	Sets the minimum length of the wires for each layer in um.The value is a string and is optional.

`-snap_wire_center_to_grid {layer1 {none|grid|half_grid|either} layer2 {none|grid|half_grid|either}}`	
	Specifies the wire center alignment style for middle layer jenga wires. If you do not specify this parameter, stripes are not snapped to the routing grid. Specify one of the following options: • `none`: Does no snapping of the wires. • `grid`: Snaps the center of the wire to the routing grid of the same layer as the wire. • `half_grid`: Snaps the center of the wire to the half-routing grid. The half-routing grid is a virtual grid with the tracks at the center of every two adjacent tracks of the routing grid. • `either`: Snaps the center of the wire to the closer of the routing grid or half-grid track.
`-wireCount {layer1 value1|auto layer2 value2|auto … }`	
	Sets the count of wires for each layer in integer or 'auto'. If the value of a layer is not set, the tool takes '2' as default. If `-wireCount {Mx auto}` is specified, the wire count on Mx will be max wire count calculated by intersection area, wire width and wire spacing. The 'auto' setting is mostly used for adding split power vias between paralleled wires. The value is a string and is optional.
`-wireOffset {layer1 value1 layer2 value2 ...}`	
	Sets the wire offset from the intersection edge of the selected wires in floating value. It also defines the left edge for vertical and bottom edges for horizontal middle layer split wires. The value is a string and is optional.
`-wireWidth {layer1 value1 layer2 value2 ...}`	
	Sets the width of the wires for each layer in um. The value is a string and is optional.
`-pinLayer {layer1 layer2...}`	
	Lists pin layers in a macros used to create via with crossover wire.
`-prerouteAlign {none|samelayer|alllayer}`	
	Defines the alignment of via wires with preexisting wires on the same net. The value is numerical and is optional.
`-stackedCheckerBoard`	Creates stacked checker board vias between intermediate layers.
`-uda`	Adds the user-defined attribute to the to-be-built split vias and wires.
`-wires_only`	Generates only those wires, which are without violations. By default, the command generates both wires and vias. Prior to implementing this option, if any via was not dropped because of violation, the tool was not generating any wires.

Examples

Note: The command will add split power via after the user selects the wires which need to add the split power via (else, no split power via will be added).

- The command will add split power via and merge wires which are within 1.2 for both x and y direction
  ```
  addSplitPowerVia -mergeDistance 1.2
  ```
- The command will add split power via and merge wires which are within 1.2 for x direction and 1.5 for y direction.
  ```
  addSplitPowerVia -mergeDistance { 1.2 1.5 }
  ```
- The command will add split power via and merge wires of count 2 in both x and y direction.
  ```
  addSplitPowerVia -mergeCount 2
  ```

- The command will add split power via and merge wires of count 2 in x direction and count of 4 in y direction.
  ```
  addSplitPowerVia -mergeCount { 2 4}
  ```
- The command will add split power via and create wire lengths to a max of 1.3 in both x and y direction for all intermediate layers within a crossover b/w wire and a wire or b/w wire and a pin.
  ```
  addSplitPowerVia -maxWireLength 1.3
  ```

```

Creates power stripes within the specified area. If the router encounters an obstruction, the stripe connects to the last stripe on the same net. Otherwise, the stripes stop at the core row boundary. Use this command after creating an initial floorplan.

Adding Stripes in Multi-Threading Mode

You can generate stripes in multi-threading mode by using the following command before `addStripe`:
`setMultiCpuUsage`

When the specified CPU number is bigger than the estimated CPU number, `addStripe` uses the estimated CPU number for multi-threading. Otherwise, it uses the specified CPU number.

Estimated CPU number = (free memory – 512 MB)/(added memory*2)

If any of the following options are specified, `addStripe` will internally disable the multi-threading mode:

- `{-over_bumps {0 | 1} | -between_bumps {0 | 1}} | -over_pins {0 | 1} -pin_layer layer {-master master_cells | -all_blocks}}`
- UDM global variable `pwStripeRouteOverRowsOnly` is equal to 1

`addStripe` supports the new `setMultiCpuUsage` command use model.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `addStripe` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man addStripe`
`-all_blocks {0 | 1}`	Specifies that stripes should be generated over all blocks. *Default:* `0`
`-allow_snapping_override_custom_spacing {0 | 1}`	When set to `1`, it allows snapping of stripes overriding the specified spacing to the closest track. If the closest track has conflicts, the stripe is removed. When set to `0`, it snaps the stripes in the first set to the inward direction, and the other stripes to the closest track. This parameter keeps the actual spacing greater than or equal to the specified spacing. *Default:* `0`
`-area {{x1 y1 x2 y2}{x1 y1 x2 y2 x3 y3 x4 y4 ...} ...}`	
	Specifies the coordinates of the design area in which the stripes must be created. The `-x_left_offset` and `-x_right_offset` values are measured from this boundary area for vertical stripes, and the `-y_top_offset` and `-y_bottom_offset` values are measured from this boundary area for horizontal stripes. **Note:** • If a core ring exists in the design, the stripes automatically connect to the core ring if you do not use the `-area` parameter. You can also create stripes in an area defined by a polygon (rectilinear). For example: `addStripe -area {100 100 100 200 150 200 150 150 200 150 200 100}` *Default:* If you do not specify this parameter, stripes are created for the entire core box. • `-area` and `-extend_to design_boundary` are mutually exclusive. The following error is issued on them being used together: *You cannot specify stripes over design boundary and set an area constraint. Instead, specify area to cover design boundary.* • `-area` and `-extend_to first_padring/ last_padring` are mutually exclusive. The following error is issued on them being used together: *You cannot specify stripes over padring and set an area constraint. Instead, specify area to cover padring.* • When this parameter is used with `setAddStripeMode -domain_offset_from_core true`, the `-start_offset` value for specified area is measured from core on using `addStripe -area`.
`-area_blockage {{x1 y1 x2 y2}{x1 y1 x2 y2 x3 y3 x4 y4 ...} ...}`	

	Specifies the blockage coordinates to restrict the addition of any stripes to this region.
	This parameter supports rectangular and rectilinear area_blockages. Their spacing is 0 during stripe generation.
	Examples
	• Rectangular area_blockage:
	`-area_blockage {100 100 200 200}`
	• Rectilinear area_blockage:
	`-area_blockage {100 100 100 200 150 200 150 150 200 150 200 100}`
	You can add multiple blockages at the same time.
	Rectangular areas or rectilinear area or their mixture can be specified. For multiple areas, each of them must be inside brace.
	Examples
	• multiple rectangles
	`-area_blockage {{x1 y1 x2 y2} {a1 b1 a2 b2} ...}`
	• multiple rectilinear area
	`-area_blockage {{x1 y1 x2 y2 ... } {a1 b1 a2 b2 a3 b3 ...} ...}`
	• mixture of them
	`-area_blockage {{x1 y1 x2 y2} {a1 b1 a2 b2} ... {x1 y1 x2 y2 x3 y3 ...} {a1 b1 a2 b2 a3 b3 ...} ...}`
	The specified areas that are not included inside brace will be ignored. For example
	`-area_blockage {{x1 y1 x2 y2} a1 b1 a2 b2 a3 b3 ... {c1 d1 c2 d2 c3 d3 ...}}`
	`{x1 y1 x2 y2}` and `{c1 d1 c2 d2 c3 d3 ...}` will be used, and `a1 b1 a2 b2 a3 b3 ...` are ignored

`-between_bumps {0 | 1}`	Specifies that stripes should be generated between bumps. *Default*: `0`
`-block_ring_bottom_layer_limit` *layer_name*	
	Specifies the lowest layer that stripes can switch to when encountering a block ring. Stripes that encounter a block ring can only switch to this layer or higher.
`-block_ring_top_layer_limit` *layer_name*	
	Specifies the highest layer that stripes can switch to when encountering a block ring. Stripes that encounter a block ring can only switch to this layer or lower.
`-create_pins {0 | 1}`	If set to `1`, IO pins are created for each stripe. Any overlap with existing IO pins at the design boundary is flagged as a warning after the stripes are created. If set to `0`, pins are not created. By default, `addStripe` would create pins for any stripe touching the design boundary. When `-extend_to design_boundary` is used the option `-create_pins` is 1 by default.
`-direction {horizontal | vertical}`	
	Sets the stripe direction. *Default:* If you do not specify this parameter, the new generated stripe follows the preferred direction defined in the `tlef` file.

`-extend_to`	The boundary for the stripes. Specify one of the following values:
	`all_domains`
	Stripes are created over all power domains for each power and ground net within each power domain. Stripes start and stop at each power domain boundary or ring around the power domain, and ignore the values in the `-nets` parameter.
	`first_padring`
	Stripes are created within the area enclosed by the pad ring closest to the core area.
	`last_padring`
	Stripes are created within the area enclosed by the pad ring closest to the design boundary.
	`design_boundary`
	Stripes are created within the design boundary

`-insts` *instance_name*	Specifies the instance name for generating power stripes.
`-layer` *layer*	Specifies the name of the layer in which to create stripes. Stripes can be created on only one layer at a time. The following types of formulas are supported: 1. Lefname 2. Metal layer number **Example:** If Metal2 is named by 'MET2' in LEF file, then you can use 1. MET2 2. 2 to identify metal2.
`-master` *master_cells*	Specifies the instances of the standard cell (or block) masters over which stripes should be generated. The option supports regular expression: `?` matches any single characters and `*` matches any sequence of characters.
`-max_same_layer_jog_length` *value*	
	The maximum length, in micrometers, that a stripe can jog on the same layer before switching to an adjacent layer. For example, if you specify a value of 2 micrometers, and an obstruction causes a stripe on layer METAL4 to jog for 3 micrometers, the jog will occur on layer METAL3 or METAL5. However, if an obstruction causes the stripe to jog for only 1 micrometer, the jog occurs on layer METAL4. *Default:* `2` (If you do not specify this parameter, the stripe automatically switches to an adjacent layer if the jog length is two times the width of the stripe.)
`-merge_stripes_value` *value*	
	Merges a stripe with a nearby block ring if the threshold spacing between the stripe and ring is smaller than the *value* (in micrometers) specified with this parameter. The stripe jogs to connect to the nearby ring only on the stripe layer. **Note:** To prevent stripes from merging with block rings, set the value of this parameter to `– 1`. *Default:* 10 (If you do not specify this parameter, stripes do not jog to merge with rings that are more than 10 µm away.) To merge the stripe on all layers, set the following variable of the `setAddStripeMode` command: `-merge_with_all_layers 1`
`-narrow_channel {0 | 1}`	Generates stripes over narrow channel area. Narrow channel usually exists between two blocks/power domains, or between core boundary and blocks/power domains. If there are part of rows without a certain net and layer of power mesh crossing over, the area of neighboring part of rows is defined as a narrow channel for that net and layer. When adding overall stripes,

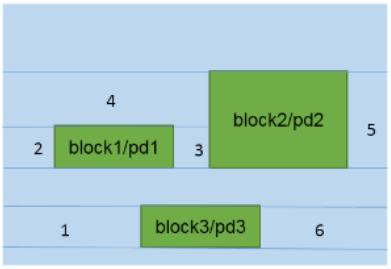
some narrow channels might be missed because of start offset and set to set distance. In this circumstance, adding stripes in narrow channel can help to supply power to stdcells in that channel. The recommended flow is to add overall stripes first and then to add stripes in narrow channel, if needed.

> ⚠ When the `-narrow_channel` parameter is used with `setAddStripeMode -extend_to_closest_target stripe`, the narrow channel stripes are extended to connect the closest followpin and stripes.

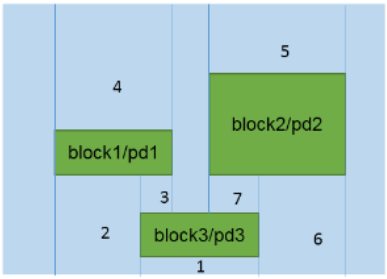
Default : `0`

Examples of narrow channels:

Narrow potential channels for vertical stripes

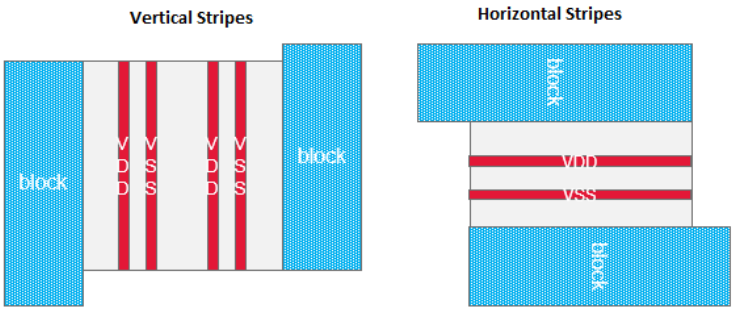


Narrow potential channels for horizontal stripes



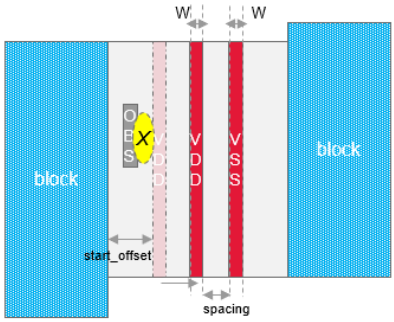
Note: This parameter can be used with the `-power_domains` and `-over_power_domain` parameters.

The `-narrow_channel` parameter generates stripes with uniform channel width in both the vertical and horizontal directions, if the `-number_of_sets` parameter is set to an integer value greater than `1`. The added wires are created at the channel evenly, as shown below:



If the `-start_offset` parameter is used for specifying the starting offset value before the above setting of the `-narrow_channel` parameter, and the specified offset location has a DRC, the added wire shifts to the left or up to the closed DRC clean location, as shown below:

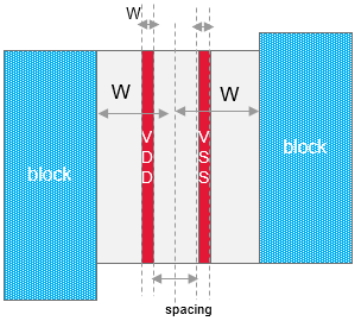
```
addStripe -width $W -spacing $spacing -number_of_sets N -narrow_channel 1 -nets
{$net1 $net2 ...} ...
```



If the `-start_offset` parameter is not used before the above setting of the `-narrow_channel` parameter, the wires are added to the center of the channel. With this setting:

- When the `-number_of_sets` parameter is set to `1`, this center has the same distance from the channel boundaries, as shown below:

  ```
  addStripe -width $W -spacing $spacing -number_of_sets 1 -narrow_channel 1 -nets
  {$net1 $net2 ...} ...
  ```

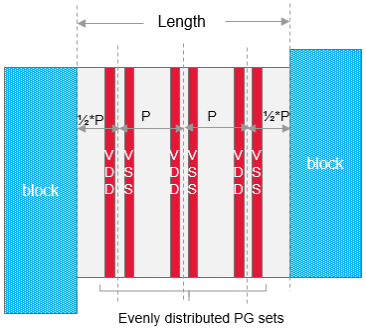


- When the `-number_of_sets` parameter is set to an integer value (`N`) greater than `1`, `addStripe` calculates the pitch to evenly distribute the PG in the channel.

  ```
  Pitch: P = Length / N
  ```

  Additionally, the two PG stripes set at the edge of the channel are at the same distance from the middle of the PG set and the channel boundary is at `P/2`, as shown below:

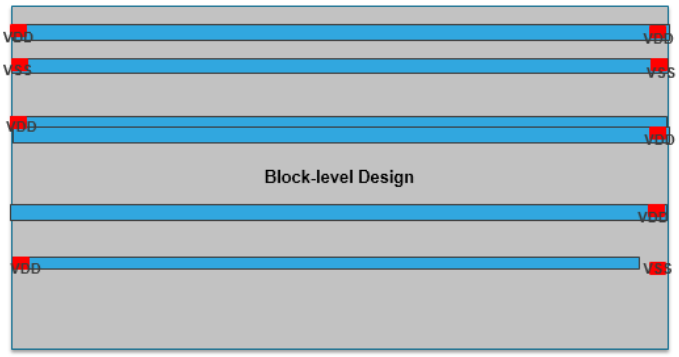
  ```
  addStripe -width $W -spacing $spacing -number_of_sets $N -narrow_channel 1 -nets
  {$net1 $net2 ...} ...
  ```



`-nets {list_of_nets}`	Specifies the names of the nets for which stripes are to be created. The number of net names determines the number of stripes within each set of stripes. The first net in the name list is created first and corresponds to the left or bottom stripe of the set. Separate multiple net names with a space and enclose the list in curly braces, for example, `-nets {net1 net2 net3 net3}`. Braces are not required for one name.
`-number_of_sets integer`	Specifies the number of stripe sets to be created. You must specify either this parameter or the `-set_to_set_distance` parameter. *Default:* If you do not specify this parameter, the number of sets is derived from the `-set_to_set_distance` parameter.

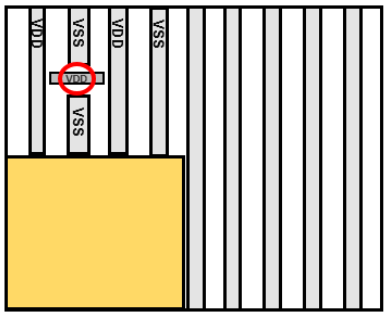
`-over_bumps {0 | 1}`	Specifies that stripes should be generated over bumps. When used with `-area`, it extends stripes to the boundary of the specified area.
	Run `setAddStripeMode -extend_to_closest_target area_boundary` before generating stripes over bumps using the `addStripe -over_bumps` parameter. See the example below:
	`setAddStripeMode -extend_to_closest_target area_boundary`
	`addStripe -net VDD -direction horizontal -area {x1 y1 x2 y2} -over bumps 1 …`
	Following is the output of the above commands:
	 	
	Default: `0`

`-over_physical_pins {0 | 1}`	

	Adds stripes over the physical pins to detect the physical PG terminals and add stripes to continue them. Following is the use model of this option:
	`addStripe -over_physical_pins 1 -nets {net_names} -width {pin_width|width_value} -direction {vertical|horizontal} [-pin_layer Mx] [-pin_offset offset_value]`
	While using this option:
	◦ The tool generates one stripe on one physical pin separately, except for the following special cases:
	▪ When two same net pins (left and right) are totally aligned. In this case, one stripe between two pins is generated.
	▪ When two different net pins are partially or totally aligned. In this case, one stripe on left/bottom pin is generated and break at right/up pin with DRC clean distance.
	◦ `-width pin_width` makes stripe width same as that of related physical P/G pin.
	◦ When `offset_value` in `-pin_offset offset_value` is greater than zero, stripes shift up for left/right pins and right for up/down pins.
	◦ If both `-over_physical_pins` and `-over_pin` are specified, `-over_physical_pins` is ignored.
	In the following example, stripes are added over the physical pins in the horizontal direction for the `vdd` and vss nets:
	`addStripe -over_physical_pins 1 -nets {VDD VSS} -width 10 -direction horizontal -pin_layer metal11`
	Following is the block-level design of the output:
	 


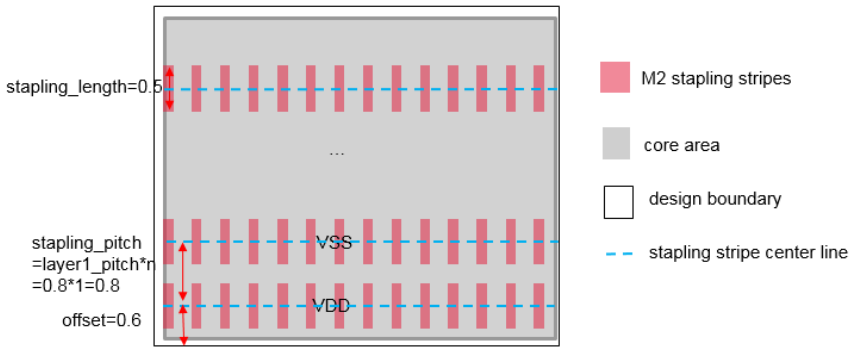
`-over_pins {0 | 1}`	Specifies that stripes should be generated over power/ground pins in a standard cell or block. *Default*: `0` **Note:** With this option, user could define value "pin_width" in option "-width", then tool will generate stripe according to pin width automatically.
`-over_power_domain {0 | 1}`	

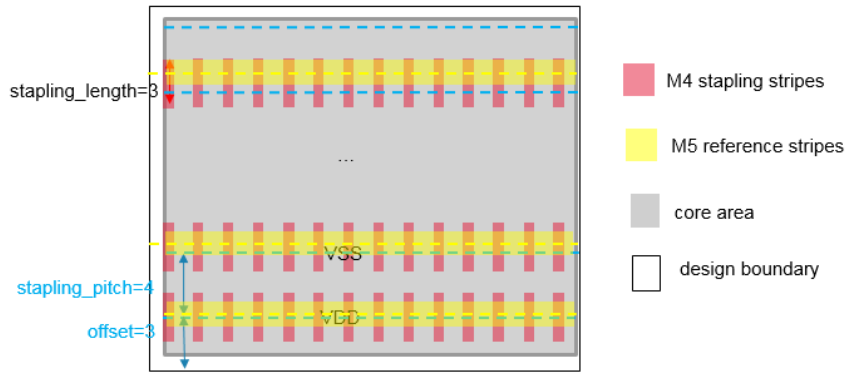
	If set to `1`, adds stripes only within power domain boundaries or the fence around a soft block. For power domains, these stripes start and stop at the power ring that surrounds the selected power domain boundary. For fences, these stripes start and stop at the fence. If both a power domain and a fence are selected, the power domain takes precedence.If you do not specify this parameter or if you specify it with a value of `0`, stripes are prevented from extending to the power domain boundary. **Note:** • When this option is specified, you can use `-start_from {bottom | top | left | right} and -start_offset` parameters to set boundaries, but you cannot use the `-start` and `-stop` parameters to specify an absolute location. • In addition, the software issues a warning message if the specified power and ground nets do not match the power domain's power or ground nets. • When `addStripe -over_power_domain 1` is used with `setAddStripeMode -domain_offset_from_core true`, the `-start_offset` value for the selected power domain/block is measured from core on using `addStripe -over_power_domain 1`. *Default:* `0`
`-padcore_ring_bottom_layer_limit` *layer_name*	
	Specifies the lowest layer that stripes can switch to when encountering a pad or core ring. Stripes that encounter a pad or core ring can only switch to this layer or higher.
`-padcore_ring_top_layer_limit` *layer_name*	
	Specifies the highest layer that stripes can switch to when encountering a pad or core ring. Stripes that encounter a pad or core ring can only switch to this layer or lower.
`-pin_layer` *layer*	Specifies the layer on which the stripe is generated. **Note:** The layer you specify with this parameter is the same as the layer you specify with the `-layer` parameter. *Default*: `TOP`
`-pin_offset`	Offsets the stripe a specified distance from the pin edge to make well tap cell connections. The offset is from the left edge of the stripe to the left edge of the same net pin. This can be a negative number and is in user units.
`-pin_width {`*min_value max_value*`}`	
	Specifies the range of minimum and maximum pin width for `-over_pins` or `-over_physical_pins`.
`-power_domains` *domain_name*	
	Specifies the power domain name for generating power stripes. **Note:** This parameter cannot be used with the `-narrow_channel` parameter. Use the `-area` parameter to generate `-narrow_channel` stripes over certain areas.
`-report_cut_stripe` *filename*	

	Saves the information related to a cut stripe in a DRC file. This helps in identifying the power stripe that has been removed/cut from the design to avoid any DRC violation following user settings.
	You can use the following command to load the generated DRC file into the design and view the cut stripe mark in the GUI:
	`loadDrc *.drc`
	The following example shows how the information related to a cut stripe is stored in the a.drc file:
	`addStripe -report_cut_stripe a.drc`
	The following figure depicts that the place highlighted in red circle will be marked, because here the VSS stripe is cut to avoid short violation to VDD segment:
	 


`-same_layer_target_only`	Specifies connection to overlapping targets on the same layer only.
`-set_to_set_distance` *real*	
	Specifies the distance (pitch) from the reference stripe of one set to the reference stripe of the next set. The value of this parameter must be a positive number specified in micrometers. You must specify either this parameter or the `-number_of_sets` parameter. *Default:* If you do not specify this parameter, the distance between sets is derived from the `-number_of_sets` parameter.
`-snap_wire_center_to_grid {None | Grid | Mask1_Grid | Mask2_Grid | Half_Grid | Either}`	
	Controls the snapping of the center of the stripes. If you do not specify this parameter, stripes are not snapped to the routing grid. **Note:** When tech LEF specifies `RIGHTWAYONGRIDONLY` on a specific layer, stripes are automatically snapped to the routing grid. Specify one of the following options: • `None`: Does no snapping of the wires. • `Grid`: Snaps the center of the wire to the routing grid of the same layer as the wire. • `Mask1_Grid`: Snaps the center of the wire to the routing track of `Mask1`. • `Mask2_Grid`: Snaps the center of the wire to the routing track of `Mask2` . • `Half_Grid`: Snaps the center of the wire to the half-routing grid. The half-routing grid is a virtual grid with the tracks at the center of every two adjacent tracks of the routing grid. • `Either`: Snaps the center of the wire to the closer of the routing grid or half-grid track. *Default:* None
`-spacing` *spacing*	Specifies the width of the gap between stripes in each set. You can specify different spacing between each pair of stripes. For *n* number of stripes, you can specify *n* –1 spacing values. If fewer values are specified, the last-specified spacing is used for the remaining unmatched stripe pairs.
`-stapling {length | auto {offset layer1_pitch:n | reference_layer1 [reference_layer2]}}`	

Turns on the stapling stripe generation feature and controls the stapling pattern. In the syntax:

- `length`: Specifies the length of stapling stripes.
- `auto`: When specified, stapling length is calculated by the tool automatically, with the minimum length that can be DRC clean.
- `offset`: Specifies the distance from design boundary to the center of the first stapling stripe by default. Refer to the following example:
  Example 1
  ```
  addStripe -stapling {0.5 0.6 0.8:1} -nets {VDD VSS} -layer metal2 -width 0.1 -
  direction vertical -set_to_set_distance 0.5
  ```
  


- `pitch:n`: Specifies the center to center distance between two stapling stripes in end direction (refer to **Example 1** above). It is defined by `n` times of the track pitch on `layer1`, where stripes are needed to be connected by stapling stripes.
- `reference_layer1`: When the stripes on `layer1` to be connected already exist, you can directly specify the reference layer 1 name. It specifies that the stapling stripe center is on the center line of the reference stripes (offset value is the center offset of first bottom/left stripe; the `pitch:n` is the set-to-set distance of stripes on `layer1`).
- `reference_layer2`: When the stripes on `layer2` to be connected already exist, you can specify the reference layer 2 name, so that the stapling stripes are generated referring to both `layer1` and `layer2` and connect them. When `reference_layer2` is specified, the real offset and stapling pitch will be the average value from `layer1` and `layer2` settings. It aims to find the center of two layers of wires to be connected by stapling stripes. Refer to the example below:
  Example 2
  ```
  set metal3_track_offset 3
  set metal3_pitch 0.8
  addStripe -stapling '3 $metal3_track_offset $metal3_pitch:5 metal5' -nets {VDD
  VSS} -layer metal4 -width 0.5 -direction vertical -set_to_set_distance 2
  ```
  


You can use `-stapling` in the following ways:

- `-stapling {length|auto offset pitch:n}`
- `-stapling {length|auto reference_layer}`

	• `-stapling {length|auto offset pitch:n reference_layer2}` • `-stapling {length|auto reference_layer1 reference_layer2}`
`-start` *value*	The start coordinate for adding stripes.
`-start_from {bottom | top | left | right}`	
	For horizontal stripes: • `bottom` indicates that stripes should be generated from bottom to top, taking the bottom offset into account. • `top` indicates that stripes should be generated from top to bottom, taking the top offset into account. *Default*: `bottom` For vertical stripes: • `left` indicates that stripes should be generated from left to right, taking the left offset into account. • `right` indicates that stripes should be generated from right to left, taking the right offset into account. *Default*: `left` **Note:** Offset values set with this parameter are considered "hard": The power planning software adheres strictly to the values. However, the opposite values are considered "soft": Such values could be greater than the hard values, but will never be less than the hard values. For example, if you set a `right` offset value of 4 µm, the `left` value will be at least 4 µm, but could be greater.
`-start_offset` *real_value*	
	Specifies the starting offset value off of the appropriate boundary of the stripe generation area to the nearest edge of the first stripe. For example, for vertical stripes starting from the left, offset is measured from the left side of the stripe generation area to the left edge of the first stripe. This is an optional field. **Note:** The parameters `-start` and `-start_offset` are exclusive, and cannot be used together.
`-stop`	The stop coordinate for the region for adding the stripe.
`-stop_offset` *real_value*	
	Specifies the stopping offset value off of the appropriate boundary of the stripe generation area. For example, for vertical stripes starting from the left, the offset is measured from the right side of the stripe generation area. This is an optional field. **Note:** The parameters `-stop` and `-stop_offset` are exclusive, and cannot be used together.
`-switch_layer_over_obs {0 | 1}`	
	Specifies if the switch layer is placed over obstructions. It controls whether a stripe switches layers, is routed over blocks, and then continues on the original layer. Using this parameter eliminates the need for a power routing mesh layer, and avoids maximum via stack rule violations. *Default*: 0 *Type: Boolean, optional*
`-uda` *subclass_string*	Displays the user defined attribute attached to each created stripe segment.
`-use_interleaving_wire_group {0 | 1}`	

	If set to 1, connects multiple wires from the same net together, even if separated by wires from a different net. You can only specify this parameter if you also specify `-use_wire_group 1`. If you do not specify this parameter or if you specify it with a value of `0`, interleaving wire groups are not used. *Default:* `0`
`-use_wire_group {-1 | 0 | 1}`	
	If set to `1`, connects wires from the same net together. If you do not specify this parameter or if you specify it with a value of `0`, wire groups are not used. If set to `-1` and multiple same net are specified in -nets, the wire group property will not be updated or created. **Note:** For stripes to connect to rings using wire groups, you must specify the `-useWireGroup` parameter in both the `addRing` and `addStripe` commands. *Default:* `0`
`-use_wire_group_bits` *integer*	
	Specifies how many nets are to be included in the wire group. You can only specify this parameter if you also specify `-use_wire_group 1`. *Default:* The same number of nets as specified in the `-nets` parameter.
`-via_rows` *integer*	
`-via_columns` *integer*	
	Specifies the number of cuts to make in the power vias (for both stack and non-stack). Default: `0`
`-width` *width*	
	Specifies the width of the stripes. You can specify a different width for each net within a set. If the number of widths specified does not match the number of net names, the last-specified width is used for the rest of unmatched nets.

Example

The following command adds stripes in the vertical direction for the `vdd` and `gnd` nets:

