

Connectivity, Process Antennas, or AC Limit Violations

Overwrites connectivity, process antenna, and AC limit violation markers if the `verifyConnectivity` or `verifyACLimit` commands are run more than once during an Innovus session. These commands are net-based, not area-based, so the browser does not make incremental updates for them. As a result of this behavior, the Innovus software does not keep the information from the first verification run.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `violationBrowser` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man violationBrowser`
`-aclimit`	Displays AC limit violations.
`-all`	Displays all the violations that are present in the design. This is the default behavior.
`-area {`*`x1 y1 x2 y2`*`}`	Specifies the coordinates of the area whose violations to display. For example, `violationBrowser -area {0 0 100 100}`.
`-connectivity`	Displays connectivity violations.
`-density`	Displays metal density violations.
`-displayByLayer`	Displays the list of violations by the layer instead of route type.
`-filter` *`filterString`*	Specifies a text string in the violation message. Violation Browser searches the message of each violation and displays only the violations whose messages match the search conditions. To specify a list of strings, separate each string with a space. To specify a literal string with space in it, enclose the string in double quotation marks. For example, you can specify strings such as the following: • `METAL5` • `{"(600, 500)"}` • `{METAL3 "(700, 400)"}` • `"Pin of Net"`
`-filter_mode {AND | OR | NOT}`	Specifies the condition for searching multiple strings in the violation browser. You cannot filter complex expressions because the `AND`, `OR`, and `NOT` parameters are mutually exclusive. • The `AND` and `OR` conditions work on single strings or multiple strings. • The `NOT` condition works only on a single string.

`-filter_query` *`LO_formula`*	Specifies a complex logical expression for filtering violations. This option cannot be used along with `-filter` or `-filter_mode`. You can specify the AND, OR, and NOT conditions in the search expression. Use:
	• `&&` between strings in the expression to specify the AND condition.
	• `||` between strings in the expression to specify the OR condition.
	• ! before a string to specify the NOT condition. Note that ! is an one's complement operator. So for example, `!{object(net1) && layer(m2)}` is not allowed.
	The `-filter_query` parameter supports searches in the object, layer, and description areas. The area can be specified using the `object`, `layer`, and `desc` keywords. For example:
	`object(net1) || layer(m2) && desc(xxx)`
	You can also use the wildcards * and ? in the search expression. For example: `!object(clk*) && layer(m?)`
	To specify a literal string with space in it, enclose the string in double quotation marks. For example:
	`!object(clk*) && desc("prl spacing")`

`-geometry`	Displays geometry violations.
`-max_error_per_type` *`value`*	Specifies a limit for the number of violations parsed for each violation type. For example, if you set `violationBrowser -max_error_per_type 500`, the Violation Browser parses and displays only 500 markers per error type. Use this parameter if you are loading a large DRC file with millions of violations to prevent the databse from becoming slow while loading the file and to limit the number of violations you review in the browser. By default, the Violation Browser displays **all** markers.
`-no_display_false`	Prevents the Innovus software from displaying false violations.
`-overlap`	Displays overlaps in the design.
`-process_antenna`	Displays process antenna violations.
`-search_desc`	Searches for text in the violation message and the violation description.
`-short`	Displays short violations.

Examples

- The following command displays all violations whose marker title contains `METAL3`:

```
violationBrowser -all -filter METAL3 -filter_mode OR
```

- The following command displays geometry violations whose marker title contains `METAL3` and `tdsp`:

```
violationBrowser -geometry -filter {METAL3 tdsp} -filter_mode AND
```

- The following command displays geometry violations whose marker title or marker description field contains `Min` and `0.24` and `METAL3`:

```
violationBrowser -geometry -filter {Min 0.24 METAL3} -filter_mode AND -search_desc
```

- The following command displays violations occuring on Metal4 or Metal5 layers but excludes short violations:

```
violationBrowser -filter_query {!Short && (metal4 || metal5)}
```

Related Information

- The following section in the Identifying and Viewing Violations chapter of *User Guide*.
  - Viewing Violations With the Violation Browser
  - Clearing Violations
- "Evaluating Violations" in the Using the NanoRoute Router chapter of *User Guide*.

violationBrowserDeleteByArea

```
violationBrowserDeleteByArea
[-help]
[-all]
[-area {x1 y1 x2 y2}]
```

Deletes markers from a specified area or the entire design area. When the `-area` and `-all` parameters of this command are specified at the same time, `-all` is applied.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `violationBrowserDeleteByArea` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man violationBrowserDeleteByArea`
`-all`	Deletes markers from the entire design area.
`-area {x1 y1 x2 y2}`	Specifies a bounding box for the area from which to delete markers. For example, `violationBrowserDeleteByArea -area {0 0 100 100}`.

Related Information

- Identifying and Viewing Violations chapter of *User Guide*.
- "Evaluating Violations" in the Using the NanoRoute Router chapter of *User Guide*.

violationBrowserReport

```
violationBrowserReport
[-help]
[-all]
[-aclimit]
[-connectivity]
[-density]
[-geometry]
[-max_error_per_type integer]
[-no_display_false]
[-overlap]
[-process_antenna]
[-short]
[-area {x1 y1 x2 y2}]
[-report filename]
[-filter filterString]
[-filter_mode {AND | OR | NOT}]
[-search_desc]
```

Reports violations flagged by the verification commands. The report file and violation browser list the violations in the same order.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `violationBrowserReport` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man violationBrowserReport`
`-aclimit`	Reports AC limit violations.
`-all`	Reports all violations.
`-area {x1 y1 x2 y2}`	Specifies the coordinates of the area for which to report violations. For example, `violationBrowserReport -area {0 0 100 100}`.
`-connectivity`	Reports connectivity violations.
`-density`	Reports metal density violations.

`-filter` *`filterString`*	Specifies a text string in the violation message (in the bottom portion of the Violation Browser). When you specify a text string, the Violation Browser searches the message of each violation and displays only the violations whose messages match the search conditions. To specify a list of strings, separate each string with a space. To specify a literal string with space in it, enclose the string in double quotation marks. For example, you can specify strings such as the following: • `METAL5` • `(600, 500)` • `METAL3 (700, 400)` • `"Pin of Net"`
`-filter_mode {AND | OR | NOT}`	
	Specifies the condition for searching multiple strings in the violation browser. You cannot filter complex expressions because the AND, OR, and NOT parameters are mutually exclusive. • The `AND` and `OR` conditions work on single strings or multiple strings. • The `NOT` condition works only on a single string.
`-geometry`	Reports geometry violations.
`-max_error_per_type` *`integer`*	
	Specifies the error marker number limit for each type of error. Specifies a limit for the number of violations parsed for each violation type. For example, if you set `violationBrowserReport -max_error_per_type 500`, the Violation Browser parses and displays only 500 markers per error type in the report. Use this parameter if you are loading a large DRC file with millions of violations to prevent the database from becoming slow while loading the file and to limit the number of violations you review in the browser. By default, the Violation Browser displays **all** markers in the report.
`-no_display_false`	Prohibits the Innovus software from displaying false violations.
`-overlap`	Reports overlap violations.
`-process_antenna`	Reports process antenna violations.
`-report` *`filename`*	Specifies the report file for the violation information. *Type:* String
`-search_desc`	Searches the description field for each marker in addition to the table entries.
`-short`	Reports short violations.

Examples

- The following command reports all violations whose marker title contains `METAL3`:

```
violationBrowserReport -all -filter METAL3
```

- The following command reports geometry violations whose marker title contains `METAL3` or `tdsp`:

```
violationBrowserReport -geometry -filter {METAL3 tdsp} -filter_mode OR
```

- The following command reports geometry violations whose marker title or marker description field contains `Min` and `0.24` and `METAL3`:

```
violationBrowserReport -geometry -filter {Min 0.24 METAL3} -filter_mode AND -search_desc
```

What-If Timing Commands

- checkWhatIfTiming
- createWhatIfInternalGeneratedClock
- deleteWhatIfTimingAssertions
- getWhatIfTimingAssertions
- getWhatIfTimingMode
- saveWhatIfConstraints
- saveWhatIfTimingAssertions
- saveWhatIfTimingModel
- setWhatIfClockLatency
- setWhatIfClockPort
- setWhatIfDriveType
- setWhatIfLoadType
- setWhatIfPortParameters
- setWhatIfPortPriority
- setWhatIfTimingMode

The what-if timing analysis commands do not support the Multi-Mode Multi-Corner (MMMC) feature.

checkWhatIfTiming

```
checkWhatIfTiming
blackBoxCellName
[-outfile fileName]
```

Checks that at least one timing arc is defined for every port of a blackbox or blackblob. You use this command to output the status of the timing arcs for all ports to complete the blackbox or blackblob timing arc specifications for the remaining ports.

You can use this command after the module definition of the blackbox or the blackblob is available with the I/O's in the Verilog netlist.

Parameters

blackBoxCellName	Specifies the name of the blackbox or blackblob cell.
-outfile *fileName*	Specifies the name of the file to save the information.

Related Information

- What-If Timing Analysis chapter in the *Innovus User Guide*
  - Performing What-If Timing Analysis
  - Using the What-If Timing Commands

createWhatIfInternalGeneratedClock

```
createWhatIfInternalGeneratedClock
blackBoxCellName
[-help]
-clockName genClkName
-clockPin internalPinName
-masterPin clockInputPort
[-edge_shift edge_shift_list]
[-noCreateInternalPin]
[-invert]
{-multiplyBy integer | -divideBy integer | -edges edge_list}
```

Creates an internal pin on a blackbox or a blackblob, and creates a generated clock on this internal pin. The timing graph is updated accordingly.

The following points apply to the usage of this command:

- The internal pin created with this command will be treated as a clock port. This internal pin can, therefore, be used to create check arcs.
  The latency of the generated clock should include the latency of the master clock. Therefore, the latency of the generated clock should be greater than or equal to the latency of the master clock.

  The delay specified during defining the timing arcs from the internal pins must be greater than or equal to the generated clock latency.
- You can use the generated clock to define timing arcs--these timing arcs are used for timing analysis. Instead of the clock name, the clock pin is referenced while defining the timing arcs. Any timing arc related to the internal pin must include the clock latencies defined on both: the internal pin *and* the master pin.
- You can also use this command to specify that a generated clock should be created on an existing internal pin by specifying the `-noCreateInternalPin` parameter.
- If a cell has multiple instances, a generated clock will be defined for each instance of the cell.
- You can set the latency of the generated clock by using the setWhatIfClockLatency command. The generated clock appears in the block SDC file generated by the saveWhatIfTimingModel command.
- Ensure that the latencies of the generated clock and the master clock are defined before creating any timing arc using the what-if timing analysis commands.

- The internal pin and the generated clock will be treated as what-if assertions and can be deleted with the deleteWhatIfTimingAssertions command.

You can use this command after the module definition of the blackbox or the blackblob is available with the I/O's in the Verilog netlist.

Parameters

blackBoxCellName	Specifies the name of the blackbox or blackblob cell.
-clockName *genClkName*	Specifies the name of the clock.generated on the internal pin.
-clockPin *internalPinName*	Specifies the name of the pin generated inside the blackbox or blackblob.
-divideBy *integer*	Specifies the frequency division factor. The generated clock period is equal to the master clock period multiplied by this parameter. For example, if the value of this parameter is 2, the generated clock period is two times the master clock period. This parameter takes an integer value.
-edge_shift *edge_shift_list*	Specifies the amount of shift for each edge in the specified edge list.
-edges *edge_list*	Specifies the list of edges from source clock to the derived clock.
-invert	Inverts the source clock.
-masterPin *clockInputPort*	Specifies the source from which the derived clock is generated. **Note:** The source must be an existing clock port. and a clock should be available on this port.
-multiplyBy	Specifies the frequency multiplication factor. The generated clock period is equal to the master clock period divided by this parameter. For example, if the value of this parameter is 2, the generated clock period is half the master clock period. This parameter takes an integer value.

`-noCreateInternalPin`	Specifies that a generated clock should be created on an existing internal pin. In this case, the `-clockPin` *`internalPinName`* parameter should specify the existing internal pin.

Related Information

- Using the What-If Timing Commands section in the *Innovus User Guide*.

Examples

The following command created an internal pin named `internalPin1` and a generated clock named `genCLK1` on the blackbox or blackblob named `block3`. The master pin specified is `genCLK1` and the divide-by-frequency specified is `2`.

```
createWhatIfInternalGeneratedClock block3 -clockName genCLK1 -clockPin internalPin1 -masterPin CLK1-divideBy 2
```

deleteWhatIfTimingAssertions

```
deleteWhatIfTimingAssertions
[blackBoxCellName]
[-port portName | -from port -to port | -from port | -to port]
[-assertion_type {comb | setup | hold}]
[-rising | -falling]
```

Removes the timing arc specifications of the specified blackbox or blackblob. When you use this command, the Innovus software restores the timing arcs of the initial library.

You can use this command after the module definition of the blackbox or the blackblob is available with the I/O's in the Verilog netlist.

Note: You can delete the internal pin and the generated clock created by the createWhatIfInternalGeneratedClock command by specifying the `-port` parameter of this command. However, the clock and the pin will not be deleted if you use the `-from` *port*, `-from` *port* `-to` *port*, or the `assertion_type` parameters.

Parameters

blackBoxCellName	Specifies the name of the blackbox or blackblob cell. If you do not specify this parameter, all timing arc specifications are removed.
-port *portName*	Specifies the name of one or more ports.
-falling	Specifies that timing arcs should be deleted for falling clock transitions.
-from *port* -to *port*	Specifies that all arcs starting from the port specified with -from and ending at the port.specified with -to.will be deleted. **Note:** Any constraints specified with the -assertion_type parameter and the -rising parameter will be applicable. **Note:** The deletion of a timing arc using the -from and/or -to parameter does not delete the what-if driver assertion on the output ports.
-from *port*	Specifies that all arcs starting from the port specified with -from will be deleted. **Note:** Any constraints specified with the -assertion_type parameter and the -rising parameter will be applicable.
-rising	Specifies that timing arcs should be deleted for rising clock transitions.
-to *port*	Specifies that all arcs ending at the port.specified with -to.will be deleted. **Note:** Any constraints specified with the -assertion_type parameter and the -rising parameter will be applicable.
-assertion_type {comb | setup | hold}	Specifies whether the timing arcs should be deleted for rising clock transitions or for falling clock transitions. Default: If you do not specify this parameter, timing arcs are deleted for both rising and falling clock transitions.

getWhatIfTimingAssertions

```
getWhatIfTimingAssertions
blackBoxCellName
-port portName
[-tclList]
```

Displays the what-if timing arc specifications of the specified port in the command window.

You can use this command after the module definition of the blackbox or the blackblob is available with the I/O's in the Verilog netlist.

Parameters

blackBoxCellName	Specifies the name of the blackbox or blackblob cell.
-port *portName*	Specifies the name of the port.
-tclList	Generates the specifications as a Tcl list. The Tcl list is useful for integrating what-if timing with custom Tcl functions and customizing specification generation.

Related Information

- Using the What-If Timing Commands
- saveWhatIfTimingAssertions
- deleteWhatIfTimingAssertions

getWhatIfTimingMode

```
getWhatIfTimingMode
[-quiet]
```

Displays the following information about `setWhatIfTimingMode` parameters in the system log file and in the system console:

- Parameter name
- Current value
- Type (Boolean, string, and so on)
- Whether the current value was set by user

If you do not specify a parameter, the software displays values for all of the `setWhatIfTimingMode` mode parameters.

Parameters

parameter_names	
	Returns information for the specified parameter. You can specify one or more parameters. See setWhatIfTimingMode for parameter descriptions.
`-quiet`	Returns the current settings for the specified parameters in Tcl list format only. If you specify `-quiet` without any parameters, the software returns the current settings of all `setWhatIfTimingMode` parameters in Tcl list format.

Related Information

- `setWhatIfTimingMode`

saveWhatIfConstraints

```
saveWhatIfConstraints
[blackBoxCellName]
[-pt | -dc]
[-dir dirName]
[-filePrefix prefix]
```

Saves the what-if timing constraints in Design Compiler format. You can use this command after the module definition of the blackbox or the blackblob is available with the I/O's in the Verilog netlist.

Parameters

blackBoxCellName	Specifies the name of the blackbox or blackblob cell. *Default:* If you do not specify a name for the blackbox or blackblob cell, constraints are saved for all blackbox or blackblob cells.
-dir *dirName*	Specifies the name of the directory in which the constraints file will be generated. This directory must reside within the current working directory. *Default:* The constraints file is saved in the current working directory.
-filePrefix *prefix*	Specifies the prefix for the constraints file name. This prefix is added to the name of the blackbox or blackblob cell to generate the name of the constraints file. For example, if you specify the prefix `constraintsFile` and the blackbox or blackblob cell name is `Block1`, the name of the file in which the constraints are saved will be `constraintsFileBlock1.pt` or `constraintsFileBlock1.dc`. *Default:* If you do not specify a prefix, the constraints file is saved as *blackBoxCellName*`.pt` or *blackBoxCellName*`.dc`, where *blackBoxCellName* is the name of the blackbox or blackblob cell.
-pt | -dc	Specifies the constraint format. *Default:* Constraints are saved both in PT and DC format.

- Performing What-If Timing Analysis
- Using the What-If Timing Commands

saveWhatIfTimingAssertions

```
saveWhatIfTimingAssertions
[blackBoxCellName]
-outfile fileName | -tclList
```

Writes timing arcs to the specified file or Tcl list. The Innovus software saves the final state of the timing arc. The history of all the modifications is not saved. You can source the generated file, regrouping the whole timing arc specifications of the blackbox or blackblob in a new Innovus session.

You can use this command after the module definition of the blackbox or the blackblob is available with the I/O's in the Verilog netlist.

Parameters

blackBoxCellName	Specifies the name of the blackbox or blackblob cell. If the name is not specified, all timing arc specifications are saved.
`-outfile` *fileName*	Specifies the name of the output file in which to save the information.
`-tclList`	Generates the timing arcs as a Tcl list. The Tcl list is useful for integrating what-if timing with custom Tcl functions.

  - Performing What-If Timing Analysis
  - Using the What-If Timing Commands

saveWhatIfTimingModel

```
saveWhatIfTimingModel
[-help]
blackBoxCellName
[-outfile fileName]
```

Saves the specification of black boxes or black blobs at the top level, including the timing arc specifications in the dotlib library file format.

You can use this command after the module definition of a black box or black blob is available with the I/O's in the Verilog netlist.

Parameters

`-help`	Prints out the command usage.
`blackBoxCellName`	Specifies the name of the black box or black blob cell.
`-outfile` *`fileName`*	Specifies the name of the file to save the information. *Default:* *`BBoxName`*`.lib`

setWhatIfClockLatency

```
setWhatIfClockLatency
blackBoxCellName
[-clockFrom clockPortName]
[-init value]
[-new value]
[-genConstr value]
```

Specifies the clock insertion delay from a clock input port to register clock input pins within a blackbox or blackblob.

You can use this command after the module definition of the blackbox or the blackblob is available with the I/O's in the Verilog netlist.

Parameters

blackBoxCellName	Specifies the name of the blackbox or blackblob cell.
-clockFrom *clockPortName*	Specifies the name of the clock input port. If you do not specify this parameter, the clock insertion delay is specified for all input and bidirectional clock ports.
-init *value*	Specifies the current clock insertion delay value. This value indicates the clock insertion delay used when the software generates the original timing model. This value is used for timing checks or sequential timing arcs. You must specify this value before modifying a timing check or a sequential timing arc. If you modify at least one timing arc, you cannot directly change the clock latency value. You must first delete the timing arc specifications of the blackboxes or blackblobs using the `deleteWhatIfTimingAssertions` command.
-new *value*	Specifies the new clock latency value. This value modifies the clock insertion delay. As the clock insertion delay is included in the timing arc value, the software adds the difference between the current and new clock latency value to all timing arcs starting from the specified clock port. Therefore all timing arcs starting from the specified clock port, including the timing arcs that were not modified using the what-if timing commands, are modified.
-genConstr *value*	Specifies the latency to consider in the what-if timing constraints generation. By default, the value is automatically set to the current clock insertion delay. If you do not modify the latency value, the generated SDC constraints reflect the timing analysis done at the top level. If you set a latency value other than current clock insertion delay, the timing analysis is not impacted.

Related Information

  - Timing Models Supported for What-If Timing Analysis
  - Using the What-If Timing Commands

setWhatIfClockPort

```
setWhatIfClockPort
blackBoxCellName
-port portName
```

Defines a port as a clock port. You can then use the clock port to create timing checks and sequential timing arcs. Therefore, you can do what-if timing analysis without loading the .lib file.

You can use this command after the module definition of the blackbox or the blackblob is available with the I/O's in the Verilog netlist.

Parameters

blackBoxCellName	Specifies the name of the blackbox or blackblob cell.
-port *portName*	Specifies the name of the clock port.

setWhatIfDriveType

```
setWhatIfDriveType
blackBoxCellName
[-port outputPortName]
[-lib libName]
-cell cellName
[-slew value [-outputCap value]]
[-inputPin libraryInputPin]
[-outputPin libraryOutputPin]
```

Sets the output and bidirectional ports that have the specified type of cell within the blackbox or blackblob as drivers on the interface nets. You can not specify two different drivers for two timing arcs ending at the same output port. The software stores the drive type specification, and uses it to create a timing arc after you specify the delay.

You can use this command after the module definition of the blackbox or the blackblob is available with the I/O's in the Verilog netlist.

Note: The timing sense of the driver is taken into account in the combinatorial what-if timing arc description--while applying the drive type, the timing sense of the combinatorial arc is replaced by the timing sense of the driver's timing arc. For sequential arcs, the timing sense is always set to `non_unate`.

Parameters

blackBoxCellName	Specifies the name of the blackbox or blackblob cell.
-cell *cellName*	Specifies the name of the cell. If there are two cells with the same name, the software uses the first one found. You can specify a complex cell (with multiple inputs and/or outputs) with this parameter.
-lib *libName*	Specifies the name of the timing library.

`-outputCap` *value*	The value for this parameter is set as follows:
	• If the value of the -context parameter of the `setWhatIfTimingMode` is set to `in`, the output capacitance value is equal to the real capacitance. The `-outputCap` parameter of the `setWhatIfDriveType` command is not applicable in this case.
	• If the value of the -context parameter of the setWhatIfTimingMode is set to `out`:
	  ◦ If the `-outputCap` parameter is specified with the `setWhatIfDriveType` command, the output capacitance is set to this value.
	  ◦ If the `-outputCap` parameter is *not* specified with the `setWhatIfDriveType` command, the outputCap value as specified with the -outputCap parameter of the `setWhatIfTimingMode` is used as the output capacitance for the `setWhatIfDriveType` command.
	ⓘ You cannot use this parameter in the intrinsic timing model mode.

`-port` *outputPortName*	Specifies the name of the output port. If you do not specify a port name, the software sets all output and bidirectional ports as drivers on the interface nets. Each time you modify the driver on an output port of the blackbox or blackblob, the software recalculates all timing arcs attached to the output port with the new driver specification.
`-slew` *value*	Specifies the slew at the input of the driver cell. If you specify the slew value, the software creates a one-dimensional timing table depending on the output capacitance. If you do not specify the slew value, the software creates a two-dimensional timing table with input slew and output capacitance values. In this case, the software assumes that there is no slew variation between the input port of the blackbox or blackblob, and the driver input pin. You must use this parameter in the normalized timing model mode. This parameter is not available in the intrinsic timing model mode

`-inputPin` *`LibraryInputPin`*	Specifies the input or inout pin of the cell (specified by the `-cell` parameter) whose source arcs will be used for setting the drive type on the port. *Default*: If this parameter is not specified, the software selects an input or inout pin automatically.
`-outputPin` *`LibraryOutputPin`*	Specifies the output or inout pin of the library whose source arcs will be used for setting the drive type on the port. *Default*: If this parameter is not specified, the software selects an output or inout pin automatically.

Related Information

- `setWhatIfTimingMode`

setWhatIfLoadType

```
setWhatIfLoadType
blackBoxCellName
[-port inputPortName]
[-lib libName]
-cell libraryCellName
[-inputPin libraryInputPin]
[-multiply_by value]
```

Specifies that the load on any input or any inout what-if port should be the same as that of the specified library input or inout pin.

Parameters

blackBoxCellName	Specifies the name of the blackbox or blackblob cell.
-cell library*CellName*	Specifies the name of the cell from which the load value will be picked.
-inputPin *libraryInputPin*	The library cell input or inout pin whose source arcs will be used for setting the load on the port. *Default*: If this parameter is not specified, the software selects an input or inout pin automatically.
-lib *libName*	Specifies the name of the timing library from which the specified cell will be picked. *Default*: The library is selected automatically based on the current context.
-multiply_by *value*	Specifies the load value multiplication factor. The applied load on the blackbox or blackblob is equal to the load of the specified cell pin multiplied by this factor. This parameter takes an integer or floating point value. *Default*: If no value is specified, the multiplication factor is set to 1.
-port *inputPortName*	Specifies the input or inout port of the blackbox or blackblob. *Default*: If no port is specified, the load is applied to all ports.

Examples

The following command sets the load on the `input_Port1` of blackbox `Blackbox1` to the same as that on input pin `Pin_A1` of cell bufx1 of library `library_DelayLogic`.

```
setWhatIfLoadType Blackbox1 -port input_Port1 -lib library_DelayLogic -cell bufx1 -
inputPin Pin_A1
```

Related Information

- `setWhatIfTimingMode`

setWhatIfPortParameters

```
 setWhatIfPortParameters
blackBoxCellName
[-port portName]
[-cap capacitanceValue]
[-cell <cell name>]
[-max_cap maxCapacitanceValue]
[-max_trans maxTransitionValue]
[-max_fanout maxFanoutValue]
[-pin <pin name>]
```

Sets the following values on the what-if cell ports:

- Capacitance
- Maximum capacitance
- Maximum transition
- Maximum fanout

You can use this command after the module definition of the blackbox or the blackblob is available with the I/O's in the Verilog netlist.

Parameters

blackBoxCellName	Specifies the name of the blackbox or blackblob cell.
-cell <cell name>	Specifies the name of library cell from which DRVs are inferred.
-pin <pin name>	Specifies the name of pin from which DRVs are inferred.

-port *portname*	Specifies the name of the clock port on which to set the value(s).
	Default: By default, the specified parameters are applied to all ports in the what-if timing analysis model.
	Note: The value specified for a particular port override the global values. For example, consider the following use case scenario for a cell `b_cell`:
	1. You specify a maximum fanout value for all ports to 20 (without specifying any port with the command):
	`setWhatIfPortParameters b_cell -max_fanout 20`
	• You then run the command again on port `out1` with a maximum fanout value of 5.
	`setWhatIfPortParameters b_cell -max_fanout 5 -port out1`
	In this case, the maximum fanout for port `out1` will be set to 5.