```
addStripe -direction vertical -nets {vdd gnd} -width 10 -spacing 1 -layer METAL6 -start_offset 50  -set_to_set_distance  50
```

colorizePowerMesh

```
colorizePowerMesh
[-help] [-reverse_with_nondefault_width {0 | 1}]
```

Use this command to colorize (assign mask information) power structures, including power wires and power via metals, in multi-pattern layers. This command also fixes color violations of power metals including via metals. It is recommended to use this command once all the power meshes are built. This command honors the FIXEDMASKS keyword in the LEF of the cell, in the case of colored LEF.

Note:

1. This command colors only the PG wires and PG via enclosure. but not the PG via cut. Also, it does not color pre-routed signal nets. All signal nets are colored while using the `place_opt_design` or `routeDesign` command.
2. The command does not fix via cut colors. To fix cut color or trim cut with violation, use the `fixVia` command. This command requires correct node setting in `setDesignMode -process/setNanoRouteMode -route_process_node`.
3. The wide NDR wires will be assigned with a different color than the track color through this command.

Parameter

`-help`	Prints a brief description that includes the type and default information for each `colorizePowerMesh` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man colorizePowerMesh`
`-reverse_with_nondefault_width {0 | 1}`	
	Reverses the 'on track' wire color to the different 'from track' color, when the wire width is not the default width.

Related Information

    | -via_height real_number -via_width real_number}]
[-via_using_exact_crossover_size {0 | 1}]
```

Modifies or deletes existing power vias or adds new power vias to the design.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `editPowerVia` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man editPowerVia`
`-add_vias {0 | 1}`	When set to `1`, adds power vias to the design. *Default:* `0`
`-area {{x1 y1 x2 y2} {x3 y3 x4 y4} ...}`	
	Adds, modifies, or deletes power vias within the area regions enclosed by the specified coordinates. *Note:* If you need to add power vias within the specified area only, run `setViaGenMode -area_only 1` before `editPowerVia`.
`-between_selected_wires {0 | 1}`	
	When set to `1`, adds, modifies, or deletes power vias between selected wires only. You can select the wires interactively in the design display area or by using the `select_obj` command. *Default:* `0`
`-bottom_layer layername`	Specifies the lowest layer to which vias can connect. *Default:* The lowest metal layer in the design.
`-create_via_on_merged_target_within micron`	
	Helps `viaGen` merge the targets within the halo distance on the specified layer.
`-create_via_on_merged_target_on_layer layerName`	
	Helps `viaGen` add a virtual target internally, ignore the original targets, and drop vias to the virtual target instead. `-create_via_on_signal_pins {0 | 1}`	

	When set to `1`, allows generation of vias from special wire to signal pins. `editPowerVia` drops vias between special route and PG/signal pins, including the flipchip route. *Default*: `0` **Note:** This parameter can be used with the `-area` parameter to specify the area for adding vias. It mainly occurs at the tie-high and tie-low cell pins.
`-delete_vias {0 | 1}`	Deletes power vias from your design. *Default:* `0`
`-exclude_stack_vias {0 | 1}`	Avoids generation of stack vias between two non-adjacent layers to handle the intersection cases of cross multiple layers. See the examples below to understand the behavior of this parameter with different values: • `editPowerVia -exclude_stack_vias 0 -add_vias 1 ...`  • `editPowerVia -exclude_stack_vias 1 -add_vias 1 ...`  *Default:* `0`
`-followpin_via_stapling {cutclass1 weight1 cutclass2 weight2}`	
	Defines two cut classes to be tried in priority in the followpin via stapling to maximize the effective number of cuts. The weight value is for via insertion ratio calculation.
`-modify_vias`	Modifies vias in the design.

`-nets net_list`	Specifies the list of nets on which to add, delete, or edit vias.
`-orthogonal_only {0 | 1}`	When set to `1`, creates vias *only* for orthogonal wires and pin intersections. *Default*: If you do not specify this parameter or if you specify it with a value of `1`, the software creates vias for orthogonal wires and pin intersections.
`-same_sized_stack_vias {0 | 1}`	When set to `1`, the software only generates same-sized stacked vias. If set to `0`, the software trims the vias as needed to meet the DRC rules. *Default:* `0`
`-selected_blocks {0 | 1}`	Specifies whether vias in the selected blocks only should be looked up.
`-selected_vias {0 | 1}`	When set to `1`, modifies or deletes the selected vias only. You can select the wires interactively in the design display area or by using the `select_obj` command.
`-selected_wires {0 | 1}`	When set to `1`, drops vias between selected wires and all same net objects across the selected wires. You can select the wires interactively in the design display area or by using the `select_obj` command.
`-skip_via_on_pin {[Pad] [Block] [Cover] [Standardcell] [Physicalpin]}`	
	Prevents vias from being generated on the specified types of pins. If you specify `-skip_via_on_pin {}`, the power planning software makes connections to all five categories of pins. *Default:* If you do not specify this parameter, vias are generated for block pins, pad pins, and cover macro pins, but not for standard cell pins.
`-skip_via_on_wire_shape {[Blockring] [Stripe] [Followpin] [Corewire] [Blockwire] [Iowire] [Padring] [Ring] [Fillwire] [Noshape]}`	
	Prevents vias from being generated for the specified wire shapes. *Default:* If you do not specify this parameter, vias are generated for all wire shapes.
`-skip_via_on_wire_status {[routed] [fixed] [cover] [shield]}`	
	Prevents vias between wires with routed, cover, fixed, or shield status and other power wires. *Default:* If you do not specify this parameter, vias are generated for any wire status.
`-split_long_via {threshold step offset length}`	
	Splits vias longer than the specified length (`threshold`, in micrometers) into smaller vias with specified center-to-center spacing (`step`, in micrometers), left/bottom end offset (`offset`, in micrometers) and vertical/horizontal length (`length`, in micrometers) values . This is independent of the option `-split_via`. *Default*: If you do not specify this parameter, the software does not split vias. **Note:** If the `offset` is given as negative, the vias will be placed symmetrically on both ends. The default value of `offset` is `-1`.

`-split_vias {0 | 1}`	When set to `1`, two or more partial vias can be created at the crossover between a stripe and any target (pin or wire) if an obstruction (macro obstruction; wire or pin on a different net) prevents the creation of a full-size via. This can be useful, for example, if several metal blockages partially obstruct the area where a full-size via would normally be placed. This parameter permits the creation of partial vias that would not violate the process rules, in the open areas. A value of 1 allows multiple partial vias to be created. A value of 0 prevents multiple partial vias from being created. *Default:* `0`
`-top_layer` *layername*	Specifies the highest layer to which vias can connect. *Default:* The highest metal layer in the design.
`-uda`	Indicates the user defined attribute subclass for wires to route. This option is of type string and is optional.
`-via_height` *real_number*	Specifies the absolute height of the added or modified power vias. You can use this parameter only if you choose the `-add_vias` or `-modify_vias` parameter. Default: `0.0`
`-via_width` *real_number*	Specifies the absolute width of the added or modified power vias. You can use this parameter only if you choose the `-add_vias` or `-modify_vias` parameter.
`-via_rows` *integer*	Specifies the number of cuts to make in the power vias (for both stack and non-stack). You can use this parameter only if you choose the `-add_vias` or `-modify_vias` parameter. Default: `0`
`-via_columns` *integer*	Specifies the number of cuts to make in the power vias (for both stack and non-stack). You can use this parameter only if you choose the `-add_vias` or `-modify_vias` parameter. Default: `0`
`-via_scale_height` *integer*	Specifies the percentage to scale the power via height. You can use this parameter only if you choose the `-modify_vias` or `-add_vias` parameter.
`-via_scale_width` *integer*	Specifies the percentage to scale the power via width. You can use this parameter only if you choose the `-modify_vias` or `-add_vias` parameter.
`-via_using_exact_crossover_size {0| 1}`	When set to `1`, generates partial vias of the exact crossover size. A value of 1 allows partial vias to be generated. A value of 0 prevents partial vias, and the software always generates full-size vias. *Default:* `1`

Examples

- The following command creates a power via between selected wires with a cut pattern of 3 by 3:
  ```
  editPowerVia -add_vias 1 -between_selected_wires 1 -via_rows 3 -via_columns 3
  ```
- The below command deletes all power vias in the area defined by {0 0 500 600}:
  ```
  editPowerVia -delete_vias 1 -area {0 0 500 600}
  ```
- The following command adds power vias on the VDD net, in the area defined by {0 0 100 100}:
  ```
  editPowerVia -add_vias 1 -net VDD -area {0 0 100 100}
  ```

get_add_target_pg_mode

```
  get_add_target_pg_mode
[-help]
[-allow_weak_connect]
[-max_extension_distance]
[-pins]
[-pins_group_distance]
[-respect_routes]
[-share_resource]
[-quiet]
[-nonDefault]
```

Returns the information for the specified parameter. Note that you can specify one or more parameter. When you invoke this command without any argument, the software prints the current values stored in the database for all the options. If you provide an option, then the software prints the value currently stored in the database.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `get_add_target_pg_mode` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man get_add_target_pg_mode`
`-parameter_names`	Returns the information about the specified parameters. You can specify one or more parameters. See `set_add_target_pg_mode` for the description of the `get_add_target_pg_mode` parameters.
`-quiet`	Returns the current settings for the specified parameters only in the Tcl list format. If you specify `-quiet` without any parameters, the software returns the current settings of all the `set_add_target_pg_mode` parameters in Tcl list format.

Related Information

[-split_long_via]
[-stacked_via_bottom_layer]
[-stacked_via_top_layer]
[-via_using_exact_crossover_size]
[-wire_center_offset]
[-quiet]
```

Returns information for the specified parameter. The user can specify one or more parameter. When you invoke these commands without any argument, Innovus prints the current values stored in the database for all the options. If you provide any option, then Innovus would print the value currently stored in the database.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `getAddRingMode` parameter. For a detailed description of the command and all its parameters, use the man command: `man getAddRingMode`.
`-parameter_names`	Displays information for the specified parameters. You can specify one or more parameters. See `setAddRingMode` for descriptions of the parameters you can specify.
`-quiet`	Displays the current settings for the specified parameters in Tcl list format only.

Example

The following command returns information for the specified parameter:

```
getAddRingMode

-ring_target default (default: default)

-extend_over_row 0 (default: 0)

-skip_crossing_trunks none (default: none)

-avoid_short 0 (default: 0)

-extend_merge_with_prewires 1 (default: 1)

-extend_corering_search_distance 0.00 (default: 0.0)
```

`-extend_blockring_search_distance` *`0.00`* `(default: 0.0)`

`-extend_stripe_search_distance` *`0.00`* `(default: 0.0)`

`-ignore_rows` *`0`* `(default: 0)`

`-avoid_short` *`0`* `(default: 0)`

[-via_using_exact_crossover_size]
```

```
[-quiet]
[-nonDefault]
```

Returns the current settings of the `setAddStripeMode` command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `getAddStripeMode` parameter. For a detailed description of the command and all its parameters, use the man command: `man getAddStripeMode`
`-parameter_names`	Returns information for the specified parameters. You can specify one or more parameters. See `setAddStripeMode` for descriptions of the `setAddStripeMode` parameters you can specify.
`-quiet`	Returns the current settings for the specified parameters in Tcl list format only. If you specify `-quiet` without any parameters, the software returns the current settings of all `setAddStripeMode` parameters in Tcl list format.

Examples

- The following command returns the current settings of `setAddStripeMode -offset_from_core` in the Tcl list format:
  ```
  setAddStripeMode -offset_from_core -quiet
  ```
  The software returns the following information:
  ```
  true
  ```
- The following command returns the current settings for `setAddStripeMode -offset_from_core`:
  ```
  setAddStripeMode -offset_from_core
  ```
  The software returns the following information:
  ```
  -offset_from_core true # bool, default=true
  ```

[-symmetrical_via_only]
[-use_track_offset]
[-use_trim_metal_enclosure]
[-viarule_preference]
[-quiet]
[-nonDefault]
```

Returns the current settings of the `setViaGenMode` command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `getViaGenMode` parameter. For a detailed description of the command and all its parameters, use the man command: `man getViaGenMode`
`-parameter_names`	Returns information for the specified parameters. You can specify one or more parameters. See `setViaGenMode` for descriptions of the parameters you can specify.
`-quiet`	Displays the current settings for the specified parameters in Tcl list format only. If you specify the `-quiet` parameter without any the other parameter(s), the software returns the current settings of all the `setViaGenMode` parameters in Tcl list format.

Examples

The following command returns the current settings of the `setViaGenMode -genvia_naming_prefix` parameter:

```
getViaGenMode -genvia_naming_prefix
```

The software returns the following information:

```
-genvia_naming_prefix {} # string, default=""
```

Related Information

- Power Planning and Routing chapter in the *Innovus User Guide*.
- `setViaGenMode`

loadSpecialRoute

```
loadSpecialRoute
[-help]
filename
```

Loads the spr file generated through the `saveSpecialRoute` command. It also clears all special routes and loads the specified spr file. If the spr files are loaded incrementally, the `addSpecialRoute` command must be used. If the specified filename is compressed (with the .gz extension), the file is read in directly.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `loadSpecialRoute` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man loadSpecialRoute`
`filename`	Specifies the name of the file that contains special route information, to be used as input for the design.

Related Information

- `addSpecialRoute`
- `saveSpecialRoute`
- Power Planning and Routing chapter in the *Innovus User Guide*.

reinforce_pg

```
  reinforce_pg
[-help]
[-area {x1 y1 x2 y2}]
[-area_blockage {{x1 y1 x2 y2} {x1 y1 x2 y2 x3 y3 x4 y4 ...} ...}]
[-pattern_file file_name]
[-snap_wire_center_to_grid {default | Grid}]
{-pattern_map {{irdrop_value1 pattern_name1} {irdrop_value2 pattern_name2}..} | -write_pattern_template file_name | -boxes_file
file_name | -auto_ir_fix {preroute | postroute}}
[[-tile_row_column {x y}  | -tile_size {x y} | -number_region value] | -write_pattern_template file_name]
[-rail_analysis_directory {directory} | -write_pattern_template file_name]
```

Reinforces PG stripes between the existing original PG stripes in Innovus to fix the IR drop violations reported from Voltus.

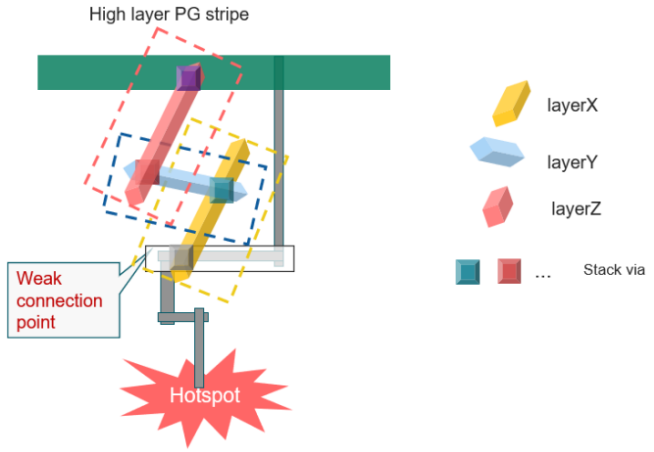
Parameters

`-help`	Outputs a brief description that includes the type and default information for each `reinforce_pg` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man reinforce_pg`
`-area {x1 y1 x2 y2}`	Specifies the coordinates of the area in which the IR drop violation boxes from Voltus can be fixed by the `reinforce_pg` command.

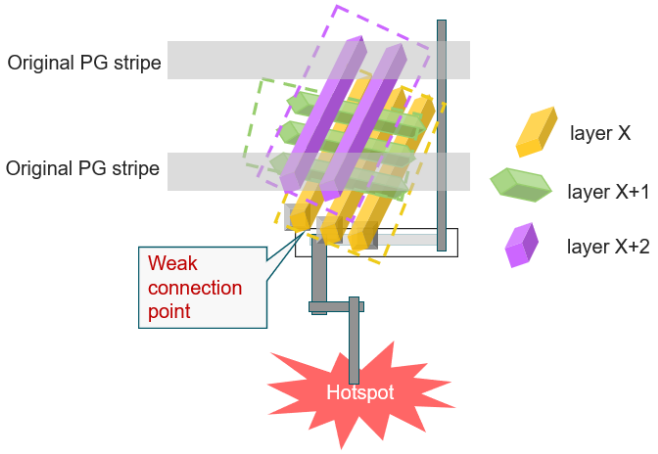
`-area_blockage {{x1 y1 x2 y2} {x1 y1 x2 y2 x3 y3 x4 y4 ...} ...}`	Specifies the blockage coordinates of one or more area regions to restrict the addition of any stripes. This parameter supports both the rectangular and rectilinear area regions along with their combinations. Their spacing is `0` during the stripe generation. Following are the possible parameter usage scenarios:
	• Single Rectangular Area:
	`-area_blockage {x1 y1 x2 y2}`
	For example:
	`-area_blockage {100 100 200 200}`
	• Single Rectilinear Area:
	`-area_blockage {x1 y1 x2 y2 x3 y3 x4 y4 x5 y5 x6 y6}`
	For example:
	`-area_blockage {100 100 100 200 150 200 150 150 200 150 200 100}`
	• Multiple Rectangular Areas:
	`-area_blockage {{x1 y1 x2 y2} {a1 b1 a2 b2} ...}`
	• Multiple Rectilinear Areas:
	`-area_blockage {{x1 y1 x2 y2 ... } {a1 b1 a2 b2 a3 b3 ...} ...}`
	• Combination of Rectangular and Rectilinear Areas:
	`-area_blockage {{x1 y1 x2 y2} {a1 b1 a2 b2} ... {x1 y1 x2 y2 x3 y3 ...} {a1 b1 a2 b2 a3 b3 ...} ...}`
	While blocking multiple areas using this parameter, each of them must be inside the braces. The areas that are not included inside the braces will be ignored. For example, `-area_blockage {{x1 y1 x2 y2} a1 b1 a2 b2 a3 b3 ... {c1 d1 c2 d2 c3 d3 ...}}`, `{x1 y1 x2 y2}`, and `{c1 d1 c2 d2 c3 d3 ...}` will be accepted by the parameter, and `a1 b1 a2 b2 a3 b3 ...` will be ignored.

`-auto_ir_fix {preroute | postroute}`	Fixes IR drop with an automated flow. No pattern is needed with the automated flow provided by this parameter. This parameter extracts violation tiles based on RLRP, and automatically fixes the IR drop based on the location provided by Voltus at each layer. When this parameter is used, Voltus rail analysis is performed. ⚠ The tile size and location is provided by Voltus. Use one of the following values with this parameter:

- `preroute`: Fixes IR drop using minimum resources. Use this flow before signal routing to ensure a good stripe connection. When this parameter value is specified, the software adds several metal layers between the weak point and high PG stripe. The location and layer are automatically controlled by the software analyzer. The following figure presents an example of using `-auto_ir_fix preroute`:



- `postroute`: Fixes IR drop with all the remaining available metal resources. Use this flow after routing so that all the available resources can be used. When this parameter value is specified, the software adds all the rest metal resources at every metal layer according to the information received from Voltus. By this, every metal layer makes connection with the adjacent layer. The layer and tile location are automatically controlled by the software analyzer. By default, `set_reinforce_pg_mode -respect_routes` is set to `all` when `reinforce_pg -auto_ir_fix postroute` is specified, which you can change manually. The following figure presents an example of using `-auto_ir_fix postroute`:



⚠ When the `-auto_ir_fix` parameter is used with pattern flow, the pattern is ignored.

Default: `none`

`-boxes_file` *file_name*	Specifies the file for including the list of boxes and corresponding pattern names. The format of the file is mentioned below:
	`Pattern1 x01 y01 x02 y02`
	`Pattern2 x11 y11 x12 y12`
	……

`-number_region` *value*	Specifies the number of regions to be analyzed by the software. The integer value of this parameter ranges from 1 to 65536. *Default:* `100`
`-pattern_map {{`*irdrop_value1 pattern_name1*`} {`*irdrop_value2 pattern_name2*`}..}`	
	Specifies the pattern for IR drop fixing through the IR drop value and pattern name defined by the `-pattern_file` parameter. If `irdrop_value1` is lesser than `irdrop_value2`, the `reinforce_pg` command uses `pattern_name1` to fix the IR drop between `irdrop_value1` and `irdrop_value2`. And `pattern_name2` is used to fix the IR drop bigger than or equal to `irdrop_value2`. It is recommended to specify the `irdrop_value` in the ascending order.
`-rail_analysis_directory {`*directory*`}`	Allows the `reinforce_pg` command to read the rail analysis information available in the specified directory.
`-snap_wire_center_to_grid {default | Grid}`	Specifies the snap wire center for routing grid. Use this parameter to control the added stripe for turning on or off the grid for the `reinforce_pg` command. Following are the parameter values: • `default`: Snaps the added wires to gird or half grid, according to the wire width. • `grid`: Snaps the the added wires only to the grid. *Default:* `default`
`-tile_row_column {`*x y*`}`	Specifies the number of tiles for power analysis in the x and y directions. This parameter enables tile-based analysis of the hot-spot regions to divide the design based on user-defined tile count and reports IR drop violations on each tile.
`-tile_size {`*x y*`}`	Specifies the size of tiles for power analysis in the x and y directions. This parameter enables tile-based analysis of the hot-spot regions to divide the design based on user-defined tile size and reports IR drop violations on each tile.
`-write_pattern_template` *file_name*	Specifies the template of the pattern file. This parameter cannot be used with other parameters. Refer to the following example to understand the usage of this parameter: `reinforce_pg -write_pattern_template pattern.cfg`

`-pattern_file` *file_name*	Defines the pattern for the pattern template of reinforce stripes. The `reinforce_pg` command uses different patterns for fixing the corresponding IR drop value sections.
	The following is the file syntax of the pattern template for single metal layer:
	`NAME pattern_name`
	`NETS {list_of_nets}`
	`LAYER metal_layer`
	`MAXPITCH real_value`
	`MINDISTANCE real_value`
	`WIDTH real_value`
	`VIACONTROL {metal_of_viaHookUpBot metal_of_viaHookUpTop}`
	`SPACING real_value ##optional`
	`UDA subclass_string ##optional`
	Note: You can define the density of the added PG using the `MAXPITCH` and `MINDISTANCE` parameters.
	The following is the description of the pattern template parameters for a single metal layer:
	◦ `NAME`: Specifies the name of the pattern. The `pattern_name` used at `pattern_map` should be the

same as the name defined in the pattern file.

- NETS: Specifies the names of the nets for which the stripes are required to be generated.
- LAYER: Specifies the name of the layer in which the stripes are required to be generated.
- WIDTH: Specifies the width of the stripes.
- VIACONTROL: Specifies the metal layers to which the generated PG wires will be connected.
- SPACING: Specifies the spacing between the stripes/nets defined for the NETS attribute. If SPACING is not defined, the Multi nets defined through NETS will use the minimum DRC free distance.
- UDA: Displays the user-defined attribute attached to every generated stripe segment.
- MAXPITCH: Specifies the maximum distance between the generated PG stripes. The distance between the added PG wires and original PG stripes cannot be more than MAXPITCH.
- MINDISTANCE: Specifies the minimum distance between the generated PG stripes. The distance between added PG wires and original PG stripes should be more than MINDISTANCE.

Note: You can define the density of the added PG using the MAXPITCH and MINDISTANCE parameters. If the distance between the two PG wires for any net is smaller than MINDISTANCE after adding the PG, the added PG wires will be deleted.

The following is the file syntax of pattern template for two metal layers:

```
NAME  pattern_name
NETS    {list_of_nets}
LAYER  metal_layer1 metal_layer2
MAXPITCH         real_value1   [real_value2]
MINDISTANCE         real_value1   [real_value2]
WIDTH  real_value1   [real_value2]
VIACONTROL      {metal_of_viaHookUpBot metal_of_viaHookUpTop} [{metal_of_viaHookUpBot
metal_of_viaHookUpTop}]
SPACING  real_value                    ##optional
UDA  subclass_string                   ##optional
```

Note: If both the MAXPITCH and MINDISTANCE parameters define the same value and the two added metal layers are in the same direction, then metal_layer2 should align with metal_layer1.

The following is the description of the pattern template parameters for two metal layers:

- NETS: Specifies the net names of the two metal layers to be created.
  Note: The list of nets is not based on the metal layers. Every metal layer needs to generate all the nets defined.
- LAYER: Specifies the name of the layers in which stripes are to be created. Two metal layers are required in this scenario.
- WIDTH, VIACONTROL, SPACING, MAXPITCH, and MINDISTANCE: These parameters can be defined twice for the corresponding metal layer. If only one value is specified for these parameters, two metal layers will use the same value.

You can use an optional keyword, OVERVIAMETAL *metal_layer*, which makes the reinforce_pg command create PG over the via metal of same PG net. Else than the OVERVIAMETAL keyword, the *metal_layer* parameter is also optional. If *metal_layer* is defined with the OVERVIAMETAL keyword, only the defined metal layers follow the OVERVIAMETAL rule. Else, all the metal layers defined at the LAYER need to follow the OVERVIAMETAL rule.

The following is the syntax of the OVERVIAMETAL keyword:

```
OVERVIAMETAL metal_layer*
```

The following is the file syntax of the special pattern template for multiple layers:

```
NAME pattern_name
TYPE SMART
NETS {list_of_nets}
LAYERS layer1:layer2                                          ##optional
PITCHFACTOR integer_value                                     ##optional
VIACONTROL {metal_of_viaHookUpBot metal_of_viaHookUpTop}      ##optional
```

	`UDA subclass_string ##optional` Following are the pattern template attributes: • `NAME`: Specifies the name of pattern. The `NAME` attribute used with `pattern_map` should be same as the name defined in the pattern file. • `TYPE`: Specifies the type of the PG pattern. If `TYPE` is specifies as `SMART`, `reinforce_pg` runs PG pattern by smart PG flow. Otherwise, it runs PG pattern with the normal pattern flow. • `NETS`: Specifies the names of the nets for which stripes are to be created. • `LAYERS`: Specifies the name of the layer in which stripes need to be created. This is an optional attribute and presents smart PG pattern support layer range. Following are various attribute values: ◦ `layer1:layer2`: Signifies all the layers from `layer1` to `layer2`. ◦ `-`: Presents the default top or bottom routing layer. ◦ `-:layer2`: Signifies the default bottom routing layers to `layer2`. ◦ `layer1:-`: Specifies that `layer1` will be default for top routing layers. ◦ `default`: Includes all the routing layers. • `UDA`: Displays the user-defined attribute attached to each created stripe segment. This is an optional attribute. *Default*: `rpg_$pattern1` • `PITCHFACTOR`: Specifies the average pitch number between two added stripes. This is an optional attribute. *Default*: `1` • `VIACONTROL`: Specifies the metal layers to which the generated PG of bottom layer and top layer will be connected. *Default*: The adjacent lower layer of defined `layer1` and the adjacent upper layer of defined `layer2` of `LAYERS`.

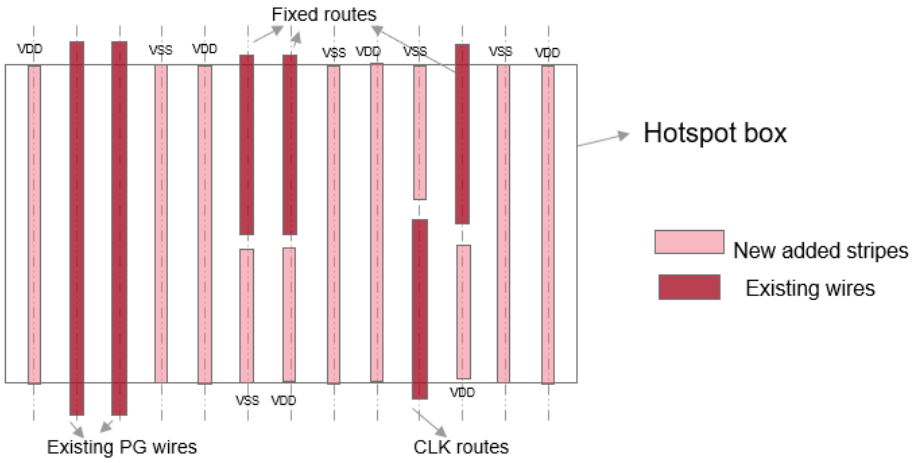
Examples

- The following command defines pattern for the pattern template of reinforce stripes with the following `pattern.tcl` file values:

```
NAME   smart1
TYPE   SMART
NETS   VDD VSS:

reinforce_pg -pattern_file pattern.tcl -pattern_map {0.04 smart1}
```

The following is the output of the above command:

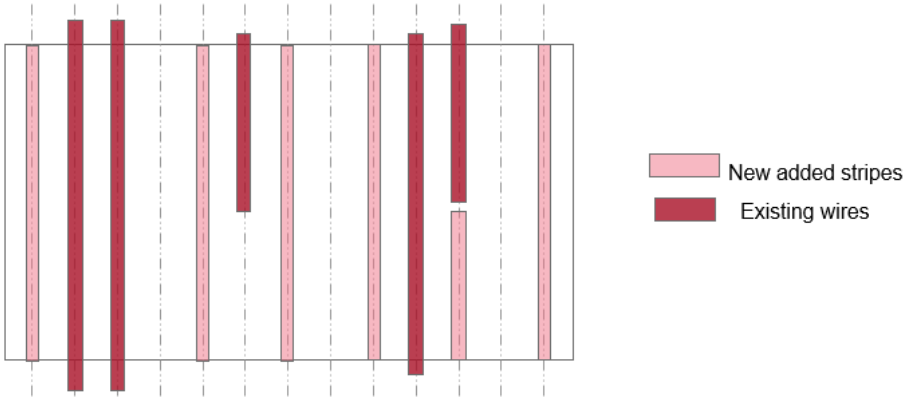


- The following command defines pattern for the pattern template of reinforce stripes with the following `pattern.tcl` file values:

```
NAME    smart1
TYPE    SMART
NETS    VDD
LAYERS    M5
PITCHFACTOR    2
VIACONTROL    M2 M6
UDA    PGSmart_1

reinforce_pg -pattern_file pattern.tcl -pattern_map {0.04 smart1}
```

The following is the output of the above command:

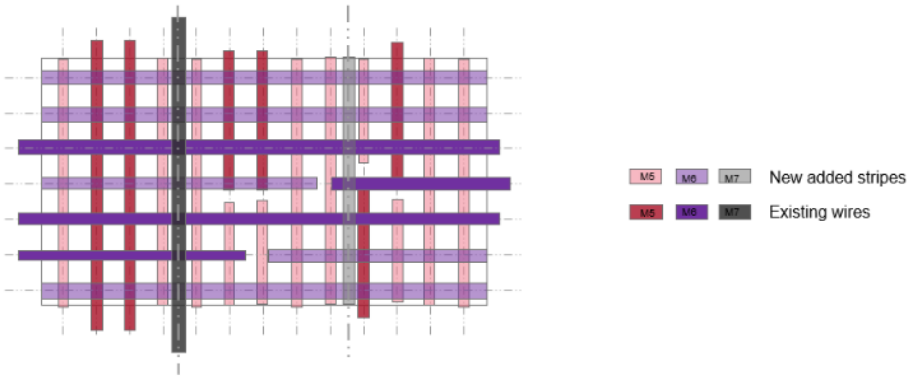


- The following command defines pattern for the pattern template of reinforce stripes on multiple layers with the following `pattern.tcl` file values:

```
NAME    smart1
TYPE    SMART
NETS    VDD VSS
LAYERS    M5:M7
VIACONTROL    M4 M10
UDA    PGSmart_1

reinforce_pg -pattern_file pattern.tcl -pattern_map {0.04 smart1}
```

The following is the output of the above command:



- The following command presents an example of defining a pattern file parameters and calculating the number of additional stripes to be added between two adjacent stripes of the same net:

  ```
  reinforce_pg -pattern_file pattern.tcl -pattern_map {0.03 PATTERN1}
  ```

  The following is the output of the above command:

  
  The following are the contents of the defined `pattern.tcl` file:

  ```
  NAME  PATTERN1

  NETS   VDD

  LAYER  M5

  MAXPITCH    15

  MINDISTANCE      5

  WIDTH  0.3

  VIACONTROL  {M4 M6}

  UDA  PGFIX_1
  ```

  Additional stripes can only be added when the distance between the two adjacent stripes of the same net is more than `MAXPITCH` and `2*MINDISTANCE`, as shown below:

  ```
  Distance1 > MAXPITCH  &&  Distance1 > 2*MINDISTANCE
  ```

  To calculate the number of additional stripes to be added between two adjacent stripes of the same net:

  ```
  N = ceil (distance1 / MAXPITCH)
  ```

  The `N-1` stripes will be evenly distributed between two adjacent stripes with:

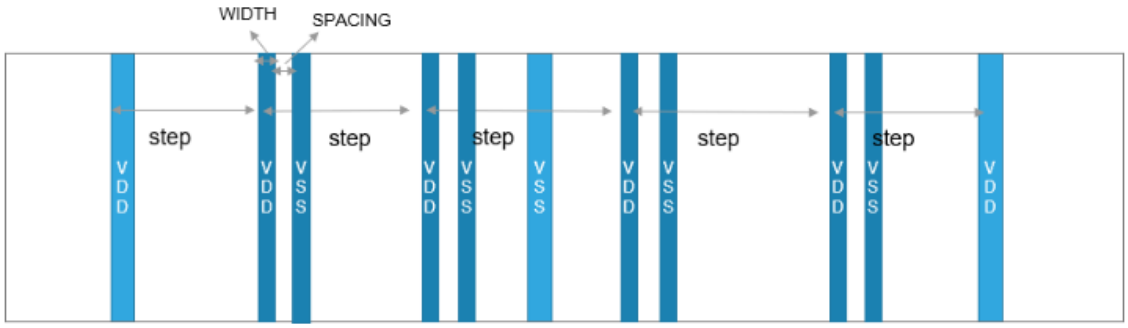
  ```
  step = distance1/N
  ```

  Note: When some new stripes added between two adjacent stripes are shifted and the distance between them is more than the `Maxpitch`, the tool adds extra stripe to satisfy the `Maxpitch` defined.

- The following command defines a metal layer with two nets:

  ```
  reinforce_pg -pattern_file pattern.tcl -pattern_map {0.06 pattern2}
  ```

The following is the output of the above command:



The following are the contents of the defined `pattern.tcl` file:

```
NAME        pattern2
NETS         VDD VSS
LAYER                M5
MAXPITCH          10
MINDISTANCE    3
WIDTH         0.3
SPACING         0.3
VIACONTROL     {M2 M8}
UDA         PGFIX_2
```

- The following command defines two metal layers in the same direction and the `MAXPITCH` and `MINDISTANCE` parameters with one value. Here, the `M6` metal layer should align with `M4`. The number and location of the additional stripes will depend on the first layer defined:

  ```
  reinforce_pg -pattern_file pattern.tcl -pattern_map {0.06 pattern3}
  ```

  The following is the output of the above command:

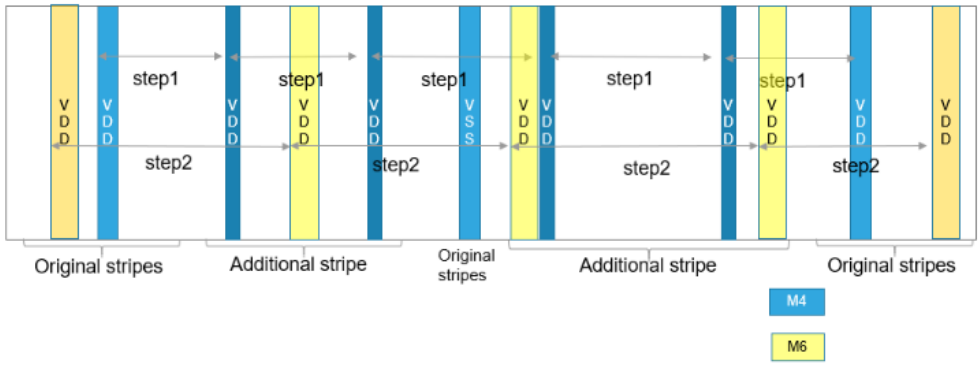
  The following are the contents of the defined `pattern.tcl` file:

  ```
  NAME  pattern3
  NETS   VDD
  LAYER  M4 M6
  MAXPITCH       20
  MINDISTANCE    5
  WIDTH  0.3  0.5
  VIACONTROL {M3 M5}  {M5 M7}
  UDA  PGFIX_3
  ```

- The following command defines two metal layers with same direction and and `MAXPITCH` and `MINDISTANCE` parameters with two values. The additional stripes of two metal layers will also be added respectively:

  ```
  reinforce_pg -pattern_file pattern.tcl -pattern_map {0.06 pattern4}
  ```

  The following is the output of the above command:



The following are the contents of the defined `pattern.tcl` file:

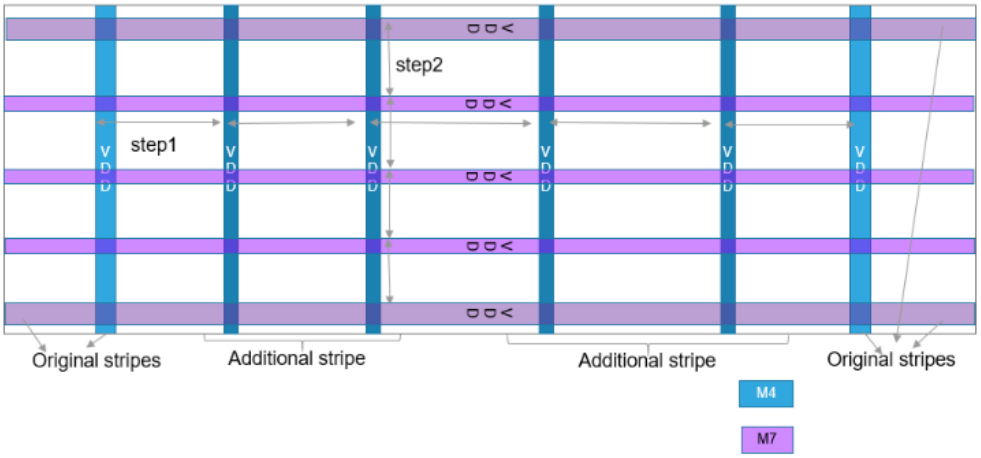
```
NAME  pattern4
NETS   VDD
LAYER  M4 M6
MAXPITCH       20 30
MINDISTANCE    5   8
WIDTH  0.3  0.5
VIACONTROL {M3 M5}  {M5 M7}
UDA  PGFIX_3
```

The `M4` and `M6` metal layers calculate this step respectively, where `M4` uses `step1` and `M6` uses `step2` to generate PG.

- The following command defines two metal layers with different directions and `MAXPITCH` and `MINDISTANCE` parameters with two values. The additional stripes of two metal layers will also be added respectively:

  ```
  reinforce_pg -pattern_file pattern.tcl -pattern_map {0.06 pattern5}
  ```

  The following is the output of the above command:



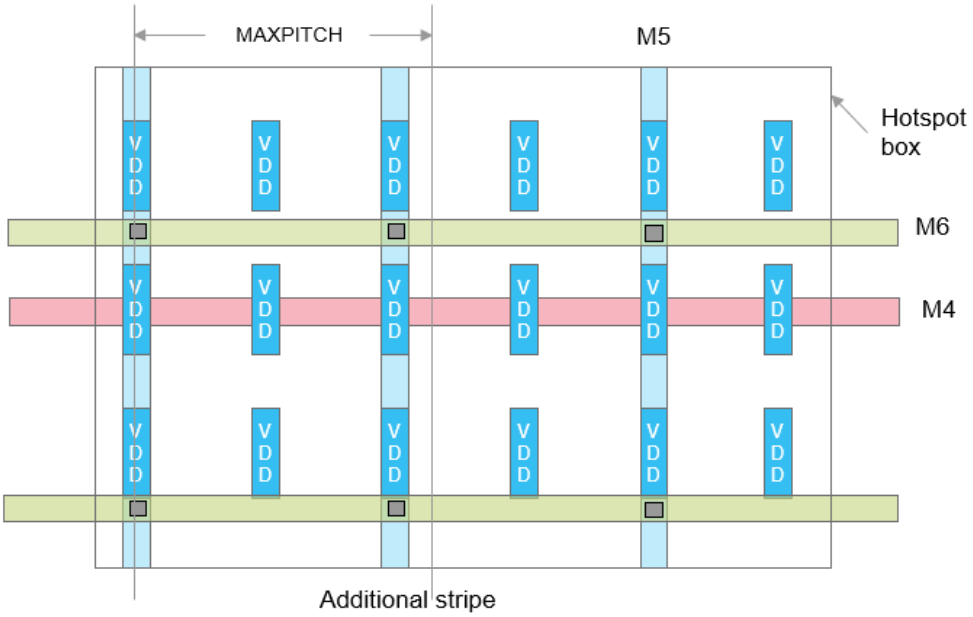
The following are the contents of the defined `pattern.tcl` file:

```
NAME  pattern5
NETS   VDD
LAYER  M4 M7
MAXPITCH       20 30
MINDISTANCE    5   8
WIDTH  0.3  0.5
VIACONTROL {M1 M5}  {M6 M10}
UDA  PGFIX_3
```

- The following command defines a metal layer with the `OVERVIAMETAL` keyword:

  ```
  reinforce_pg -pattern_file pattern.tcl -pattern_map {0.06 pattern6}
  ```

  The following is the output of the above command:



The following are the contents of the defined `pattern.tcl` file:

```
NAME pattern6
OVERVIAMETAL
NETS VDD
LAYER M5
MAXPITCH    15
MINDISTANCE      5
WIDTH 0.3
VIACONTROL  {M4 M6}
UDA PGFIX_1
```

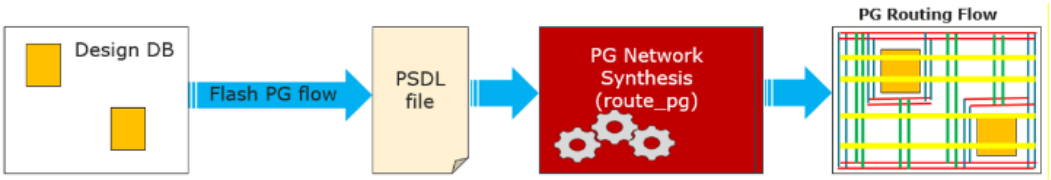
route_pg

```
  route_pg
[-help]
[-check_psdl_only]
[-delete_floating]
[-fast]
[-psdl_file file_name]
[-skip_block_pin]
[-skip_partial_overlap_via]
[-skip_via]
[-write_psdl output_file]
```

Uses the Innovus database, builds the region with the help of PSDL, where the PG structure is to be created, and parses it. This command also uses all the syntax in PSDL to build the PG structure.

The following figure presents the process of developing a PG routing flow using the `route_pg` command:



Parameters

`-help`	Outputs a brief description that includes the type and default information for each `route_pg` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man route_pg`
`-check_psdl_only`	Performs sanity check only on the PSDL input file.
`-delete_floating`	Removes floating wires.
`-fast`	Generates PG routing flow in the Fast PG mode.
`-psdl_file file_name`	Specifies the PSDL input file.
`-skip_block_pin`	Skips the formation of connection to the block pins.
`-skip_partial_overlap_via`	Skips building of via on partial overlap intersection. See the example below: 
`-skip_via`	Skips building via object.
`-write_psdl` *output_file*	Writes a PSDL file to ensure that the input numerical/string Tcl variable is correctly calculated and applied.

Examples

- The following command checks the `-psdl_file` syntax only (without running the `route_pg` command):
  `route_pg -fast -psdl_file` *filename* `-check_psdl_only`
- The following command removes a floating wire:
  `route_pg -fast -psdl_file` *psdl_file* `-delete_floating`
- The following command does not generate via while running the `route_pg` command:
  `route_pg -fast -psdl_file` *psdl_file* `-skip_via`
- The following command skips partial generated vias:
  `route_pg -fast -psdl_file` *psdl_file* `-skip_partial_overlap_via`
- The following command generates a PG structure in the Fast PG mode and writes a PSDL file during its run:
  `route_pg -fast -psdl_file` *file_name* `-write_psdl` *output_file*
- The above command generates a PG structure in the Complete PG mode and writes a PSDL file during its run:
  `route_pg -psdl_file` *file_name* `-write_psdl` *output_file*
- The above command checks the PSDL syntax and writes a PSDL file without generating the PG structure:
  `route_pg -psdl_file` *file_name* `-check_psdl_only -write_psdl` *output_file*

saveSpecialRoute

```
saveSpecialRoute
[-help]
filename
-pre10
```

Saves special route information in a file. If the specified filename is compressed (with the `.gz` extension), the file is gzipped.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `saveSpecialRoute` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man saveSpecialRoute`
`filename`	Specifies the name of the output file into which special route information to include metal fill is saved. The file is saved in the `.spr` format.
`-pre10`	Saves the routing file with an older version.

Related Information

- `addSpecialRoute`

set_add_target_pg_mode

```
  set_add_target_pg_mode
[-help]
[-allow_weak_connect {true | false}]
[-max_extension_distance value]
[-pins {cell1:pin1 cell1:pin2 cell2:pin1 ...}]
[-pins_group_distance value]
[-reset]
[-respect_routes {none | fixed | fixed_and_clock | all}]
[-share_resource {true | false}]
```

Sets global variables for the `add_target_pg` command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `set_add_target_pg_mode` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man set_add_target_pg_mode`
`-allow_weak_connect {true | false}`	When this parameter is set to `false`, the number of wires created on every stack layer need to satisfy the defined count with DRC clean. Else, the PG pin is left open. When set to `true`, the count lesser than defined can also be accepted while creating the total count causing DRC. *Default*: `false`
`-max_extension_distance value`	Specifies the maximum distance that the target PG pin can extend to the target layer. If the distance between the target PG pin and the candidate target layer is lesser than or equal to the specified distance, the candidate target is treated as the real target. If the target PG wire cannot be found within `-max_extension_distance`, the instance is left open. If this parameter is not used, the software connects the stripe layer to the closest target PG wire with DRC clean, by default. See the figure below for understanding:  *Default*: `2147483647`
`-pins {cell1:pin1 cell1:pin2 cell2:pin1 ...}`	

	Specifies the cell pins to be connected. *Default*: ""
`-pins_group_distance value`	Specifies the side-to-side distance of the pins to be treated as a group while connecting the target PG pins. The pins belonging to the same group share the same target PG stripes connection. When this parameter is set to its default value, `auto`, the `add_target_pg` command uses the default behavior of target PG generation to group the pins. If this parameter is not specified, the software uses the pitch of metal layer above the pins layer with same direction (`layer_pin+2`) as the group distance. If the pitch of metal layer above the pins layer with the same direction (`layer_pin+2`) is not defined, the pins will be connected separately. If the distance between two pins is lesser than `group_distance`, they will be treated as one group. See the figure below for understanding:  When `pins_group_distance` is not defined, the software uses the pitch of the metal layer above the pins layer with the same direction (`layer_pin+2`) as the group distance. See the figure below for understanding:  The following figure presents how the target PG pin's horizontal offset affects the stapling sharing:

	`-reset`	Resets all or specified parameters to their default values.
`-respect_routes {none | fixed | fixed_and_clock | all}`	
	Specifies the route types to respect for DRC check during target PG generation. This parameter always honor all covers and PGs, but does not honor the trail routes, Following are the parameter values: • `none`: Specifies that no route types are respected. • `fixed`: Respects fixed regular wires. • `fixed_and_clock`: Respects fixed and routed clocks. • `all`: Respects fixed and routed clocks along with the routed signals. For more information on the support of the `set_add_target_pg_mode -respect_route` parameter values with various statuses of net, see Support of set_add_target_pg_mode -respect_route Parameter Values. *Default*: `fixed_and_clock`
`-share_resource {true | false}`	When set to `true`, the newly added PGs of the intermediate stacked layer can connect to the existing PG wire of the same layers and are preferred to be shifted to the track of the existing PG to save the track resource. If there are DRCs between the added PG and the existing PG after shifting, the added PG will follow the behavior explained below: • If the added wire is on different net from the existing PG, it will be shifted again to avoid DRC. • If the added wire is on the same net of the existing PG, it will be merged with the existing wire. When set to `false`, the stacked layer cannot connect to the existing intermediate layers between the cell PG pin and target PG layer. Additionally, the newly added PG will be shifted if its original location causes DRC. *Default*: `true`

Support of set_add_target_pg_mode -respect_route Parameter Values

The following table presents the support of the `set_add_target_pg_mode -respect_route` parameter values with various statuses of net:

Target PG Honoring a Wire			-respect_route Values			
Net Use	**Status**		**none**	**fixed**	**fixed_and_clock**	**all**
P/G			Yes	Yes	Yes	Yes
Non-P/G	**Cover**		Yes	Yes	Yes	Yes
	Fixed		No	Yes	Yes	Yes
	Routed	**Clock**	No	No	Yes	Yes
		Signal	No	No	No	Yes
	Unknown		No	No	No	No

- `add_target_pg`
- `get_add_target_pg_mode`

set_reinforce_pg_mode

```
  set_reinforce_pg_mode
[-help]
[-auto_ir_fix_effort {low | medium | high}]
[-critical_path_slack {slack}]
[-irdrop_hierarchical_block {block1 block2 ... | *}]
[-irdrop_hierarchical_top_rail_analysis_directory {directory_name}]
[-reset]
[-respect_defined_nets {file_name}]
[-respect_routes {none | fixed | fixed_and_clock | all}]
[-respect_stdcell_geometry {none | sequential | all}]
[-timing_aware_effort {none | low | medium | high}]
```

Sets global variables for the `reinforce_pg` command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `set_reinforce_pg_mode` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man set_reinforce_pg_mode`
`-auto_ir_fix_effort {low | medium | high}`	
	Specifies the IR fixing effort level during the stripe generation. Use this parameter to control the IR fixing effort. The number of fixed tiles is changed according to the effort settings. The higher the effort value, the larger number of tiles are passed back from Voltus to RPG for polygon insertion, which results in insertion of more polygons. ⚠ This parameter works only with the `reinforce_pg -auto_ir_fix` parameter. *Default*: `low`
`-critical_path_slack {slack}`	
	Specifies a slack threshold value (in nanoseconds) for critical nets during timing-driven PG stripe reinforcement. It means that `reinforce_pg` honors all the violation paths with slack value lesser than the specified `-critical_path_slack` value, since all such associated nets are considered critical. *Default:* `0`
`-irdrop_hierarchical_block {block1 block2 ... | *}`	
	Reports the IR drop violations on the specified list of hierarchical block(s) to fix IR drop. The names of the specified hierarchical blocks should be instantiations of the same master block, which is the loaded block. If you specify the `*` value of this parameter, all the instantiations of the loaded block are considered.
`-irdrop_hierarchical_top_rail_analysis_directory {directory_name}`	
	Reads the rail analysis information of full chip available in the specified directory for the hierarchical flow blocks. It collects the IR drop information of the specified block and uses it to fix the IR drop.
`-reset`	Resets all or specified parameters to their default values.
`-respect_defined_nets {file_name}`	
	When this parameter is used, `reinforce_pg` respects the user-defined nets listed in the specified file, which are critical in stripe generation. This helps in reserving space around the specified nets, and the newly added PG wires are DRC clean with these nets. This parameter is independent of the `-respect_routes` parameter. However, when it is used together with the `-respect_routes` parameter, `reinforce_pg` respects all of them. *Default*: ""

`-respect_routes {none | fixed | fixed_and_clock | all}`

Specifies the route types to honor check of pre-existing routes during stripe generation. This parameter always honor all covers and PGs, but does not honor the trail routes, Following are the parameter values:

- `none`: Specifies that no route types are respected.
- `fixed`: Respects fixed regular wires.
- `fixed_and_clock`: Respects fixed and routed clocks.
- `all`: Respects fixed and routed clocks along with the routed signals.

For more information on the support of the `set_reinforce_pg_mode -respect_route` parameter values with various statuses of net, see Support of set_reinforce_pg_mode -respect_route Parameter Values.

Default: `fixed_and_clock`

`-respect_stdcell_geometry {none | sequential | all}`

Specifies all types of geometries (including `pin` and `obs`) to be respected in via generation. This parameter checks the standard cell types to decide weather the DRC violation needs to be checked on its geometries (including `pin` and `obs`) in via generation.

Default: `all`

`-timing_aware_effort {none | low | medium | high}`

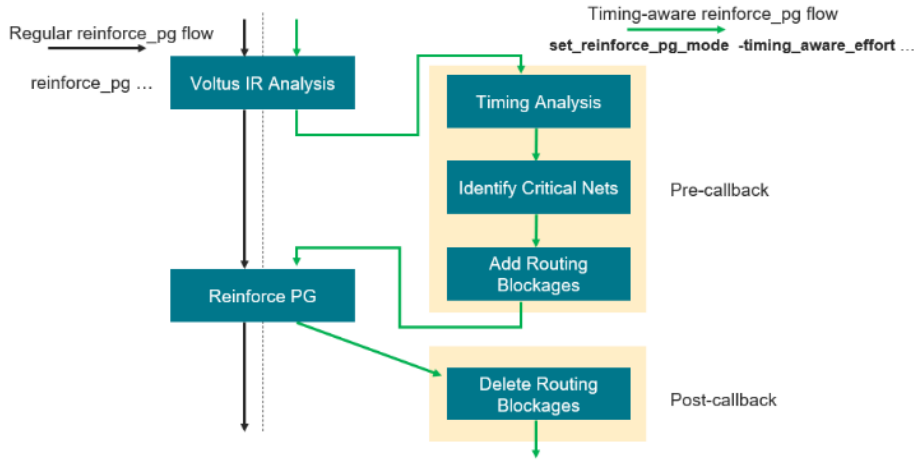
Specifies the timing aware effort level on critical paths of `reinforce_pg`. The `reinforce_pg` command performs timing analysis, when the `-timing_aware_effort` parameter is set to `low`, `medium`, or `high`. Use the `set_reinforce_pg_mode -critical_path_slack` parameter to determine the slack range.

When the `set_reinforce_pg_mode -critical_path_slack` parameter is not defined, following will be the behavior of the non-default values of `-timing_aware_effort`:

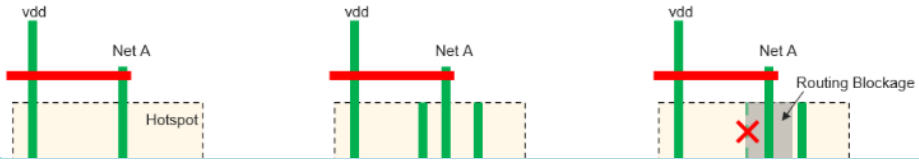
- `low`: Timing clock protection is performed, which uses slack value and reserve space size.
- `medium`: Performs clock protection, with `max_slack` as 10+ ps (since 10ps is used to cover the borderline paths), `max_path` as `number_of_flops`, and `nworst` as 1. You can set the `-critical_path_slack` parameter to overwrite this value, `max_path` to cover all the end points and single worst path per end point.
- `high`: Performs clock protection, with `max_slack` as 10+ ps (since 10ps is used to cover the borderline paths), `max_path` as `10 * number_of_flops`, and `nworst` as `10,2 * blockage_size`. You can set the `-critical_path_slack` parameter to overwrite this value, `max_path` to cover all the end points and single worst path per end point, with covering 10 worst paths per end point.

⚠ The `-critical_path_slack` parameter can work only when the `-timing_aware_effort` parameter is set to `low`, `medium`, or `high`.

See the figure below for understanding the timing aware reinforce PG flow:



The following figure presents reserving of spaces around critical net using with and without the `-timing_aware_effort` parameter:



Support of set_reinforce_pg_mode -respect_route Parameter Values

The following table presents the support of the `set_reinforce_pg_mode -respect_route` parameter values with various statuses of net:

Target PG Honoring a Wire			-respect_route Values			
Net Use	**Status**		**none**	**fixed**	**fixed_and_clock**	**all**
P/G			Yes	Yes	Yes	Yes
Non-P/G	**Cover**		Yes	Yes	Yes	Yes
	Fixed		No	Yes	Yes	Yes
	Routed	**Clock**	No	No	Yes	Yes
		Signal	No	No	No	Yes
	Unknown		No	No	No	No

Sets global variables for block rings and core rings when you use the `addRing` command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `setAddRingMode` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man setAddRingMode`
`-avoid_short {true | false}`	
	Specifies whether to prevent a ring or a ring segment from being created if it would cause a short violation to occur. Specify `1` to prevent the creation of rings that would cause a short violation. Specify `0` to enable the creation of rings that cause a short violation. *Default:* `false`
`-break_core_ring_io_list io_list`	
	Breaks or excludes core rings for specific instances.
`-continue_on_no_selection {true | false}`	
	If the design has no power domain, or no fences are selected, `addRing` ignores the option `-around power_domain` and generates core rings. Default: false
`-detailed_log {true|false}`	
	Setting this option will make `addRing`, `addStripe` output an extensive log or a detailed log. *Default:* false
`-extend_blockring_search_distance` *distance*	

	Extends the block ring search a specified distance beyond the initial block ring target to enable the connection of multiple block ring targets. For example, if VDD consists of three bits (segments) running parallel to one another, each having a width of two microns and a spacing between them of one micron, using this variable with a specified distance of eight microns will extend the block ring search a distance of eight microns to enable a connection to the multiple block ring targets. The *distance* is specified as the measured distance from the first to last bits. Units in microns.
	Note: You must specify this variable before using the addRing command. When using the command, you must include the following parameters:
	`-use_wire_group_bits 1`
	`-use_wire_group 1`

`-extend_corering_search_distance` *distance*	
	Specifies the wire group search distance for connecting all bits of the wire group stripes. *Default*: 0.0
`-extend_merge_with_prewires {true | false}`	
	Automatically merges newly-created ring wires with same net pre-routed wires. *Default*: `true`
`-extend_over_row {true | false}`	
	If 1 is specified, the cut row is not considered a blockage by the addRing command, which generates the ring over the cut row. If `0` is specified, the cut row is considered a blockage and the ring is not generated over the row. Rings are created based on the parameters that you specify in the addRings command. *Default: false*
`-extend_search_nets {* | {net_names}}`	
	Specifies the net names to append to the wire group search distance properties.
`-extend_stripe_search_distance` *distance*	
	Specifies the wire group search distance for connecting all bits of the wire group core rings. *Default*: `0.0`

`-gap_width_without_io  width`	
	Specifies the max missing IO Pads area width between IO Pads. *Default:* `0`
`-ignore_rows {true | false}`	
	Specifies whether the power planning software ignores all rows (cut rows and native rows) when rings are created. Specify `1` to create rings that ignore rows. Specify `0` to create rings that do not ignore rows. *Default:* `false`
`-max_via_size {`*`shape width% height% target_penetration%`*`}`	
	The maximum size of a crossover via, specified as a percentage of a full-size via. You must specify three values for each shape that you specify. The type values are: • Pad • Ring • Stripe • Blockring • Blockpin • Cover • Noshape The three values you must specify for each shape are: • The maximum width for the crossover via, as a percentage of a full-size via • The maximum height for the crossover via, as a percentage of a full-size via • The target penetration, which specifies a smaller size for vias connecting to targets of the specified shape.
`-orthogonal_only {true | false}`	
	Creates vias *only* for orthogonal wires and pin intersections. *Default*: If you do not specify this parameter or if you specify it with a value `true`, the software only creates vias for orthogonal wires and pin intersections.
`-reset`	Resets all parameters to their default values. Any values that do not already match the default value and are reset. will be reported.
`-ring_target {core_ring | default | first_ring | pad_ring | stripe}`	
`core_ring`	Ring wires can consider core rings as targets, even when core rings are inside the I/O pad area. Only rings are considered targets.
`pad_ring`	Ring wires can be extended to pad rings.
`first_ring`	Ring wires consider either the first core ring or the pad ring as a target.

`stripe`	Both rings and stripes are considered targets.
	Note: You can specify that rings are extended to both pad rings and to stripes. To do this you must specify the ring_target parameter twice, as show in the following example:
	`-ring_target stripe`
	`-ring_target pad_ring`

`-skip_crossing_trunks {horizontal | vertical | none}`	
	Removes the horizontal or vertical portion of rings (shared or inside edges) when used in conjunction with the addRing -block_rings -around shared_cluster command.
`-skip_via_on_pin {[Pad] [Block] [Cover] [Standardcell] [Physicalpin]}`	

	Prevents vias from being generated on the specified types of pins. If you specify `-skip_via_on_pin {}`, the power planning software makes connections to all five categories of pins. *Default:* If you do not specify this parameter, vias are generated for block pins, pad pins, and cover macro pins, but are not generated for standard cell pins.
`-skip_via_on_wire_shape {blockring | stripe | followpin | corewire | blockwire | iowire | padring | ring | fillwire | noshape}`	
	Prevents vias from being generated on the specified wire shapes. If you specify `-skip_via_on_wire_shape {}`, the power planning software makes connections to all five categories of wire shapes. *Default:* If you do not specify this parameter, vias can be generated on all wire shapes *except* no-shape wires.
`-spacing_from_block` *value*	
	To be used together with `-break_core_ring_io_list` *io list* to specify the spacing from block.
`-split_long_via {`*threshold_value step_value offset_value height_value*`}`	
	Splits vias longer than the specified length (`threshold_value`, in micrometers) into smaller vias with specified center-to-center spacing (`step_value`, in micrometers), left/bottom end offset (`offset_value`, in micrometers) and vertical/horizontal height (`height_value`, in micrometers) values . This is independent of the option `-split_via`. *Default:* If you do not specify this parameter, the software does not split vias. **Note:** If the offset_value is given as negative, the vias will be placed symmetrically on both ends. The default value of `offset_value` is `-1`.
`-stacked_via_bottom_layer` *layername*	
	Specifies the lowest layer in which vias can be stacked. *Default:* The lowest metal layer in the design.
`-stacked_via_top_layer` *layername*	
	Specifies the highest layer in which vias can be stacked. *Default:* The highest metal layer in the design.
`-wire_center_offset{true | false}`	
	Used for calculating the offset. When set to 1 `addRing` will use wire centre. When set to 0, `addRing` will use wire boundary. *Default*: false
`-via_using_exact_crossover_size {true | false}`	
	Specifies whether to generate partial vias of the exact crossover size. A value of `1` allows partial vias to be generated. A value of `0` prevents partial vias, and the software always generates full-size vias. *Default:* `true`

Example

The following command specifies that rings can use stripes as targets and that the rings generated around clusters of block rings with shared edges do not have horizontal wires between the blocks.