-cap *capacitanceValue*	Specifies the capacitance value in picoFarad. This is the capacitance within the blackbox or the blackblob, on the specified I/O port. The value can be in decimal, for example, `0.75`.
-max_cap *maxCapacitanceValue*	Specifies the maximum capacitance value. This is the maximum value of capacitance permitted on the net going through the I/O port.
-max_fanout *maxfanOutValue*	Specifies the maximum fanout value. The value should be an integer, for example 20.
-max_trans *maxTransitionValue*	Specifies the maximum transition value in nanoseconds. The value can be in decimal, for example, 5.3.

Examples

- The following command sets the maximum capacitance value to `1.0` and the maximum fanout value to `20` for the port `a1_outport1` of the blackbox or blackblob cell named `blockCell2A`.

  ```
  setWhatIfPortParameters blockCell2A -port a1_outport1 -max_fanout 20 -max_cap 1.0
  ```

- The following command is similar to the previous command, except that it sets the values for all ports (as no port is specified with the command)

  ```
  setWhatIfPortParameters blockCell2A -max_fanout 20 -max_cap 1.0
  ```

- The following set of commands set the values as follows
  - the maximum maximum fanout value to `20` for all the ports except port `a1_outport1`
  - the maximum fanout value to 5 and the maximum capacitance value to 1.3 for port `a1_outport1`

    ```
    setWhatIfPortParameters blockCell2A -max_fanout 20

    setWhatIfPortParameters blockCell2A -max_fanout 5 -max_cap 1.3 -port
    a1_outport1
    ```

setWhatIfPortPriority

```
setWhatIfPortPriority
[-driveCell | -portParam]
```

> Command `setWhatIfPortPriority` is obsolete and has been replaced by setWhatIfTimingMode.

On output ports, parameters such as capacitance value, maximum capacitance values, maximum transition value, or the maximum fanout value can come from the driver (`setWhatIfDriveType` command) or they can be set through the `setWhatIfPortParameters` command.

The `setWhatIfPortPriority` command defines which of these values will take precedence in case of a conflict.

You can use this command after the module definition of the blackbox or the blackblob is available with the I/O's in the Verilog netlist.

Note: This feature is available only in the CTE mode.

Parameters

`-driveCell`	Specifies that the values set through the setWhatIfDriveType command will take precedence
`-portParam`	Specifies that the values set through the setWhatIfPortParameters command will take precedence.

The default value is `-portParam`.

setWhatIfTimingMode

```
setWhatIfTimingMode
[-help]
[-reset]
[-context {in | out}]
[-defaultOutputCap value ]
[-model {intrinsic | normalized}]
[-portPriority {cellType | portParam}]
```

Sets the timing model mode for all blackboxes or blackblobs of the design. You can select only one mode for all blackboxes or blackblobs. For more information on the timing models, see " What-If Timing Analysis ," in the *Innovus User Guide*.

If you modify at least one timing arc, you cannot directly change the mode for the blackboxes or blackblobs. You must first delete the timing arc specifications of the blackboxes or blackblobs using the deleteWhatIfTimingAssertions command.

You can use this command after the module definition of the blackbox or the blackblob is available with the I/O's in the Verilog netlist.

Parameters

`-context [{in | out}]`	Specifies whether the timing mode description is `in-context` or `out-context`. The context refers to the chip-level context. • In-context: The timing mode description is created once the chip environment is ready, that is, after placement and routing. In this case, the software takes into consideration the capacitance of the design. • Out-context: The timing model is described outside the chip environment and can be described before floorplanning. You provide the value of the timing arc for a given capacitance. The value of the `-outputCap` parameter of the setWhatIfDriveType command is set based on whether the context is `in` or `out`. ⓘ The `-context` parameter can be used only in the normalized mode. The value of the `-context` parameter is frozen once a timing arc is defined. This is done to avoid having an incorrect timing assertion file later in the flow. *Default*: The default value is `out`.
`-defaultOutputCap [ value ]`	Specifies the value of the default output capacitance on the port. ⓘ The `-defaultOutputCap` parameter can be used only in the normalized mode. The value of the `-defaultOutputcap` parameter is frozen once a timing arc is defined. This is done to avoid having an incorrect timing assertion file later in the flow. The unit is pico farads. *Default*: The default value is 0.

`-help`	Outputs a brief description that includes type and default information for each `setWhatIfTimingMode` parameter. For a detailed description of the command and all of its parameters, use the man command: `man setWhatIfTimingMode`.
`-model {intrinsic | normalized}`	Specifies whether the timing model mode is *intrinsic* or *normalized*. *Default:* The default mode is *normalized*.
`-portPriority {cellType | portParam}`	On output ports, parameters such as capacitance value, maximum capacitance values, maximum transition value, or the maximum fanout value can come from the driver (`setWhatIfDriveType` command) or they can be set through the `setWhatIfPortParameters` command. You can use the -portPriority parameter to specify which of these values take precedence in case of a conflict. • The value `cellType` specifies that the parameter values set through the `setWhatIfDriveType` command take precedence. • The value `portParam` specifies that the parameter values set through the `setWhatIfPortParameters` command take precedence. *The value of the portPriority parameter is frozen once a what-if timing arc has been defined. This avoids inconsistencies between he timing analysis files and the files that you can generate (such as whatif assertions, timing model, or SDC) if you change the port priority subsequently.* *Default*: The default value is `portParam`.
`-reset`	Resets parameters to their default values. The `-reset` parameter *must* be the first parameter specified. If you specify `-reset` by itself, the software resets all `setWhatIfTimingMode` parameters to their default values. If you specify parameters after `-reset`, the software resets only those parameters to their default values. **Note**: Any values that do not already match the default value and are reset will be reported.

Examples

- The following command sets the timing model mode to intrinsic and specifies that in case of a conflict, the parameter values set through the `setWhatIfDriveType` command takes precedence over the parameter values set through the setWhatIfPortParameters command. Because the `-defaultOutputCap` parameter and the -context parameter were not specified, the output capacitance is set to 0, and the context is set to out.

  ```
  setWhatIfTimingMode -model intrinsic -portPriority cellType
  ```

- The following command resets the value of the `-model` and the `-portPriority` parameters. Note that the `-reset` parameter is the first parameter in the command.

  ```
  setWhatIfTimingMode -reset -model -portPriority
  ```

- The following command resets the value of all the `setWhatIfTimingMode` parameters

  ```
  setWhatIfTimingMode -reset
  ```

deleteSecondaryPGNet

```
deleteSecondaryPGNet
[-help]
-insts inst+
-net net
```

Deletes Power/Ground (P/G) net wire segments from specified instances. This command provides an easy way to delete the routing from specific instance P/G pins to stripes.

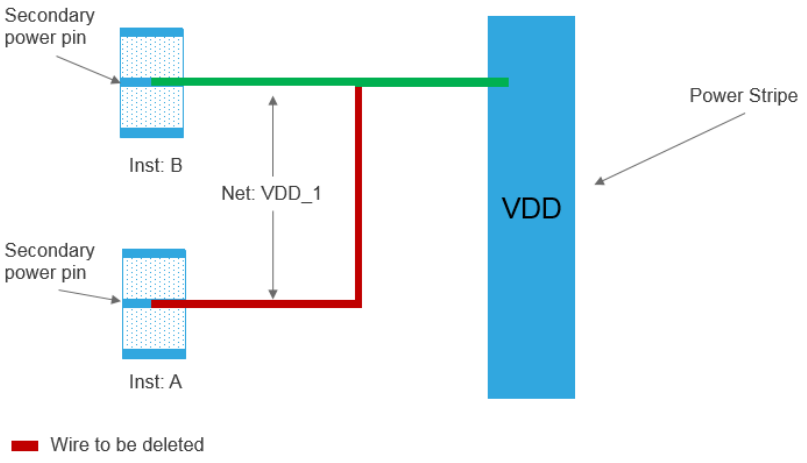
Note: This command does not support dangling secondary P/G nets.

Parameters

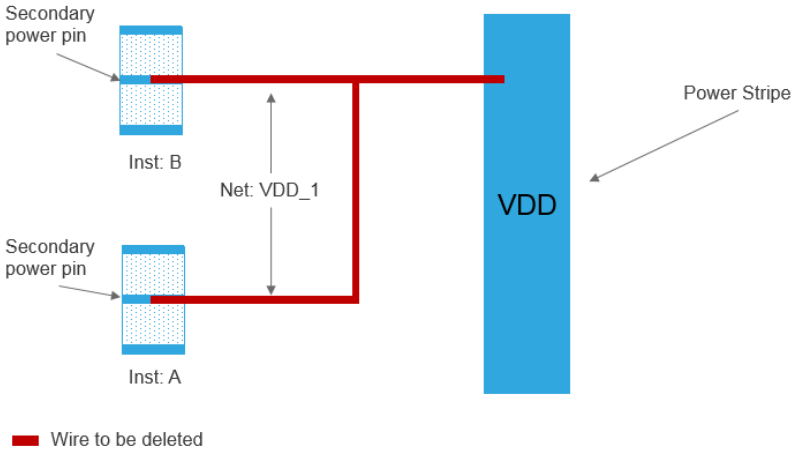
`-help`	Prints the usage of the command. For a detailed description of the command, use the `man` command: `man deleteSecondaryPGNet`
`-insts inst+`	Specifies the list of instances that have a secondary PG pin. Wildcards are supported in instance names. If one or more specified instances does not connect with the specified net, the tool displays a warning and ignores those instances.
`-net net_name`	Specifies the net name. **Note**: *net_name* does not take any wildcard values.

Examples

- The following command deletes the routing from the instance `A` P/G pin in net `VDD_1` to the power stripe:
  ```
  deleteSecondaryPGNet -net VDD_1 -insts {A}
  ```



- The following command deletes the routing from the P/G pins in instances `A` and `B` in net `VDD_1` to the power stripe:
  ```
  deleteSecondaryPGNet -net VDD_1 -insts {A B}
  ```



- The following command deletes the routing from the P/G pins in instances `A/B1` and A/B2 in net `VDD_1` to the power stripe:
  `deleteSecondaryPGNet -net VDD_1 -insts {A/*}`

deselectSecondaryPGNet

```
deselectSecondaryPGNet
[-help]
-insts inst+
-net net
```

Deselects Power/Ground (P/G) net wire segments from specified instances. This command provides an easy way to deselect the routing from specific instance P/G pins to stripes.

Note: This command does not support dangling secondary P/G nets.

Parameters

`-help`	Prints the usage of the command. For a detailed description of the command, use the `man` command: `man deselectSecondaryPGNet`
`-insts inst+`	Specifies the list of instances that have a secondary PG pin. Wildcards are supported in instance names. If one or more specified instances does not connect with the specified net, the tool displays a warning and ignores those instances.
`-net net_name`	Specifies the net name. **Note**: `net_name` does not take any wildcard values.

Examples

- The following command deselects the routing from the instance `A` P/G pin in net `VDD_1` to the power stripe:
  ```
  deselectSecondaryPGNet -net VDD_1 -insts {A}
  ```
- The following command deselects the routing from the P/G pins in instances `A` and `B` in net `VDD_1` to the power stripe:
  ```
  deselectSecondaryPGNet -net VDD_1 -insts {A B}
  ```
- The following command deselects the routing from the P/G pins in instances `A/B1` and A/B2 in net `VDD_1` to the power stripe:
  ```
  deselectSecondaryPGNet -net VDD_1 -insts {A/*}
  ```

editAddFillet

```
editAddFillet [-help]
```

Adds a tear-drop fillet between a wire and bump connection. A teardrop fillet is used to reinforce the mechanical strength of the connection to the bump. This applies to all bumps in the design. If the connected wire is too short to create the fillet, a marker is created to indicate the failure.

Parameters

`-help`	Prints the usage of the command. For a detailed description of the command, use the `man` command: `man editAddFillet`

Related Information

editAddPoly

```
editAddPoly
[-help]
point
```

Defines a vertex or corner of a polygon. By issuing the `editAddPoly` command `n` times, you can create a polygon with `n+1` sides. You can then specify the `editCommitPoly` command to end the polygon at the specified coordinates. `editAddPoly` honors the `setEditMode -shape` option. This means if you want to create a polygon of a specific shape, you can first use `setEditMode -shape` to specify the required shape and then use `editAddPoly` and `editCommitPoly` to create the polygon.

The `editAddPoly` command is DRC aware. When you create a polygon shape using this command, the tool marks any DRC violations in the shape during creation, provided that `setEditMode -dcr_on` is set to `1` (default).

Parameters

`-help`	Prints a brief description that includes type and default information for each `editAddPoly` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man editAddPoly`
`point`	Specifies the `x` and `y` coordinates of a vertice or corner of a wire polygon.

Example

- The following commands create three-sided wire polygon that ends at the point specified by `editCommitPoly`.

  ```
  editAddPoly 700 300
  editAddPoly 700 500
  editCommitPoly 200 400
  ```

  The first side of the wire polygon starts at `700, 300` and ends at `700, 500`. The second side starts at `700, 500` and ends at `200, 400`. The third side is formed by joining the starting point of the polygon (`700,300`) and the ending point specified by `editCommitPoly` (`200,400`).

  - *Wire* section

editAddRoute

```
editAddRoute
[-help]
point
```

Creates a wire segment that starts or ends at the specified coordinates. Splits diagonal wires whose width is greater than the LEF `MAXWIDTH` parameter for that layer as they are drawn.

If required, the tool allows you to change the net order while adding wire segments. Check the **Examples** sections for details.

Note: Before running any Wire Editor command, all objects and pre-routed wires/vias must be colorized already.

If you do not want to view flight lines between Power and Ground (PG) wires and pins when drawing PG nets, use `setLayerPreference flightLine -isVisible 0` to turn off the display of these flightlines. `editAddRoute` as well as `editCommitRoute` honor this setting.

Parameters

`-help`	Prints a brief description that includes type and default information for each `editAddRoute` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man editAddRoute`
`point`	Specifies the `x` and `y` coordinates for the start point or end point of the wire segment. Note that if the points you specify with each successive `editAddRoute` command are not aligned vertically or horizontally, the tool adjusts the coordinates to align the end point of one segment with the start point of the next segment.

Example

- The following commands create wire segments that start and stop at the specified points. The complete wire ends at the point specified by `editCommitRoute`.

```
editAddRoute 33.392 36.831    #Start of first wire segment
editAddRoute 32.985 32.766    #End of first wire segment, start of second
editAddRoute 18.064 32.115    #End of second wire segment
editAddRoute 20.951 27.073    #End of third wire segment
editCommitRoute 20.992 27.114 #End of wire
```

- Use the following set of commands to add wire segments with different orders of nets:

```
uiSetTool addWire
setEditMode -layer_horizontal M10
setEditMode -nets { a b c d e f}

editAddTrimMetal

```
editAddTrimMetal
[-help]
[-layer string]
-location {x y}
[-mask integer]
[-snap_to_end]
```

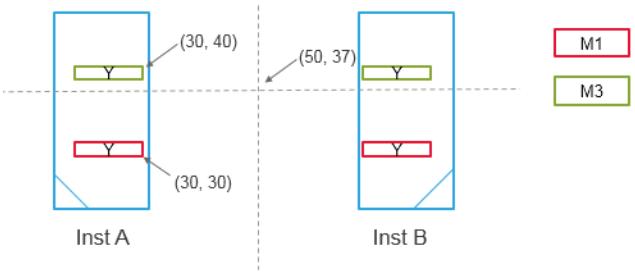
Adds trim metal at the specified location.

Parameters

`-help`	Prints a brief description that includes type and default information for each `editAddTrimMetal` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man editAddTrimMetal`
`-layer string`	Specifies the layer on which the trim metal is to be added. The layer name should be a routing layer defined in the LEF file. Note that you can specify only one valid layer name. That is, a layer name list is not supported. If the `-layer` option is not specified, `editAddTrimMetal` adds the trim metal on the nearest object. Check the **Examples** section below to see how to use this option.
`-location {x y}`	Specifies the coordinates for the center point of the trim metal. The tool may adjust automatically to the closest location that is best for the trim metal.
`-mask integer`	Specifies the mask value for the trim metal. However, if `USEMETALMASK` is already defined for the trim layer in the tech LEF, you cannot define the mask value here.
`-snap_to_end`	Specifies that the trim metal should be snapped to the closest end of the selected pin or wire.

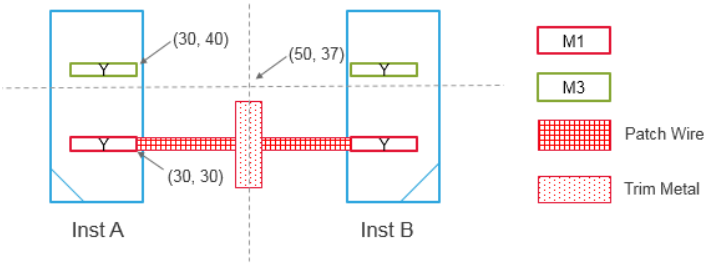
Examples

In the following illustration, the pin Y has two pin shapes, one on `M1` and the other on `M3`. The Pin Y on Inst A is selected.



- If you add trim metal with the `-layer` option (as specified below), the tool will add the trim metal on the pin shape that is on layer `M1`.

  ```
  editAddTrimMetal -layer M1 -location {50 37}
  ```



- If you add trim metal without the `-layer` option (as shown in the command below), the tool will add the trim metal on the nearest pin, which in this case is

on M3.

```
editAddTrimMetal -location {50 37}
```

editAddVia

```
editAddVia
[-help]
point
```

Creates a via instance and places the origin at the specified coordinates. The origin of the instance's via cell may or may not be at its center. Specify the via parameters with the `setEditMode` command.

Parameters

`-help`	Prints a brief description that includes type and default information for each `editAddVia` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man editAddVia`
`point`	Specifies the `x` and `y` coordinates of the via origin.

Example

- The following command adds a via with origin at coordinates `550, 675`:

  ```
  editAddVia 550 675
  ```

Related Information

editAdjust

```
editAdjust
[-help]
[-adjust_size]
-refer_obj {top bottom left right}
{[-align_edge {left center right top middle bottom diag45_top diag45_middle diag45_bottom diag135_top diag135_middle diag135_bottom}]
 [-space_mode {horizontal vertical dist_horizontal dist_vertical diag45 diag135 dist_diag45 dist_diag135}
   [-space float_value]]}
```

Aligns wires and pins on the basis of the specified options. The following objects can be aligned using this command:

- Regular, special, and patch wires
- Physical pins
- Macro pins

The `editAdjust` command enables you to align objects in one or both of the following modes:

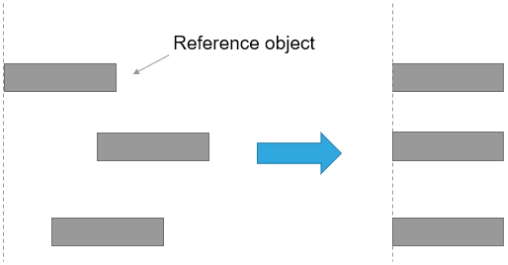
- Align by edge: Use the `-align_edge` parameter to align objects with the reference object by the specified edge.
- Align with spacing: Use the `-space_mode` parameter to adjust the spacing between objects.

Parameters

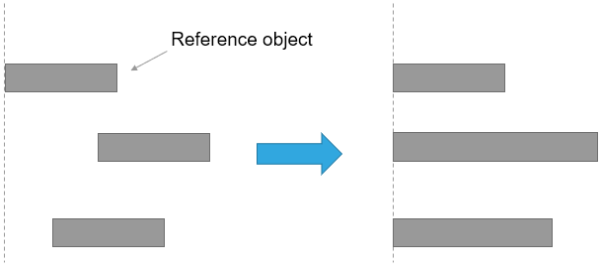
`-help`	Prints a brief description that includes type and default information for each `editAdjust` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man editAdjust`
`-adjust_size`	Resizes the objects being aligned to match the reference object. If `-align_edge` is specified, the specified edge of the objects is stretched or shrunk to align with the edge of the reference object. If `-space_mode` is specified, the objects being aligned are resized to be equal to the reference object.
`-align_edge {left center right top middle bottom diag45_top diag45_middle diag45_bottom diag135_top diag135_middle diag135_bottom}`	
	Specifies the edge by which the objects should be aligned with the reference object.
`-refer_obj {top bottom left right}`	
	Specifies the object of reference for alignment. For example, `-refer_obj left` means that objects should be aligned with reference to the leftmost object. This option is mandatory.
`-space float_value`	
	Specifies the spacing value for aligning objects in the space mode. This option can be specified only if `-space_mode` is specified.
`-space_mode {horizontal vertical dist_horizontal dist_vertical diag45 diag135 dist_diag45 dist_diag135}`	
	Specifies that objects should be aligned in the space mode. In this mode, the objects are aligned such that there is equal spacing between them. You can specify one of the following space mode options: • `horizontal` - Aligns the objects such that the horizontal spacing between them is equal to the value specified with `-space`. • `vertical` - Aligns the objects such that the vertical spacing between them is equal to the value specified with `-space`. • `dist_horizontal` - Distributes the objects horizontally. • `dist_vertical` - Distributes the objects vertically. • `diag45` - Aligns the objects in the 45-degree direction such that the spacing between them is equal to the value specified with `-space`. • `diag135` - Aligns the objects in the 135-degree direction such that the spacing between them is equal to the value specified with `-space`. • `dist_diag45` - Distributes the objects in the 45-degree direction. • `dist_diag135` - Distributes the objects in the 135-degree direction.

Examples

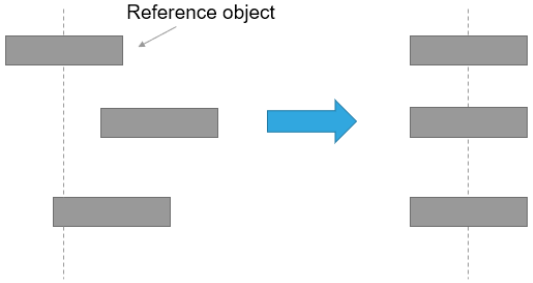
- The following command aligns the left edge of all the wires using the leftmost object as reference:
```
editAdjust -align_edge left -refer_obj left
```



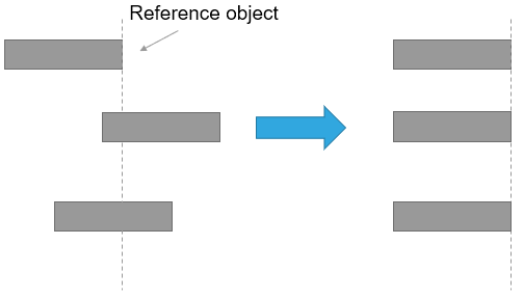
- The following command uses the leftmost wire as reference and resizes the other wires so that their left edges align with the left edge of the reference wire:
```
editAdjust -align_edge left -refer_obj left -adjust_size
```



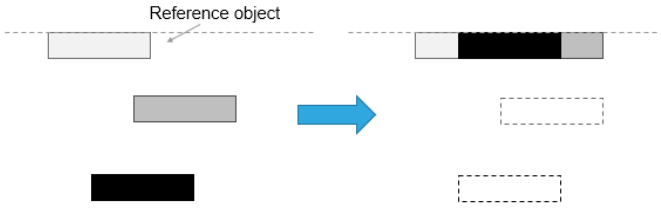
- The following command aligns the center of all the wires using the leftmost object as reference:
```
editAdjust -align_edge center -refer_obj left
```



- The following command aligns the right edge of all the wires using the leftmost object as reference:
```
editAdjust -align_edge right -refer_obj left
```

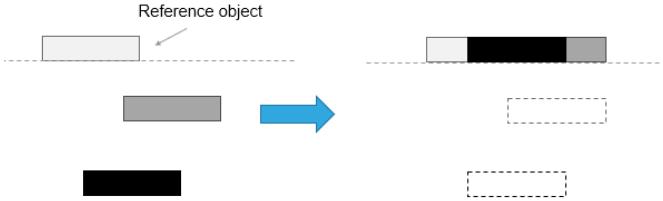


- The following command aligns the top edge of all the wires using the leftmost object as reference:
```
editAdjust -align_edge top -refer_obj left
```



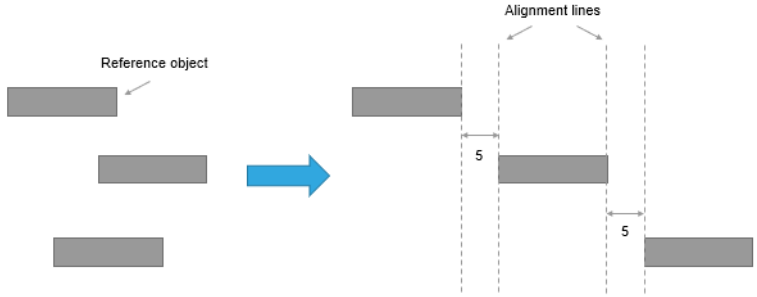
- The following command aligns the bottom edge of all the wires using the leftmost object as reference:

```
editAdjust -align_edge bottom -refer_obj left
```



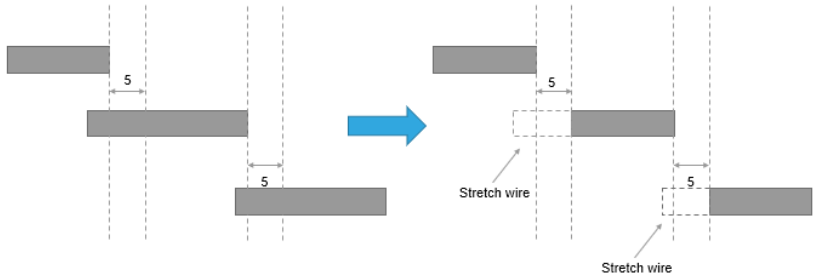
- The following command uses the leftmost object as reference and aligns the wires in the horizontal direction in the space mode with a spacing of 5 units:

```
editAdjust -space_mode horizontal -space 5 -refer_obj left
```



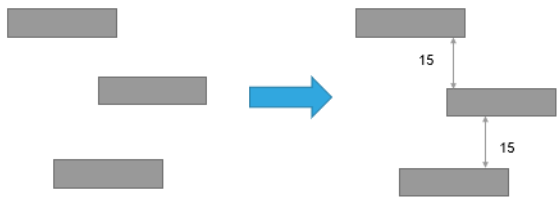
- The following command uses the leftmost object as reference and aligns the wires in the horizontal direction in the space mode with a spacing of 5 units. The command also resizes the objects being aligned to match the reference object:

```
editAdjust -space_mode horizontal -space 5 -refer_obj left -adjust_size
```



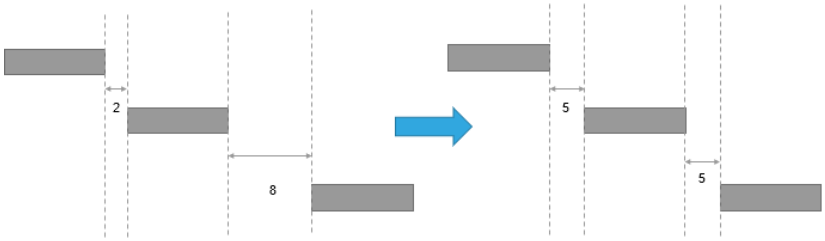
- The following command uses the leftmost object as reference and aligns the wires in the vertical direction in the space mode with a spacing of 15 units:

```
editAdjust -space_mode vertical -space 15 -refer_obj left
```



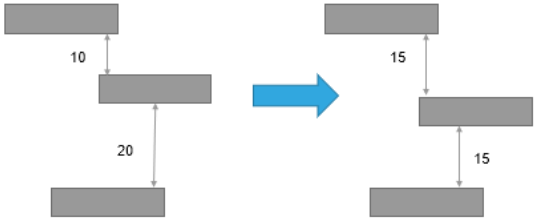
- The following command uses the leftmost object as reference and distributes the wires horizontally:

```
editAdjust -space_mode dist_horizontal -refer_obj left
```



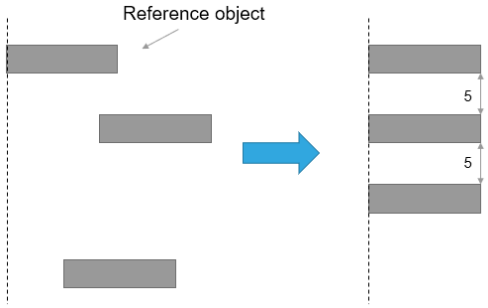
- The following command uses the leftmost object as reference and distributes the wires vertically:

```
editAdjust -space_mode dist_vertical -refer_obj left
```



- The following command uses the leftmost object as reference and aligns the left edge of all the wires, keeping a spacing of 5 units between the wires in the vertical direction:

```
editAdjust -align_edge left -space_mode vertical -space 5 -refer_obj left
```



- The following command uses the leftmost object as reference and aligns the wires in the 135-degree direction in the space mode with a spacing of 5 units:

```
editAdjust -space_mode diag135 -space 5.0 -refer_obj left
```

editChangeLayer

```
editChangeLayer
[-help]
[-layer_horizontal layer]
[-layer_vertical layer]
```

Changes the layer of selected wires and updates vias connecting to the wires that change layers.

Note: Use the `editSelect` command to select the wires.

Parameters

`-help`	Prints a brief description that includes type and default information for each `editChangeLayer` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man editChangeLayer`
`-layer_horizontal layer`	Specifies the new layer for the selected horizontal wires.
`-layer_vertical layer`	Specifies the new layer for the selected vertical wires.

Example

- The following command moves all selected horizontal wires to the *METAL3* layer and all selected vertical wires to the *METAL4* layer:
  ```
  editChangeLayer -layer_horizontal METAL3 -layer_vertical METAL4
  ```

editChangeMask

```
editChangeMask
[-help]
{-to {0 1 2} | [[-top {0 1 2}] [-bottom {0 1 2}] [-cut {0 1 2}]] | -trim_metal {0 1 2}}
```

Changes the mask for the selected wires, vias, physical pins, or trim metal to the specified color.

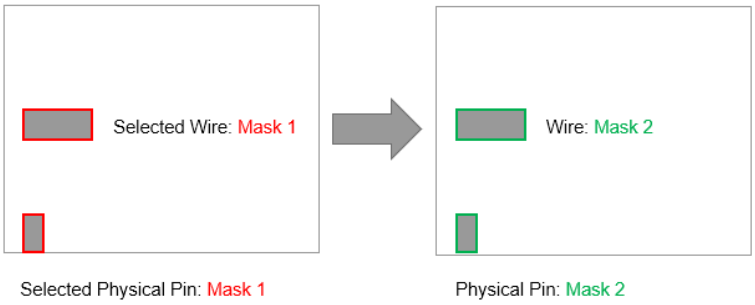
Parameters

`-help`	Prints a brief description that includes type and default information for each `editChangeMask` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man editChangeMask`
`-bottom {0 1 2}`	Changes the mask for the bottom layer of the selected vias to the specified color.
`-cut {0 1 2}`	Changes the mask for the cut layer of the selected vias to the specified color.
`-to {0 1 2}`	Changes the mask for the selected wires and physical pins to the specified color.
`-top {0 1 2}`	Changes the mask for the bottom layer of the selected vias to the specified color.
`-trim_metal {0 1 2}`	Changes the mask for the trim metal of the selected patch wires to the specified color. If the trim metal being edited completely covers another trim metal, the mask of the covered trim metal is also changed simultaneously.

Examples

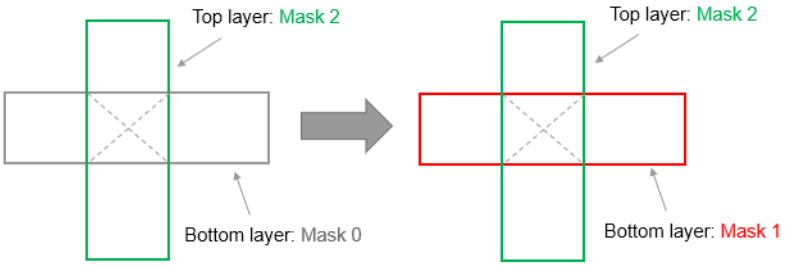
- The following command changes the mask for the selected wire and physical pin to `2`:

  ```
  editChangeMask -to {2}
  ```

- The following command changes the mask for the bottom layer of the selected via to `1`:

  ```
  editChangeMask -bottom {1}
  ```

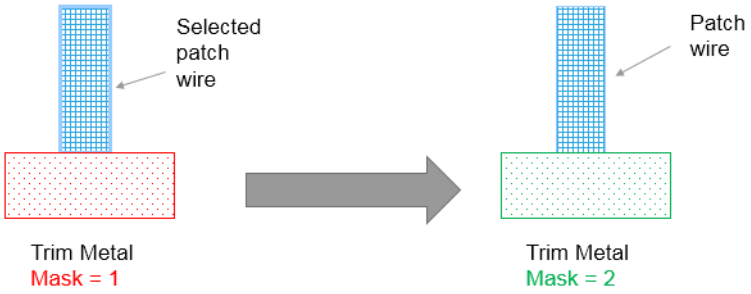
  


- The following command changes the mask for the trim metal of the selected patch wires to `2`:

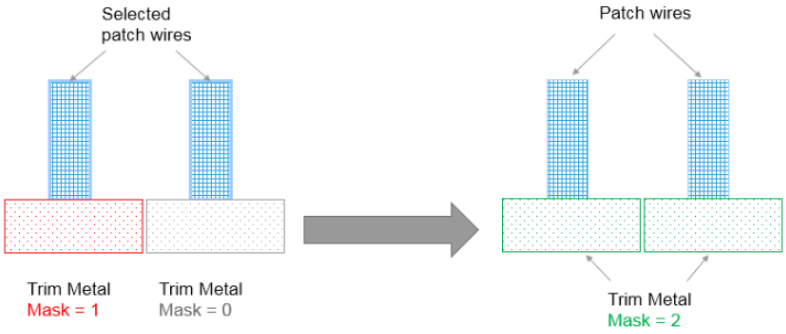
  ```
  editChangeMask -trim_metal {2}
  ```

  Given below are the results of running this command in various situations:

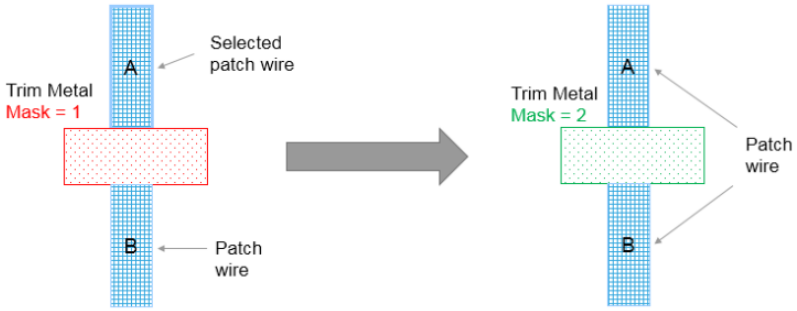
  - If a single patch wire was selected before running the command:



- If multiple patch wires were selected before running the command:



- If the trim metal for the selected patch wire (Patch Wire A) completely overlaps the trim metal for another patch wire that is not selected (Patch Wire B):



- If the trim metal for the selected patch wire (Patch Wire A) partially overlaps the trim metal for another patch wire that is not selected (Patch Wire B):

editChangeNet

```
editChangeNet
[-help]
-to netName
```

Changes the net associated with selected physical pins, wires, and vias.

You can also use `editChangeNet` to change the net name of the patch wire (pWire) generated by NanoRoute.

Parameters

`-help`	Prints a brief description that includes type and default information for each `editChangeNet` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man editChangeNet`
`-to`	Specifies the name of the net to which to assign the selected physical pins, wires and vias.

Example

- The following set of commands selects the physical pins, wires, and vias that belong to net `VDD1` and reassigns them to net `VDD2`:

```
editSelect -net VDD1
editChangeNet -to VDD2
```

editChangeRule

```
editChangeRule
[-help]
[-from old_rule]
-to new_rule
```

Changes the LEF rule associated with selected wire segments from the *old_rule* to the *new_rule*. You must select the wires for which the rule needs to be changed before running `editChangeRule`. You can select wires either using the GUI or by using the `editSelect` command.

Note: This command does not change the routing rule for the net. If the net is re-routed by NanoRoute, these changes will be lost. To change the routing rule, use `setAttribute -net -non_default_rule`. For more information, see setAttribute.

Parameters

`-help`	Prints a brief description that includes type and default information for each `editChangeRule` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man editChangeRule`
`-from old_rule`	Specifies the qualifying rule. Only wire segments whose associated rule matches *old_rule* are changed. If you do not specify this parameter, the tool will change the rule of all selected wires.
`-to new_rule`	Specifies the destination rule. Wire segments originally associated with *old_rule* are associated with *new_rule* after this command runs. Specify one of the following: • A nondefault rule defined in the LEF `LAYER` (Routing) section • `default` (applies the default routing rule)

Example

- The following command changes the wire segments that are associated with the rule `SP` to the default rule. If the wire width or extension of `SP` is different from its counterpart in the default rule, the wire geometry is changed accordingly.
  ```
  editChangeRule -from SP -to default
  ```

editChangeStatus

```
editChangeStatus
[-help]
[shield_net_name]
[-nets <net>+]
-to {ROUTED | FIXED | COVER | SHIELD | NOSHIELD}
```

Changes the DEF status of selected wires or vias to the specified status. Use this command to change the net status of the selected net. If `-nets` is specified with `editChangeStatus`, the tool changes the status of all the objects belonging to the specified nets to the status specified with the `-to` parameter.

Note: Before using this command to change the status of a wire, you must select the wire by either clicking it or using the `editSelect` command.

Parameters

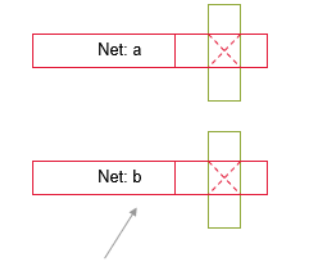
`-help`	Prints a brief description that includes type and default information for each `editChangeStatus` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man editChangeStatus`
shield_net_name	Specifies the name of the net to be shielded by the selected wire. Use this parameter if you want to change the selected wire to a `SHIELD` for the specified net. **Note**: You can use this parameter only if you have specified `-to SHIELD`.
`-nets <net>+`	Specifies the names of the nets for which the object status is to be changed. If `-nets` is specified with `editChangeStatus`, the tool changes the status of all the objects (regular wires, special wires, regular vias, and special vias) belonging to the specified nets to the status specified with the `-to` parameter.
`-to {ROUTED | FIXED | COVER | SHIELD | NOSHIELD}`	Specifies the DEF status of the selected wires or vias after you issue this command. Type the status in all upper-case letters. **Note:** You cannot change a special wire to `NOSHIELD` status or change a signal wire to `SHIELD` status.

Examples

- The following commands select and then freeze the wires and vias on the `METAL1` and `METAL2` layers by changing their status to `COVER`. Innovus does not delete wires or vias with status `COVER`:

```
editSelect -layer {METAL1 METAL2}
editChangeStatus -to COVER
```

- Consider the nets depicted below:



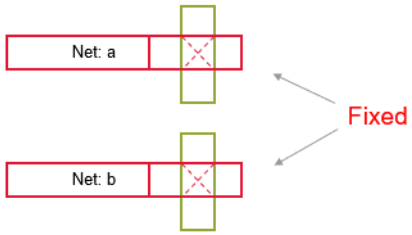
The wire/via under net b is **selected**

  - The following command changes the status of only the wire and via under net `a` to `FIXED`. The status of the wire and via under net `b` is not changed even though net `b` is selected:

```
editChangeStatus -nets a -to FIXED
```

  - The following command changes the status of the wires and vias under both nets `a` and `b` to `FIXED`:

```
editChangeStatus -nets {a b} -to FIXED
```



Related Information

    - *Wire* section

editChangeVia

```
editChangeVia
[-help]
[-net net_name]
[-signal_only {0 | 1}]
{[-from string [-area {x1 y1 x2 y2} | -at {x y} ]] | [-selected]}
{-to string | [-via_columns integer -via_rows integer [-cut_class class_name]]}
```

Replaces the selected vias or the vias listed in `-from` with the specified vias or with vias having the specified cut class and pattern.

While modifying a via with `editChangeVia`, the `setEditMode -drc_on` and `-keep_via` settings are used in combination to decide whether or not a via should be replaced if the new via cell results in DRC violations:

- `setEditMode -drc_on false`
  With this setting, the tool does not check for Design Rule Check (DRC) violations when you modify a via using the `editChangeVia` command.
- `setEditMode -drc_on true -keep_via false`
  With this setting, the tool checks for DRC violations and allows you to replace the via even if the new via is generating violations. The DRC violations are displayed on the layout.
- `setEditMode -drc_on true -keep_via true`
  With this setting, the tool checks for DRC violations and retains the original via if the new one is generating violations.

The behavior defined above applies for all via modifications with `editChangeVia`, irrespective of whether you use the `-to string` option or the `-via_columns integer -via_rows integer` options.

Note that the `setEditMode -drc_on true` option does not check cut spacing, enclosure spacing, or other geometry of the via cell itself.

Parameters

`-help`	Prints a brief description that includes type and default information for each `editChangeVia` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man editChangeVia`
`-area {x1 y1 x2 y2}`	Specifies the coordinates of the area in which vias are to be replaced. If a via indicated by the `-from` parameter is in this area, replaces the via with the via indicated by the `-to` parameter.
`-at {x y}`	Specifies the coordinates for the origin of the via to be replaced. The via at this location is replaced by the via indicated by the `-to` parameter.
`-cut_class class_name`	Specifies the cut class of the replacement vias.
`-from string`	Specifies a via or list of vias to replace. Enclose the via names on the list in curly braces and separate each name with a space. Vias whose masters are not specified in *string* are not changed. **Notes:** • You must specify the `-from` or the `-selected` parameter. If you do not specify at least one of these parameters, the software does not change any vias. • The number of via names on the `-from` list must be equal to the number of via names on the `-to` list. In addition, the corresponding pair of vias in each list must be on the same layer.
`-net net_name`	Specifies the net name on which to change vias.
`-selected`	Replace vias for selected ones only. **Note:** You must specify the `-from` or the `-selected` parameter. If you do not specify at least one of these parameters, the software does not change any vias.
`-signal_only {1 | 0}`	Specifies whether signal vias only or signal and special vias are changed. Specify `1` to change signal via only. Specify `0` to change signal and special vias. *Default:* `0`
`-to string`	Specifies a via or a list of vias to replace the vias indicated by the `-from` parameter. If you specify more than one via, enclose the via list in curly braces and separate each via name with a space. **Note:** The number of via names on the list must be the equal to the number of via names on the list for the `-from` parameter. In addition, the corresponding pair of vias in each list must be on the same layer.
`-via_columns integer`	Specifies the number of columns in the replacement vias.
`-via_rows integer`	Specifies the number of rows in the replacement vias.

Examples

- The following command changes all `VIA_XX` vias of the net `VDD1` located within a specified region to `VIA_YY` vias:
  ```
  editChangeVia -net VDD1 -area {x1 y1 x2 y2} -from VIA_XX -to VIA_YY
  ```
- The following command replaces the selected vias with vias having a cut pattern of 3 by 3:
  ```
  editChangeVia -selected -via_columns 3 -via_rows 3
  ```

editCommitPoly

```
editCommitPoly
[-help]
point
```

Ends a newly created polygon at the specified coordinates. Use this command after at least one `editAddPoly` command has been issued.

Parameters

`-help`	Prints a brief description that includes type and default information for each `editCommitPoly` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man editCommitPoly`
point	Specifies the `x` and `y` coordinates for the end point of a newly created wire polygon.

Example

- The following commands create a three-sided wire polygon that ends at the point specified by `editCommitPoly`.

  ```
  editAddPoly 700 300
  editAddPoly 700 500
  editCommitPoly 200 400
  ```

  The first side of the wire polygon starts at `700, 300` and ends at `700, 500`. The second side starts at `700, 500` and ends at `200, 400`. The third side is formed by joining the starting point of the polygon (`700,300`) and the ending point specified by `editCommitPoly` (`200,400`).

editCommitRoute

```
editCommitRoute
[-help]
point
```

Ends a newly created wire segment at the specified coordinates. Splits diagonal wires whose width is greater than the LEF `MAXWIDTH` parameter for that layer as they are drawn. Use this command after at least one `editAddRoute` command has been issued.

Parameters

`-help`	Prints a brief description that includes type and default information for each `editCommitRoute` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man editCommitRoute`
`point`	Specifies the `x` and `y` coordinates for the end point of a newly created wire segment.

Example

- The following commands create a wire that ends at the point specified by `editCommitRoute`:

```
editAddRoute 33.392 36.831
editAddRoute 32.985 32.766
editAddRoute 18.064 32.115
editAddRoute 20.951 27.073
editCommitRoute 20.992 27.114
```

editCutWire

```
editCutWire
[-help]
[-only_visible_wires]
[-selected]
{-lines {x1 y1 x2 y2 ...} | -box {x1 y1 x2 y2} }
```

Cuts wires, bus guides, or rectangles at the specified location. You can choose to cut by line (using the `-lines` parameter) or by box (using the `-box` parameter. `editCutWire` honors `setEditMode -cut_wire_overlap` settings.

Patch wires are also supported.

Parameters

`-help`	Prints a brief description that includes type and default information for each `editCutWire` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man editCutWire`
`-box {x1 y1 x2 y2}`	Specifies the lower-left and upper-right coordinates of the box for cutting wires, bus guides, or rectangles. The `-box` option currently has the following limitations: • The cut-box must be a rectangle (or square). A polygon shape will be ignored. • Only the wires that are perpendicular to the cut-box edge are cut. In addition, the cut-box edge must pass across the wire, bus guide, or rectangle completely. • This option can be used to cut only horizontal and vertical wires. 45-degree wires are not yet supported.

`-lines {x1 y1 x2 y2 ...}`	Specifies the start and end coordinates of one or more line segments for cutting wires, bus guides, or rectangles.
	
	If you specify multiple cut-line segments, they should be parallel to each other. For instance, you cannot specify one horizontal cut-line and one vertical cut-line with the `-lines` parameter. If you do, the tool reports the following error:
	
	`Cut lines are not parallel.`
	
	In addition, a cut-line must cut across the wire, bus guide, or rectangle from one edge to the other. Once cut, the signal wire pieces maintain a one-half wire-width extension. Special wires do not maintain an extension.
	
	When you run `editCutWire`, the tool snaps the cut-line to the manufacturing grid automatically. The change in coordinates is displayed at the prompt as a warning such as follows:
	
	`WARNING: Cut-line is auto-snapped from (966.343500 1227.245500 966.811500 1227.245500) to (966.345000 1227.245000 966.810000 1227.245000).`
	
	Note that the tool records only the cut-line coordinate before snapping in the log file.
	
	Note: The `-lines` option supports editing of 45-degree wire segments.
	
	 	
	In addition, you can also draw a 45-degree cut-line to cut a group of wires in a stair pattern as shown below:
	
	 	
	Both regular and special wires can be cut with a 45-degree cut-line. However, patch wires cannot be cut in this way. When you use a 45-degree cut-line, the wires are cut from the touch point of the center line. You can use a single 45-degree cut-line to cut wires in different directions as shown below:

`-only_visible_wires`	Specifies that only the wires on the visible layers are cut. If this parameter is not specified, the tool cuts all the wires overlapping with the cut-line or box.

`-selected`	Specifies that only the selected wires, bus guides, or rectangles should be cut.

Examples

- The following command cuts the wires through which the specified cut-line passes:
  ```
  editCutWire -lines {200 300 200 310}
  ```
- Consider the wire depicted below:

  
  The following command cuts the wire, along the specified 45-degree cut-line segments, `{95.30 -641.16 95.39 -641.08}` and `{95.69 -641.17 95.78 -641.08}`:
  ```
  editCutWire -lines {95.30 -641.16 95.39 -641.08 95.69 -641.17 95.78 -641.08}
  ```

- The following diagrams show examples of using a cut-box to cut wires:
  - In a), the horizontal wire is cut. The vertical wire is not cut because the cut-box edges that are perpendicular to the wire do not pass through it completely.
  - In b), both the horizontal and vertical wires are cut.
  - In c), the vertical wire is cut at tje two places where the perpendicular edges of the cut-box pass through it completely. The horizontal wire is not cut.
  - In d), the horizontal wire is cut. The 45-degree wire is not cut because 45-degree wire edits are not yet supported while cutting by box.
  - In e), no cuts are made.

editDelete

```
editDelete
[-help]
[-area {x1 y1 x2 y2}]
[-direction {H | V | 45 | 135}]
[-floating_via]
[-layer {list_of_layers}]
[-nets net*]
[-parallel_routing]
[-physical_pin_only]
[-regular_wire_with_drc]
[-selected]
[-shape {RING STRIPE FOLLOWPIN IOWIRE COREWIRE BLOCKWIRE
         PADRING BLOCKRING FILLWIRE FILLWIREOPC DRCFILL None}]
[-shield]
[-shield_only]
[-status {FIXED NOSHIELD ROUTED SHIELD UNKNOWN}
[-subclass sublass_name]
[-trim_metal]
[-type {Regular| Special | Patch}]
[-use {CLOCK POWER SIGNAL}]
[-via_cell cell_name_list]
[-with_edit_flag {0 | 1}]
[-object_type {Wire Via} ]
```

Deletes physical wires, any vias connected to the wires, and violation markers associated with the wires. Use `editDelete -physical_pin_only` to delete physical pins in the design.

By default, when you delete a wire or via with `editDelete`, the tool searches and deletes all related DRC markers. If you do not want the related DRC markers to be cleared when you delete a wire or via, set the `setEditMode -drc_on` parameter to `false` before using `editDelete`. This can improve the run time if have to delete a large number of wires and vias.

By default, the `editDelete` command retains TSVs and deletes only the real routing layers and vias. You can change this behavior by setting the `setEditMode -delete_tsv` parameter to `true` before using `editDelete`.

Note: The `editDelete` command deletes only those vias that are connected to wires. To delete vias that are not connected to wires, use the `deleteMetalFill` command.

The `editDelete` command deletes physical wires. The `deleteNet` command deletes logical nets. For more information, see `deleteNet`.

Parameters

`-help`	Prints a brief description that includes type and default information for each `editDelete` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man editDelete`
`-area {x1 y1 x2 y2}`	Specifies the coordinates for the area from which to delete the wires. *Default:* Deletes all wires.
`-direction {H | V | 45 | 135}`	Specifies the orientation of the wires to delete. *Default:* If you do not specify this parameter, deletes wires with either orientations. `H`: Specifies that only horizontal wires are to be deleted. `V`: Specifies that only vertical wires are to be deleted. 45: Specifies that 45-degree wires are to be deleted. 135: Specifies that 135-degree wires are to be deleted.
`-floating_via`	Specifies that only floating vias should be deleted.

`-layer {list_of_layers}`	Specifies the layers from which to delete wires. You must use LEF layer names or a routing layer index value (1 for the first routing layer, 2 for the second routing layer, and so on). This option supports backside and Through Silicon Via (TSV) layers as well. If you are specifying multiple layers, enclose them in braces. *Default:* If you do not specify this parameter, deletes wires from all layers.
`-nets net*`	Specifies the net or list of nets from which to delete wires. You can use wildcard values in this field. For example, if you specify `V*`, deletes wires from nets `VDD` and `VSS`. If you are specifying multiple nets, enclose them in braces. **Note**: By default, the wires and vias shielding the nets specified with `editDelete -nets` are not deleted. If you want to delete the shielding as well, specify `-shield` along with `-nets`. `-object_type {Wire Via}`	Specifies whether wires or vias should be deleted. You can specify both as well. If `-object_type` is not specified, `editDelete` deletes both wires and vias by default.
`-parallel_routing`	Specifies that the wires created by NanoRoute parallel routing are to be deleted.
`-physical_pin_only`	Specifies that the physical pins in the design are to be deleted. You can use filter options, such as `-net`, `-layer`, `-area`, and `-selected` along with `-physical_pin_only` to delete specific physical pins.
`-regular_wire_with_drc`	Deletes the regular wires with violation markers. This parameter works only when `-nets` or `-status` are specified as filters. **Note**: `editDelete -selected` parameter deletes only physically selected objects. To delete wires with violations from a specific net, specify the net name with the `editDelete -nets` parameter: `editDelete -nets netName -regular_wire_with_drc`
`-selected`	Deletes selected wires, vias, and physical pins. **Note**: Only physically selected objects are deleted. If `selectNet` is used to select a net, `editDelete -selected` cannot be used to delete that net's wires. This is because `selectNet` selects the net only logically. If you want to delete the entire net, use `editSelect -nets` instead of `selectNet` to ensure the wires of the net are physically selected.
`-shape {{RING STRIPE FOLLOWPIN IOWIRE COREWIRE BLOCKWIRE PADRING BLOCKRING FILLWIRE FILLWIREOPC DRCFILL None}}`	
	Specifies the shapes of the wires to delete. The status must be in all upper-case letters. If you specify multiple shapes, enclose the shapes in braces. For shape definitions, see *Shapes,* in the "DEF Syntax" chapter of the LEF/DEF Language Reference. *Default:* If you do not specify this parameter, deletes wires of all shapes.
`-shield`	Deletes the wires and vias of the nets specified with the `-nets` parameter, along with the wires and vias shielding the specified nets. **Note**: This parameter cannot be used with `-shield_only`.

`-shield_only`	Deletes only the wires and vias shielding the nets specified with the `-nets` parameter. The signal nets being shielded are retained.  **Note**: This parameter cannot be used with `-shield`.
`-status {FIXED NOSHIELD ROUTED SHIELD UNKNOWN}`	
	Specifies the status of wires to delete. The status must be in uppercase letters. If you specify more than one status, enclose the status list in braces. **Note:** If you select `-type Special -status NOSHIELD` or `-type Regular -status SHIELD` the software generates an error message.
`-subclass` *`sublass_name`*	Specifies the subclass name of the wires to be deleted. Use this parameter if you want to delete rings, stripes, or other wires belonging to a specific subclass. **Note:** You can use wildcards in *`subclass_name`*. Only special wire is supported by this option.
`-trim_metal`	Deletes the trim metal attached to all patch wires, without deleting the patch wires. If `-selected` is also specified, deletes only the trim metal attached to the selected patch wire without deleting the patch wire.
`-type {Regular| Special | Patch}`	
	Specifies whether to delete regular wires, special wires, or patch wires. **Note:** If you specify `Regular`, omit the `-shape` parameter or specify `-shape None`.
`-use {CLOCK POWER SIGNAL}`	
	Indicates that wires will be deleted on the basis of the specified use: `CLOCK`: Specifies that only wires for clock nets will be deleted. `POWER`: Specifies that only wires for power nets will be deleted. `SIGNAL`: Specifies that only wires for general signal nets will be deleted.
`-via_cell` *`cell_name_list`*	
	Specifies the via cells of the vias to be deleted. You can use wildcards while specifying the via cell names. If you are specifying multiple cell names, enclose them in braces.
`-with_edit_flag {0 | 1}`	Deletes all modified wires, that is wires with value `1` for the `isEdit` property on the net. **Notes** • As the `isEdit` property is added on the whole net, all the wires on the net with `isEdit` value set to `1` will be deleted. • The `isEdit` property is used to flag nets with modified wires and vias. This is useful when evaluating how many objects need to be modified for fixing DRC violations and then deciding whether to fix the violations manually or through ECO routing. The `isEdit` property is controlled through the `-create_is_edit_flag` parameter of `setEditMode`. By default, this parameter is set to `0`. If you set the value of this parameter to `1`, the `isEdit` property is set to `1` for nets with modified wires or vias.

Examples

- The following command removes wires from the *METAL1* and *METAL2* layers:
  ```
  editDelete -layer {METAL1 METAL2}
  ```
- The following command removes horizontal fillwires from the *METAL1* layer:
  ```
  editDelete -layer METAL1 -direction H -shape FILLWIRE
  ```
- The following command removes wires from the specified area:
  ```
  editDelete -area 100 100 200 200
  ```
- The following command removes the selected wires and vias from the specified area:

```
editDelete -area 100 100 200 200 -selected
```

- The following command only deletes the special wires that belong to the net `carry4` leaving the vias untouched:
  ```
  editDelete -type Special -nets carry4 -object_type {Wire}
  ```
- The following command deletes all physical pins:
  ```
  editDelete -physical_pin_only
  ```
- The following command deletes all physical pins from net VSS:
  ```
  editDelete -nets VSS -physical_pin_only
  ```
- The following command deletes all physical pins from nets VSS and VDD:
  ```
  editDelete -nets {VDD VSS} -physical_pin_only
  ```
- The following command deletes all physical pins from layer METAL2:
  ```
  editdelete -layer METAL2 -physical_pin_only
  ```
- The following command deletes all physical pins from the specified area:
  ```
  editDelete -area {26 0 31 4} -physical_pin_only
  ```
- The following set of commands deletes the selected physical pin:
  ```
  select_obj <ptr of layerShape> #Selects the pointer of the layer shape
                                 #belonging to a physical pin
  editDelete -selected
  ```
- The following command deletes the regular wires with violation markers from only the specified net:
  ```
  editDelete -nets B -regular_wire_with_drc
  ```

- The following command deletes only routed regular wires with violation markers from the specified net:
  ```
  editDelete -nets B -regular_wire_with_drc -status ROUTED
  ```

editDeleteFillet

```
editDeleteFillet [-help]
```

Deletes the tear-drop fillet that was added between a wire and bump connection with the `editAddFillet` command.

Parameters

`-help`	Prints the usage of the command. For a detailed description of the command, use the `man` command: `man editDeleteFillet`

Related Information

- `editAddFillet`

editDeselect

```
editDeselect
[-help]
[-area {x1 y1 x2 y2}]
[-direction {H | V | 45 | 135}]
[-floating_via]
[-layer list_of_layers]
[-nets net*]
[-physical_pin_only]
[-regular_wire_with_drc]
[-shape {RING STRIPE FOLLOWPIN IOWIRE COREWIRE BLOCKWIRE PADRING
         BLOCKRING FILLWIRE FILLWIREOPC DRCFILL None}]
[-shield]
[-shield_only]
[-status {COVER FIXED NOSHIELD ROUTED SHIELD UNKNOWN}]
[-subclass sublass_name]
[-type {Regular Special Patch}]
[-use {CLOCK POWER SIGNAL}]
[-via_cell cell_name_list]
[-with_edit_flag {0 | 1}]
[-object_type {Wire Via} ]
[-from_pin pin_name -to_pin pin_name]
```

Deselects wires and vias based on specified parameters. Use this command when nets are selected.

You can use this command to deselect nets by property. For example, to delete all regular nets except clock nets, select all regular nets with `editSelect`, deselect the clock nets with this command, then delete the selected nets with `editDelete`.

Parameters

`-help`	Prints a brief description that includes type and default information for each `editDeselect` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man editDeselect`
`-area {x1 y1 x2 y2}`	Specifies the coordinates for the area from which to deselect wires and vias.
`-direction {H | V | 45 | 135}`	Specifies the orientation of the wires to deselect. *Default:* If you do not specify this parameter, deselects wires in any orientation. • `H`: Specifies that horizontal wires are to be deselected. • `V`: Specifies that vertical wires are to be deselected. • 45: Specifies that 45-degree wires are to be deselected. • 135: Specifies that 135-degree wires are to be deselected.
`-floating_via`	Specifies that only floating vias are to be deselected. A via, or a stack of vias, is floating, if it is not connected to another object, wire, pin, or via, on either its top or bottom metal layer or on both these layers.
`-from_pin pin_name`	Specifies the name of the starting pin of the wire to be deselected. The starting pin you specify should be connected to the same net as the ending pin specified with `-to_pin`. If they connect to different nets, the tool reports an error. **Note**: Deselection of wires between specified pins is supported only for signal and clock nets.
`-layer list_of_layers`	Specifies the layers from which to deselect wires and vias. This option supports backside and Through Silicon Via (TSV) layers as well. If you are specifying multiple layers, enclose the names in braces. *Default:* If you do not specify this parameter, deselects wires and vias from all layers.

`-nets net*`	Specifies the net names from which to deselect wires and vias. **Note:** You can use wildcard values in this field. For example, if you specify `V*`, deselects wires and vias from nets `VDD` and `VSS`.
`-object_type {Wire Via}`	Specifies whether wires or vias or both should be deselected. If the parameter is not specified, only wires are deselected. *Default*: `Wire`
`-physical_pin_only`	Specifies that physical pins are to be deselected. By default, `editDeselect` does not deselect physical pins. You can use the `-physical_pin_only` parameter along with `-area`, `-layer`, or `-nets` to deselect the physical pins in the specified area, layer, or net, respectively.
`-regular_wire_with_drc`	Deselects regular wires with violation markers.
`-shape {RING STRIPE FOLLOWPIN IOWIRE COREWIRE BLOCKWIRE PADRING BLOCKRING FILLWIRE FILLWIREOPC DRCFILL None}`	
	Specifies the shapes of the wires and vias to be deselected. Use all upper-case letters for the shapes. If you specify multiple shapes, enclose the list of shapes in braces. For shape definitions, see *Shapes,* in the "DEF Syntax" chapter of the LEF/DEF Language Reference. *Default:* If you do not specify this parameter, deselects wires and vias of all shapes.
`-shield`	Deselects the wires and vias of the nets specified with the `-nets` parameter, along with the wires and vias shielding the specified nets. **Note**: This parameter cannot be used with `-shield_only`.
`-shield_only`	Deselects only the shield wires associated with the nets specified using the `-nets` parameter. The signal nets being shielded remain selected. **Note**: This parameter cannot be used with `-shield`.
`-status {COVER FIXED NOSHIELD ROUTED SHIELD UNKNOWN}`	
	Specifies the status of the wires and vias to be deselected. Use all upper-case letters for the status. If you specify more than one status, enclose the status list in curly braces. **Note:** If you select `-type Special -status NOSHIELD` or `-type Signal -status SHIELD` the software generates an error message.
`-subclass sublass_name`	Specifies the subclass name of the wires and vias to be deselected. Use this parameter if you want to deselect wires or vias belonging to a specific subclass. Here, *`subclass_name`* is a user-defined attribute that has been previously defined using the `-uda` parameter of the `addSplitPowerVia`, `addRing`, `addStripe`, or `sroute` command. For wires, use this parameter if you want to deselect or delete rings, stripes, or other wires belonging to a specific subclass. Only special wire is supported by this option. **Note:** You can use wildcards in *`subclass_name`*.
`-to_pin pin_name`	Specifies the name of the ending pin of the wire to be deselected. The ending pin you specify should be connected to the same net as the starting pin specified with `-from_pin`. If they connect to different nets, the tool reports an error. In addition, the from and to pins you specify should be connected to the same wire. If there there are more than one wire or via between the specified starting and ending pins, the command is not able to deselect the wire path and returns an error. The `-from_pin` and `-to_pin` parameters are compatible with only the `-direction`, `-layer`, `-object_type`, and `-status` options of the `editDeselect` command. If you use `-from_pin` and `-to_pin` with any other `editDeselect` parameters, the tool returns an error. **Note**: Deselection of wires between specified pins is supported only for signal and clock nets.
`-type {Regular Special Patch}`	Specifies whether to deselect regular wires and vias, special wires and vias, or patch wires. **Note:** If you specify `Regular`, you must omit the `-shape` parameter or specify `-shape None`.
`-use {CLOCK POWER SIGNAL}`	Specifies whether to deselect only CLOCK wires/vias, POWER wires, or SIGNAL wires.
`-via_cell cell_name_list`	Specifies the via cells of the vias to be deselected. You can use wildcards while specifying via cell names. If you are specifying multiple cell names, enclose them in braces.

`-with_edit_flag {0 | 1}`	Deselects all modified wires and vias, that is wires and vias with value `1` for the `isEdit` property on the net. **Notes** • As the `isEdit` property is added on the whole net, all the wires and vias on the net with `isEdit` value set to `1` will be deselected. • The `isEdit` property is used to flag nets with modified wires and vias. This is useful when evaluating how many objects need to be modified for fixing DRC violations and then deciding whether to fix the violations manually or through ECO routing. The `isEdit` property is controlled through the `-create_is_edit_flag` parameter of `setEditMode`. By default, this parameter is set to `0`. If you set the value of this parameter to `1`, the `isEdit` property is set to `1` for nets with modified wires or vias.

Examples

- The following command deselects all horizontal fillwires on the *METAL1* layer:
  ```
  editDeselect -layers METAL1 -direction H -shape FILLWIRE
  ```
- The following command deselects all vias:
  ```
  editDeselect -object_type Via
  ```
- The following command deselects all wires:
  ```
  editDeselect
  ```
- The following command deselects all wires and vias:
  ```
  editDeselect -object_type {Wire Via}
  ```

editDuplicate

```
editDuplicate
[-help]
-layer_horizontal layer
-layer_vertical layer
```

Copies the geometry of selected special wires and pastes them at the same coordinates. If you do not specify a layer, the software pastes them onto the same layer. If you specify a layer, the software copies them to the specified layer and generates vias to maintain connectivity for the duplicated wire.

After duplicating the wires, the software selects the new wires and deselects the original wires. Use the `editMove` command to move duplicated wires to new locations.

Note: Use the `editSelect` command to select wires.

Parameters

`-help`	Prints a brief description that includes type and default information for each `editDuplicate` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man editDuplicate`
`-layer_horizontal layer`	Specifies the new layer for duplicated horizontal wires.
`-layer_vertical layer`	Specifies the new layer for duplicated vertical wires.

Example

- The following command duplicates selected horizontal wires and places them on the *METAL3* layer and duplicates selected vertical wires and places them on the *METAL4* layer. It generates vias for the new wires.
  ```
  editDuplicate -layer_horizontal METAL3 -layer_vertical METAL4
  ```

editFixWideWires

```
editFixWideWires [-help]
```

Splits wires that violate the MAXWIDTH value in the LEF LAYER (Routing) statement. Also splits diagonal wires whose width is greater than the MAXWIDTH value as they are drawn.

Parameters

-help	Prints the usage of the command. For a detailed description of the command, use the man command: `man editFixWideWires`

editMerge

```
editMerge [-help]
```

Merges all wires of the same width, layer, and net that are colinear with and electrically connected to a selected wire. Does not merge signal wires that contain branches. This command also supports 45-degree wire edits.

This command can also be used to merge selected bus guides.

Note: Use the `editSelect` command to select the wire. Use the `selectBusGuide` command to select bus guides or segments.

Parameters

`-help`	Prints the usage of the command. For a detailed description of the command, use the `man` command: `man editMerge`

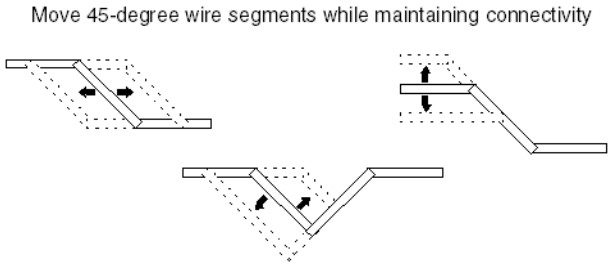
editMove

```
editMove
[-help]
{[[-direction {x y diag45 diag135} -distance float] | [-dx float -dy float] | -to {x y}] }
```

Moves selected wires, boundary pins, or vias.

Moving Wires

`editMove` moves selected wires in the orthogonal direction. When used with the `-direction` and `-distance` or `-dx` and `-dy` combination, `editMove` maintains connectivity by stretching connected wires in the orthogonal direction. This command also supports 45 and 135-degree wire edits.



Use the `setEditMode -connect_with_specified_layer` parameter to control whether layer preference settings are honored when wires are moved. The default value of this parameter is `0`. If you set this parameter to `1`, `editMove` honors the `setEditMode -layer_horizontal` and `-layer_vertical` settings while jogging metal layers. For instance, if you cut a vertical wire on `M4` by using `editCutWire` such that the wire is divided into three wire segments and then move the wire segment in the middle in the horizontal direction, the tool automatically creates new connecting wires on the layer defined by `setEditMode -layer_horizontal` and drops vias correctly. This means you no longer need to perform the additional step for layer change (`editChangeLayer` or `Shift+L`) while moving wires to create a jog. This feature is applicable for both regular and special wires.

To get the current value of the `-connect_with_specified_layer` parameter, you can use the corresponding `getEditMode` parameter.

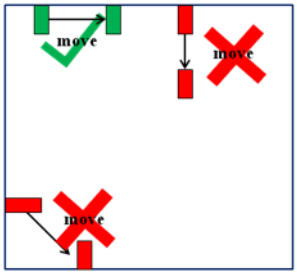
Note: You can use the `setEditMode -snap_to_track` and `-snap_to_track_regular` parameters to specify whether or not to snap wires to the track. To get the current values of these parameters, use the corresponding `getEditMode` options.

Moving Physical Pins

`editMove` moves selected physical pins along with connected wires.

Keep the following considerations in mind while trying to move a physical pin with `editMove`:

- `editMove` can be used to move only the physical pins on the design boundary. Pins inside the design cannot be moved with this command.
- A pin can be moved only along a boundary.
- It cannot be moved between design boundaries.



- Pins on the top or bottom boundary can be moved only horizontally.
- Pins on the left or right boundary can be moved only vertically.

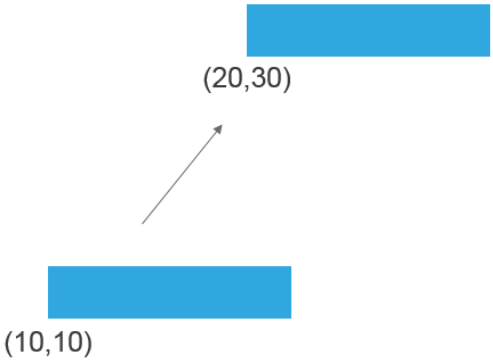
Note: You can use the `setEditMode -snap_to_track_pin` parameter to specify whether or not to snap moved pins to the track. This parameter is set to `true` (`1`) by default. To get the current value of this parameter, use the corresponding `getEditMode` option.

Parameters

`-help`	Prints the usage of the command. For a detailed description of the command, use the `man` command: `man editMove`
`-direction {x y diag45 diag135}`	
	Specifies the direction of movement. Use one of the following options: • `diag45` - Moves selected wires the specified *`-distance`* in a 45-degree direction. This option cannot be used for moving physical pins. • `diag135` - Moves selected wires the specified *`-distance`* in a 135-degree direction. This option cannot be used for moving physical pins. • `x` - Moves selected vertical wires or pins to the right (if you specify a positive value for *`-distance`*) or left (if you specify a negative value for *`-distance`*). • `y` - Moves selected horizontal wires or pins up (if you specify a positive value for *`-distance`*) or down (if you specify a negative value for *`-distance`*).
`-distance` *`float`*	Specifies the distance to move the wire or pin in microns.
`-dx` *`float`*	Specifies the distance in microns by which the selected wire should be moved in the x direction. You must specify the `-dy` value along with it. For example, if you want to move the wire in the x direction by 0.2 microns, specify the following command: `editMove -dx 0.2 -dy 0`
`-dy` *`float`*	Specifies the distance in microns by which the selected wire should be moved in the y direction. You must specify the `-dx` value along with it. For example, if you want to move the wire in the y direction by 0.2 microns, specify the following command: `editMove -dx 0 -dy 0.2`
`-to {x y}`	Specifies the coordinates of the new location to which the selected wire or via is to be moved. If you are moving a via, the `x` and `y` values specify the new coordinates of the via origin. In the case of a wire, the `x` and `y` values specify the new coordinates of the lower left corner of the wire. See Examples. When you move the selected wire or via with `editMove -to`, connected wires are not moved.

Examples

- The following command moves the selected wire such that its lower-left corner lies on the coordinates {`20, 30`} after the move:
  ```
  editMove -to {20 30}
  ```



- The following command moves the selected via such that its origin lies on the coordinates {`20, 30`} after the move:
  ```
  editMove -to {20 30}
  ```

editResize

```
editResize
[-help]
[-keep_center_line {0 1 auto}] [-no_conn]
[-polygon_edge_start {x y} | -to float_value]
{[[[-direction {x y diag45 diag135} -side {high low}] | [-polygon_edge_start {x y} -polygon_edge_end {x y}]] [-offset float_value | -
to float_value]] | [-corner {low_left low_right up_left up_right} -dx float_value -dy float_value]}
```

Resizes wires, bus guides, and pins. The `editResize` command can be used to:

- Change the length of wires and bus guides.
- Change the width of wires and bus guides.
- Enlarge or shrink wires by changing both the length and width of a wire simultaneously.
- Change the width of physical pins.

> While changing the wire width to fix EM violations, apply the following setting before invoking the `editResize` command:
>
> `setEditMode -unrestricted_regular_wire_width true`
>
> By default, when you are changing the width of a wire, it snaps to the closest non-default route (NDR) available. If you set the `-unrestricted_regular_wire_width` parameter to `true`, a wire can be stretched to any width without any restrictions.

Typically, the `editResize` command can be used in two modes:

Mode 1 - Change the size of a wire or pin in only one direction at a time

If `-direction` is specified, the tool changes the size in the specified direction only. In this mode, the `editResize` command can be used to:

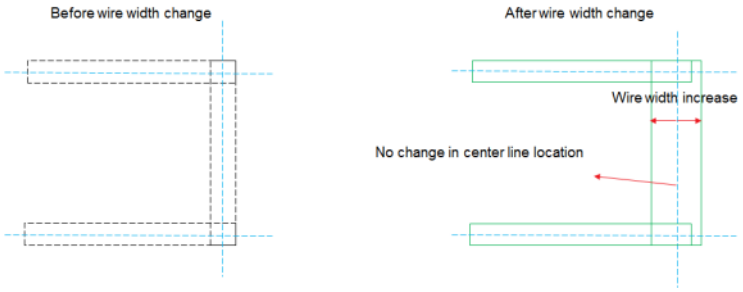
- Change the length of selected regular and special wires by stretching or shrinking them and then snapping them to the closest manufacturing grid point. The `editResize` command also supports the stretching/shrinking of 45 and 135-degree wires.

  Stretch wire to support 45-degree wire segments

  
  Note: Use the `editSelect` command to select the wires.

- Change the width of selected wires and update vias connected to the changed wires to maintain the via-to-wire dimension ratio. `editResize` can be used to change the width of regular as well as special wires:
  - For regular wires, if the width value you specified is not defined in the tech LEF, the tool snaps the width of the regular wire to the closest value defined in the default or non-default rule and prints the following message in the log file:
    `WARNING: The wire width is not defined in default or non default rule, snap wire width to the closest value defined in LEF file`
    The tool also selects a suitable via cell defined in the tech LEF file. If a suitable via cell is not available, the tool does not drop any via.

    When you change the width of a regular wire, the center line is still connected with the neighboring wires after the change:

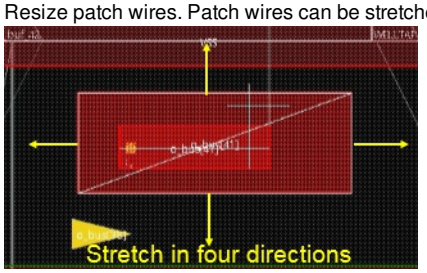


- For a special wire, you can change the wire width freely by specifying an incremental value. The tool uses viagen to generate a via after the width change of a special wire.

Note: Use the `editSelect` command to select the wires.

If you change the width of a wire, and then change it back to the original width, you might see a discrepancy due to rounding.
Note: If you specify a width value that is not an even multiple of the manufacturing grid value, the software displays a warning.

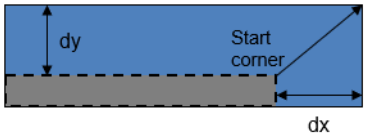
- Resize patch wires. Patch wires can be stretched in four directions:



- Change the width of physical pins. While using the `editResize` command to change the pin width, keep the following points in mind:
  - If `setEditMode -drc_on true` has been specified before modifying the pin width, the tool follows the rules from the LEF file while changing pin width.
  - The pin width, whether vertical or horizontal, should not be less than the minimum width defined in the LEF file.
  - If you specify a value less than minimum width for a pin, the tool uses the minimum width for that pin.

Mode 2 - Change the size of a wire in both the x and y directions simultaneously

If `-direction` is not specified, the tool changes both the width and height of the selected wire at the same time. You can use `-corner` to specify the start corner from which to stretch or shrink the wire. This mode works for only horizontal or vertical special wires in the no_connection (`-no_conn`) mode. Use `-dx` and `-dy` to specify the distance to stretch the wire in x and y directions, respectively.

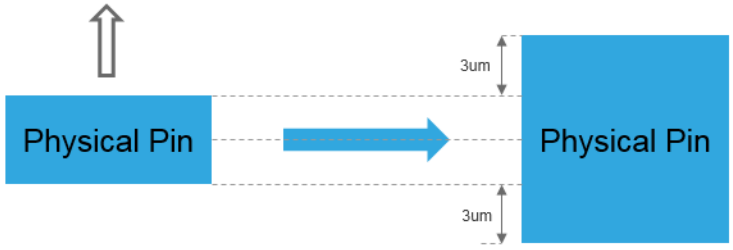


Parameters

`-help`	Prints a brief description that includes type and default information for each `editResize` parameter. For a detailed descriptic `man editResize`
`-corner {low_left low_right up_left up_right}`	
	Specifies the starting corner from which the wire should be stretched.
`-direction {x y diag45 diag135}`	

	Specifies the direction in which the wire or pin is to be stretched or shrunk: • `x` - Resizes wires or pins horizontally. For a horizontal wire, specify the direction as `x` if you want to modify the length of t wire, specify the direction as `x` if you want to modify the width of the wire. • `y` - Resizes wires or pins vertically. For a horizontal wire, specify the direction as `y` if you want to modify the width of the modify the length of the wire (i.e stretch or shrink the vertical wire). • `diag45` - Resizes the selected wires in the 45-degree direction by the specified offset value. **Note**: This parameter can be used only for wires. • `diag135` - Resizes the selected wires in the 135-degree direction by the specified offset value. **Note**: This parameter can be used only for wires.
`-dx float_value`	Specifies the distance to which the wire should be stretched in the x direction.
`-dy float_value`	Specifies the distance to which the wire should be stretched in the y direction.
`-keep_center_line {0 1 auto}`	Controls whether the wire or physical pin is resized with the center line unchanged: • `0` - Resizes the wire or pin from the specified side only. This option works in both the connection and no_connection (`-n` This setting cannot be used for changing the width of signal wires. • `1` - Resizes the wire or pin from both the low and high sides, even if you are stretching it from only one side. This is done  This option works in both the connection and no_connection (`-no_conn`) modes for wires. However, a physical pin can k mode only. • `auto` - When set to `auto`, the software automatically detects when to keep the center line unchanged. *Default*: `auto`
`-no_conn`	Resizes the wire without auto via/wire creation and DRC checking. If `-no_conn` is not specified, the tool will reprocess the via and do basic DRC checking:  **Note:** Patch wires are resized without auto via/wire creation and DRC checking even if `-no_conn` is not specified.
`-offset float_value`	Specifies, in microns, the distance to which the wires or pins should be stretched or shrunk.
`-polygon_edge_end {x y}`	Specifies the end point for a polygon edge {x y}. This option is used only to resize a polygon.
`-polygon_edge_start {x y}`	Specifies the start point for a polygon edge {x y}. This option is used only to resize a polygon.
`-side {high low}`	Specifies the side from which the wire or pin is to be stretched or shrunk: • `high` - Stretches or shrinks wires or pins from the top or the right. • `low` - Stretches or shrinks the wires or pins from the bottom or the left.
`-to float_value`	Specifies, in microns, the new height for selected horizontal wires or the new width for selected vertical wires.

Examples

- The following command stretches the selected vertical wire from the top by 8.5 µm.
  ```
  editResize -direction y -offset 8.5 -side high
  ```
- The following command stretches the selected vertical wire from the bottom by 0.511 µm.
  ```
  editResize -direction y -offset -0.511 -side low
  ```
- The following command shrinks the selected vertical wire from the bottom by 0.619 µm.
  ```
  editResize -direction y -offset 0.619 -side low
  ```
- The following command stretches the selected horizontal wire from the right by 1.27 µm.
  ```
  editResize -direction x -offset 1.27 -side high
  ```
- The following command shrinks a horizontal wire from the left by 0.443 µm.
  ```
  editResize -direction x -offset 0.443 -side low
  ```
- The following command stretches a horizontal wire from the left by 0.86 µm.
  ```
  editResize -direction x -offset -0.86 -side low
  ```
- The following command increases the width of the selected horizontal special wire by 0.01 µm:
  ```
  editResize -direction y -offset 0.01 -side high
  ```
- The following command changes the width of the selected horizontal regular wire to 0.48 µm:
  ```
  editResize -to 0.48 -direction y -side high
  ```
  If 0.48 is not defined in the NDR, the tool snaps the width to the closest value defined in the NDR.
- The following command increases the vertical width of the selected physical pin by 3 µm each from both top and bottom, keeping the center line unchanged:
  ```
  editResize -direction y -offset 3 -side high -no_conn -keep_center_line 1
  ```
  


- The following command reduces the horizontal width of the selected physical pin by 3 µm each from both left and right, keeping the center line unchanged:
  ```
  editResize -direction x -offset -3 -side low -no_conn -keep_center_line 1
  ```

editRotate