```
setAddRingMode -ring_target stripe -skip_crossing_trunks horizontal
```

Sets global variables for power stripes.

Parameters

`-help`	
	Outputs a brief description that includes the type and default information for each `setAddStripeMode` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man setAddStripeMode`
`-allow_jog {none|{[padcore_ring ][block_ring ]}}`	
	Specifies the type that stripe can jog to connect. If set to `padcore_ring` and/or `block_ring`, the stripes are allowed to be on the same/different metal layer to connect to `padcore_ring`/`block_ring`. If set to `none`, the stripe is not allowed to jog on any layer. A straight/direct connection (no jog) with switch layer is allowed to make the connection. *Default:* `padcore_ring block_ring`
`-allow_nonpreferred_dir {none | blockring| corering | padring | stripe}`	
	Specifies whether to allow non-preferred direction to jog to target. When set to `none`, the non-preferred direction jogging is disabled. **Note:** 1. '0' or 'false' is not a legal value in this option. 2. There are five available option values in this option. 3. The value 'none' is exclusive to other option values. 4. The default value is `padring`.
`-area { lx ly ux uy | x1 y1 x2 y2 x3 y3 ...}`	

	Specifies the coordinates of the rectangular and/or rectilinear areas in which the stripes to be created. It appends the specified area to previous ones.
	Default:""
	Note:
	• If `setAddStripeMode -area` conflicts with `addStripe -area`, `addStripe -area` being on higher priority, `setAddStripeMode -area` is ignored.
	• If stripes are only to be created in the area in current command, reset the previous areas by one of the following three ways:
	`setAddStripeMode -reset -area`
	`setAddStripeMode -area {}`
	`setAddStripeMode -area ""`
	• When this parameter is used with `setAddStripeMode -domain_offset_from_core true`, the `-start_offset` value for specified area is measured from core on using `setAddStripeMode -area`.

`-break_at {none|{[block_ring] [selected_block] [unassigned_bump][overlap_ringpin] [outer_ring][outside_ringmacro] [blocks_without_same_net]}}`	

Specifies the break point of stripes.

Default: `none`

If any of the options `block_ring`, `selected_block`, `unassigned_bump`, `overlap_ringpin`, `outer_ring` or `outside_ringmacro` is specified, the stripe breaks when it encounters the specified structure that are not in the same wire group.

`block_ring`
Stripes break and connect to the block rings and ring pins if they are encountered.

Note: This parameter applies only to block rings that surround a block, and does not apply to block rings that surround rows or standard cells. If the block
is a ring macro, the stripe will break at the ring pin inside the block ring.

`selected_block`
Stripes stop at the block boundary when the block does not contain a blockage.

Stripes stop at the block boundary when the block contains a blockage and spacing from the block boundary to the edge of the blockage is greater than the minimum spacing value of that layer.

Stripes stop at the minimum spacing away from the blockage when the spacing from the block boundary to the edge of the blockage is less than the minimum spacing of that layer.

Note: If the selected block has block ring, stripes break and connect to the block ring.

`unassigned_bumps`
Stripes break at unassigned bumps. It prevents the unassigned bumps from being ignored and shorted with the power and ground nets by the stripes created in the same metal layer.

`overlap_ringpin`
Prevents stripes from overlapping with same direction ring pins of a different net.

Note: This option is only valid if the ring pin is more than half the length of the macro in the direction of the ring pin.

`outer_ring`
When a stripe encounters nested block rings or ring pins that are not in the same wire group, the stripe breaks at the outer ring. If not specified, the stripe breaks at the innermost ring.

Note: This parameter works only in conjunction with the following values of `setAddStripeMode -break_at`:

- `block_ring`
- `selected_block`

`outside_ringmacro`
Stripes break at a small distance outside the block if the selected block has ring pins.

Note: This parameter is available only if you also specify `setAddStripeMode -break_at selected_block`

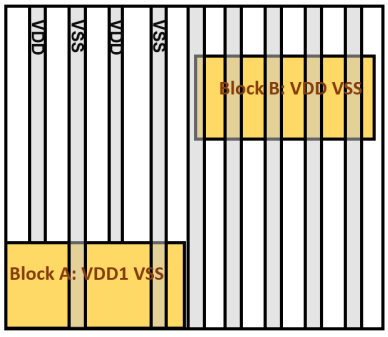
`blocks_without_same_net`
Breaks stripes at blocks, where no pin has same net as the nets specified in the `addStripe` command.

Example

Block A has power supply VDD1 and VSS, Block B has power supply VDD and VSS, commands are as follows:

```
setAddStripeMode -break_at blocks_without_same_net
addStripe -nets {VDD VSS}…
```

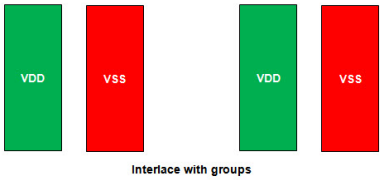
In the above commands, VDD breaks at Block A, VSS goes through Block A, VDD and VSS will go through Block B. Refer to the screen below:



`-color_balance {same_color | alternate_color | none}`

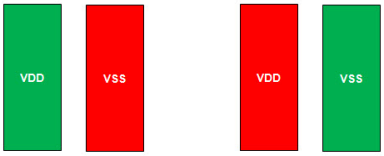
Specifies addition of VDD/VSS stripes with balanced color.

`same_color`
Corresponds to interlace with groups.



Interlace with groups

`alternate_color`
Corresponds to interlace within the group.



Interlace within groups

To achieve color balancing, the color of stripes occupying even number tracks is picked alternatively.

Note: The stripes location will always be either on full grid/track or half grid/track:

- If the stripes occupy odd number of tracks, they must be on full grid.
- If the stripes occupy even number of tracks, they must be on half grid.

To achieve color balance, the stripes color will be as mentioned below:

- If the stripes occupy odd number of tracks, the color is opposite to the center track color.
- If the stripes occupy even number of tracks, the color can be any of red or green and will keep alternating.

Only two nets are supported.

The option must be specified along with `-recommend_width`.

`-continue_on_no_selection {true | false}`

If the design has no power domain, or no fences are selected, `addStripe` ignores the option `-over_power_domain`, and generates stripes extending to core ring.

Default: `false`

`-detailed_log {true | false}`

Setting this parameter will make the `addStripe` output an extensive log or a detailed log.

Default: `false`

`-domain_offset_from_core {true | false}`

Creates stripes over a power domain to align with the global stripes in your design by enabling you to use the offset that was used for the global stripes as the offset for the power domain stripes. This parameter uses the offset from the core, which is the default for global stripes.

Default: `false`

`-extend_to_closest_target {none | stripe | ring | same_dir_stripe | area_boundary}`

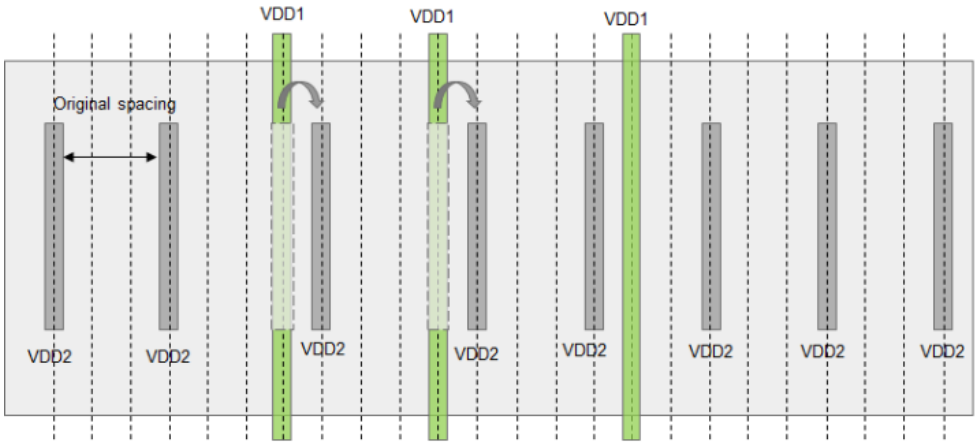
	Extends the stripe to the specified target. This parameter can work in conjunction with: `setAddStripeMode -max_extension_distance` Following is the description of the parameter values: • `none`: Restricts the stripe from extending to any target. • `stripe`: Allows the stripe to extend to the nearby stripe. • `ring`: Allows the stripe to extend to the nearby ring. • `same_dir_stripe`: Allows the stripe to extend to the stripe in the same direction. • `area_boundary`: Allows the stripe to extend to certain area boundary. *Default*: `none`
`-extend_to_first_ring {true | false}`	
	If set to `true`, stripe antennas are extended to the closest ring. If set to `false`, stripes stop at the boundary specified by the `-extend_to` parameter of the command. *Default*: `false`
`-ignore_block_check {true | false}`	
	If set to `false`, when a stripe encounters a ring, the software does not check whether that ring is surrounding a block. If set to `true`, when a stripe encounters a ring, the software automatically checks whether a block is enclosed within the ring. **Note:** This parameter only works in conjunction with the `-break_at` parameter of the `addStripe` command. *Default:* `false`
`-ignore_blockring_when_breaking {true | false}`	
	If set to `true`, breaks the stripe outside the block if the stripe cannot go over the block. If set to `false`, breaks the stripe at the block ring if it cannot go over the block. Default: `false`
`-ignore_nondefault_domains {true | false}`	
	Creates global stripes over domains without breaking. If you do not want the stripes to break at the non-default domains, set this variable to `true` before using the `addStripe` command. *Default*: `false`
`-ignore_DRC {true | false}`	
	Setting this parameter creates stripes ignoring DRCs but honoring user defined values. To be used for prototyping only. Default: `false`
`-inside_cell_allow_shift {true | false}`	

Allows to shift the newly created pillars when meeting DRC, if there is already an existing `special_wire` on the given track. This parameter works only when the `-inside_cell_only` parameter is set to `true`.

When the `-inside_cell_allow_shift` parameter is set to `false`, the pillar is removed when meeting violation. When set to `true`, the newly created pillar is shifted to right among the three tracks when meeting violation. The next pillar's position depends on the final position of the current pillar.

The distance between these pillars should satisfy the user specified spacing. The spacing between the two pillars should not be smaller than the user-specified spacing.

The following example shows that using the `-inside_cell_allow_shift` parameter, the newly created pillars of `VDD2` are shifted right to avoid DRC with `VDD1`.



Default: `false`

`-inside_cell_only {true | false}`

Control whether the stripe will be generated inside selected or specified instances. If no instance is selected or without the `addStripe -master`, no stripe will be generated.

Default: `false`

Note: When `setAddStripeMode -inside_cell_only true` is used with `setAddStripeMode -domain_offset_from_core true`, the `-start_offset` value for the value specified std-cell area is measured from core on using `setAddStripeMode -inside_cell_only true`.

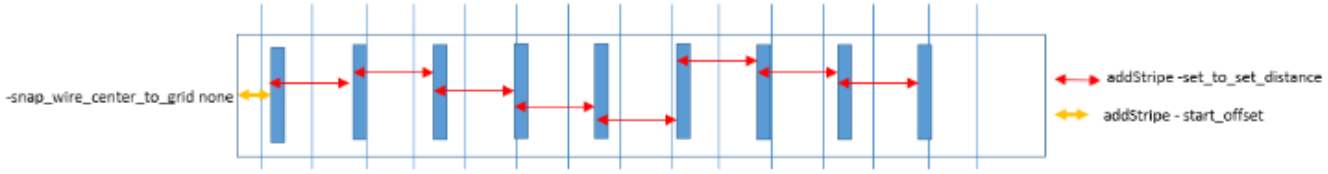
`-keep_pitch_after_snap {true | false}`

When set to `true`, the distance between two PG sets for snapping is set to greater than or equal to the pitch value specified through the `addStripe -set_to_set_distance` parameter. When set to `false`, the newly created PG sets are snapped from the current location to the nearest location valid for the `-keep_pitch_after_snap` parameter. The average pitch of the newly generated stripe is approximately equal to the specified `addStripe -set_to_set_distance` parameter value.

This parameter works with the `addStripe -snap_wire_center_to_grid` parameter. The behavior of the `-keep_pitch_after_snap` parameter under different scenarios is explained below.

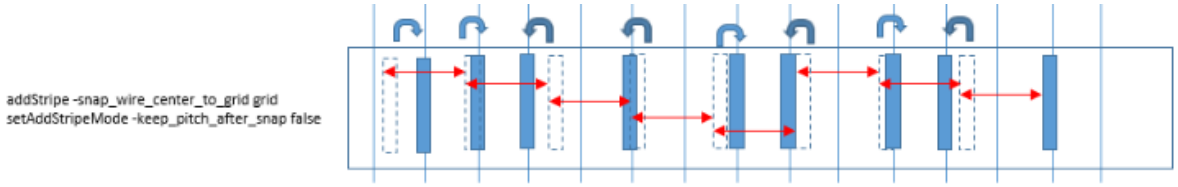
Scenario 1:

When the `addStripe -snap_wire_center_to_grid` parameter is set to `none`, the `setAddStripeMode -keep_pitch_after_snap` parameter does not work. See the example below for understanding:



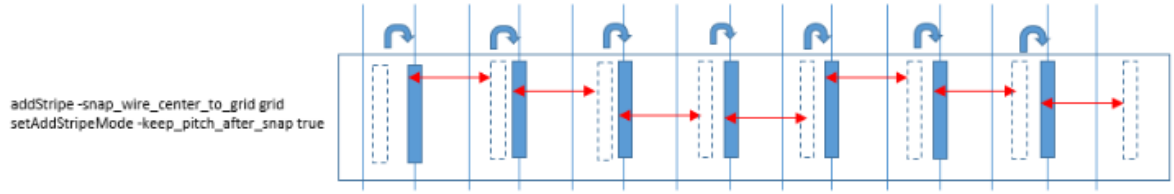
Scenario 2:

When the `addStripe -snap_wire_center_to_grid` parameter is set to `grid`, and the `setAddStripeMode -keep_pitch_after_snap` parameter is set to `false`, all the locations for snapping are decided based on the start location. Post then, the stripes are snapped to the nearest track. The average distance between of newly generated stripes is approximately equal to the specified pitch (`addStripe -set_to_set_distance` parameter value). See the example below for understanding:



Scenario 3:

When the `addStripe -snap_wire_center_to_grid` parameter is set to `grid`, and the `setAddStripeMode -keep_pitch_after_snap` parameter is set to `true`, the location for snapping is decided based on the previous location. Post then, the stripes are snapped to the next track. See the example below for understanding:



Note:

- The first stripe of the design always snaps to the next track to meet the `addStripe -start_offset` value. To start the first stripe snapping at the nearest track, set the `addStripe -allow_snapping_override_custom_spacing` parameter to `1`.
- By default, the `setAddStripeMode -keep_pitch_after_snap` parameter is turned on only at the `N10` nodes.

Default: `false`

`-max_extension_distance` *distance*

Sets the maximum extension distance between stripes to nearby stripes in the same layer and the same direction.

Default: `2.14748e+09`

`-max_via_size {shape width% height% target_penetration%}`

	The maximum size of a crossover via, specified as a percentage of a full-size via. You must specify three values for each shape that you specify. The shape values are: • Pad via size between stripe and pad pin/ring • Ring via size between stripe and core ring • Stripe via size between stripes • Blockring via size between stripe and block ring • Blockpin via size between stripe and block pin, including ring pin • Cover via size between stripe and the macro which has CLASS COVER defined in LEF • Selected via size between stripe and selected objects • No shape via size between stripe and wires with shape None • Standardcell via size between stripe and standard cell pin The three values you must specify for each shape are: • The maximum width for the crossover via, as a percentage of a full-size via • The maximum height for the crossover via, as a percentage of a full-size via • The target penetration, which specifies a smaller size for vias connecting to targets of the specified shape *Default*: ""
`-merge_with_all_layers {true | false}`	
	Merges a stripe to a block ring or pin on all layers. This parameter is similar to the `-merge_stripes_value` parameter of the `addStripe` command, except that it merges a stripe to all layers instead of only the stripe layer. *Default*: `false`
`-mesh_via {true | false}`	

Enables to use mesh via pillars to reduce memory.

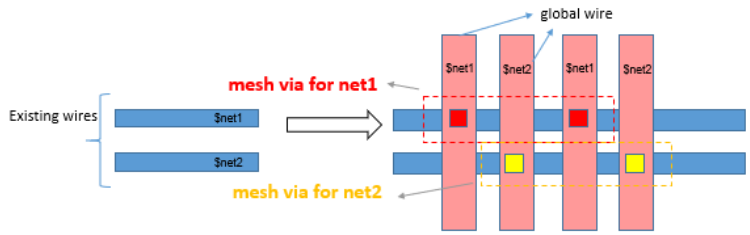
Default: `false`

Example 1:

The following commands use mesh via pillars with the help of the `-mesh_via` parameter:

```
setAddStripeMode -mesh_via 1
addStripe -nets {$net1 $net2 $net1 $net2} ...
```

Following is the output:

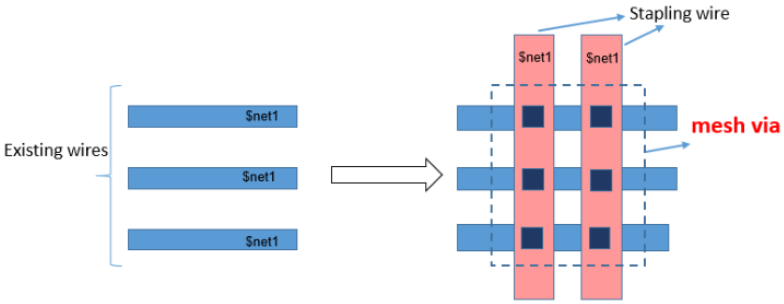


Example 2:

The following commands generate mesh via automatically in one stapling stripe:

```
setAddStripeMode -mesh_via 1
addStripe -stapling{ …} -nets {$net1 …$net1…} …
```

Following is the output:



`-offset_from_core {true | false}`

If set to `true`, the first or last stripe is offset from the core area of the design. If set to `false`, the first or last stripe is offset from core ring, pad ring, depending on the parameters specified with the option.

Note: This parameter does not affect the offset if you specify the `addStripe` command with any of the following parameters:

- `-over_power_domain 1`
- `-extend_to all_domains`
- `-area`

Default: `true`

`-optimize_stripe_for_routing_track {shift | none}`

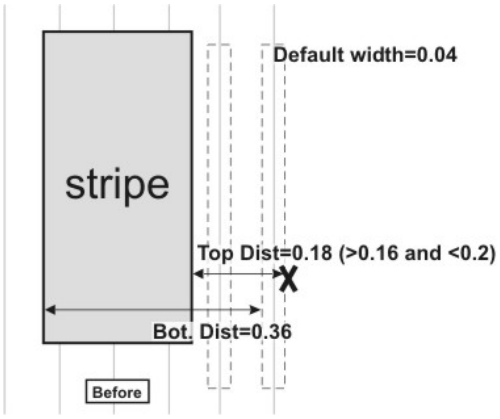
Specifies the location setting to move stripe center line to avoid the forbidden spacing. If both sides cannot be fixed at the same time, one side is always fixed.

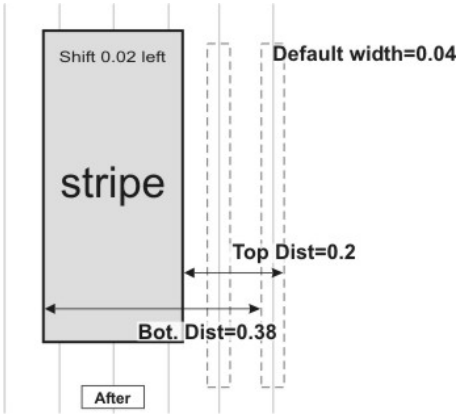
When set to `shift`, addStripe automatically shifts stripes to preserve routing resource.

Default: `none`

Example
For the rule below,

```
FORBIDDENSPACING 0.16 0.2 WIDTH 0.05 PRL 0;
```





After shifting the stripe 0.02 left, Top Dist. and Bot. Dist. are >=0.2, and one track is saved.

`-over_row_extension {true | false}`

Extends the stripes to cover the followpin at the row end.

Default: `false`

`-orthogonal_offset {[{edge1 orthogonal_offset1} {edge2 edge3 orthogonal_offset2} {edge4 edge5 … orthogonal_offset3 } …]|[all orthogonal_offset]}`

	Defines `orthogonal_offset` of stripes for every edge of block level designs, blocks or standard cells for specifying the offsets for edges orthogonally. Edge number starts from the left bottom vertical edge. When this option is set for the second time, all the `orthogonal_offset` values are reset firstly.
	Default: `{none}`
	Example
	`setAddStripeMode -orthogonal_offset {{1 orthogonal_offset1} {2 orthogonal_offset2} {3 orthogonal_offset3} {5 orthogonal_offset5} {7 orthogonal_offset7} {8 orthogonal_offset8} {9 orthogonal_offset9} {11 orthogonal_offset11} {13 orthogonal_offset13}}`
	`addStripe -layer green …`
	`addStripe -layer blue …`
	`setAddStripeMode -orthogonal_offset {{1 orthogonal_offset1} {3 orthogonal_offset3} {7 orthogonal_offset7} {11 orthogonal_offset11}}`
	`addStripe -layer red …`
	 	See the Examples section below for more examples on this parameter.

`-orthogonal_only {true | false}`	
	Creates vias *only* for orthogonal wires and pin intersections. *Default*: If you do not specify this parameter or if you specify it with a value of `1`, the software creates vias for orthogonal wires and pin intersections.
`-partial_set_thru_domain {true | false}`	
	Specifies whether to go over the power domain if domain contains the specified net. *Default:* `false`
`-recommend_width` *`file_name`*	
	The `file_name` specifies a list of recommended width values for the stripes. **Note:** This option must be specified along with `-color_balance`.
`-remove_floating_stapling {true | false}`	
	Removes those floating stapling stripes that are not connected to the power stripe/follow pin, when the stapling stripes are generated using a reference layer. This parameter does not remove floating stapling stripes when they are added through the user-specified offset and pitch. *Default:* `true`
`-remove_floating_stripe_over_block {true | false}`	
	If set to `true`, stripe fragments that start and end inside the same block or ring macro are removed. If set to `false`, stripe fragments are not removed. *Default:* `true`
`-reset`	Resets all parameters to their default values. Any values that do not already match the default value and are reset, will be reported.
`-remove_stripe_under_ring {true | false}`	
	Removes stripe segments, which have overlapped area and are in the same direction as the existing ring. The stripe can be in a different layer to the existing ring. Default: `false`
`-respect_routes {none | fixed | fixed_and_clock | all}`	

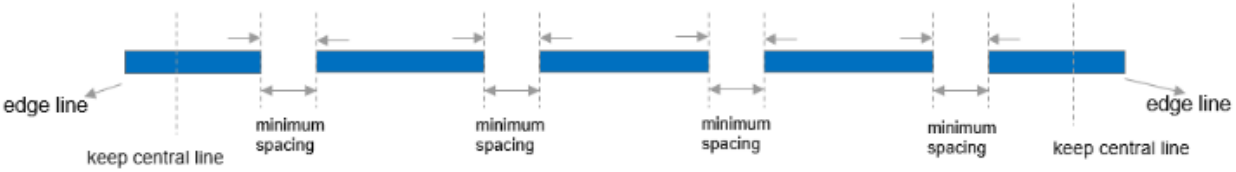
	Specifies the route types to ignore DRC check during stripe generation. This parameter always honor all covers and PGs, but does not honor the trail routes, Following are the parameter values: • `none`: Specifies that no route types are respected. • `fixed`: Respects fixed regular wires. • `fixed_and_clock`: Respects fixed and routed clocks. • `all`: Respects fixed and routed clocks along with the routed signals. For more information on the support of the `setAddStripeMode -respect_route` parameter values with various statuses of net, see Support of setAddStripeMode -respect_route Parameter Values. *Default*: `fixed_and_clock`
`-route_over_rows_only {true | false}`	
	If set to `true`, route stripes only over standard cells rows. If set to `false`, stripes are not limited to being routed over rows within this boundary. *Default:* `false`
`-rows_without_stripes_only {true | false}`	
	If set to `true`, global stripes are generated as specified by other parameters. Then stripes are also generated over row clusters that do not already contain stripes. If set to `false`, stripes are generated as specified by other parameters and not over row clusters without stripes. *Default:* `false`
`-same_sized_stack_vias {true | false}`	
	If set to `true`, the software always generates same-sized stacked vias. If set to `false`, the software trims the vias as needed to meet the DRC rules. *Default:* `false`
`-skip_via_on_pin {[Pad] [Block] [Cover] [Standardcell] [Physicalpin]}`	
	Prevents vias from being generated on the specified types of pins. If you specify `-skip_via_on_pin {}`, the power planning software makes connections to all five categories of pins. If you do not specify this parameter, vias are generated for block pins, pad pins, and cover macro pins, but are not generated for standard cell pins. *Default*: `Standardcell`
`-skip_via_on_wire_shape {blockring | stripe | followpin | corewire | blockwire | iowire | padring | ring | fillwire | noshape}`	
	Prevents vias from being generated on the specified wire shapes. If you specify `-skip_via_on_wire_shape {}`, the power planning software makes connections to all five categories of wire shapes. *Default:* If you do not specify this parameter, vias can be generated on all wire shapes *except* no-shape wires.
`-spacing_from_block` *float*	
	If the value is less than 0, over-the-block stripes end the specified distance from the boundary. If the value is greater than 0, global stripes break at the specified user units from the obstructed blocks. If the value is equal to 0, the stripe offset is 0. *Default*: 0
`-spacing_type {edge_to_edge|center_to_center}`	
	Specifies the type of spacing for `addStripe -spacing`. *Default:* `edge_to_edge`
`-split_long_via {`*threshold_value step_value offset_value height_value*`}`	

	Splits vias longer than the specified length (`threshold_value`, in micrometers) into smaller vias with specified center-to-center spacing (`step_value`, in micrometers), left/bottom end offset (`offset_value`, in micrometers) and vertical/horizontal height (`height_value`, in micrometers) values . This is independent of the `-split_vias` parameter. *Default:* If you do not specify this parameter, the software does not split vias. **Note:** If the offset_value is given as negative, the vias will be placed symmetrically on both ends. The default value of `offset_value` is `-1`.
`-split_vias {true | false}`	
	Specifies whether two or more partial vias can be created at the crossover between a stripe and any target (pin or wire) if an obstruction (macro obstruction; wire or pin on a different net) prevents the creation of a full-size via. This can be useful, for example, if several metal blockages partially obstruct the area where a full-size via would normally be placed. This parameter permits the creation of partial vias that would not violate the process rules, in the open areas. A value of `1` allows multiple partial vias to be created. A value of `0` prevents multiple partial vias from being created. *Default:* false
`-split_wire_spacing` *`floating_point_value`*	
	Specifies the spacing between each split wire. *Default*: If you omit this parameter, or set its value to `0`, the software uses the spacing rule in the LEF file.
`-split_wire_weight` *`integer_0_to_10`*	
	When split wires from a stripe on one layer attempt to make a target connection on another layer but are obstructed by I/O wires, some I/O wires might be deleted so that approximately *n* of 10 split stripe wires complete the target connection. **Note:** When you specify this option, the software deletes the fewest I/O wires to accommodate approximately *n* of 10 split stripe wires. *Default*: If you omit this parameter, or set its value to `0`, no I/O wires are deleted when the above connections are made.
`-split_wire_width` *`floating_point_value`*	
	Specifies the width of each split wire. *Default*: If you omit this parameter, or set its value to `0`, the software uses the maximum width value in the LEF file.
`-stacked_via_bottom_layer` *`layername`*	
	Specifies the lowest layer in which vias can be stacked. *Default:* The lowest metal layer in the design.
`-stacked_via_top_layer` *`layername`*	
	Specifies the highest layer in which vias can be stacked. *Default:* The highest metal layer in the design.
`-stapling_extend_to_minimum_spacing {true | false}`	

Automatically extends the newly created adjacent stapling to satisfy the end-to-end minimum spacing requirement, which will also be free from DRCs. This parameter works only with the stapling wires.

When set to to `false`, the length of the newly added stripe follows the length defined through the `addStripe -stapling` parameter. The following figure presents the placing of stripes when the parameter is set to `false`:

When set to `true`, the newly added stripes are extended automatically. The wire on the edge with only one end will have end-to-end spacing with the newly generated stripes. Only the end-to-end side is extended and the edge line end is not extended. The extended stripe still remains within the die area. The following figure presents the placing of the extended stripes when the parameter is set to `true`:



Default: `false`

`-stapling_nets_style {end_to_end | side_to_side | side_to_side_full_nets}`

Specifies the stapling style, if multiple nets are used. It controls the stapling stripe arrangement style specified in `addStripe -nets`. The default value of this parameter is `end_to_end`. Please note that:

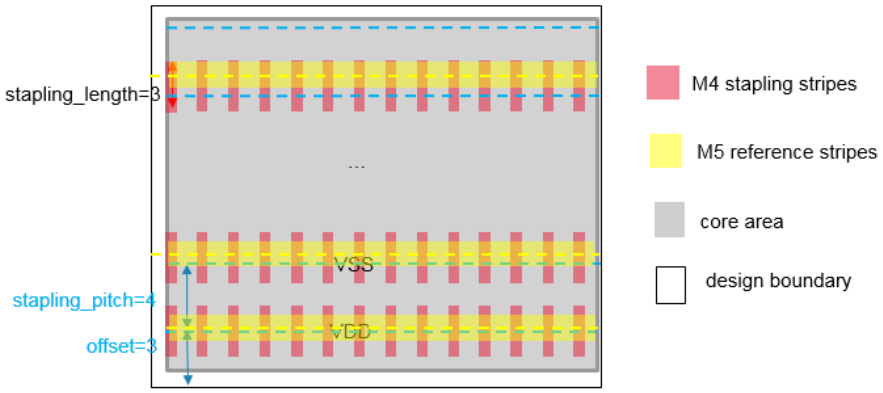
- When `end_to_end` (default value) is specified, nets are arranged in end direction. Refer to the following examples:

  Example 1

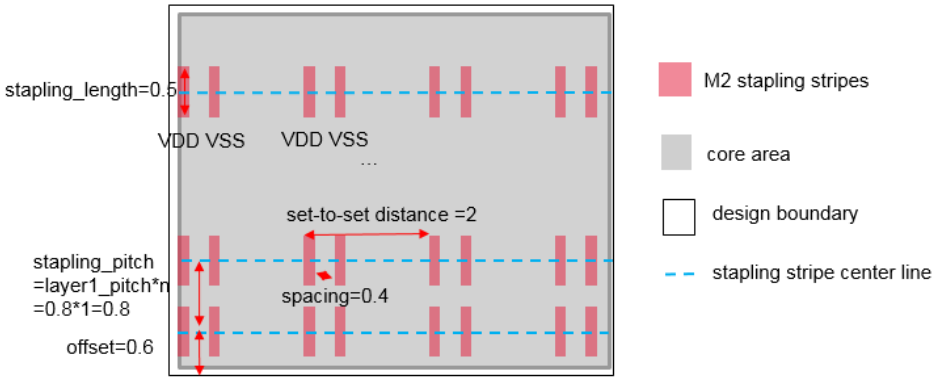
  ```
  addStripe -stapling {0.5 0.6 0.8:1} -nets {VDD VSS} -layer metal2 -width 0.1 -direction vertical -set_to_set_distance 0.5
  ```

  
  Example 2

  ```
  set metal3_track_offset 3
  set metal3_pitch 0.8
  addStripe -stapling '3 $metal3_track_offset $metal3_pitch:5 metal5' -nets {VDD VSS} -layer metal4 -width 0.5 -direction
  vertical -set_to_set_distance 2
  ```



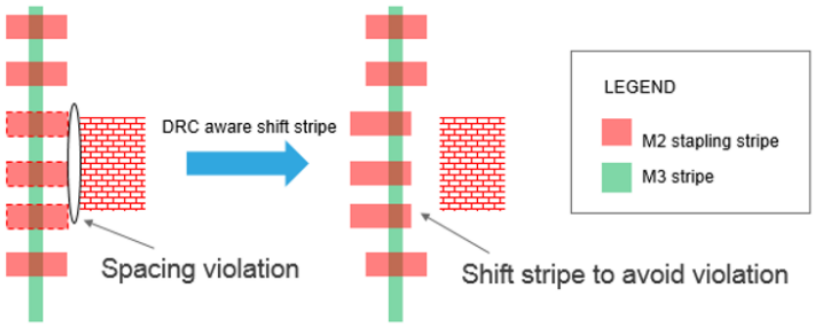
- When `side_to_side` is specified, nets are arranged in the side direction. Refer to the following example:
  Example 3
  ```
  addStripe -stapling {0.5 0.6 0.8:1} -nets {VDD VSS} -spacing 0.4 -layer metal2 -width 0.1 -direction vertical -
  set_to_set_distance 2
  ```



- When `side_to_side_full_nets` is specified, nets are arranged in the side direction. Besides the `side_to_side` behavior, it creates other net stapling according to the reference nets. The `side_to_side_full_nets` value can be generated only over the existing reference stripe (with `-stapling {length refer_layer}`). Refer to the following example:
  Example 4
  ```
  -stapling_nets_style side_to_side_full_nets #Besides side_to_side behavior, creating other net stapling according to the
  reference nets
  ```

`-stapling_shift {true | false}`

Shifts the stapling stripes automatically to avoid the DRC. See the example below:



Default: `true`

`-stop_at_closest_target {none | block_ring | core_ring | stripe}`

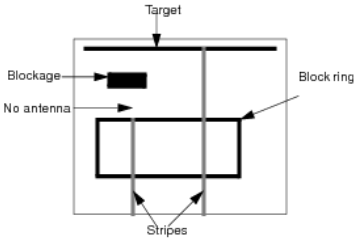
	Stops the stripe at closest target while drawing the stripe on the master cell. *Default*: `none`
`-stop_at_last_wire_for_area {true | false}`	
	If set to `false`, the stripe antennas are trimmed back to the closest wire or pin of the same net. If set to `true`, stripe antennas are not trimmed. **Note:** This option is only available if you specify the `-area` parameter. *Default:* `false`
`-stripe_min_length {floating_point_value | stripe_width}`	
	Specifies the minimum stripe length. `stripe_width` is a fixed string. The fixed string here refers to the width of present wire. *Default*: `stripe_width`
`-stripe_min_width floating_point_value`	
	Specifies the minimum width of the remaining stripe after being trimmed. *Default*: `0.0`
`-switch_cellname {cellAcellB ...}`	
	Treats the specified switch cell as a ring. Pins in the switch cell can then be used as targets for stripes. If the switch cell is in the core area, the software treats it as a block ring. If the switch cell is outside of the floorplan row, the cell is treated as a core ring, and used as the stripe boundary. You can specify one or more switch cell names. To turn off this functionality, specify one of the following: • `-switch_cellname ""` • `-switch_cellname none` *Default*: `none`
`-switch_layer_overlap_length floating_point_value`	
	Controls the overlap distance used for the via between a stripe layer and the layer being switched to. **Note:** The overlap applies *only* to vias created for straight (non-jogging) connections. *Default*: If you omit this parameter, or set its value to `0`, the power planning software creates a square via.
`-trim_antenna_back_to_shape {none | block_ring | core_ring | pad_ring | stripe}`	

Prevents stripes from creating antennas when a wire of the specified shape is the last target before a blockage that prevents connection to another target. Specify one of the following shapes:

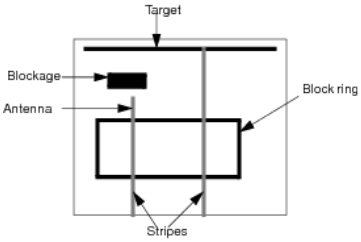
- `block_ring`
- `core_ring`
- `pad_ring`
- `stripe`

Default: none

The following figure illustrates the software behavior if you specify this parameter with a value of `block_ring`.



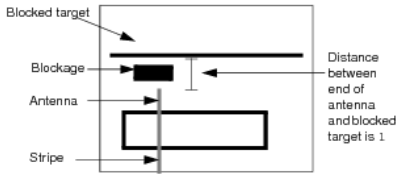
Default: Stripes extend to the blockage, leaving an antenna between the last connection and the blockage. The following figure illustrates the software behavior if you do not specify this parameter.



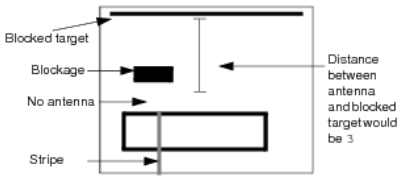
`-trim_antenna_max_distance` *distance*

Use this option to specify a distance, in micrometers, between the end of the antenna and a blocked target. This value controls whether an antenna is kept or trimmed for the selected shape. Cadence recommends that you specify a value equivalent to the distance between the core area and the pad ring or core ring.

- If the blocked target is within the specified distance, the antenna is kept, and you can use the SRoute software to complete the connection. For example, if you specify a distance of `2` micrometers and the distance between the end of the antenna and the blocked target is `1` micrometer, the antenna is not trimmed.



- If the blocked target is beyond the specified distance, the antenna is trimmed back to the last connection. For example, if you specify a distance of `2` micrometers and the distance between the antenna and the blocked target would be `3` micrometers, the antenna is trimmed back.



Default: `0.0`

`-trim_stripe {none | design_boundary | core_boundary}`

Specifies if shape is trimmed by the specified shape.

Default: `None`

`-use_exact_spacing {true | false}`

If set to `true`, the power stripe breaks using the exact spacing rule from the obstructing blockage, pin, or wire to avoid a design rule violation. If set to `false`, the power stripe breaks at 1.5 times of the maximum range rule spacing of all layers.

Default:

- `true`: For advance/N7 nodes
- `false`: For non-advance/non-N7 nodes

`-use_stripe_width {true | false}`

If set to `true`, stripes that jog to connect to a ring always use the stripe width for the jog. If set to `false`, the jog is either the width of the stripe or the width of the ring segment, which ever is smaller.

Note: This parameter only works in conjunction with the following parameter of the `addStripe command`:

`-jog_to_connect` 1

Default: `true`

`-use_point2point_router {true | false}`

If set to `false`, the point-to-point router engine is turned off. If set to `true`, the `addStripe` command automatically calls the internal point-to-point router engine to route the difficult power stripe connections (such as connecting power stripe antennas that were not connected by the `addStripe` command).

Default: `false`

`-via_using_exact_crossover_size {true | false}`

	Specifies whether to generate partial vias of the exact crossover size. A value of `1` allows partial vias to be generated. A value of `0` prevents partial vias, and the software always generates full-size vias. *Default:* `true`

Support of setAddStripeMode -respect_route Parameter Values

The following table presents the support of the `setAddStripeMode -respect_route` parameter values with various statuses of net:

Target PG Honoring a Wire			-respect_route Values			
Net Use	**Status**		**none**	**fixed**	**fixed_and_clock**	**all**
P/G			Yes	Yes	Yes	Yes
Non-P/G	**Cover**		Yes	Yes	Yes	Yes
	Fixed		No	Yes	Yes	Yes
	Routed	**Clock**	No	No	Yes	Yes
		Signal	No	No	No	Yes
	Unknown		No	No	No	No

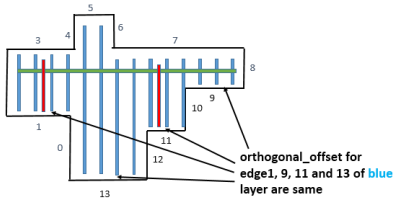
Examples

The following command specifies that stripes that jog to connect to a target always use the stripe width.

```
setAddStripeMode -use_stripe_width 1
```

The following examples include commands for specifying that stripes are generated in the block with a specified orthogonal offset:

```
setAddStripeMode -orthogonal_offset {{1 9 11 13 orthogonal_offset1} {2 orthogonal_offset2} {3 orthogonal_offset3} {5 orthogonal_offset5}
{7 orthogonal_offset7} {8 orthogonal_offset8}}
addStripe -layer green …
addStripe -layer blue …
setAddStripeMode -orthogonal_offset {{1 orthogonal_offset1} {3 orthogonal_offset3} {7 orthogonal_offset7} {11 orthogonal_offset11}}
addStripe -layer red …
```



```
setAddStripeMode -orthogonal_offset {{3 7 orthogonal_offset3} {1 5 9 11 13 orthogonal1}}
addStripe -layer blue …
```

```

Sets global variables for vias that connect rings and stripes when you use the `addRing`, `addStripe`, `editPowerVia`, `sroute`, `addSplitPowerVia` or `editAddRoute` commands.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `setViaGenMode` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man setViaGenMode`
`-accuracy_effort {low | medium | high}`	

	Controls the balance between accuracy and runtime during via generation. • When set to `high`, viagen checks full DRC rules and creates DRC clean vias. • When set to `medium`, viagen runs DRC check in the moderate mode. • When set to `low`, viagen runs in the quick DRC check mode. With this value specified, some available vias may be missed, since the conservative rules are checked. The vias generated through this parameter are DRC clean. This parameter generates vias with reduced runtime in the special scenarios where complex DRC rules are triggered. These complex rules include (but are not limited to) `same metal aligned cuts spacing`. *Default:* `high`
`-add_pin_to_pin_via {true | false}`	
	Inserts vias to connect pins between different cover macros. *Default*: `false`
`-align_merged_stack_via_metals {true | false}`	
	Aligns merged stack vias. *Default:* `false`
`-allow_via_expansion {true | false}`	
	Allows via to expand out of intersection area to meet LEF rules. *Default:* `true`
`-allow_wire_shape_change {true | false}`	

	Allows the via to change the metal shape of existing wires. *Default:* true **Note:** For stack vias, the option is only valid for top and bottom metal layers. **Example:** • `-allow_wire_shape_change true`  • `-allow_wire_shape_change false` `-area_only {true | false}`	
	Adds vias only within the specified areas. *Default:* `false`
`-create_double_row_cut_via {0 | 1 | 2}`	

	Try to expand vias to have one additional cut than original when set the option to `1` or `2`. That is, expand original vias of `1xn` or `nx1` cuts to vias of `1x(n+1)` or `(n+1)x1` cuts. • 1: create vias with one additional cut where wires on both top and down layers are enough and need no shape change. • 2: create vias with one additional cut where wires on one of the layers are enough. *Default*: `0` **Example:** • `create_double_row_cut 0`  • `create_double_row_cut 1` `-create_max_row_cut_via {true | false}`	
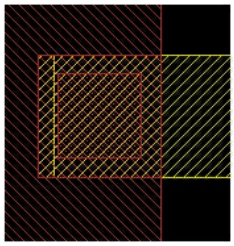
	Try to expand vias to have one additional row or column of cuts than original when the option is set to true. It works similar to `-create_double_row_cut_via` except that there is no restriction on one row or one column via. *Default*: `false`
`-cutclass_preference {default | {[square] [bar] [large]} | cutclass_name_list | file_name}`	

	Specifies the preference for the via cut class while inserting special vias. You can specify one of the following values: • `default`: Prefers to use the first viacell in tech LEF without drc violation or the first generate viarule to generate maximum cut area. For example, `cutWidth * cutHeight * cutNumber`. • `square`: Prefers to use the SINGLE cut vias. In the LEF definition, the cut width and length are usually the same and the smallest in that layer. For example, 0.032 by 0.032. • `bar`: Prefers to use the DOUBLE cut vias. In the LEF definition, the cut width is the usually the smallest. For example, 0.032 by 0.08. It mostly equals to 2 SINGLE cut. • `large`: Perfers to use the LARGE cut vias. In the LEF definition, the neither the cut width not the length is the smallest. For example, 0.08 by 0.08, equals to 4 SINGLE cut. The following figure shows the difference between the square, bar, and large values:    **Note:** 1. Parameter setting does not support incremental specification. The last cutClass preference setting is used. 2. When you specify `{[square] [bar] [large]}`, there should be 2 or 3 cutClass defined in the LEF file. If Innovus detects that there are more than 3 or less than 2 cutClasses, the setting is ignored. 3. In the specified file, different arguments can be separate by space or line break.
`-disable_via_merging {true | false}`	
	Disables via merging in the layers next to the followpin layer within the range of two when set the option to true and there is followpin layer in the design. Triming will be the only way to solve drc issues. For example, if the followpin layer is in 1, disable via merging in 1/2/3; if the followpin layer is in 2, disable via merging in 1/2/3/4. This function helps if the merging of via consums additional wire track unnecessarily. *Default:* • `false` in normal scenarios • `true` for advance nodes (with designs of 12 nm or below)

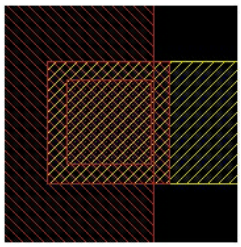
`-extend_out_wire_end {true | false}`

Allows via extending outside of existing wire ends at T-type of intersection. When set to false, via extending outside of the existing wire end are not allowed and may shift inside.

- `-extend_out_wire_end 1`



- `-extend_out_wire_end 0`



Default: `true`

`-full_cut_via_only {true | false}`

Allows the user to create only full cut vias.

Example
The following via is generated because of the second left cut will have drc violations when the option is set to false.

- `-full_cut_via_only 0`

When set the option to true, only full cut vias will be generated:

- `-full_cut_via_only 1`

&

Default: `false`

`-genvia_naming_prefix` *`viaNamePrefix`*

Sets the specified prefix name as the prefix for all generated vias created by the Innovus software.

This helps user to select and edit the vias that need further modification.

Default: `none`

`-hookup_contact_max {`*`distance1_max distance2_max`*`}`

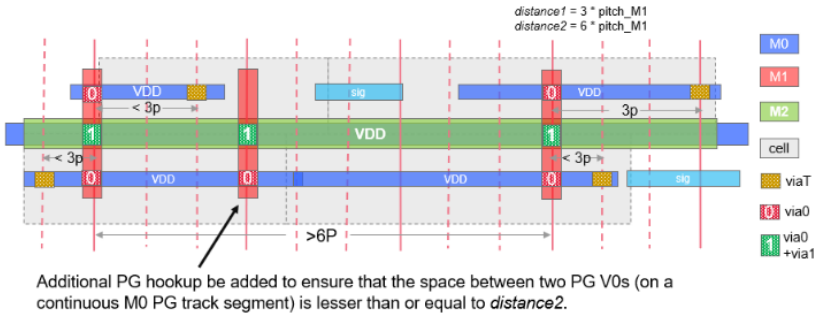
Sets the maximum distance to create hookup via from contact, and the maximum distance between two hookup via on a continuous `M0` PG pin. Following are the parameter values:

- `distance1_max`: Specifies the distance required by every viaT for at least one hookup via drop. For deciding the location of hookup via for `distance1_max`, every viaT needs at least one hookup via drop within `distance1`.
- `distance2_max`: Specifies the maximum distance between any two PG hookup vias on a continuous `M0` PG pin. An additional hookup via must be dropped from the previous hookup via on a continuous `M0` PG segment with `distance2_max`. Also, an additional hookup via must be dropped within the maximum `distance2` from the endpoint of a continuous `M0` PG pin.

Default: `0 0`

The following scenarios depict the usage of this parameter:

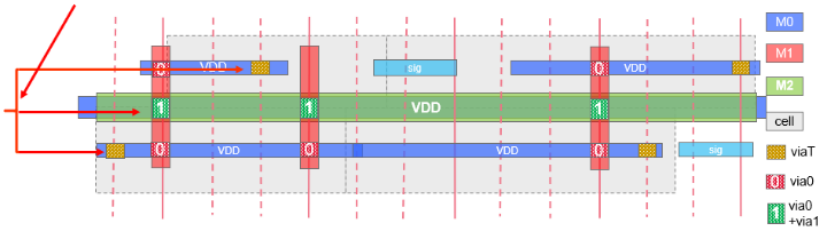
- Deciding the location of hookup via by viaT:



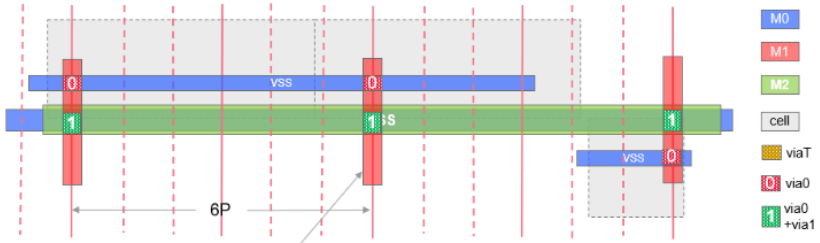
Additional PG hookup be added to ensure that the space between two PG V0s (on a continuous M0 PG track segment) is lesser than or equal to *distance2*.

- Referencing of the location of viaT by the tool to add hookup vias:

The location of hookup via is decided by viaT. The tool references only the viaT, which aligns with the cuts defined by via cells.



- At least one hookup via needs to be available for each continuous `M0` PG segment, including PG segment at both sides of the row edge and the PG pin. The continuous `M0` PG segment without viaT also needs to follow the decision rule of `distance2`:



Add an additional hookup via to meet 6P max distance

- Four individual via cells are defined in the LEF file and VIAMAP. Of these, one is 3-cut, two are 2-cut, and the remaining one is 1-cut. The further breakup of these via cells is mentioned below:
  - 3-cut via cells: Include three `v0` cuts, three `m0` metals, and one `m1` metals
  - 2-cut via cells: Include two `v0` cuts, two `m0` metals, and one `m1` metals
  - 1-cut via cell: Include one `v0` cuts, one `m0` metals, and one `m1` metals

`-hookup_contact_pg_track {start_value pitch_value}`

Sets start point and the pitch of PG track used by hookup contact. Following are the parameter values:

- `start_value`: Specifies the location of the first PG track.
- `pitch_value`: Specifies the distance (steps) between two adjacent PG tracks. It needs to be an integer multiple of the `m1` pitch.