```
editRotate
[-help]
[-mode {group | single}]
[-rotate_point {x y}]
{-flip {MX MY} | -rotate {R90 R180 R270}}
```

Flips or rotates selected wires and vias. Use this command for more flexible custom routing and fixing DRC violations using existing wires. Using the `editRotate` command, you can:

- Flip selected wires or vias on the X or Y axis (`MX` or `MY`)
- Rotate the selected wires or vias by 90, 180, or 270 degrees (`R90`, `R180`, or `R270`).

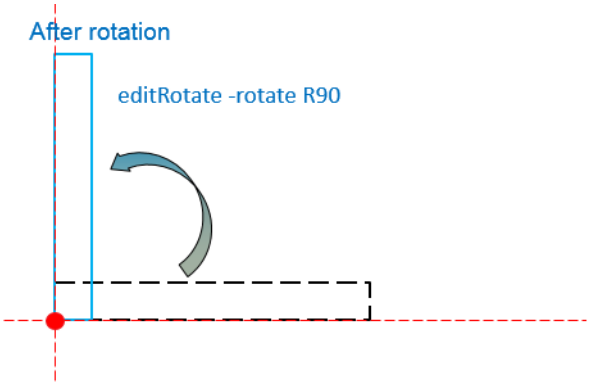
The selected object is rotated or flipped based on current orientation, and the lower-left coordinate of the wire/via remains the same after rotation or flip.

You can also flip or rotate multiple objects simultaneously as one group.

Parameters

`-help`	Prints the usage of the command. For a detailed description of the command, use the `man` command: `man editRotate`
`-flip {MX MY}`	Flips a wire or via. If you specify `MX`, the selected object is flipped on the X axis. If you specify `MY`, the object is flipped on the Y axis.
`-mode {group single}`	Rotates multiple selected wires and vias at the same time using the specified mode: • `group` - Flips or rotates the selected objects as a group. This is the default mode when multiple objects are selected. In this mode, the tool flips or rotates the bounding box which encloses all the selected objects. • `single` - Flips or rotates the selected objects individually.
`-rotate {R90 R180 R270}`	Rotates wires or vias by 90, 180, or 270 degrees, as specified.
`-rotate_point {x y}`	Specifies the point around which the wire should be rotated. If this option is not specified, the selected wires/vias are rotated around the lower-left corner of bounding box of wires/vias.

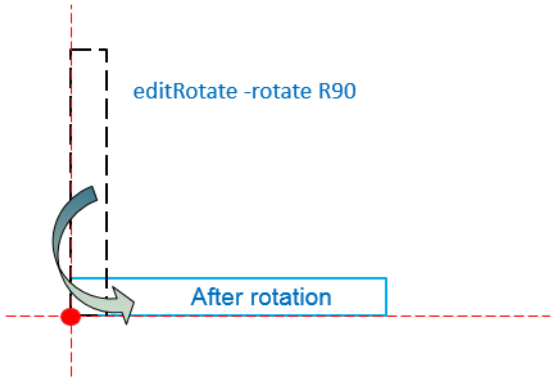
Examples

- The following command rotates the selected wire by 90 degrees:
  ```
  editRotate -rotate R90
  ```
  


- The following command rotates the selected object, which originally has `R90` as its original orientation by 90 degrees:

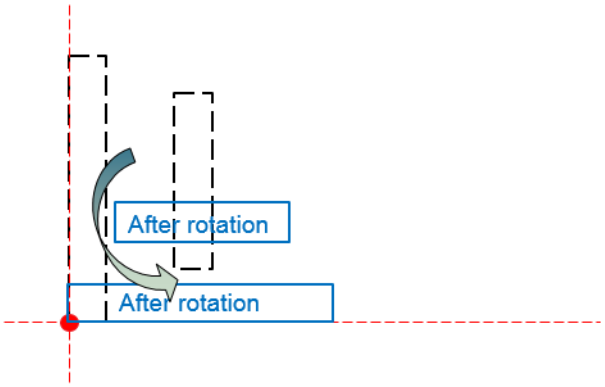
```
editRotate -rotate R90
```

The final orientation of the object will be `R180` as shown below:



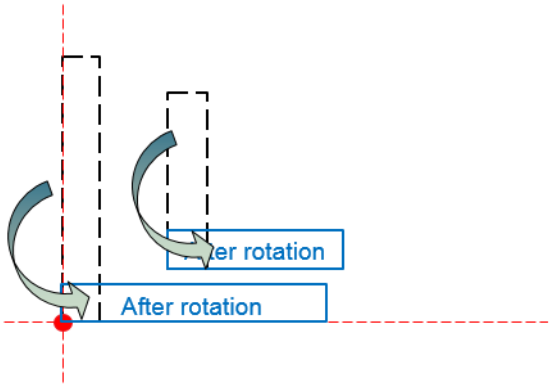
- The following command rotates the bounding box of the selected wires by 90 degrees to rotate the wires as one group:

```
editRotate -rotate R90 -mode group
```



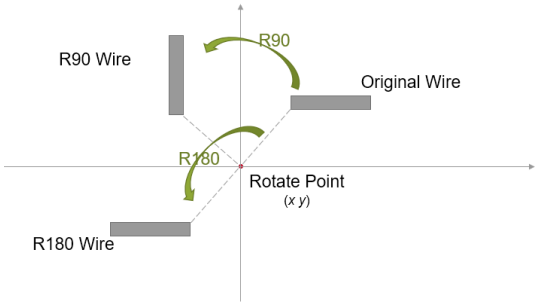
- The following command rotates the selected wires individually by 90 degrees:

```
editRotate -rotate R90 -mode single
```



- The following commands rotate the selected wire by 90 and 180 degrees, respectively, around the specified rotation point, *x y*:

```
editRotate -rotate R90 -rotate_point x y
editRotate -rotate R180 -rotate_point x y
```



- The following commands rotate the selected group of wires by 90 and 180 degrees, respectively, around the specified rotation point, `x y`:

```
editRotate -rotate R90 -mode group -rotate_point x y
editRotate -rotate R180 -mode group -rotate_point x y
```

editSelect

```
editSelect
[-help]
[-area {x1 y1 x2 y2}]
[-direction {H | V | 45 | 135}]
[-floating_via]
[-layer list_of_layers]
[-nets net*]
[-physical_pin_only]
[-regular_wire_with_drc]
[-shape {RING STRIPE FOLLOWPIN IOWIRE COREWIRE BLOCKWIRE PADRING
         BLOCKRING FILLWIRE FILLWIREOPC DRCFILL None}]
[-shield]
[-shield_only]
[-status {COVER FIXED NOSHIELD ROUTED SHIELD UNKNOWN}]
[-subclass sublass_name]
[-type {Regular Special Patch}]
[-use {CLOCK POWER SIGNAL}]
[-via_cell cell_name_list]
[-with_edit_flag {0 | 1}]
[-object_type {Wire Via}]
[-from_pin pin_name -to_pin pin_name]
```

Selects wires and vias using the specified parameters. The wires are updated by subsequent wire editing commands.

Parameters

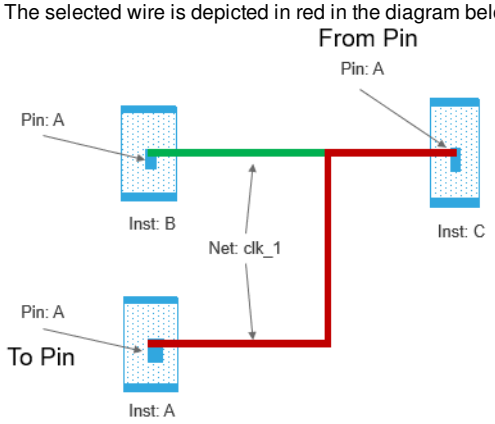
`-help`	Prints the usage of the command. For a detailed description of the command, use the `man` command: `man editSelect`
`-area {x1 y1 x2 y2}`	Specifies the coordinates for the area from which to select wires and vias. *Default:* Entire area *x1*: Specifies the lower left x coordinate. *y1*: Specifies the lower left y coordinate. *x2*: Specifies the upper right x coordinate. y2: Specifies the upper right y coordinate.
`-direction {H | V | 45 | 135}`	Specifies the orientation of the wires to be selected. *Default:* If you do not specify this parameter, selects wires with any orientation. H: Specifies that horizontal wires are to be selected. V: Specifies that vertical wires are to be selected. 45: Specifies that 45-degree wires are to be selected. 135: Specifies that 135-degree wires are to be selected.
`-floating_via`	Specifies that only floating vias are to be selected. A via, or a stack of vias, is floating, if it is not connected to another object, wire, pin, or via, on either its top or bottom metal layer or on both these layers.
`-from_pin pin_name`	Specifies the name of the starting pin of the wire to be selected. The starting pin you specify should be connected to the same net as the ending pin specified with `-to_pin`. If they connect to different nets, the tool reports an error. In addition, the from and to pins you specify should be connected to the same wire. **Note**: Selection of wires between specified pins is supported only for signal and clock nets.
`-layer list_of_layers`	Specifies the layers from which to select wires and vias. This option supports backside and Through Silicon Via (TSV) layers as well. If you are specifying multiple layers, enclose them in braces. *Default:* If you do not specify this parameter, selects wires and vias on all layers.

`-nets net*`	Specifies the net names from which to select wires and vias. You can use wildcard values in this field. For example, if you specify `V*`, selects wires/vias from nets `VDD` and `VSS`.
`-object_type {Wire Via}`	Specifies whether wires or vias or both should be selected. If the parameter is not specified, only wires are selected. *Default*: `Wire`
`-physical_pin_only`	Specifies that physical pins are to be selected. By default, `editSelect` does not select physical pins. You can use the `-physical_pin_only` parameter along with `-area`, `-layer`, or `-nets` to select the physical pins in the specified area, layer, or net, respectively.
`-regular_wire_with_drc`	Selects regular wires with violation markers. Clock nets are also selected.
`-shape {RING STRIPE FOLLOWPIN IOWIRE COREWIRE BLOCKWIRE PADRING BLOCKRING FILLWIRE FILLWIREOPC DRCFILL None}`	
	Specifies the shapes of the wires and vias to be selected. Use all upper-case letters for the shapes. If you specify multiple shapes, enclose the list of shapes in braces. For shape definitions, see *Shapes,* in the "DEF Syntax" chapter of the LEF/DEF Language Reference. *Default:* If you do not specify this parameter, selects wires and vias of all shapes.
`-shield`	Selects the wires and vias of the nets specified with the -nets parameter, along with the wires and vias shielding the specified nets. **Note**: This parameter cannot be used with `-shield_only`.
`-shield_only`	Selects only the shield wires associated with the nets specified using the `-nets` parameter. The signal nets being shielded are not selected. **Note**: This parameter cannot be used with `-shield`.
`-status {COVER FIXED NOSHIELD ROUTED SHIELD UNKNOWN}`	
	Specifies the status of wires and vias to be selected. Use all upper-case letters for the status. If you specify more than one status, enclose the status list in braces. **Note:** If you select `-type Special -status NOSHIELD` or `-type Signal -status SHIELD` the software generates an error message.
`-subclass sublass_name`	Specifies the subclass name of the wires and vias to be selected. Use this parameter if you want to select wires or vias belonging to a specific subclass. Here, *`subclass_name`* is a user-defined attribute that has been previously defined using the `-uda` parameter of the `addSplitPowerVia`, `addRing`, `addStripe`, or `sroute` command. For wires, use this parameter if you want to select or delete rings, stripes, or other wires belonging to a specific subclass. Only special wire is supported by this option. **Note:** You can use wildcards in *`subclass_name`*.
`-to_pin pin_name`	Specifies the name of the ending pin of the wire to be selected. The ending pin you specify should be connected to the same net as the starting pin specified with `-from_pin`. If they connect to different nets, the tool reports an error. In addition, the from and to pins you specify should be connected to the same wire. If there there are more than one wire or via between the specified starting and ending pins, the command is not able to select the wire path and returns an error. The `-from_pin` and `-to_pin` parameters are compatible with only the `-direction`, `-layer`, `-object_type`, and `-status` options of the `editSelect` command. If you use `-from_pin` and `-to_pin` with any other `editSelect` parameters, the tool returns an error. **Note**: Selection of wires between specified pins is supported only for signal and clock nets.
`-type {Regular Special Patch}`	
	Specifies whether to select regular wires and vias, special wires and vias, or patch wires. **Note:** If you specify `Regular`, you must omit the `-shapes` parameter or specify `-shapes None`.
`-use {CLOCK POWER SIGNAL}`	
	Specifies whether to select only CLOCK wires/vias, POWER wires, or SIGNAL wires.

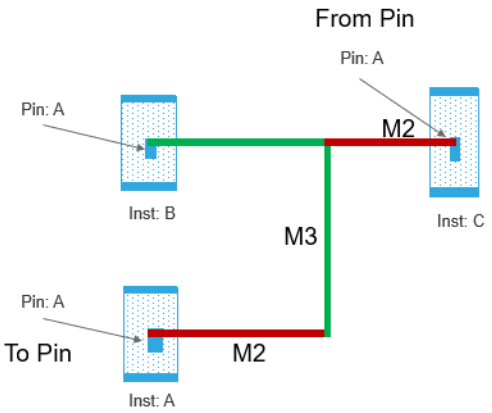
`-via_cell` *`cell_name_list`*	Specifies the via cells of the vias to be selected. You can use wildcards while specifying via cell names. If you are specifying multiple cell names, enclose them in braces.
`-with_edit_flag {0 | 1}`	Selects all modified wires and vias, that is wires and vias with value `1` for the `isEdit` property on the net. **Notes** • As the `isEdit` property is added on the whole net, all the wires and vias on the net with `isEdit` value set to `1` will be selected. • The `isEdit` property is used to flag nets with modified wires and vias. This is useful when evaluating how many objects need to be modified for fixing DRC violations and then deciding whether to fix the violations manually or through ECO routing. The `isEdit` property is controlled through the `-create_is_edit_flag` parameter of `setEditMode`. By default, this parameter is set to `0`. If you set the value of this parameter to `1`, the `isEdit` property is set to `1` for nets with modified wires or vias.

Examples

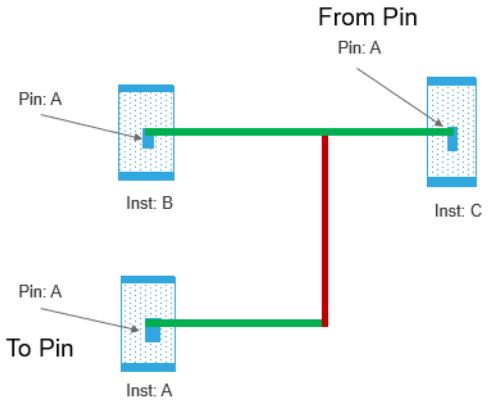
- The following command selects all wires on the *METAL1* and *METAL2* layers:
  ```
  editSelect -layer {METAL1 METAL2}
  ```
- The following command selects all vias on the cut layer `VIA12`:
  ```
  editSelect -layer VIA12 -object_type Via
  ```
- The following command selects all vias on the cut layers `VIA12` and `VIA23`:
  ```
  editSelect -layer {VIA12 VIA23} -object_type Via
  ```
- The following command selects all wires on the *METAL1* and *METAL2* layers and vias on the cut layer `VIA12`:
  ```
  editSelect -layer {METAL1 METAL2 VIA12} -object_type {Wire Via}
  ```
- The following command selects all horizontal fillwires on the *METAL1* layer:
  ```
  editSelect -layer METAL1 -direction H -shape FILLWIRE
  ```
- The following command selects VDD STRIPEs with subclass "stripe_A":
  ```
  editSelect -nets VDD -shape STRIPE -type Special -subclass stripe_A
  ```
- The following command selects all vias of shape `FOLLOWPIN` with names that match the pattern `tapcellvia_VIA1_RUL*`:
  ```
  editSelect -shape FOLLOWPIN -via_cell tapcellvia_VIA1_RUL* -object_type Via
  ```
- The following command selects all the modified wires and vias:
  ```
  editSelect -with_edit_flag 1 -object_type {Wire Via}
  ```
- The following command selects the complete wire between the specified from and to pins:
  ```
  editSelect -from_pin C/A -to_pin A/A
  ```
  The selected wire is depicted in red in the diagram below:



- The following command selects only the wire segments on the `M2` layer between the specified from and to pins:
  ```
  editSelect -from_pin C/A -to_pin A/A -layer M2
  ```
  The selected wire segments are depicted in red in the diagram below:

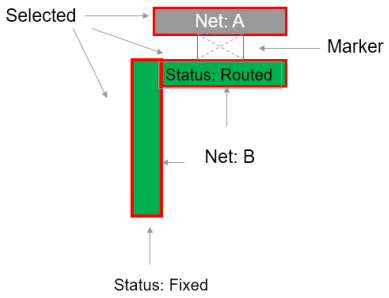


- The following command only the vertical wire segments between the specified from and to pins:
  ```
  editSelect -from_pin C/A -to_pin A/A -direction V
  ```
  The selected wire segment is depicted in red in the diagram below:



- Consider the example below:

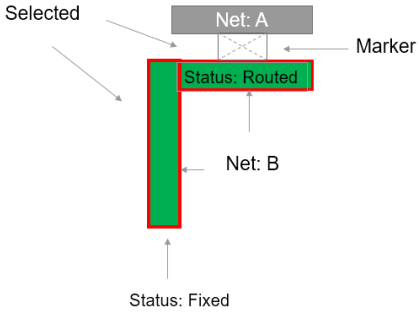
  - The following command selects all nets that have DRC markers:
    ```
    editSelect -regular_wire_with_drc
    ```



Both nets A and B are selected.

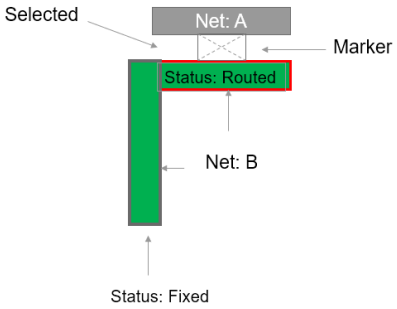
- The following command selects wires with DRC markers from only Net B:

```
editSelect -nets B -regular_wire_with_drc
```



- The following command selects only routed wires with DRC markers from Net B:

```
editSelect -nets B -regular_wire_with_drc -status ROUTED
```



- The following set of commands select and delete nets with DRC markers while excluding clock nets:

```
editSelect -regular_wire_with_drc
editDeselect -use CLOCK
editDelete -selected
```

editSplit

```
editSplit [-help]
```

Splits selected special wires at connection points with orthogonal wires. This command can also be used to split selected bus guides.

Note: Use the `editSelect` command to select the wires. Use the `selectBusGuide` command to select bus guides or bus guide segments

Parameters

`-help`	Prints the usage of the command. For a detailed description of the command, use the `man` command: `man editSplit`

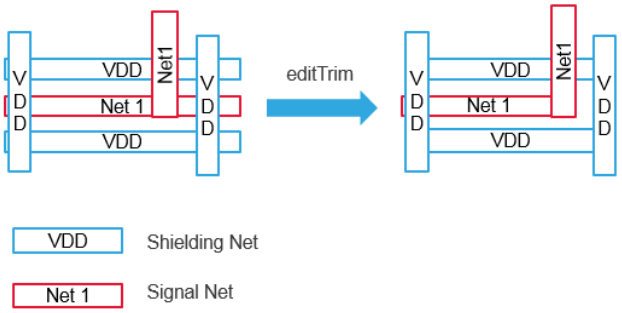
editTrim

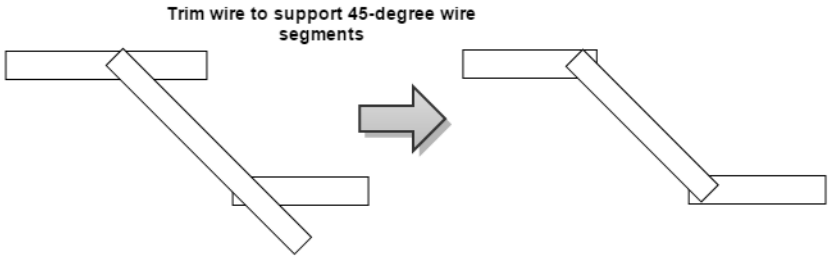
```
editTrim
[-help]
[-keep_floating_stubs]
[-status {COVER FIXED NOSHIELD ROUTED SHIELD}]
[-type {float}]
[-all | -selected | -nets net* | -layers layer_names | -area {x1 y1 x2 y2}]
```

Removes or trims wires. Wires are trimmed or removed as follows:

- Trims floating stubs of wires back to the closest connection point.
- Removes wires that do not have electrical connections to other wires or pins (floating wires).
- Removes wires with only one connection to another wire or pin, along with connecting vias. Removing a wire with one connection might cause the wire to which the just-removed wire is connected to change from being a wire with two connections to a wire with one connection and thus it will also be removed. This process is repeated until no wires with one connection are left.
  Note: The `editTrim` command recognizes patch wires and detects the patch wire connection with the via. Therefore, it does not delete patch wires even if they are connected from only one side.
- Trims shield wires along with signal wires.

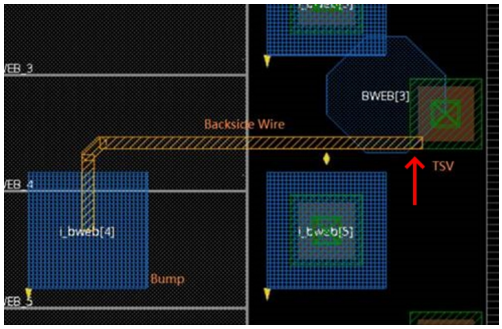


- Trims wires to support 45-degree wire segments.



Notes

- The `editTrim` command recognizes Through Silicon Via (TSV) connections and detects the backside wire connection with the TSV so it does not remove the backside routes connected to TSV.



- The `editTrim` command does not trim metal fill segments. To trim metal fill segments use the `trimMetalFill` command.

Parameters

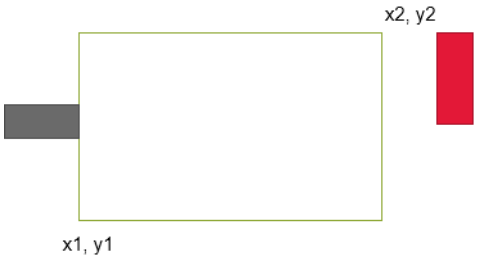
`-help`	Prints the usage of the command. For a detailed description of the command, use the `man` command: `man editTrim`
`-all`	Trims all special wires and floating stubs.
`-area {x1 y1 x2 y2}`	Specifies the coordinates for the box area from which to trim the wires. Here: • `x1` - Specifies the lower left x coordinate. • `y1` - Specifies the lower left y coordinate. • `x2` - Specifies the upper right x coordinate. • `y2` - Specifies the upper right y coordinate. Only the wires that overlap with the specified box area are trimmed. The wires that just touch the box area are not trimmed.
`-keep_floating_stubs`	Selects the floating wires but does not remove the floating stubs. Use this parameter if you want to assess the impact before actually trimming.
`-layers layer_names`	Specifies the layers from which to trim wires. If you are specifying multiple layers, enclose the layer names in braces. *Default*: If you do not specify this parameter, the command trims wires on all layers.
`-nets net*`	Trims wires on the nets you specify. You can use wildcards to specify the nets.
`-selected`	Trims selected wires. Use the `editSelect` command to select the wires. This is the default value.
`-status {COVER FIXED NOSHIELD ROUTED SHIELD}`	
	Allows you to filter the wires to be trimmed by status. If you specify `-status` without specifying `-all`, `-nets`, or `-selected`, the tool will trim selected wires with the specified status.
`-type {float}`	Removes only wires that do not have electrical connections to other wires or pins (floating wires). The tool will not trim the wire with connection to other wires at one end if this option is specified.

Examples

- The following command trims the wires overlapping the box area specified by the coordinates `{x1 y1 x2 y2}`:
  `editTrim -area {x1 y1 x2 y2}`

  Before

  
  After

- The following command trims the wires in the specified layers:
  `editTrim -layers {Metal1 Metal3}`

end_parallel_edit

```
end_parallel_edit
[-help]
-out_file parallel_edit_file_name
```

Ends parallel editing. The command:

- compares the data in memory with the original data saved in binary files by `start_parallel_edit`
- saves the parallel edit file with the specified name

Multiple `end_parallel_edit` commands are allowed after one `start_parallel_edit`.

Parameters

`-help`	Prints a brief description that includes type and default information for each `end_parallel_edit` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man end_parallel_edit`
`-out_file parallel_edit_file_name`	Specifies the name of the parallel edit file.

Example

- The following command compares the data in memory with the data saved in the binary files and writes the parallel edit information to `PE1.txt` file:

```
innovus 8> end_parallel_edit -out_file PE1.txt
Start saving parallel edit information to PE1.txt
************************************************************************
Comparing net attribute and regular wire/via with reference DB
Comparing instance with reference DB
Comparing physical pin with reference DB
Comparing NDR rule with reference DB
Comparing routing blockage with reference DB
Comparing placement blockage with reference DB
Comparing via cell with reference DB
Comparing special wire/via with reference DB
************************************************************************
End saving parallel edit information
```

```

Returns information about the specified `setEditMode` parameter in the Innovus log file and the console. The following information is returned:

- Parameter name
- Current value
- Type (Boolean, string, and so on)
- Whether the current value was set by user

If you do not specify a parameter, the software returns information for all of the `setEditMode` parameters.