Note: The PG track needs to be aligned with the `m1` track.

Default: `0 0`

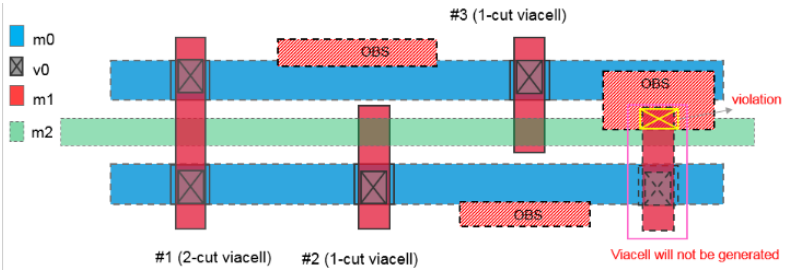
`-hookup_rail_pair {0 | 1}`

Adds hookup via over the pairing `M0` followpins that are distributed on both sides of a row with specially defined viacells at LEF file. Note that while using this parameter, the PG pins need to be on track, and the width of the `M0` followpin needs to be uniform.

This parameter works only with setting the `loose` value of the `-hookup_via_style` parameter. Three viacells are defined in the LEF file. One of those is 2-cut, and the remaining two are 1-cut. Refer to their details below:

- 2-cut viacell = Two `v0` cuts + Two `m0` metals + One `m1` metals
- 1-cut viacell = One `v0` cuts + One `m0` metals + One m1 metals

For the 1-cut viacell, `m1` needs to overlap completely with `M2`. If this is not possible, the viacell will not be generated. Refer to the example below:



Default: `0`

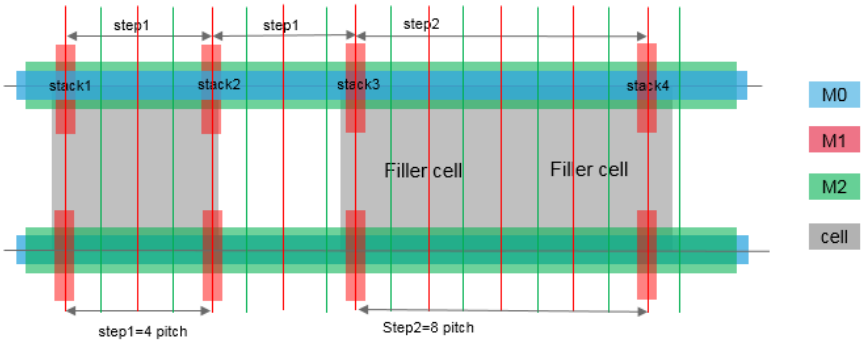
`-hookup_via_distance {distance_value1 [distance_value2 [boundary_spacing]]}`

Enables control to put the first pg via for each followpin. You can use this parameter in the following ways:

```
-hookup_via_distance {distance_value1}
-hookup_via_distance {distance_value1 distance_value2}
-hookup_via_distance {distance_value1 distance_value2 boundary_spacing}
```

Following are the parameter's various possible values:

- *`distance_value1`*: Specifies the distance (step) between via stacks and is rounded down to `M1 pitch*n`. Default value is `M1 pitch*4`.
- *`distance_value2`*: Specifies the distance between via stacks on filler cell. This value can work with all hookup styles. Default value is `M1 pitch*4`. It indicates the via distance when two neighboring via stacks are over filler cells. Refer to the figure below:



- *`boundary_spacing`*: Specifies the distance between the first via and core boundary. It also refers the minimum distance between the last via and core boundary.

`-hookup_via_fixed_grid {true | false}`

When set to `false` (default value), the added hookup via can be shifted to avoid DRC. When set as `true`, the hookup via can only be added at the fixed grid.

The fixed grid works with `-hookup_via_style`. For the `loose` and `moderate` styles, the hookup via will be removed, if it has DRC, when created. For the `compact` style, the hookup via will be kept, whether or not it has DRC.

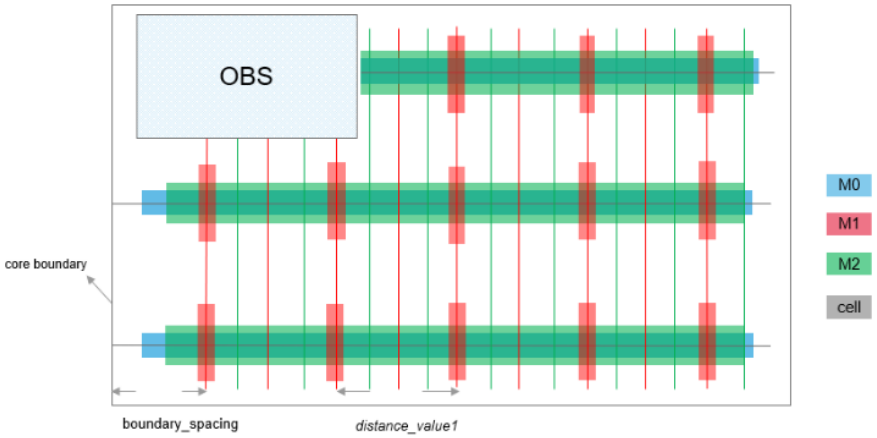
The fixed grid is controlled by the following parameter:

`-hookup_via_distance {distance_value1 [distance_value2 [boundary_spacing]]}`

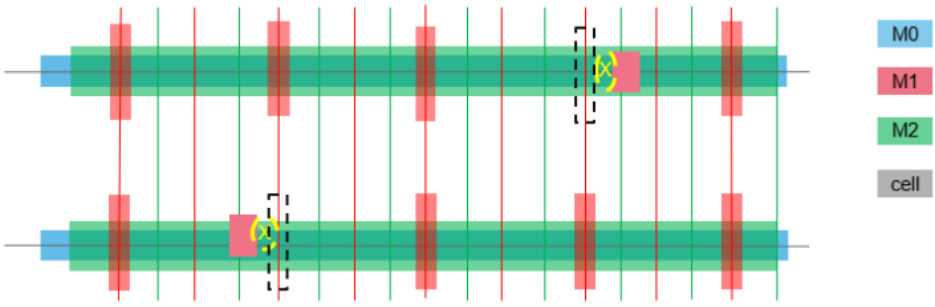
Here:

- `distance_value1` is the pitch of grid.
- `boundary_spacing` is the distance between the first grid and core boundary.
- The fixed grid does not get influenced by the shape of the design or macros.
- `distance_value2` needs to be set same as `distance_value1`.

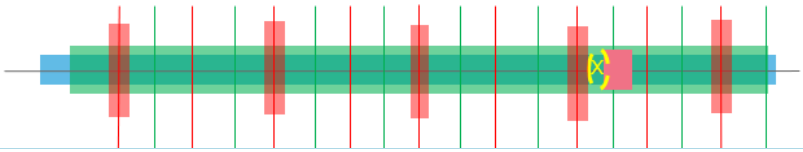
Below is an example of formation fixed grid using `boundary_spacing` and `distance_value1`. Note that all the vias of different lines need to be aligned.



Below is an example of DRC control for the `loose` and `moderate` types of hookup via styles. Here, the hookup vias are removed, if DRC exists.



Below is an example of DRC control for the `compact` type of hookup via style. Here, the hookup via will be kept, irrespective of the existence of DRC.



`-hookup_via_min_distance` *`distance`*

Specifies the minimum constrained distance between two PG vias. This parameter works with the distance between:

1. Two newly added PG vias
2. Existing PG vias and newly added PG vias on the followpin

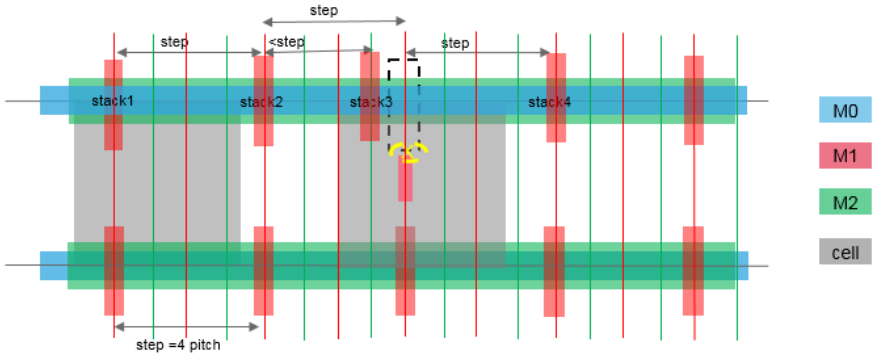
Default: `min`

`-hookup_via_style {none | loose | compact | moderate}`

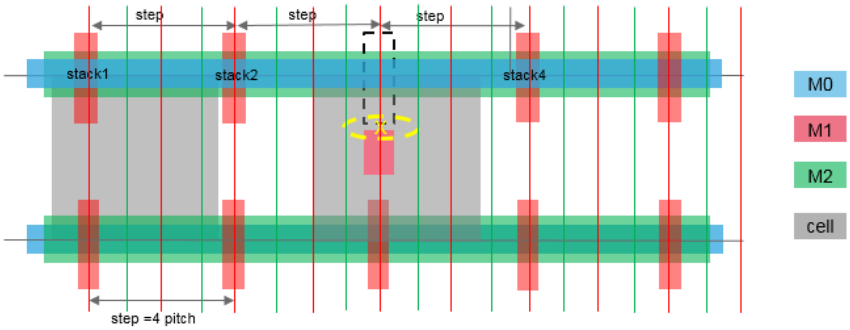
Sets hookup via style. The hookup via works between two parallel metal layers (like `M0` and `M2`, or `M1` and `M3`). Assuming it for `M0` and `M2`, viagen adds stack vias between `M0` and `M2` according to the hookup via settings.

The associated functionality of various options is provided below:

- `none`: No via hookup style is set. This is the default value.
- `loose`: The tool inserts vias between paralleled wires with the specified step in `-hookup_via_distance`. The center of the left-most via needs to be on the track, which is inside the intersection. The via also needs to be inside the intersection. If a via stack (like `stack3`) cannot be dropped at a certain step position (dot line area in the figure below) because of the DRC violation, it is moved to a closer or farther position with the previous stack (`stack2`) to ensure DRC clean. Additionally, the next via (`stack4`) needs to keep the step value with the original position of moved stack (dot line area in the figure below).

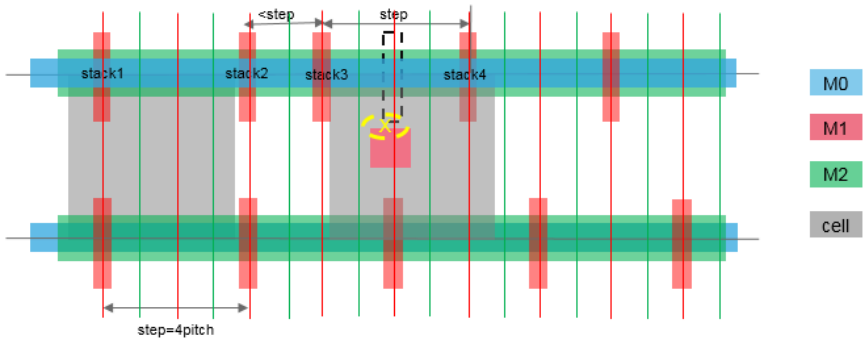


If DRC clean does not occurs, the via stack is removed, refer to the figure below:

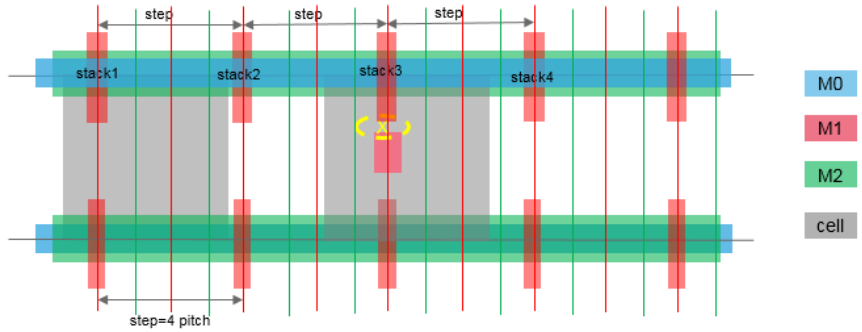


Note: The hookup style is `loose` by default, if the via map table does not exist.

- `compact`: If a via stack (like `stack3`) cannot be dropped at a certain step position (dot line area in the figure below) because of DRC violation, it is moved to a closer position with the previous stack (`stack2`) to ensure DRC clean. And the next via (`stack4`) needs to keep the step value with the said via (`stack3`). Refer to the figure below:

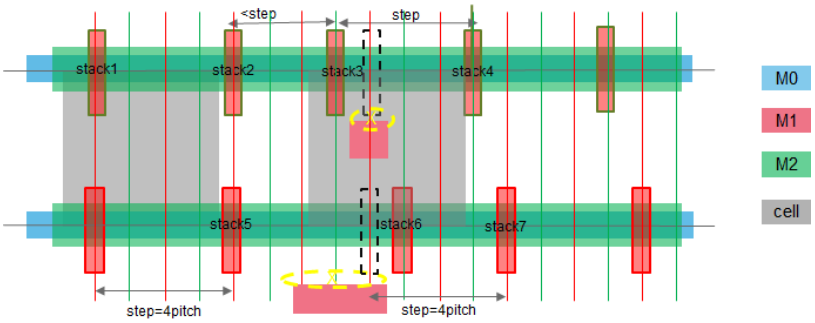


If DRC clean does not occurs by moving the stack, insert the via stack at the original position with DRC violation marker. Refer to the figure below:

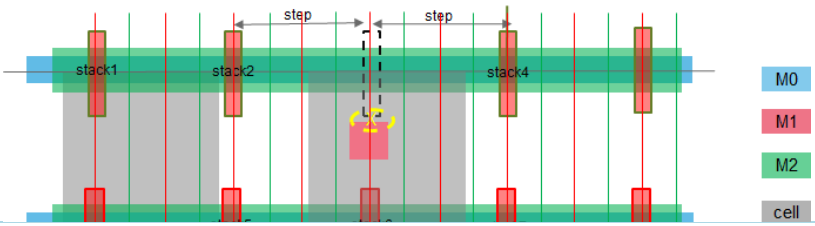


Note: The hookup style is `compact` by default, if the via map table exists.

- `moderate`: If a via stack (like `stack3`) cannot be dropped at a certain step position (dotted line area in the figure below) due to the DRC violation, it is moved to a closer or farther position with the previous stack (`stack2`) to ensure DRC clean. If the via stack (`stack3`) is dropped to a closer position with the previous stack (`stack2`), the next via (`stack4`) needs to keep the step value with the said stack (`stack3`). If the via stack (`stack6`) is dropped to a farther position with the previous stack (`stack5`), the next via (`stack7`) needs to keep the step value with the original position of the moved stack.



If DRC clean is not occurred, `viaGen` checks the next tracks followed to insert the via stack at the nearest DRC clean track.



`-hookup_via_viarule {filler {default |{list_of_via rule/cell_names }} ...}`

Specifies the preferred viarule for the designated cell area during the hookup via generation. The *default* value of the parameter follows the rule of the `-viarule_preference` parameter to generate a hookup via. The *list_of_via rule/cell_names* value uses the list of via rules or cells as the preferred usage for filler cell during the hookup via generation. The `-hookup_via_viarule` parameter can also work with the `-preferred_vias_only` parameter to use different types of viarule orders for filler cell to be DRC clean.

`-hookup_virtual_trim_grid {default |{-layer -mask1 {-pitch -core_offset...}}}`

Creates a virtual trim grid for PG hookup via generation. The created virtual trim grid should align with the via metal of the newly created hookup via. When this parameter is specified, the existing trim grid is ignored.

To honor the existing trim grid, either remove this parameter or define the existing trim grid within this parameter. The `-core_offset` parameter is calculated from the bottom core boundary to the center of the first grid.

Note: The width value for this parameter is taken from the LEF file.

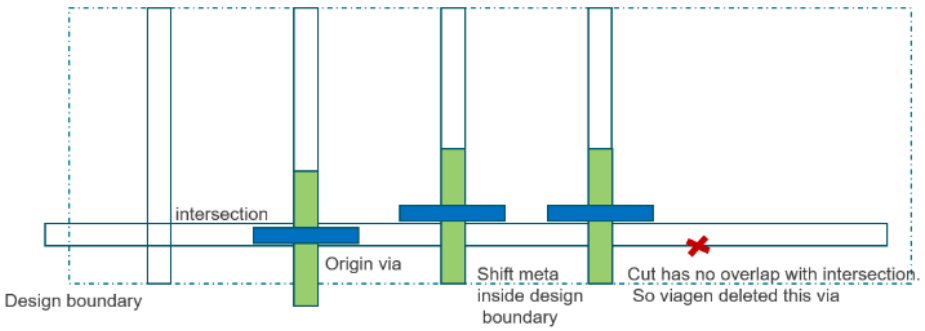
Default: `""`

`-ignore_design_boundary {true | false}`

Specifies whether a via can be extended out of the design boundary (floorplan area).

- When set to `true`, viagen generates vias and ignores the design boundary.
- When set to `false`, viagen tries to shift vias first inside the boundary area. If it does not overlap with the intersection point after shifting, viagen deletes it. If it overlaps with the intersection point after shifting with DRC clean, viagen keeps it.

See the figure below for understanding the usage of this parameter:



Default: `false`

`-ignore_DRC {true | false}`

	Setting this option ignores DRC but honors user-defined values when creating vias. This speeds up via creation during power-planning but normally causes DRC violations. It should only be used during early prototyping to experiment with different power-planning choices that will be updated later to be DRC clean. **Note:** This parameter ignores only the DRC violations from third party objects, and the software will still check the violation inside via. *Default:* `false`
`-ignore_viarule_enclosure {true | false}`	
	When set to `true`, tool will ignore enclosure value in VIARULE GENERATE and use the optimized enclosure from cut layer rules, to get the maximum number of cuts, minimum via metal shape. When set to `false`, the enclosure value in VIARULE GENERATE must be satisfied. When this VIARULE fails DRC check, tool will take next VIARULE or viacell from LEF file. *Default*: `true`
`-inherit_wire_status {true | false}`	
	Inherits the wire status. *Type: Boolean* *Default:* `false`
`-invoke_verifyGeometry {true | false}`	
	Enables or disables the `verify_drc` command called by the via generation software. • When set to `true`, the via generation software calls the `verify_drc` command to detect any `minStep` violations, then calls the `fixVia -minStep` command to fix them. This may impact the run-time performance. • When set to `false`, the via generation software will not call the `verify_drc` command. This may leave `minStep` violations in the design. **Note:** When both the `-invoke_verifyGeometry` and `-optimize_cross_via` parameters are set to `true`, and the process node is above `10N`, DRC violations can be reported. *Default*: `false`
`-keep_existing_via {0 | 1 | 2}`	
	If a via exists in an intersection and does not cover the whole intersection, a new via is tried to be dropped in the same intersection. Following are the parameter values: • `0`: Prevents keeping an existing via, while dropping a new via. • `1`: Keeps an existing via, while dropping a new via. • `2`: Keeps an existing via and does not drop a new via at the same intersection, even when the existing via does not cover the whole intersection area. *Default*: `0` (`1` for 10 nm designs)
`-keep_fixed_via {true | false}`	
	Controls whether to preserve the fixed vias or not when `viaGen` is called for via generation. *Default:* `true`
`-mincut_preference` *value*	

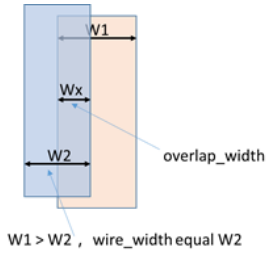
	Specifies the minimum number of cuts during via generation at an intersection. For example: • If this parameter is set to `1`, viagen generates at least one cut at an intersection, as shown below:  • If this parameter is set to `2`, viagen generates at least two cuts at an intersection, as shown below:  *Default*: `1`
`-optimize_cross_via {true | false}`	

	Generates vias with the minimum enclosure value on each layer. The different results with false or true values are shown below:   *Default*: `false` **Note:** The default value is `true` for advanced node (10 NM and 7 NM) designs.
`-optimize_via_on_routing_track {true | false}`	
	Free up routing tracks by shift or modify the vias minimally in intermediate layers and not applied to layers where the wires or pins exist. This option only supports generated vias and not predefined vias. The default is `false`. **Note:** Free up routing tracks against forbidden spacing rule for cross via and save routing tracks against end of line spacing rule for non cross via. `setViaGenMode -optimize_cross_via true` will try to generate cross via.
`-reset`	Resets all or specified parameters to their default values. Any values that do not already match the default value and are reset. will be reported.
`-parameterized_via_only {true | false | auto}`	
	Generates parameterized vias only. When set to: • `true`, ViaGen generates parameterized vias only, which means the DEF syntax of generated vias is with VIARULE. It helps in OpenAcceess designs. • `false`, ViaGen generates both parameterized and fixed vias. • `auto`, it is `true` for OpenAccess design, `false` for non-OpenAccess design. *Default:* • `false`, when the `setOaxMode -saveCdsFixedVias` parameter is enabled in the OpenAccess design. • `auto`, for all other cases.
`-partial_overlap_threshold` *float*	

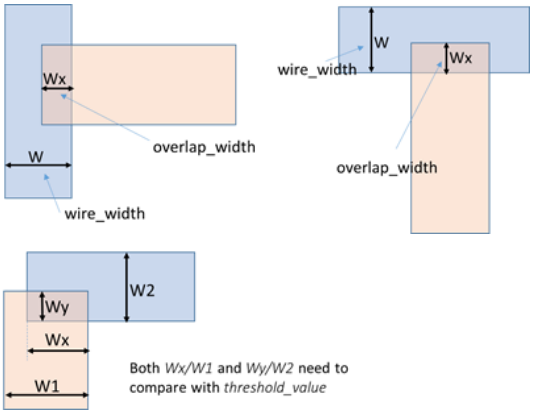
Specifies ratio threshold of via creation on partial overlap wires. The parameter value may range from `0` to `1`. The parameter value `1` specifies that no via is dropped on partial overlap intersection. The tool drops via only when `overlap_width`/`wire_width` is greater than or equal to the `threshold_value`.

Default: `0`

The following figure depicts parallel overlapping wires:



The following figures depict vertical cross wires:



`-preferred_vias_only {use_lef | open | keep}`

Generates only the vias set in `-viarule_preference`.

Default: `use_lef`

Note: This option must be used with the `-viarule_preference` option.

When the value of this parameter is set to:

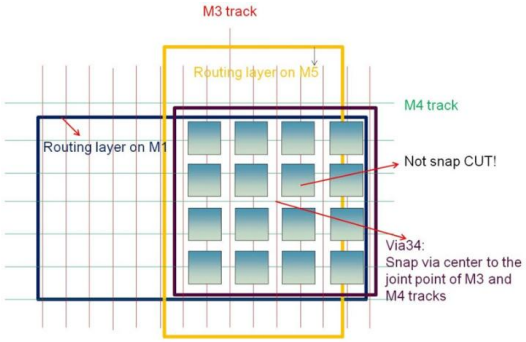
- `use_lef`: viarule or via cell specified in `-viarule_preference` is firstly considered. If none of them fits, viagen chooses the first DRC clean predefined viarule in the LEF file or auto viarule that can bring maximum cut area.
  Note that:
  - Cut area = single cut area * cut number
  - Auto viarule includes generate viarule and virtual viarule. Virtual viarule means viarule generated by viagen based on the cut layer rule.
- `open`: Only predefined viarule or via cell specified in `-viarule_preference` is considered. The first one with DRC clean is kept. If all of them have DRC issues, the whole stack is left open.
- `keep`: Only predefined viarule or via cell specified in `-viarule_preference` is considered. The first one with DRC clean is kept. If all of them have DRC issues, keep the first one which is DRC clean with surrounding. If all of them have DRC issues with surrounding, the whole stack is left open.