Parameters

`-help`	Prints a brief description that includes type and default information for each `getEditMode` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man getEditMode`
`parameter_name`	Returns value for the specified `setEditMode` parameters. You can specify one or more parameters. See `setEditMode` for names and descriptions of the parameters you can specify.
`-quiet`	Returns the current settings for the specified parameters in the Tcl list format only. If you specify `-quiet` without any parameters, the software returns the current settings of all `setEditMode` parameters in the Tcl list format.

Examples

- The following command returns the current value for the `setEditMode -shape` parameter, which specifies the shape associated with the wire you draw:

```
getEditMode -shape
-shape STRIPE                # enums={RING STRIPE FOLLOWPIN IOWIRE COREWIRE BLOCKWIRE PADRING BLOCKRING FILLWIRE FILLWIREOPC DRCFILL
None}, default=STRIPE
STRIPE
```

- The following command returns the current value of the `setEditMode -via_cut_layer` parameter, which specifies the via layer name for the via to be created or modified:

```
getEditMode -via_cut_layer
-via_cut_layer V12           # string, default=V12
V12
```

prepareForEcoRoute

```
prepareForEcoRoute
[-help]
[-exclude nets]
[-nets nets]
```

Converts special nets to geometrically equivalent regular nets. You can convert all special nets, named special nets, or all special nets except those you specify. The `prepareForEcoRoute` command supports polygon shapes as well.

Notes

- If you do not specify any parameters, the `prepareForEcoRoute` command converts all special nets to signal nets.
- Use the `prepareForEcoRoute` command to convert physical nets. To convert logical nets, use `setNet`.
- The `prepareForEcoRoute` command does not work for PG nets.

Parameters

`-help`	Prints a brief description that includes type and default information for each `prepareForEcoRoute` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man prepareForEcoRoute`
`-exclude nets`	Specifies the special nets that you do not want to convert. You can use wildcards. • If a name contains a special character, enclose it in braces (`{}`). • If you specify multiple net names, enclose the names in braces (`{}`).
`-nets nets`	Specifies the special nets to be converted. You can use wildcards. • If a name contains a special character, enclose it in braces (`{}`). • If you specify multiple net names, enclose the names in braces (`{}`).

Note: For backward compatibility, this command also supports the following syntax for nets to convert:

```
prepareForEcoRoute netName [netName2 netName3 ...]
```

Examples

- The following command converts special nets named `clk*` to regular nets:
  ```
  prepareForEcoRoute -nets clk*
  ```
- The following command converts all special nets, except those named `clk1*`, to regular nets:
  ```
  prepareForEcoRoute -exclude clk1*
  ```
- The following command converts special nets named `clk*` to regular nets, except nets named `clk1*`:
  ```
  prepareForEcoRoute -nets clk* -exclude clk1*
  ```
- The following command converts all special nets named `clk*`, `a2`, and `s2[1]`, except for nets `clk1` and `clk2`, to regular nets:
  ```
  prepareForEcoRoute -nets {clk* a2 s2[1]} -exclude {clk1 clk2}
  ```

read_parallel_edit_files

```
read_parallel_edit_files
[-help]
[-check]
[-conflict_mode {only_one stop_all}]
-files list_of_files
[-ignore_error]
[-report_file file_name]
```

Loads all the specified parallel edit files and implements the editing changes recorded in them.

During parallel editing, there is a possibility of a conflict if the same attribute of an object is changed in different parallel edit files. Some cases in which a conflict can occur are listed below:

- Two users edit the layer of the same wire segment.
- Two users edit the width of the same NDR rule.
- One user cuts the wire segment, and another user changes the status of the same wire.

In the following examples of parallel edits, there is no conflict:

- One user edits the layer of wire, and another user edits its mask.
- One user edits the width of an NDR rule, and another user edits its spacing.

In case of any conflict in the parallel edit files, the tool implements changes as per the specified conflict mode and writes the conflicting information to a report file.

For information on the parallel edit flow, format of a parallel edit file, and conflict handling examples see the "*Parallel Editing Capability"* section in the Editing Wires chapter of the *Innovus User Guide.*

Parameters

`-help`	Prints a brief description that includes type and default information for each `read_parallel_edit_files` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man read_parallel_edit_files`
`-check`	Specifies that the tool should only check the syntax and conflict of the files but should not actually implement the changes.
`-conflict_mode {only_one stop_all}`	Specifies the conflict mode. The two possible modes are: • `only_one` - In case of conflicting commands, the first read command is implemented and the other command is recorded in the conflict report. • `stop_all` - In case of conflicting commands, the tool implements neither of the conflicting commands and records both of them in the conflict report.
`-files list_of_files`	Specifies the list of parallel editing files.
`-ignore_error`	Specifies whether errors in files should be ignored. When this option is specified, the tool skips lines with issues in the files but continues to read the other wires on the same net.
`-report_file file_name`	Specifies the name of the conflict report.

reportLegalWireWidthForBump

```
reportLegalWireWidthForBump
[-help]
-location x y
-width value
```

Reports two legal widths for a 45-degree wire to connect to the 45-degree side of an octagon-shaped bump in the wire editor.

Parameters

`-help`	Prints out the command usage.
`-location x y`	Specifies the location inside the bump near the (45-degree) side of the connection (point, required).
`-width value`	Sets the initial width value of the 45-degree wire in microns.

Example

- The following command reports two legal widths for a 45-degree wire to connect to the 45-degree side of an octagon-shaped bump at the specified location with the specified initial width:

  ```
  reportLegalWireWidthForBump -location 681.83 777.28 -width 9.25
  ```

  The reported values are:

  ```
  9.230000 9.260000
  ```

selectSecondaryPGNet

```
selectSecondaryPGNet
[-help]
-insts inst+
{-net net_name | -pin pin_name}
```

Selects Power/Ground (P/G) net wire segments from specified instances. The wire segments are selected from the instance P/G pins to stripes (swire targets). This provides an easy way to select and delete routing from specific instance P/G pins to stripes.

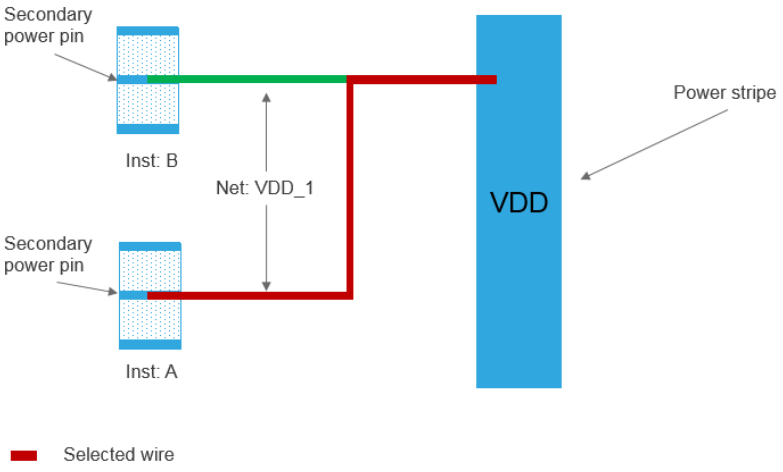
Note: This command does not support dangling secondary P/G nets.

Parameters

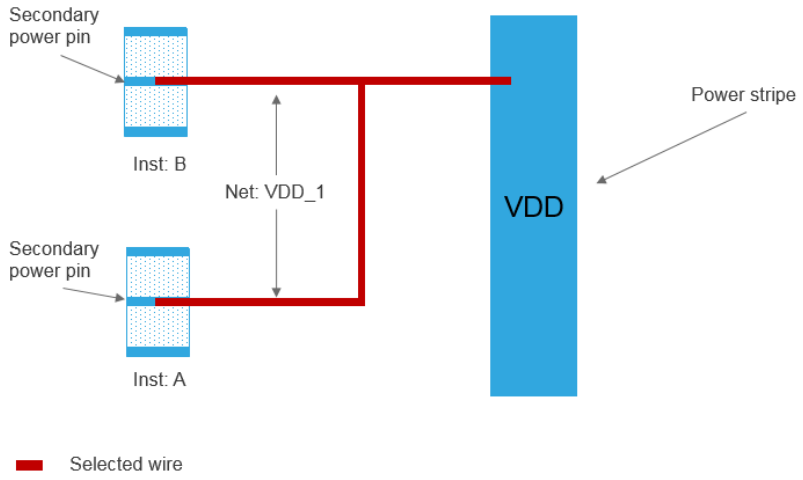
`-help`	Prints the usage of the command. For a detailed description of the command, use the `man` command: `man selectSecondaryPGNet`
`-insts inst+`	Specifies the list of instances that have a secondary PG pin. Wildcards are supported in instance names. If one or more specified instances does not connect with the specified net, the tool displays a warning and ignores those instances.
`-net net_name`	Specifies the net name. This parameter cannot be used with `-pin`. **Note**: *net_name* does not take any wildcard values.
`-pin pin_name`	Specifies the pin name. This parameter cannot be used with `-net`.

Examples

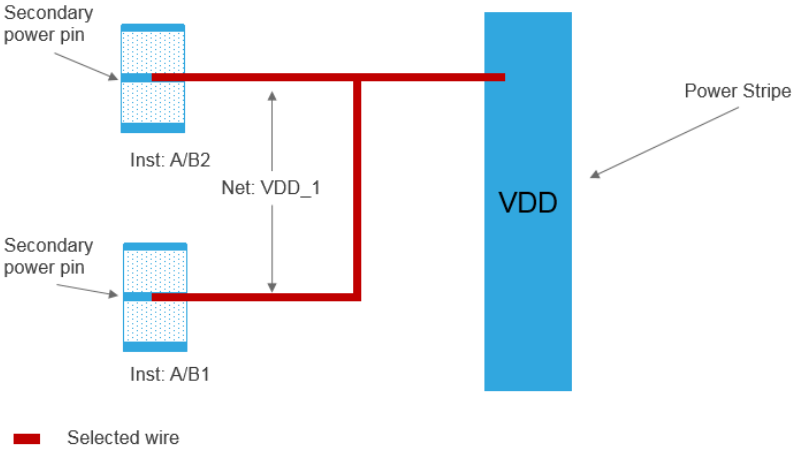
- The following command selects the routing from the P/G pin in instance `A` of net `VDD_1` to the power stripe:
  ```
  selectSecondaryPGNet -net VDD_1 -insts {A}
  ```



- The following command selects the routing from the P/G pins in instances `A` and `B` in net `VDD_1` to the power stripe:
  ```
  selectSecondaryPGNet -net VDD_1 -insts {A B}
  ```



- The following command selects the routing from the P/G pins in instances `A/B1` and A/B2 in net `VDD_1` to the power stripe:
  ```
  selectSecondaryPGNet -net VDD_1 -insts {A/*}
  ```



- The following command selects secondary PG net through the `VDDO` pin and checks all its ports:
  ```
  selectSecondaryPGNet -insts $instn -pin VDDO
  ```
  If a port of the the `VDDO` pin has an open, the tool prints a message as follows:
  ```
  **WARN: (IMPSPR-405): There is no route for secondary pin "VDDO" to
  inst "PD_CHIPLET2_PADS_PD_CHIPPADS_pads_out_balanced_ls_padring_chiplet2_u_DISP_LSYNC_C_UPF_LS" at '3.085500 1.902500'.
  ```

Updates the Edit Route and Edit Via forms, the design display area, and vias that are subsequently created with the `editAddVia` command, with the information specified by the parameters. Use the `getEditMode` command to check the current value of a specific `setEditMode` parameter.

Note: Before running any Wire Editor command, all objects and pre-routed wires/vias must be colorized already.

Parameters

`-help`	Prints a brief description that includes type and default information for each `setEditMode` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setEditMode`
`-align {true|false}`	Specifies whether or not to support alignment of objects during interactive edits using the GUI. *Default:* `true`
`-allow_45_degree {true|false}`	Allows creation of a 45 degree wire. *Default:* `false`
`-arrow_increment` *value*	Specifies the step increments in microns to move wires with the arrow keys. *Default:* `1.0`.
`-assign_multi_pattern_color {auto|mask1|mask2|mask3}`	
	Specifies how to assign mask color on the double patterning technology (DPT) layer of the wire segment to be crea Select one of the following: • `auto`: Mask color is assigned automatically. • `mask1`: Assigns `mask1` color to the added wire segment. • `mask2`: Assigns `mask2` color to the added wire segment. • `mask3`: Assigns `mask3` color to the added wire segment. *Default*: `auto`
`-auto_distribute_bus {true|false}`	Auto-distributes a group of wires, and sets the same spacing based on option `-bus_total_width_vertical` or `-bus_total_width_horizontal`. If `-auto_distribute_bus` is set to `true`, the tool ignores the `-spacing_horizontal` and `-spacing_vertical` settings. While drawing a bus, the tool auto-sets spacing as: `wire spacing = (total bus width - total wire width)/ (wire number - 1)` If the spacing is less than the minimum spacing, the tool auto-sets it to min spacing. *Default:* `false`

`-auto_split_bus {true|false}`	Specifies whether or not Wire Editor should split buses automatically around power structures to avoid DRC violati  Auto bus split around power trunk  Auto bus split around power vias By default, there is no detour around via array and anchor wires of the bus being drawn always snap to the routing The `-auto_split_bus` parameter also supports busses of special wires with different widths. *Default:* `false`
`-bus_honor_start_params {true|false}`	Specifies that the wire width and spacing of the start points (pins) should be honored when drawing routes for a bus following diagram depicts how the width and spacing of the bus is maintained through turns for the the 2nd to N-1 w segment, if you set `-bus_honor_start_params` to `true`:  *Default*: `false`

`-bus_honor_width_setting {true|false}`	Specifies whether or not the tool should adjust the wire width when snapping bus wires to pin. By default, if `-snap_bus_to_pin` is specified, the tool adjusts the wire width to be the same as the macro or IO pin width. If you do r the wire width to be adjusted to match the pin width, set the `-bus_honor_width_setting` parameter to `true`. In this c tool uses the width value defined by `setEditMode -width_horizontal` or `-width_vertical` when snapping the bus t *Default*: `false` (Pin width is used with `-snap_bus_to_pin`)
`-bus_total_width_horizontal value`	Specifies the total width of a horizontal bus. While drawing a bus, the tool auto-sets spacing as: `wire spacing = (total bus width - total wire width)/ (wire number - 1)` *Default*: `0`
`-bus_total_width_vertical value`	Specifies the total width of a vertical bus. While drawing a bus, the tool auto-sets spacing as: `wire spacing = (total bus width - total wire width)/ (wire number - 1)` *Default*: `0`
`-change_order_at_turn {Reverse Order | Keep Order}`	
	Specifies whether the order of the wires changes or stays the same when the wire makes a 90-degree turn. *Default:* `Keep Order`
`-check_design_boundary {true|false}`	Specifies that wires and vias are to be made inside the design boundary. If `-check_design_boundary` is set to `true`, cannot manually stretch a wire into the area defined by the `-pull_back_distance` parameter. **Note:** 45-degree wires do not follow this rule. *Default*: `false`
`-circle_NDR_vias_only {true|false}`	Specifies that when the *Shift + N* bindkey is used, the Wire Editor should circle through NDR vias only. *Default:* `false`
`-close_polygons {true|false}`	Specifies whether to close a special route structure toward itself, using the `Escape` key. For the closing to complete, ending wire segments must be drawn towards the start wire segments, but do not have to touch them. If you specify parameter, the software ignores the `-extend_wires start` and the `-extend_wires end` settings. *Default:* `false`
`-color_align_with_track {true|false}`	Specifies whether the wire color is to be changed to match the track color during a move or copy operation. If you s `color_align_with_track` parameter to `true` and move or copy a wire to snap it to a track, the track color is automati assigned to the wire. Note that if the wire does not snap to a track or if the wire covers more than one track, this para will not have any effect. This parameter is turned off by default. This means when you move or copy a wire, the wire color is retained by defa *Default:* `false`
`-connect_pin {in|out|inout|nodir}`	Specifies the type of pin on which a via should be generated. You can specify the following pin types with this para • `in` - Generates a via on an input pin. • `out` - Generates a via on an output pin. • `inout` - Generates a via on an inout pin. • `nodir` - Generates a via on a pin for which no direction is specified. *Default*: `in out inout nodir`
`-connect_with_specified_layer {true|false}`	
	Specifies whether or not the layer of connecting wires should be changed as per the `-layer_horizontal` or `-layer_` setting when moving wires with the `editMove` command. If you set this parameter to `true`, `editMove` honors the `setE` `-layer_horizontal` and `-layer_vertical` settings while jogging metal layers. For instance, suppose you cut a verti on `M4` by using `editCutWire` such that the wire is divided into three wire segments. Now, if you select the wire segm middle and move it in the horizontal direction, the tool automatically creates new connecting wires on the layer defi by `setEditMode -layer_horizontal` and drops vias correctly. This feature is applicable for both regular and special *Default:* `false`

`-create_crossover_vias {true|false}`	Specifies whether the software creates a via when you draw a wire that crosses a wire or pin of the same net that is different layer. Does not create vias if minimum or maximum layer constraints prevent the creation of vias. If you dra between two pins, the software creates vias on the pins as needed, regardless of whether this option is selected or deselected. If you specify `false` for this parameter, the software does not create vias at crossovers. *Default:* `true`

`-create_is_edit_flag {true|false}`	Specifies whether to create the db property `isEdit` for wire edit. This property is used to flag nets with modified wire vias. This is useful when evaluating how many objects need to be modified for fixing DRC violations and then deci whether to fix the violations manually or through ECO routing. This property is written to the DEF file.
	By default, this parameter is set to `false`. If you set the value of this parameter to `true`, the `isEdit` property is set to with modified wires or vias. The following type of modifications can cause `isEdit` to be set to `1`:
	• Drawing a new wire through `editAddRoute` and `editCommitRoute`.
	• Moving a wire with/via `editMove`.
	• Stretching a wire/via with `editResize`.
	`dbGet` can then be used to flag nets with modified wires/vias:
	`> dbGet $wire/via_pointer.net.isEdit`
	`> 1`
	Value `1` means the wire/via on the net has been modified.
	The `isEdit` property can be reset using the `dbSet` command as follows:
	`dbSet <net>.isEdit 0`
	Note: The `isEdit` property is independent of `setEditMode -keep_status true`.
	Default: `false`

`-create_via_on_pin {true|false}`	Specifies whether the software creates vias at pins. Specify `false` to prevent the software from creating vias at pins of `false` might be needed for bump pins that are not square-shaped. *Default:* `true`
`-cut_class class_name`	Specifies the cut class name of the vias. *Default:* `""`
`-cut_wire_overlap {regular|special}`	
	Creates overlaps while cutting specified type of wires. The supported values are: • `regular` - Cuts regular wires with an overlap • `special` - Cuts special wires with an overlap If this parameter is not specified, all wires are cut without overlap. This is equivalent to setting `-cut_wire_overlap` t *Default*: `regular`, which means that regular wires are cut with an overlap while special wires are cut without an ove
`-debug_file output_file`	Specifies the file name for reporting untrimmed wires and vias if `setEditMode -verbose` is set to `true`. If you don't sp name but `setEditMode -verbose` is set to `true`, the file is named `editTrim_debug.rpt`. If the tool finds the same file i saved directory, the new file replaces the old one.
`-delete_pin_with_wire {true|false}`	Deletes the pin with the wire. *Default:* `true`

`-delete_tsv {true|false}`	Specifies whether or not `editDelete` deletes the items on a Through-Silicon Via (TSV) layer. • `true` - The tool deletes the items on TSV layers if `editDelete` is used without `-layer` or `-selected`. • `false` - The tool does not delete the items on TSV layers if `editDelete` is used without `-layer` or `-selected`. *Default*: `false` The `editDelete` command observes the layer range setting specified by `setEditMode -layer_minimum value -layer_maximum value`, where `-layer_minimum` and `-layer_maximum` specify the minimum and maximum routing laye respectively. If `-layer` is specified with `editDelete`, the tool ignores the range setting from `setEditMode` and deletes only from the specified layers. If `-selected` is specified with `editDelete`, the tool deletes only the selected wires and
`-delete_wire_via_deep_through {true|false}`	Deletes wire via in the deep through mode when set to `true`. For instance, assume you have two vertical wires `M3` and `M5` at the same location. The tool will not drop vias betwee two wires when you draw `M5` because both the wires have the same direction. However, when you draw the horizor wire, the tool will drop the vias from `M3` to `M6`. All the three wires have the same net. Now, if you delete the M6 wire, t setting for `-delete_wire_via_deep_through` determines which vias are removed. If `-delete_wire_via_deep_through true`, the tool deletes the via from `M3` to `M6`. However, if it is set to `false`, the tool only deletes the via from `M5` to `M6`. *Default*: `false`
`-display_wire_length_with_cursor {true|false}`	
	Specifies whether or not to display the total and current wire length while editing wires by using the mouse. When t parameter is set to `true`, the tool displays the total and current wire length during the following wire edit operations: • Adding a new regular, special, or patch wire • Stretching the length of a regular or special wire • Resizing a patch wire  *Default*: `true`

`-draw_shield {true|false}`	Specifies whether the wire being created is a shield wire. When `-draw_shield` is set to `true`, the wire editor creates a wire with the net name specified using the `-shielding_` option. The newly created wire/via has its status set to `shield` and its shield signal net set to the net name specifiec `-nets` option. Note that you can specify only one net with the `-nets` option when drawing a shield wire. The new sh wire/via also has its shape set to `None`. The shield wire defaults to the minimum width and spacing, unless explicitly other values. Note that NanoRoute supports only minimum width and minimum spacing. When `-draw_shield` is set to `false`, the wire editor reverts to its original behavior and draws a wire/via with the net s using the `-nets` option. To learn how to use the `-draw_shield` parameter, see the Examples section. **Notes**: • When `-draw_shield` is set to `true`, the following `setEditMode` settings are ignored: ◦ `-shield` ◦ `-shield_shape` *Default*: `false`
`-draw_with_group_centerline {true|false}`	
	Draws the bus along the center-line of whole wires when set to `true`. Enable this option if you set `-auto_distribute_bus` to `true`. If `-draw_with_group_centerline` is set to `true`, the tool ignores the `-drawing_wire` setting. *Default*: `false`
`-drawing_wire value`	Specifies which of the nets used with the `-nets` parameter corresponds to the mouse pointer location when adding of wires. For horizontal wires, a value of `1` indicates the bottom-most net. For vertical wires, a value of `1` indicates th most net. The *`value`* is an integer of the same or lower value as the number of nets. For example, if you specify 5 ne can specify `1`, `2`, `3`, `4`, or `5` as the value for this parameter. This net is also used as the reference net when changing direction. All other nets around this net are lengthened or shortened accordingly. *Default:* `1`
`-drc_aware_cross_metal {true|false}`	
	Specifies whether or not to stretch or move a wire back to the closest location available before a violation occurs wi crossing metal. This option works only if `setEditMode -stop_at_drc` is set to `true`: • If both `-stop_at_drc` and `-drc_aware_cross_metal` are set to`true`, the tool stops moving or stretching the wire at closest location available before a spacing violation occurs with the crossing metal. • If `-stop_at_drc` is set to `true` but `-drc_aware_cross_metal` is set to `false`, the tool moves or stretches the wire to desired location across the crossing metal even if it results in a spacing DRC violation. This parameter impacts the following type of modifications: • Drawing a new wire through `editAddRoute` and `editCommitRoute` • Moving a wire with/via `editMove` • Stretching a wire/via with `editResize` *Default:* `true`
`-drc_on {true|false}`	Specifies whether design rule checking (DRC) should be performed during wire and via editing. While modifyig a via with `editChangeVia`, the `-drc_on` and `-keep_via` settings are used in combination to decide wh not a via should be replaced if the new via cell results in DRC violations. For more details, see `editChangeVia`. *Default:* `true`
`-drc_use_non_default_spacing {true|false}`	

	Specifies whether non-default spacing defined in the non-default rule (NDR) of the editing net should be used for sp check during wire editing. ***Note*** • By default (`false`), the Wire Editor DRC check honors the default/minimum spacing. • If the net or via has an NDR with the `HARDSPACING` keyword, the Wire Editor DRC check honors the non-default s even if `-drc_use_non_default_spacing` is set to `false`. • After `setEditMode -drc_use_non_default_spacing true` is set, all subsequent wire editing commands honor th default spacing during the geometry check on the net/via if the NDR is defined. *Default:* `false`
`-extend_wires {start|end|start_cell_boundary|end_cell_boundary}`	
	Specifies which boundary of the wire segment extends and connects to the first logical target, after completing a sig power route. You can specify the following boundary options with this parameter: • `start` - Specifies that the startpoint of the route segment extends and connects to the first logical target, after con signal or power route. If there is no logical target, the startpoint is not changed. • `end` - Specifies that the endpoint of the route segment extends and connects to the first logical target, after compl signal or power route. If there is no logical target, the endpoint is not changed. • `start_cell_boundary` - Specifies that the startpoint of the segment always extends to the cell boundary, after con a special route. If the segment is extended to the boundary and crosses the wires on the same net, the tool make connection to the wires. In addition, the tool creates pins at the boundary. This parameter can only be used in co with `-extend_wires start`. • `end_cell_boundary` - Specifies that the endpoint of the segment always extends to the cell boundary, after comp special route. If the segment is extended to the boundary and crosses wires on the same net, the tool makes a vi connection to the wires. In addition, the tool creates pins at the boundary. This parameter can only be used in co with `-extend_wires end`. **Note**: If you do not want the wire segment to be extended, set `-extend_wires` to `""`. *Default*: `""`
`-final_check_with_verify {true|false}`	Specifies whether to do final checks with verify. When `-final_check_with_verify` is set to `true`, Wire Editor calls the Full Geometry Checker (FGC) engine for the DRC check on the bounding box of changed area after commits. This ensures that the final wire editing result is DF as per FGC. Specify this parameter if you are using advanced rules, such as 20nm and 14nm. *Default*: `false`
`-ignore_drc {conn_antenna|max_via_stack|min_cut|min_enclosed_area|min_step|protrusion}`	
	Specifies which violation type should be ignored during wire editing. You can specify the following options: • `conn_antenna` - Does not check the connection antenna for DRC violations. • `max_via_stack` - Does not check maximum via stack DRC violations during wire editing. • `min_cut` - Does not check for minimum cut DRC during wire editing. • `min_enclosed_area` - Does not perform minimum enclosed area DRC during wire editing. • `min_step` - Does not perform minimum step DRC during wire editing. • `protrusion` - Does not perform protrusion DRC during wire editing. **Note**: If you do not want any violation to be ignored, set `-ignore_drc` to `""`. *Default*: `""`

`-jog_connect_layer` *value*	Specifies the number of layers by which the new jog wire segments created on moving a wire should be moved up Note that the `-jog_connect_layer` parameter will have no impact if you have set the `setEditMode -connect_with_specified_layer` parameter to `true`. To learn how to use the `-jog_connect_layer` parameter, see the Examples section. *Default*: 0
`-keep_floating_via {true|false}`	Controls whether or not floating vias are retained when wires are deleted. By default, floating vias are deleted wher delete a wire. Set the `-keep_floating_via` parameter to `true` if you want to retain floating vias when you delete wire *Default:* `false`

`-keep_status {true|false}`

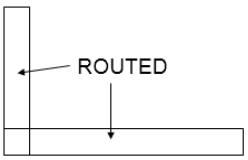
Specifies whether or not object status should be changed during editing. This option is set to `true` by default, which wire status is not changed after editing. If this option is set to `false`, the wire status is changed to `FIXED` automatically `editMove` and `editStretch`.