For more information on predefined viarule and generate viarule, see the *Via Rule* and *Generate Via Rule* sections respectively of the LEF Syntax chapter of the *LEF/DEF Language Reference* document.

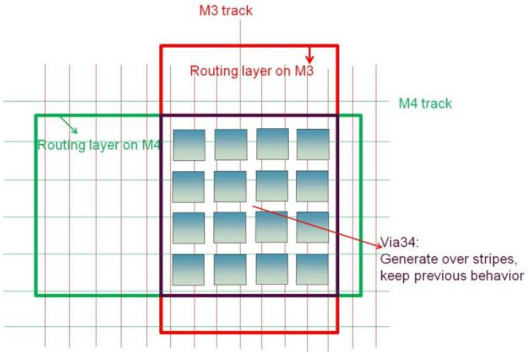
`-reference_boundary {design | core}`

	Specifies the offset reference when specifying offset values in the `-split_long_via_global_grid` parameter. Following are the parameter values: • `design`: ViaGen uses design boundary as reference. • `core`: ViaGen uses core boundary as reference. *Default:* `-reference_boundary design`
`-respect_signal_routes {0 | 1 | 2}`	
	Controls whether the via generation software honors pre-existing signal routes. If set to `1`, instructs the via generation software to read pre-existing signal routes and avoid creating DRC violations for the routes. If set to 2, instructs the via generation software to read pre-existing signal routes and avoid creating DRC violations for the routes. And improve the runtime of VIA12 process. **Note:** Using this setting can affect software performance significantly. If set to `0`, instructs the via generation software to ignore any pre-existing signal routes. **Note:** DRC violations can occur if this setting is used. *Default*: `0`
`-respect_stdcell_geometry {true | false}`	
	Respects geometry inside standard cell patterns. *Default:* `false`
`-respect_wire_ndr {true | false}`	
	Controls spacing between hookup via and signal routes. This allows viagen to support all NDR rules. • When set to `false`, viagen honors a set of NDR rules, which include PG wire NDR, PG via NDR, pin wire NDR, pin via NDR, and signal via NDR. • When set to `true`, the signal wire NDR is also honored, including those listed above with the `false` value selection of this parameter. This means that setting this parameter to `true` honors all the NDR rules. *Default:* `false`
`-set_via_expansion_dir {auto | horizontal | vertical}`	
	Sets via expansion directions. *Default:* `auto`
`-snap_via_center_to_grid {{ layer1 {none | grid | half_grid | either } [hard]} layer2 {{none | grid | half_grid | either } [hard]} … }`	

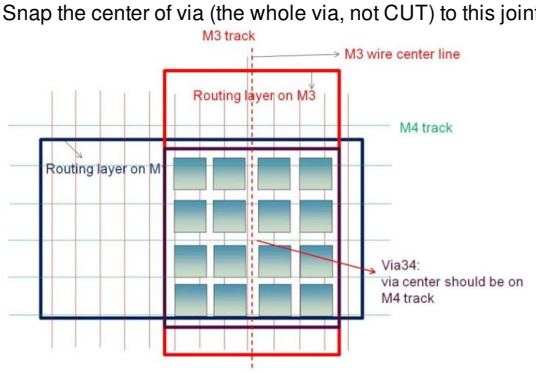
	Specifies the via center alignment style per routing layer. When this parameter is set as `hard`, the added via center will be snapped to metal track, if the added via will not be extended out of the wire side. If snap via to track will be extended out of the wire side, viagen will keep via in the stripe center to save the routing resource.
	`none`
	Keeps previous behavior, only snaps to wire center line.
	`grid`
	Snaps via to the full grid layer track.
	`half_grid`
	Ignores the full grid. Only snaps to the `half_grid` layer track.
	`either`
	Can snap to both full and half grid layer track.
	Default: `none`
	Examples
	• **Snap the vias to each adjacent up and down layers, except Metal1 and Metal2**
	◦ NO stripes on up and down layers
	◦ Snap the center of via (the whole via, not CUT) to the closest track intersection



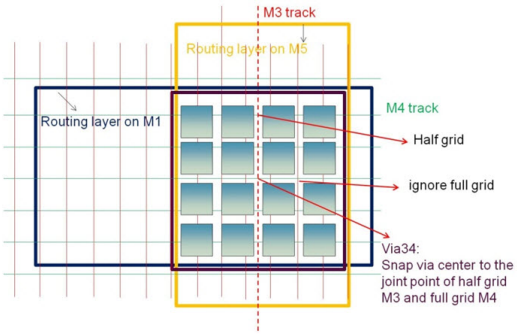
- **Stripes on both up and down layers**
  - Generate via on the stripes intersection area (the same as previous behavior, NO change)



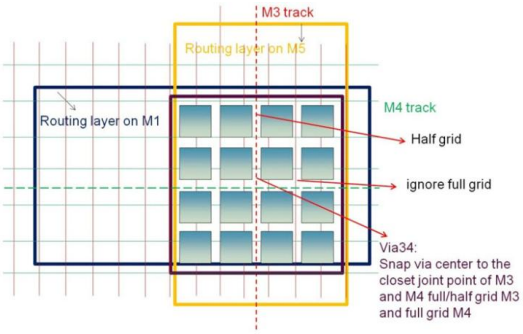
- **Stripe on adjacent layer 3 and NO stripe on the other neighboring routing layer**
  - Find the joint point between stripe center and the closest track
  - Snap the center of via (the whole via, not CUT) to this joint point



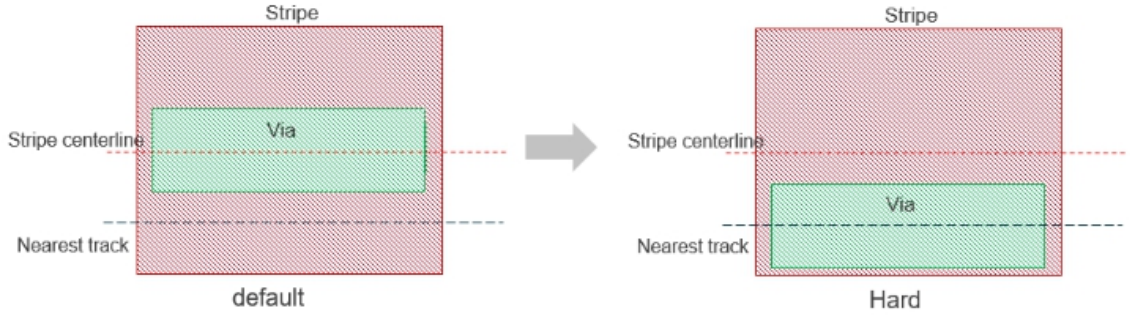
- **Snap via to the full grid of 4) and half grid of 3**
  - `setViaGenMode -snap_via_to_grid {3 half_grid 4 grid}`
  - Snap via to 3 half grid and 4 full grid



- **Snap via to full or half grid of 3 and 4**
  - `setViaGenMode -snap_via_to_grid {3 either 4 either}`
  - Tool could snap to closest full or half grid automatically



- **Snap via to track if the via is not extended out of wire side, when set as hard**



- **Keep via in stripe center if the snap via to track is extended out of the wire side, when set as hard**

`-split_long_via_global_grid {x_offset x_pitch x_length_threshold x_length_multiplier y_offset y_pitch y_length_threshold y_length_multiplier}`

	Provides options to control global grids so that vias on the grids are in line on x and/or y directions. • `x_offset, y_offset`: specifies in microns the offset from design boundry • `x_pitch, y_pitch`: specifies in microns the centre to centre distance in split vias • `x_length_threshold, y_length_threshold`: specifies vias longer or equal to threshold are being split • `x_length_multiplier, y_length_multiplier`: specifies unit via length multiplier *Default*: `default`
`-symmetrical_via_only {true | false | auto}`	
	By default the metal-width of a generated-via matches the width of the intersection of the metal above and below the via. If the width is an odd number of manufacturing grids (mgrids) wide, the resulting via cannot be represented by a parameterized via (LEF/DEF VIA with VIARULE and parameters or OpenAccess standardVia) because they require a symmetrical enclosure values on both sides of the cuts. In that case, a fixed-name via (LEF/DEF VIA with RECT statements or OpenAccess customVia) must be created to have the same width as the intersection area. If this option is true, the via metal is enlarged one mgrid in the odd-mgrid directions order to make the via symmetrical so it can be represented as a parameterized via. This does not cause any DRC violations in general because the via metal should still be covered by the metal above/below the via and avoid any min-step violations. Fixed-name vias can cause problems in hierarchical flows as the fixed-names from different blocks may collide. Parameterized via-names can be freely changed by applications and avoid this problem. If the design has odd-mgrid width wires or pins, this option is normally a good choice. If this parameter is selected as `auto`, it is `true` for OpenAccess design, `false` for non-OpenAccess design. *Default:* `auto`
`-use_track_offset {true | false}`	
	Uses track offset. *Default:* `false`
`-use_trim_metal_enclosure {true | false}`	
	Forces the tool to use enclosures with the trimmed layer. *Default:* `false`
`-viarule_preference {default | predefined | generated | list_of_via rule/cell_names | file_name}`	

	Sets the preferred via-rule usage. Use this parameter before running the `fcroute`, `sroute`, or power planning commands.
	• default
	Use the first DRC clean predefined viarule or auto rule that can bring maximum cut area.
	• `predefined`
	Uses the predefined via rule defined in the LEF technology file as the preferred usage.
	• `generated`
	Uses the generated via rule defined in the LEF technology file as the preferred usage.
	• `list of via rule/cell names`
	Uses the list of via rules/cells as the preferred usage.
	• `file name`
	Uses via rules/cells which are contained in the specific file.
	This parameter works in the incremental mode. See the example below:
	`setViaGenMode -viarule_preference {V1 V2}`
	`setViaGenMode -viarule_preference {V3}`
	`getViaGenMode -viarule_preference`
	`V1 V2 V3`
	Default: `default`

Example

The following command creates a virtual trim grid for PG hookup via generation:

```
setViaGenMode -hookup_virtual_trim_grid {-layer M1 -mask1 {-pitch p1 -core_offset s1 } -mask2 { -pitch p2 -core_offset s2 }}
```

Following is the output of the above command:

trim_pg

```
trim_pg
[-help]
[-area {x1, y1, x2, y2} | -candidate_file file_name]
-net {list_of_nets} {{-layer {layer_name1 [layer_name2]} -pattern {str1 [str2 … strN]} -type {stripe | via}} | -candidate_file file_name}
[-exclude_local_grid {{lx1 ly1 ux1 uy1} {lx2 ly2 ux2 uy2}...} | -candidate_file file_name]
[-exclude {{lx1 ly1 ux1 uy1} {lx2 ly2 ux2 uy2}...} | -candidate_file file_name]
[-keep_dangling_via]
[-threshold threshold_value | -candidate_file file_name]
```

This command offers a semi-automated mechanism that helps in trimming the redundant PG stripes and vias using an existing power grid pattern based on IR drop analysis reports. The command eliminates the need to manually adjust the power structure to reduce the power grid pessimism for area, timing, or power improvement in a design.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `trim_pg` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man trim_pg`
`-area {x1 y1 x2 y2}`	Defines the area in which stripes and vias are to be trimmed. The stripes overlapped with the box defined by `-area` are trimmed. *Default*: entire core area
`-candidate_file file_name`	Specifies the candidate filename.
`-exclude {{lx1 ly1 ux1 uy1} {lx2 ly2 ux2 uy2}...}`	
	Excludes the box areas for the stripes and vias in which the part of stripes need not to be trimmed. This parameter is used along with the `-area` parameter to specify the exclusion areas. If a stripe partially overlaps with the exclusion area, the overlapping segment of the stripe is not trimmed. The exclusion box can partially overlap the `-area` box.
`-exclude_local_grid {{lx1 ly1 ux1 uy1} {lx2 ly2 ux2 uy2}...}`	
	Excludes the areas in which the whole stripes are skipped for trimming. If a stripe is completely inside one of the `-exclude_local_grid box` (can touch the boundary), it is excluded from the trim candidates and is not counted when applying the trim pattern. It is useful when trimming is done on a large area but there are local stripes in this area, which could affect the global trim pattern. The exclusion box can partially overlap the `-area` box.
`-keep_dangling_via`	Keeps the dangling vias while trimming stripes. By default, dangling vias are removed.
`-layer {layer_name1 [layer_name2]}`	
	Specifies the metal layer names for stripe and via trimming. While trimming a stripe, specify *`layer_name1`* on which the stripes are to be trimmed. While trimming via, specify *`layer_name2`* between which the stack vias are to be trimmed. The first layer is used as the reference while applying the via trim pattern.

`-net {list_of_nets}`	Specifies the list of power or ground nets to be trimmed. The following figure presents area trimmed by the `-net` parameter: `-pattern {str1 [str2 … strN]}`	
	Specifies the trimming pattern. While trimming a stripe, specify *str1*. The string is a sequence of “0” and “1” to indicate whether to trim or keep a stripe. While trimming a via, *str1* and multiple strings (if needed) define a multidimensional trim pattern. Each string is a sequence of “0” and “1” to indicate whether to trim or keep a stack via along the corresponding stripe on the reference layer. The reference layer is the first layer in the `-layer` parameter.
`-threshold threshold_value`	Specifies the threshold value for stripe merging. The stripes with center-line spacing smaller than or equal to the threshold value are considered for trimming. *Default*: `0`
`-type {stripe | via}`	Specifies the type of trimming, which is either on the stripe of a layer or the stack via between two layers.

Examples

- The following command trims 50% of the `VDD` stripes on a `M6` metal layer inside a `{0 0 500 500}` box:
  ```
  trim_pg -net VDD -type stripe -layer M6 -area {0 0 500 500} -pattern 10
  ```
- The following command trims a via (stack) along with half of the `M9 VDD` stripes, and one-third of its stack vias between the `M9` and `M6` metal layers:
  ```
  trim_pg -net VDD -type via -layer {M9 M6} -area {0 0 500 500} -pattern {110 1}
  ```

Power Route Commands

- fixVia
- getSrouteMode
- reportPowerRoute
- setSrouteMode
- sroute

fixVia

```
fixVia
[-help]
{-short | -minCut | -minStep}
[-area]
```

This command fixes the following types of violations in special net vias: short, mincut, and minstep. If the via cannot be replaced, the violation marker is not removed. Use this command after running the `verify_drc` command. It only fix violations indicated by markers from `verify_drc`.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `fixVia` parameter. For a detailed description of the command and all its parameters, use the man command: `man fixVia`
`-area {x1 y1 x2 y2}`	
	Specifies the rectangular area. Thus, the command applies to the violations within the area only. The area option should be compatible with all existing options and supports all violations that the command can support at the moment. Specifying the area improves the run-time for large design with significant number of violations. `x1`, `y1` are the coordinates for lower left corner of the area. `x2`, `y2` are the coordinates for the upper right corner of the area. By default, this option is off and with no default value for any of its argument.
`-short`	Fixes vias which have a short violation.
`-minCut`	Replaces power vias flagged by a violation marker due to a violation of the LEF `MINIMUMCUT` rule. The via is replaced with a via that contains the minimum number of cuts based on the LEF rule, and the violation marker is removed.
`-minStep`	Replaces power vias flagged by a violation marker due to a violation of the LEF `MINIMUMSTEP` rule. The via is replaced with a via that contains the minimum number of steps based on the LEF rule, and the violation marker is removed.

Examples

The following command replaces power vias for the specified rectangular area:

```
fixVia -area {131.877 153.962 161.278 176.684} -minCut
```

reportPowerRoute

```
reportPowerRoute
[-help]
[-followpin_cut_ratio {cutClass1 weight1 cutClass2 weight2}]
[-net string]
```

Reports the cut ratio when two types of cuts are inserted between two parallel followpin rails with `editPowerVia -followpin_via_stapling` to maximize the effective number of cuts. The ratio is calculated by dividing the sum of weighted cut count of each cut class by theoretical cut count, if the smallest via is inserted along with the power rail with minimum spacing.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `reportPowerRoute` parameter. For a detailed description of the command and all its parameters, use the man command: `man reportPowerRoute`
`-followpin_cut_ratio {`*`cutClass1 weight1 cutClass2 weight2`*`}`	

	Specifies the names and weights of the two types of the cut classes.
	
	Note: The `cutClass` must be defined in the header lef file before loading the design. Otherwise, it will print error message(IMPPP-4411). Additionally, the format of the `cutClass` to be defined in the lef file should be:
	
	`PROPERTYDEFINITIONS`
	` €¦  €¦`
	`LAYER LEF58_CUTCLASS STRING ;`
	` €¦  €¦`
	`END PROPERTYDEFINITIONS`
	`LAYER VIA0`
	`TYPE CUT ;`
	`PROPERTY LEF58_CUTCLASS "`
	`CUTCLASS VSINGLECUT WIDTH 0.020 LENGTH 0.020 CUTS 1;`
	`CUTCLASS VDOUBLECUT WIDTH 0.020 LENGTH 0.050 CUTS 2;`
	`" ;`
	` €¦  €¦`
	`END VIA0`

`-net` *`string`*	Specifies the followpin net names to be reported. If this parameter is not specified, the report is calculated for all the followpin nets.

Example

The following command specifies the weights for the `VDOUBLE` and `VSINGLE` cut classes and calculates the reports for the `VSS` followpin net:

```
reportPowerRoute -followpin_cut_ratio {VDOUBLE 1.8 VSINGLE 1} -net VSS
```

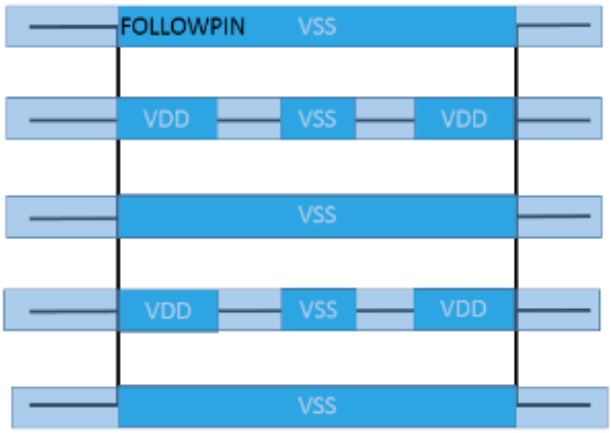
Comprises some of the `sroute -extraConfig` options. It is recommended to use `setSrouteMode` for

Compliment some of the `sroute` checking options. It is recommended to use `setSrouteMode` for `sroute`.

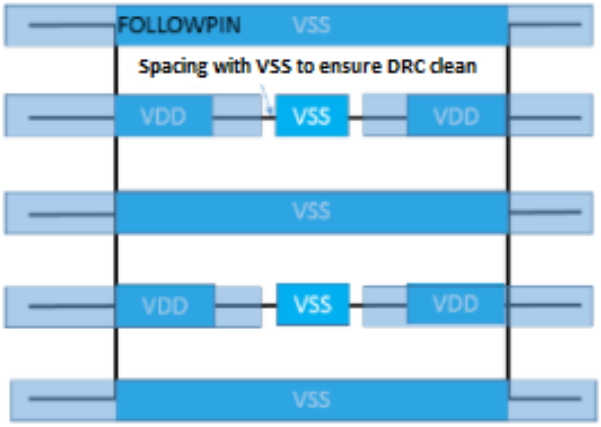
Parameters

`-help`	
	Outputs a brief description that includes the type and default information for each setSrouteMode parameter. For a detailed description of the command and all its parameters, use the `man` command: `man setSrouteMode`
`-allowWrongWayRoute {true | false}`	
	Allow wrong way routing. *Default:* `false` **Note:** If the metal1 preferred routing direction is vertical and standard cells have their VDD and VSS pins on layer metal1, sroute will route metal1 wires on horizontal direction to continue extending the followpin connections to core rings by this option.
`-avoidOverCoreRowLayer` *layerName*	
	Specifies the number of layers to avoid routing of block pin and pad pin over the core row area. *Default*: `max layer of standard cell pin`
`-blockPinConnectRingPinCorners {true|false}`	
	Specifies whether to extend the ring pins at corners. *Default:* `false`
`-blockPinRouteWithPinWidth {true|false}`	
	Specifies that the block wire used for a connection is to have the same width as the pin from which it connects. *Default:* `false`
`-corePinJoinLimit` *value*	

	Joins follow pin rail gaps smaller than this variable, bigger gaps will remain open. The option is of type *float*. *Default:* `0`
`-corePinLength` *value*	
	Connects core pins of specified length. The option is of type *float*. *Default:* `0`
`-corePinLengthAsInstance {true | false}`	
	Connects core pins whose length equals or is greater than the length of instance. *Default:* `false`
`-corePinMaxViaScale` *widthPct heightPct*	
	Controls the length and width of vias at the crossover of core pin rails and stripes. Specify this value as percentages of the width of the via at the top of the stack. Smaller vias leave room for more routing tracks on layers between the vias. *Default:* If you do not specify this parameter, the software uses a value of 100, which specifies a full-size via.
`-connectBrokenCorePin {true | false}`	
	When set to true, `sroute` checks the signal pin, second power pin, and obs, and then breaks the followpin to avoid violations. When set to false, `sroute` does not check internal geometries and does not break the followpin. Note that for ABUTMENT standardcell pins, followpins will go through the pin; for FEEDTHRU standard cell pins, followpins will break at the at the pin edge on the standard cell boundary. Refer to LEF/DEF Language Reference for more details. See the examples below for understanding the usage of this parameter: **For ABUTMENT Standard Cell Pins:** `setSrouteMode -connectBrokenCorePin false`

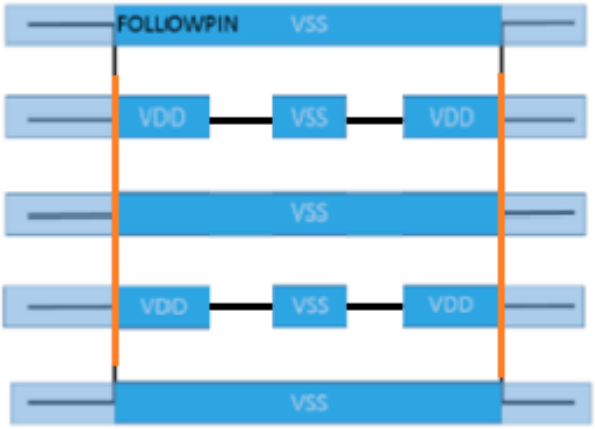


```
setSrouteMode -connectBrokenCorePin true
```

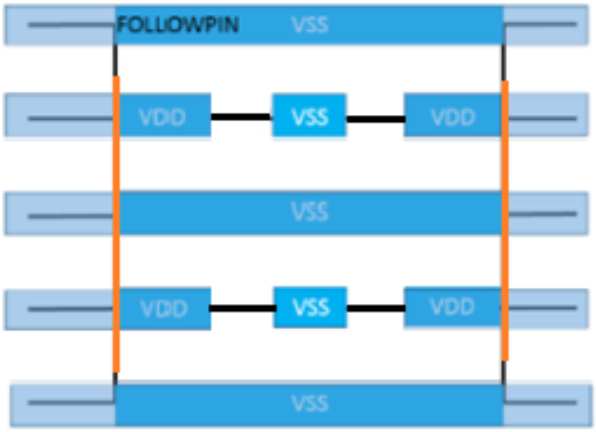


For FEEDTHRU Standard Cell Pins:

```
setSrouteMode -connectBrokenCorePin false
```



```
setSrouteMode -connectBrokenCorePin true
```



Default: `false`

`-corePinIgnoreObs {none | placement_blockage | overlap_obs | block_halo}`

Ignores the specified blockage while connecting the follow pin.

`-corePinReferenceMacro {`*`macro1 macro2 ...`*`}`

Uses specified standard cell master's cell name as references for followpin creation. If you specify multiple macros for a row height, the software picks the first macro as reference. This parameter is of *`string`* type.

Default: ""

`-corePinSiteRailWidth {{`*`site1 layer11 