Notes:

This option has impact on both regular and special wires and vias. The tool only changes the status of the wire seg is modified.

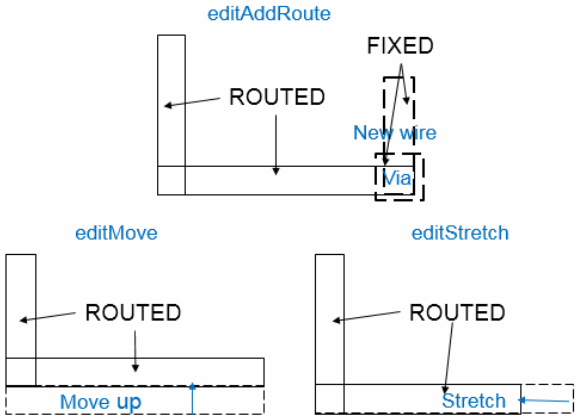
Use the `setEditMode -status fixed` command to set the status of newly drawn wires to `FIXED` after `editAddRoute`.

Consider the wire segment shown in the figure below:



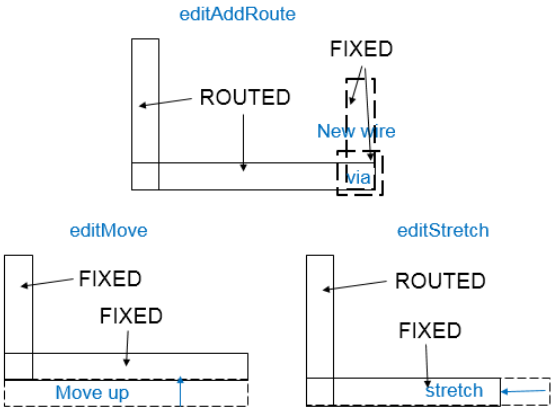
- The following command specifies that the status of the modified wire segment should be retained after `editMove` `editStretch`:

```
setEditMode -status FIXED -keep_status true
```



- The following command specifies that the status of the modified wire segment should be changed to `FIXED` after and `editStretch`:

```
setEditMode -status FIXED -keep_status false
```



Default: `true`

`-keep_via {true|false}`	Controls whether or not the original via is retained in a wire move or stretch. If this option is set to `true`, the tool keep unchanged if there is no DRC violation as a result of the move or stretch. However, the tool can change the via if a violation occurs. Set the `-keep_via` parameter to `false` if you do not want the original via to be retained when a wire moved or stretched. This parameter is applicable for both regular and special vias. While modifying a via with `editChangeVia`, the `-keep_via` and `-drc_on` settings are used in combination to decide w not a via should be replaced if the new via cell results in DRC violations. For more details, see `editChangeVia`. *Default:* `false`
`-lateral_movement_range value`	Specifies the maximum distance to which the wire you are adding or stretching can be moved laterally to avoid pote DRC violations with existing wires, nets, or blockages. The preferred lateral movement direction is up for horizontal and left for vertical wires, provided this movement does not result in a new violation. If a violation cannot be avoided even by moving the new wire within the specified lateral movement range, the tool other specified wire edit settings. For example, if the `-stop_at_drc 1` setting is specified, the tool moves or stretche wire up till the closest location available before the DRC violation occurs. **Notes**: • The `-lateral_movement_range` parameter works only if `setEditMode -drc_on` is set to `1`. If `-drc_on` is set to `0`, the ignores the `-lateral_movement_range` setting. • The `-lateral_movement_range` parameter can support multiple nets. • The `-lateral_movement_range` parameter is relevant only for avoiding violations with wires and vias. If the wire b added crosses a routing blockage or cell OBS, the `-lateral_movement_range` setting is ignored. See the Examples section below to understand how the `-lateral_movement_range` parameter works. *Default*: `0.0`
`-layer name`	Specifies the layer for patch or polygon wires. *Default*: `M1` (the first routing layer)
`-layer_horizontal name`	Specifies the layer for horizontal wires. This option supports backside layers as well. *Default*: `M1` (the first routing layer)
`-layer_maximum layerName`	Specifies the maximum layer for routing. The tool does not create wires above the specified layer. This option supp backside layers as well. *Default*: UNINITIALIZED
`-layer_minimum layerName`	Specifies the minimum layer for routing. The tool does not create wires below the specified layer. This option suppo backside layers as well. *Default*: UNINITIALIZED
`-layer_vertical name`	Specifies the layer for vertical wires. This option supports backside layers as well. *Default*: `M2` (the second routing layer)
`-look_down_layers integer`	Specifies the number of layers below the current layer that added wires will connect to with a via. *Default:* `100` (all layers)
`-look_up_layers integer`	Specifies the number of layers above the current layer that added wires will connect to with a via. *Default:* `100` (all layers)
`-max_pointer_number integer`	Specifies the maximum number of pointers to be returned by wire edit commands. Use this parameter along with `-return_object_pointer` to control object pointers returned by wire edit commands. The returned pointers make it po for you to select and further edit the newly created or modified wire or via. *Default:* `100`

`-mirror_bus_route {true|false}`	Specifies whether or not to reverse the net order for the bus route. When this option is specified, the definition of the override spec is reversed. For example, suppose you have drawn a bus route with the following setting:
	`setEditMode -nets {a1 a2 a3} -override -wire_override_spec {{1 3 2.8} {2 3 3.8} {3 3 4.8}}`
	The bus is drawn as follows, with nets counted from left to right:
	 	Now, by setting `-mirror_bus_route` to `true`, you can draw a mirror bus route with nets counted from right to left:
	`setEditMode -nets {b1 b2 b3} -override -wire_override_spec {{1 3 2.8} {2 3 3.8} {3 3 4.8}} -mirror_bu true`
	
	Default: `false`

`-nets nets`	Specifies one or more nets for editing. If you specify multiple nets, separate each net name with a space and enclos names in curly braces. You can use the following format to specify a bus: *`netName`*`[x:y]` For example, to draw eight wires for a bus, type the following: `-nets` *`netName`*`[7:0]` This is equivalent to specifying *`netName`*`[7], `*`netName`*`[6], ... `*`netName`*`[0].` Specifying `-nets` *`netName`*`[0:7]` reverses the order. The order in which you specify the nets determines the drawing arrangement of the wires. • For horizontally drawn wires, the first net specified is drawn as the bottom-most wire, followed by the next net on side, and so on. The last net specified is drawn as the top-most wire. • For vertically drawn wires, the first net specified is drawn as the left-most wire, followed by the next net, and so c last net specified is drawn as the right-most wire. *Default*: `""`
`-no_merge_special_wire {true|false}`	Specifies whether or not a wire being added should be merged automatically with any existing wire at that point. Se parameter to `true`, if you want to disable the auto merge feature. *Default*: `false`
`-only_show_edit_layer {true|false}`	

	Specifies that only the layer with the objects being edited should be shown and other layers and objects should be out during the following wire/via edit operations: • Add • Resize • Copy/Move *Default:* `true`
`-orthogonal_connection_only {true|false}`	Specifies whether to consider wires and pins that are in the same direction as a target for connection. For example, extend a wire to the left, any horizontal wire it meets is not considered for a target if the value of this parameter is se However, a vertical wire is considered a target. *Default:* `true`
`-outer_shield_spacing` *value*	Specifies a spacing value in microns to be used by the `-shield low` and `-shield high` parameter settings. *Default:* `0` (minimum spacing on the layer)
`-outer_shield_width` *value*	Specifies a width value in microns to be used for outer shield(s) depending on the values of `-shield low` or `-shiel` parameter settings. *Default:* `0` (minimum wire width on the layer) **Note:** You must define the outer shield first. The outer shield is the shielding wire beyond the first or the last wire be created manually.
`-override {true|false}`	Specifies whether to use the override specification. *Default:* `false`

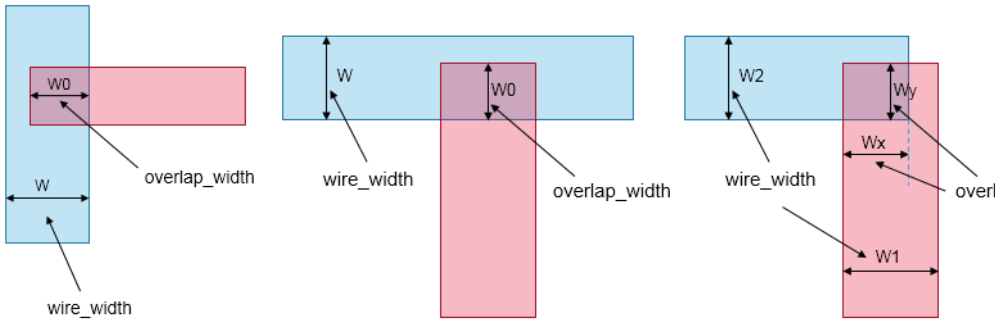
`-partial_overlap_threshold value`

Specifies the ratio threshold for special via creation on partially overlapping wires. The threshold value may range f `100`, with a value of `100` specifying that no via is dropped on a partial overlap intersection. The tool drops a via only `overlap_width` to `wire_width` ratio percentage is greater than or equal to the specified threshold value.

For example, suppose the threshold value is set to `100`. Now consider the following cases in which the pink wire is drawn over the existing blue wire:

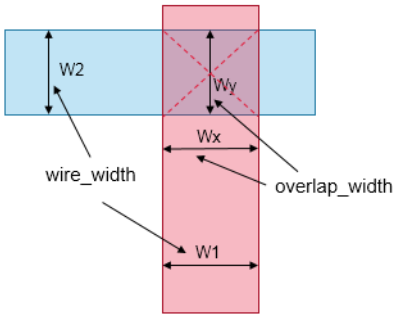
Case 1 - Overlap width less than wire width

In each of the cases depicted below, the `overlap_width` is less than the corresponding `wire_width`. As the `overlap_ wire_width` ratio percentage is less than `100`, which is the specified threshold value, the tool does not drop a via on partial overlap area:



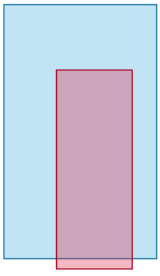
Case 2 - Overlap width equal to wire width

In the following case, the `overlap_width` is equal to the corresponding `wire_width`. As the `overlap_width` to `wire_w` percentage is equal to `100`, which is the specified threshold value, the tool drops a via on the overlap area.



Notes:

- The `-partial_overlap_threshold` parameter is applicable only if the new wire is crossing an existing wire in a c direction. If the new wire being drawn is overlapping an existing wire in the same direction, the tool does not cre



- If the `-create_crossover_vias` parameter is set to `false`, the tool ignores the setting of the `-partial_overlap_th` parameter and does not create any via on the overlap area.

Default: `0`

`-pull_back_distance` *string*	Specifies the value for forbidden distance. If the `setEditMode -check_design_boundary` parameter is set to `1`, the too into account the settings of the `-pull_back_distance` parameter during wire edit operations.
	If the `pull_back_distance` value is positive, the tool marks the corresponding area inside the boundary as an extra l area. For example, if you specify the following command, the tool marks 0.5 distance inside the die boundary on all as an extra keep-out area and does not allow you to stretch a wire into this area. You are allowed to stretch the wire till the forbidden line.
	`setEditMode -check_design_boundary true -pull_back_distance 0.5`
	 	If the `pull_back_distance` value is `0`, the tool does not allow you to manually stretch a wire beyond the die boundar try to stretch the wire edge beyond the boundary, the tool stops the wire edge at the boundary and prints a warning.
	`setEditMode -check_design_boundary true -pull_back_distance 0`
	 	If the edge of a wire is already beyond the boundary (with `setEditMode -check_design_boundary true -pull_back_distance 0`) and you attempt to stretch it further, the wire remains in the current location and the tool doe allow further stretching.
	If you stretch multiple wires with `-pull_back_distance` set to `Auto`, the tool uses the largest spacing value of each la the pull back distance for related wire. For example, the diagram below illustrates pull back distances if the spacing different layers is set as follows:
	`M1: 0.2  M2: 0.4  M3: 0.6`
	 	If you do not need the `-pull_back_distance` constraint, set `-check_design_boundary` to `false`.
	Note: 45-degree wires do not follow this rule
	Default: `auto`, which means the tool uses the largest min spacing of the layer as the forbidden distance.

`-reset`	Resets the settings.
`-reshape {true|false}`	Specifies that when you add new wires, existing redundant wires within the route are automatically removed. *Default:* `false`
`-return_object_pointer {true|false}`	

Specifies whether or not pointers are returned after wire edit operations. This parameter is set to `false` by default. W
to `true`, the following wire edit commands return pointers for new or modified wires and vias:

- `editAddVia`
- `editChangeLayer`
- `editChangeVia`
- `editCommitRoute`
- `editCopy`
- `editCutWire`
- `editDuplicate`
- `editMerge`
- `editMove`
- `editResize`
- `editRotate`
- `editSplit`
- `editTrim`

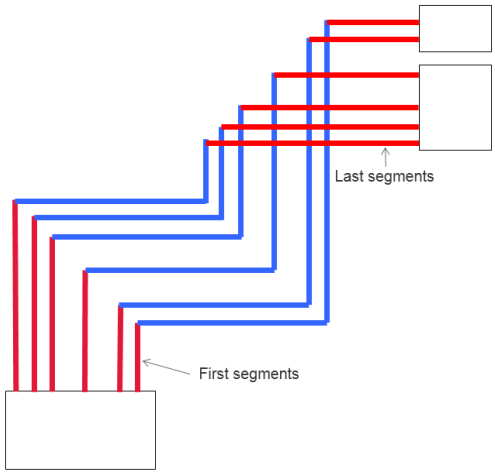
The returned pointers make it possible for you to select and further edit the newly created or modified wire or via. Th
diagrams below illustrate the pointers that are returned after some common wire edit operations:

	`-rule` *rule*	Uses the specified LEF rule for regular wires. *Default:* `default`
`-shape {RING|STRIPE|FOLLOWPIN|IOWIRE|COREWIRE|BLOCKWIRE|PADRING|BLOCKRING|FILLWIRE|FILLWIREOPC|DRCFILL|None}`	
	Specifies the shape associated with the wire you draw. Use all upper-case letters for the shape. *Default:* `STRIPE`
`-shield {high|low|adjacent}`	Specifies the side to which a minimum width shield wire should be added. Use the following options to specify the • `adjacent` - Specifies that a minimum width shield wire(s) should be added centered between two adjacent wires • `high` - Specifies that minimum width shield wires should be added at the top (High) side of horizontal routes or a side of vertical routes. The spacing of the added shield wire is determined by the value of the `-outer_shield_sp` parameter. If this value is `0`, the spacing is determined by the minimum spacing rule in the technology file. • `low` - Specifies that minimum width shield wires should be added at the bottom (Low) side of horizontal routes or left side of vertical routes. The spacing of the added shield wire is determined by the value of the `-outer_shield` parameter. If this value is `0`, the spacing is determined by the minimum spacing rule in the technology file. **Note**: If you do not want to specify the side to which the minimum width shield wire should be added, set `-shield` to *Default:* `""`
`-shield_look_down_layers` *integer*	Specifies the number of layers below the current layer that an added shield wire can connect using a via. *Default:* `100`
`-shield_look_up_layers` *integer*	Specifies the number of layers above the current layer that an added shield wire can connect using a via. *Default:* `100`
`-shield_shape {RING|STRIPE|FOLLOWPIN|IOWIRE|COREWIRE|BLOCKWIRE|PADRING|BLOCKRING|FILLWIRE|DRCFILL|None}`	
	Specifies the shape associated with the shield wire you draw. Use all upper-case letters for the shape. *Default:* `None`
`-shielding_nets` *nets*	Specifies net names for shield wires, usually power or ground names.
`-show_drc_info_for_edit_shape {true|false}`	

	Specifies that the tool should display the detailed DRC information in a violation marker nearby if a violation is gen during the following wire/via edit operations: • Add • Resize • Move In the example below, the wire being added will cause a Metal Short violation as mentioned in the DRC informatio displayed near the violation marker:  You can address the DRC issues displayed by either: • Cancelling the edit operation causing the DRC violation. • Adjusting the edit operation to meet the DRC requirement. For instance, in the example shown below, the wire b added is causing a Parallel Run Length spacing violation: In this case, you can move the right edge to save spacing. The DRC violation and related information will disap **Note**: If there are any existing violation markers, they are dimmed out so that the latest marker is more clearly visibl *Default*: `true`
`-sibling_look_down_layers` *integer*	Specifies the number of layers below the sibling layers that an added shield wire can connect using a via. *Default:* `1`
`-sibling_look_up_layers` *integer*	Specifies the number of layers above the sibling layers that an added shield wire can connect using a via. *Default:* `1`
`-snap {true|false}`	Specifies whether or not to enable wire and via snap. *Default*: `true`
`-snap_align_to {center|low|high|auto}`	

	Specifies how to align with a pin when ending a route. Select one of the following: • `center`: Snaps wires to the center of the pin. • `low`: Snaps wires to the bottom of vertical pins or to the left side of horizontal pins. • `high`: Snaps wires to the top of vertical pins or to the right side of horizontal pins. • `auto`: The software determines alignment automatically. **Note**: To ensure the proper alignment, do not specify `-snap_objects_to_track` with this parameter. *Default:* `auto`
`-snap_bus_to_pin {true|false}`	Specifies whether or not to change wire width, spacing, and order according to the connected pin. The `-snap_bus_to_pin` parameter supports macro to IO pin snapping as well as IO pin to IO pin snapping. When you set the `-snap_bus_to_pin` option to `true`: • You do not have to align the pins at the start/end macro. Just start drawing the bus from the start macro and draw subsequent wire segments until you arrive at the end macro. When you double-click to end the bus, all the start segments of the bus snap to their respective pins automatically. • The tool gets the pin width and spacing information, and changes the wire width, spacing, and order according t connected pins for the start and end segments of the bus.  • If the bus has multiple corners, the tool uses the width and spacing value defined by the wire edit options for the segments of the bus.  • The tool also changes the wire segment layer according to the pin layer when accessing the pins. If the connect on a single layer, such as M4, the tool changes the wire segment layer to M4 when accessing pins. If the connec is on multiple layers, the tool changes layers as follows: ◦ If the pin is on M2, M3, and M4, but you have defined M5 and M6 for wire edit, the tool uses M4 for the first wi segment. In that way, wire edit has minimum via when connecting the first and second wire segment. ◦ If the pin is on M2, M3, and M4, but you have defined M2 and M3 for wire edit, tool uses M3 for the first wire s when connecting to the pin in the vertical direction (Wire edit sets M2 as the horizontal layer and M3 as the v layer). For middle segments of the bus, the tool still uses the wire edit layer setting. • `snap_bus_to_pin` supports snapping from one to multiple (1->N) macros for bus. When drawing the bus, the end

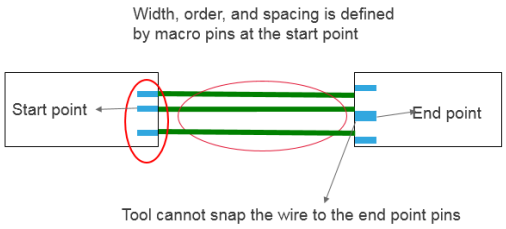
could be the pins on different macros. As long as the end point is inside a macro, the tool is able to auto snap to cell pins. The following diagram depicts how `-snap_bus_to_pin`, when enabled, supports 1->N macros.



- When you click outside the design core area after drawing a bus, the wires of the bus are snapped to the IO pin.

When using the `-snap_bus_to_pin` option, keep the following limitations in mind:

- The bus routing pattern must have at least one corner. Otherwise, the tool cannot snap the bus to both the start a target pins.



- You must click at the macros with target pins for the start and end points of the bus. The tool searches only the s macros for the connected pins.
- For a regular wire, the tool creates an NDR for each pin width automatically (the width is not defined in tech LEF cannot delete the NDR from the database.

Both regular and special wires support this feature.

By default, the `-snap_bus_to_pin` option is set to `false`, which means the tool does not snap each wire of the bus to macro pin automatically.

Note: The `-snap_bus_to_pin` option is exclusive to the `setEditMode -snap_to pin` option. When `setEditMode -sna pin` is set, the tool uses the original snapping behavior in which only the first drawing wire is snapped to the pin witl wire width and spacing change.

Default: `false`, which means the tool does not snap each wire of the bus to the macro pin automatically.

`-snap_end_to {track_regular|track_special|manufacturing_grid}`

	Snaps the end of the wire being drawn to the specified object. You can specify the following options: • `manufacturing_grid` - Specifies that the end of an off-grid wire should be snapped to the manufacturing grid. • `track_regular` - Snaps the end of regular wires to track. For a long multi-pin net, you might want to draw the trur first and then draw the branch wires along the trunk wire. The start/end points of the trunk wire are usually not or if the trunk wire start/end points do not snap to the track, it will leave an off-grid wire segment. To prevent this, sn end of regular wires to track by setting `setEditMode -snap_end_to track_regular`. The start/end points of the re wire will snap to the closest orthogonal layer preferred track. • `track_special` - Snaps the end of special routes to track. For a long multi-pin net, you might want to draw the tru first and then draw the branch wires along the trunk wire. The start/end points of the trunk wire are usually not or if the trunk wire start/end points do not snap to the track, it will leave an off-grid wire segment. To prevent this, sn end of special routes to track by setting `setEditMode -snap_end_to track_special`. The start/end points of the s route will snap to the closest orthogonal layer preferred track. **Note**: If you do not want to snap the end of the wire to any object, use `setEditMode -snap_end_to ""`. *Default:* `""`
`-snap_objects_to_track {special|regular|patch|pin}`	
	Snaps the center line of wires being added or moved to the closest routing track in the preferred direction for the lay automatically. You can specify the following options: • `special` - Snaps added or moved special wires to the closest routing track in the preferred direction for the layer automatically. This parameter also controls whether to cut special wires on the routing track. **Note**: See `-snap_to pin` for a description of the software's behavior when both `-snap_objects_to_track specia` `snap_to pin` are specified. • `regular` - Snaps added or moved signal wires to the closest routing track in the preferred direction for the layer automatically. This parameter also controls whether to cut signal wires on the routing track. **Note**: See `-snap_to pin` for a description of the software's behavior when both `-snap_objects_to_track regula` `snap_to pin` are specified. • `patch` - Snaps patch wires automatically to the closest routing track for the layer as the wires are drawn, copied, moved. • `pin` - Snaps a moved physical pin to the closest routing track in the preferred direction for the layer automatically **Note**: If you do not want to snap any object to track, use `setEditMode -snap_objects_to_track ""` to disable all tra *Default:* `regular patch`
`-snap_to {special|pg|pin|row}`	

	Snaps the end of the wires being added or moved to the specified object. You can specify the following objects: • `special` - Automatically extends a special wire for maximum via coverage when crossing over a same-net wire c adjacent layer. • `pg` - Snaps new wires whose start point is within a "snap region" to the closest end of a power or ground wire on net. The snap region is one-half the width of the target wire. ◦ The snap region for orthogonal wires forms a square with the width of the power or ground wire. ◦ The snap region for wires at 45-degree angles to the power or ground wire forms a square from the point whe wire will connect. Each side of the square is the width of the power or ground wire. ◦ The snap region for wires that are parallel to power or ground wires is the full power or ground wire. • `pin` - Snaps added or moved wires to a pin automatically. If you double-click at a pin, it snaps the wire to the pin. ensure the wire is snapped to the center of the pin, specify `-snap_objects_to_track special` (or `-snap_objects_to_track regular`) and specify a value for `-snap_align_to`. When you specify both `-snap_objects_to_track special` (or `-snap_objects_to_track regular`) and `-snap_to` software has the following behavior: ◦ If the wire will fall partially outside the pin when snapped to a track, it snaps to the pin. ◦ If the wire will fall inside the pin when snapped to a track, it snaps to both the pin and a track. ◦ If there is no track on the pin, the wire snaps to the pin. • `row` - Snaps added or moved wires to the nearest standard cell row. Use this parameter to create followpins. This parameter supports both horizontal and vertical rows. For example, if you want to snap a wire to a pin automatically, specify `setEditMode -snap_to pin`. **Note**: If you do not want to snap wires to any object, use `setEditMode -snap_to ""` to disable all object snap. *Default:* `special pg pin`
`-snap_to_track_honor_color {true|false}`	Specifies whether to snap wires to a track with the same color automatically. This option is on by default. If you nee move a wire to a track with a different color, set this option to `false`. **Notes:** This is a global setting and can be used to control all the snapping behavior in wire edit commands. This command has no impact on `editAddRoute`. When drawing wires, the tool honors the color setting specified by `setEditMode -assign_multi_pattern_color`. *Default:* true
`-snap_trim_metal_to_trim_grid {true|false}`	
	Specifies whether or not the trim metal should snap to the closest trim grid during trim-metal editing. If you set this p to `false`, the trim metal is drawn centered on the location specified by `editAddTrimMetal -location`.  **Note**: `editMove` does not follow the setting specified by the `setEditMode -snap_trim_metal_to_trim_grid` paramet *Default:* `true`
`-spacing value`	Specifies the distance between wires. *Default*: `""`

`-spacing_horizontal` *value*	Specifies the distance between horizontal wires. *Default*: `""`
`-spacing_vertical` *value*	Specifies the distance between vertical wires. *Default*: `""`
`-status {cover|fixed|noshield|routed|shield|auto}`	
	Specifies the status associated with the wire you draw. By default, when you add special wires manually using the GUI, the tool creates crossover vias with `fixed` status. U `status` parameter of `setEditMode` to draw wires and vias with the specified status. If the value is specified as `auto`, the tool sets the status of wires drawn on signal and power nets to `routed` and that drawn on clock nets to `fixed`. **Note:** • For a special wire, `noshield` is not supported. If you specify this value for a special wire, the tool gives a warning message and keeps the status as `fixed`. • For a regular wire, `shield` is not supported. If you specify this value for a regular wire, the tool gives a warning m and keeps the status as `fixed`. *Default*: `fixed`
`-stop_at_drc {true|false}`	Checks DRC rules and stops moving or stretching wires before causing a violation. • Specify `true` to stop moving or stretching the wire at the closest location available before a violation occurs. In th you cannot move a wire to the desired destination if that wire passes through a location where a DRC violation o • Specify `false` to ignore DRC rules when moving or stretching wires. The software moves or stretches a wire to t desired location even if it results in a DRC violation. *Default:* `true`
`-stretch_end {high | low}`	Specifies the direction in which to stretch or reduce wires. • `high` - Stretches or reduces wires from the top for vertical wires or from the right for horizontal wires. • `low` -Stretches or reduces wires from the bottom for vertical wires or from the left for horizontal wires. *Default:* `high`
`-stretch_with_intersect {true|false}`	Enables wires with intersects to be stretched easily. If this option is set to `true`, you can select the via and the edge and then stretch the wires and via together in a single step.  *Default*: `false`

`-subclass {subclass}`	Specifies the subclass name. *Default*: `""`
`-turn_at {center_line|wire_edge}`	Specifies the start location of the new wire segment when a wire is turned. This parameter can be used for both reg special wires. You can specify one of the following values for`-turn_at`: • `center_line` - When you turn a wire, the center line of the new wire segment aligns to the end of the old wire seg • `wire_edge` - When you turn a wire, the long edge of the new wire segment aligns to the end of the old wire segm The diagram below depicts the tool behavior for both options:  Use the `wire_edge` option when turning a wire at the *Safe Line* for an adjacent wire. With this option, the tool turns t without extending it beyond the *Safe Line* to avoid a minumum spacing rule violation with the adjacent wire:  You can use the default `-turn_at center_line` option if there is no adjacent wire. *Default*: `center_line`
`-type {regular|special|patch}`	Specifies the type of the wire being created. You can specify one of the following options: • `regular` - Creates regular wires and vias. • `special` - Creates special wires and vias. • `patch` - Creates patch wires. *Default*: `""`
`-unrestricted_regular_wire_width {true|false}`	
	Specifies whether the widening of a regular wire is unrestricted. By default, when you are changing the width of a w snaps to the closest non-default route (NDR) available. If you set the `-unrestricted_regular_wire_width` paramete a wire can be stretched to any width without any restrictions. *Default:* `false`

`-update_shield_net {true|false}`	Specifies whether the shield net attribute on a signal net should be automatically updated. Use this parameter if you Nanoroute to recognize the net as a shield net and not remove it during routing.
	If you set the `setEditMode -update_shield_net` parameter to `true` before drawing a signal net, for example `net11`, th net attribute is automatically set on that signal net. You can verify this by using the `getAttribute` command as follo
	`> getAttribute -net net11`
	The result is:
	`#NET net11 attributes:`
	`# weight = 2 (default)`
	`# non_default_rule = default (default)`
	`# non_default_rule_effort = auto (default)`
	`# shield_net = VDD`
	If you now run `routeDesign`, NanoRoute recognizes the net as a shield net and does not remove it.
	Default: `false`

`-use_fixVia {true|false}`	Specifies whether to use fixVia for special via with minStep DRC violation. **Note**: If a design is under 20nm, the tool turns on fixVia integration by default: `setEditMode -use_fixVia true` To turn off the setting, use `setEditMode -use_fixVia false`. *Default*: `false`
`-use_interleaving_wire_group {true|false}`	Alternates the specified wires in the wire group. For example, if you specify `-nets VDD VSS -use_interleaving_wire true`, the software alternates the power and ground wires in the wire group. When `-use_interleaving_wire_groups` is set to `true`,the software draws a wire group like the following:  *Default:* `false`

`-use_wire_group {true|false}`	Groups multiple wires from the same net. Specify this parameter to decrease resistance and provide stronger conne The following figure shows power and ground wires that form a wire group.  *Default:* `false` (The wire editor does not use wire groups.)
`-use_wire_group_bits` *number_of_bits*	Specifies the number of times to replicate a wire in the wire group. For example, if you specify `VSS` and `VDD` nets, an `2` for this parameter, the software creates a wire group with two power wires and two ground wires. ⓘ The value of this parameter must be greater than `1` to enable wire groups. When `-use_wire_group_bits 2` is specified, the Innovus software draws a wire group like the following:  *Default:* `0` (disabled)

`-use_wire_group_reinforcement {true|false}`	Creates slots in the wire group by creating wires that connect the wires in the wire group, but are orthogonal to then help to reduce resistance in power networks. Specifying both this parameter and `-use_interleaving_wire_group` c shorts in the wire group. When `-use_wire_group_reinforcement true` is specified, the Innovus software draws a wire group like the followir  *Default:* `false`
`-use_wire_group_reinforcement_group_via {true|false}`	
	Specifies that the wire group uses group vias. Group vias are connected vias in a wire group. Using group vias ens the contact is maintained if one of the vias in the wire group produces a void. In the following figure, the wire group has group vias:  *Default:* `false`
`-use_wire_group_reinforcement_spacing` *spacing*	
	Specifies the spacing for the orthogonal wires in the wire groups. *Default:* `0`
`-use_wire_group_reinforcement_width` *width*	
	Specifies the width of the orthogonal wires in the wire groups. *Default:* `0`

`-verbose {true|false}`	Reports untrimmed wires/vias that cannot be trimmed because either they are connected to a patch wire or their sta `cover`. Set this parameter to `true` before running `editTrim` if you want untrimmed wires/vias to be reported. You can additionally use `setEditMode -debug_file` to specify the name for the report. The default report file name is `editTrim_debug.rpt`. **Note**: Only wires and vias that have connectivity issues are reported. *Default:* `false`
`-via_allow_geom_drc {true|false}`	Checks geometry DRC. *Default:* `true`
`-via_auto_replace {true|false}`	Determines whether existing vias are replaced with new ones in case of overlap. • Specify `true` to replace existing vias with the new ones added with `editAddVia` in case of any overlap. • Specify `false` if you want to retain the existing vias even if there is some overlap with the new vias being added. *Default:* `true`
`-via_auto_snap {true|false}`	Controls whether to snap vias to the intersection of tracks or to the manufacturing grid. • Specify `true` to snap the via to the center of the intersection of tracks. • Specify `false` to keep the via in the location where it is added or moved, snapping only to the manufacturing gric *Default:* `true`
`-via_cell_name` *`cellname`*	Specifies the name of the via cell from the LEF or DEF file. *Default:* `""`
`-via_columns` *`integer`*	Specifies the number of columns in a via cut. *Default*: `0`
`-via_create_by {viacell|parameters}`	
	Controls whether the tool creates vias based on the `-via_cell_name` parameter or the cut class name. • Specify `viacell` to create the via with the same geometry as the cell specified by the `-via_cell_name` parameter • Specify `parameters` to create the via cell based on the cut class parameters. *Default:* `parameters`
`-via_cut_layer` *`cut_layer`*	Specifies the via layer name for the via to be created or modified. *Default:* `V12`

`-via_exclude_spec` *`exclude_list`*	Specifies the vias to be ignored by the wire editor. You can define the list of vias in the *`exclude_list`* as follows:
	`setEditMode -via_exclude_spec {{default via0} {rule1 via2} {rule2 {via2 via3}}}`
	For example, the wire editor will ignore the `V1L2LVH` via with the following command:
	`setEditMode -via_exclude_spec {{default V1L2LVH}}`
	Default: `""`

`-via_override_spec` *value*	Specifies the default vias to be used by wire editor. You can use this parameter if you do not want wire editor to sel automatically. `-via_override_spec` allows a regular via on NDR nets. You can define the via in the via spec as follows: `setEditMode -via_override_spec {{default via0} {rule1 via2} {rule2 via1}}` Here, if you draw a wire with NDR name `rule1`, the tool will always drop `via2` in the wire intersection area. The tool check whether `via2` belongs to NDR rule `rule1` in the Tech Lef. You can define the full set of required vias for regular as well as NDR nets in one command with the `-via_override_spec` parameter. For example: `setEditMode -via_override_spec { {default via0 via1 via2 via3 via4 via5 via6 via7 via8} {NDR_rule1 vi via4 via5 via6 via7 NDR_rule1_via2 NDR_rule1_via3 NDR_rule1_via4 NDR_rule1_via5 NDR_rule1_via6 NDR_rule1_via7} {NDR_rule2 via2 via3 via4 via5 via6 via7 NDR_rule1_via2 NDR_rule1_via NDR_rule1_via4 NDR_rule1_via5 NDR_rule2_via2 NDR_rule2_via3 NDR_rule2_via4 NDR_rule1_via5 NDR_rule2_v NDR_rule2_via7} }` This use model reduces the runtime for via selection during Wire Edit. When you perform wire edit operations, via selection happens as follows for the above definition: • For regular wire edit, the tool always picks a via from the `default` list specified with the `-via_override_spec` opti • For editing nets with the `NDR_rule1` rule, the tool picks any via from the list defined under the rule `NDR_rule1` in th above example. • For editing nets with `NDR_rule2`, the tool picks any via from the list defined under the rule `NDR_rule2`. During wire edit for DRC fixing on both regular and NDR wires, the tool always picks a via that is DRC clean after edit operation, from the above definition. To see another example of using the `-via_override_spec` parameter, see the Examples section. *Default: ""*
`-via_rows` *integer*	Specifies the number of rows in a via cut. *Default:* `0`
`-via_scale_height` *value*	Specifies the absolute height of the special vias added when drawing wires. *Default:* `100`
`-via_scale_width` *value*	Specifies the absolute width of the special vias added when drawing wires. *Default:* `100`
`-via_snap_honor_color {true|false}`	
	Specifies whether or not to snap via to the track with the same color automatically. *Default:* `true`
`-via_snap_to_intersection {true|false}`	Specifies whether to snap vias to the intersection of wires. *Default:* `true`
`-via_type {auto|regular|special}`	Specifies the type of the via to be created: • `auto` - Assigns the correct via type based on the type of connected wire. • `regular` - Creates regular vias. • `special` - Creates special vias. For example, if you specify the type as `regular` by using the following command and then run the `editAddVia` comm tool will create a regular via even if there are PG shapes on other layers overlapping the area: `setEditMode -via_type regular` *Default:* `auto`
`-width` *value*	Specifies the width of patch wires. *Default:* `0`

`-width_horizontal` *value*	Specifies the width for horizontal wires. *Default:* `0`
`-width_vertical` *value*	Specifies the width for vertical wires. *Default:* `0`

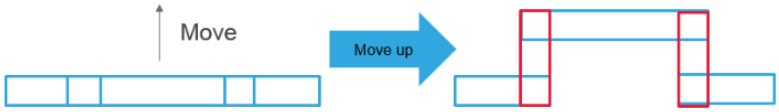
`-wire_override_spec` *specification*	Contains the details of the override specification. The specification has the following format:
	`{{wire_index width spacing layer ndr_name} {...}}`
	Specify the net numbers, followed by the override width, the override spacing to the next net, layer, or override NDF for the specified nets.
	The net number is the position of the net specified by the `-nets` parameter. If you specify more than one net, separa numbers with commas.
	For example, the following specification indicates that the first and second nets should have a width of 10.0 and a s 3.0:
	`1,2 10.0 3.0`
	Similarly, the following specification indicates that the first and second nets should be reassigned to a new NDR, `2_`
	`1,2 "" "" "" 2_wide`
	Default: ""

Examples

- If you want to draw a shield wire for the wire a1, run the following command before drawing the wire:
  `setEditMode -nets a1 -shielding_nets VDD -draw_shield true -shape none -width_horizontal 2`

  When `-draw_shield` is set to `true`, the tool automatically sets the status of the new wire to `shield` and its width to the minimum width (1.6um). If you also want to change the shield net attribute for the net, set the `-update_shield_net` parameter to `true` as well before drawing the wire.
- If the current wire is on layer 2, use the following command to drop a multi-layer pin on layer 1/layer 2:
  `setEditMode -multi_layer_pin 1 -multi_layer_via V12`
- The following command uses the `-via_override_spec` parameter to specify via selections for the default rule as well as for the nondefault rule `SP`:
  `setEditMode -via_override_spec {{default via12 via23 via45} {SP spvia12}}`
  As specified in the command, wire editor makes via selections for layers as follows:
  - For the default rule:
    - `via12` for layer `V12`
    - `via23` for layer `V23`
    - `via45` for layer `V45`
  - For the nondefault rule `SP`:
    - `spvia12` for layer `V12`

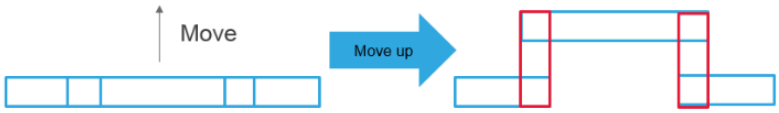
  Note: Wire editor automatically selects best vias for the layers that are not specified with `-via_override_spec`.
- The following example uses the `-jog_connect_layer` parameter to specify that the tool should automatically move up new jog wires created on moving a wire segment by 1 layer:
  `setEditMode -connect_with_specified_layer false -jog_connect_layer 1`



Here, the blue wire segments are on layer `M2` while the red jog wire segments are on the `M3` layer.

- In the following example, as the `-jog_connect_layer` parameter is set to -1, the tool automatically moves down the new jog wires by 1 layer:

```
setEditMode -connect_with_specified_layer false -jog_connect_layer -1
```



In this case, the blue wire segments are on layer M2 while the red jog wire segments are on the M1 layer.

- The following command specifies that the wire being drawn should snap to a pin automatically:

```
setEditMode -snap_to pin
```

- The following command specifies that when a physical pin is moved, it should snap automatically to the closest routing track in the preferred direction for the layer:

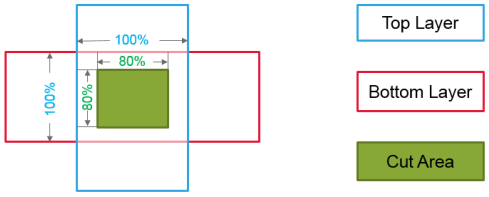
```
setEditMode -snap_objects_to_track pin
```

- The following set of commands add a via with two rows and three columns. The origin of the via is at coordinates `550`, `675`:

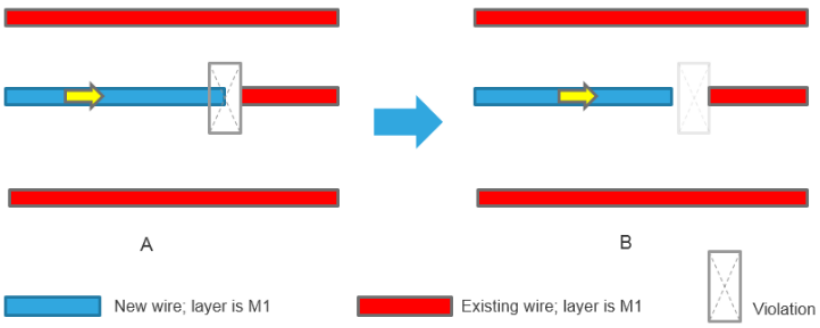
```
setEditMode -via_create_by geometry -via_add_rows 2 -via_add_columns 3
editAddVia 550 675
```

- The following command scales the via added while drawing a wire to 80% height and width:

```
setEditMode -via_scale_height 80 -via_scale_width 80
```

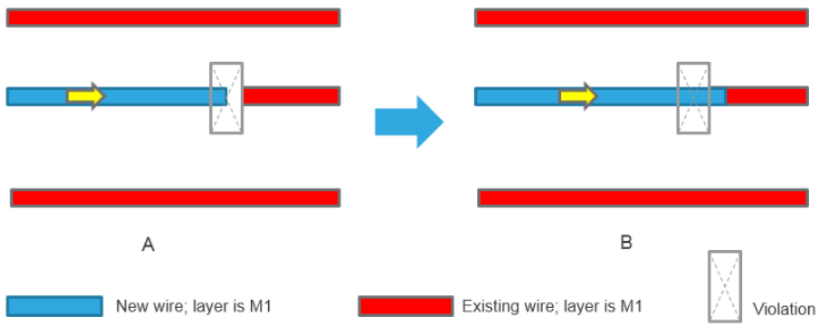


- In the following examples, the blue wire is being moved or stretched from left to right. See how the tool behavior changes with the various `setEditMode` settings given below:
  - `setEditMode -drc_on 1 -lateral_movement_range 0 -stop_at_drc 1`



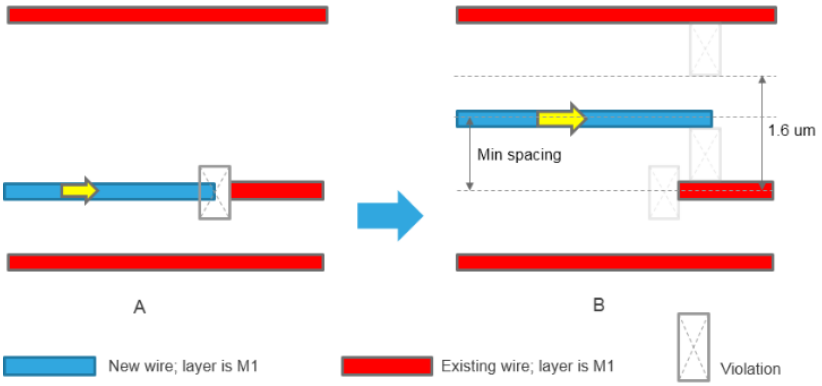
This wire edit will generate a violation with an existing wire (see A), so the tool shrinks the new wire to a distance such that there is no violation (see B).

  - `setEditMode -drc_on 1 -lateral_movement_range 0 -stop_at_drc 0`



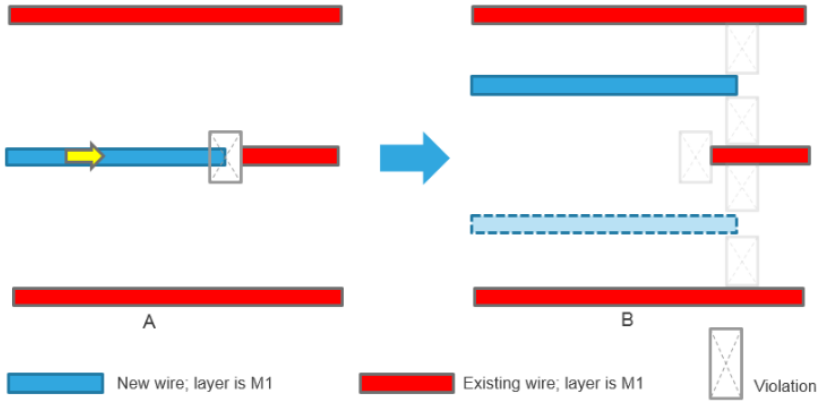
This wire edit will generate a violation with an existing wire (see A). However, the tool allows the new wire to be moved or stretched to any length and reports a violation (see B).

- `setEditMode -drc_on 1 -lateral_movement_range 1.6 -stop_at_drc 1`



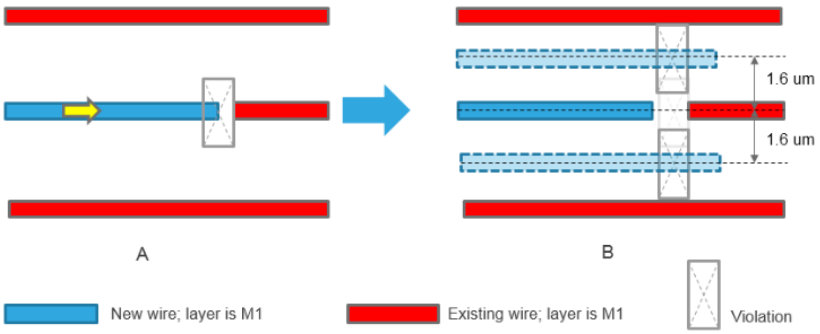
This wire edit will generate a violation with an existing wire (see A). So, the tool moves the new wire up by a minimum distance to avoid generating a violation (see B).

- `setEditMode -drc_on 1 -lateral_movement_range 1.6 -stop_at_drc 1`



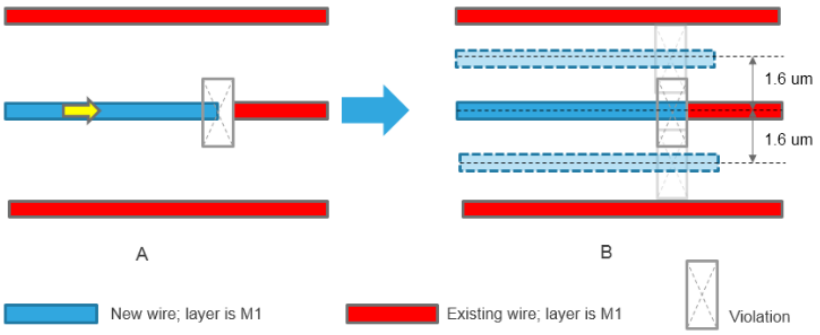
This wire edit will generate a violation with an existing wire (see A). The blue wire can be moved either up or down to avoid the violation. In this case, the tool moves the wire up, which is the preferred direction for horizontal wires (see B).

- `setEditMode -drc_on 1 -lateral_movement_range 1.6 -stop_at_drc 1`



This wire edit will generate a violation with an existing wire (see A). However, even if the blue wire is moved up or down within the specified lateral movement range, the tool still cannot avoid a violation. Therefore, the tool obeys other specified wire edit settings. In this example, the tool obeys the `-stop_at_drc 1` setting and moves or stretches the blue wire up till the closest location available before the DRC violation occurs (see B).

- `setEditMode -drc_on 1 -lateral_movement_range 1.6 -stop_at_drc 0`



This wire edit will generate a violation with an existing wire (see A). However, even if the blue wire is moved up or down within the specified lateral movement range, the tool still cannot avoid a violation. Therefore, the tool obeys other specified wire edit settings. In this example, the tool obeys the `-stop_at_drc 0` setting and allows you to move or stretch the wire even though it results in a DRC violation. (see B).

- Consider the addition of a bus `a[0] a[1] a[2]`. The NDR name is `default`, and the metal layer name is `M0`.

  - The following command reassigns the first and second nets to a new NDR, `2_wide`:

    ```
    setEditMode -wire_override_spec {1,2 "" "" "" 2_wide}
    ```

  - The following command assigns the `M2` layer to the first wire and the `M4` layer to the third wire.:

    ```
    setEditMode -wire_override_spec {{1 "" M2} {3 "" M4}}
    ```

- The following commands report untrimmed wires and vias with connectivity issues in a file named wireTest.rpt:

  ```
  setEditMode -verbose true
  ```

```
setEditMode -debug_file wireTest.rpt
editTrim
```

The report (sample) is as follows:

```
############################################################
# Generated by: Cadence Innovus 20.10-b015_1
# OS: Linux x86_64(Host ID noi-leenap1)
# Generated on: Mon Feb 10 13:50:19 2020
# Design: carve
# Command: editTrim
############################################################

Removed 0 wires and 0 vias.
1 wire can't be trimmed, because it connect a patch wire or the status is Cover.

The wires status is Cover:
Wire: ram1/subram02_lower/TESTACT_INST_PERIWDSRAM001PAA512W27C3/n7 M2 97845,-642213,100551,-642147
```

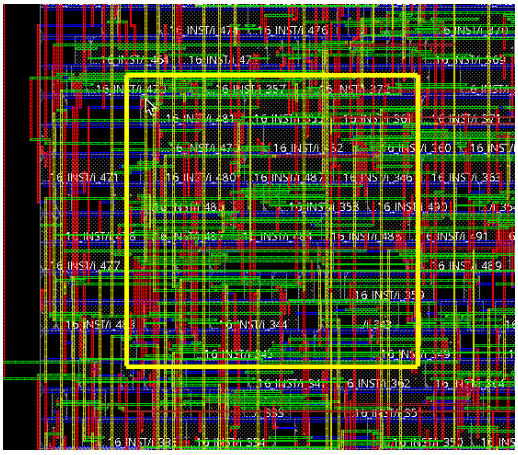
start_parallel_edit

```
start_parallel_edit
[-help]
[-area_restricted]
-region {x1 y1 x2 y2}
```

Initializes parallel editing by drawing a yellow square on the main window to indicate the edit area and saving the physical data, net attributes, via cell names and Non-Default Rules (NDRs) to a multiple binary files.



Once the DRC edits are complete, the parallel edit session can be stopped by using the `end_parallel_edit` command.

Note: If the design is freed up from the current session, the edit session is terminated automatically.

Parameters

`-help`	Prints a brief description that includes type and default information for each `start_parallel_edit` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man start_parallel_edit`
`-area_restricted`	Writes out only the different objects inside or touching the specified edit area. This is a strict interpretation of the region, and ignores the changes made outside of the region.
`-region {x1 y1 x2 y2}`	Specifies the coordinates of the edit area.

Example

- The following command marks the specified edit area in yellow and saves the design data to binary files:

```
innovus 8> start_parallel_edit -area_restricted -region {12.524 6.627 0.0 0.0}
Saving net attribute and regular wire/via information
Saving instance information
Saving physical pin information
Saving NDR rule information
Saving routing blockage information
Saving placement blockage information
Saving special wire/via information
```

Appendix A: Database Object Information

Please find the document at the following link: Innovus Database Object Information

Appendix B: Tcl Globals

This appendix lists all public Tcl globals. Public Tcl globals are saved persistently in the .globals file by `saveDesign` and can be restored by `restoreDesign`.

Note: Persistent globals are only written if different from default value.

You can use the `find_global` command to query all public variables and private variables with non-default changes. Use patterns with the `find_global` command to retrieve information on specific global variables. You can use `set` *`global_namevalue`* to change the value of a specific global variable.

List of Globals

- `aocv_chip_size`
- `aocv_core_size`
- `auto_file_dir`
- `auto_file_prefix`
- `cds_lib`
- `cvd`
- `defHierChar`
- `defInCheckMaskShifts`
- `defInShapeBasedDefFile`
- `defOutLefNDR`
- `defOutLefVia`
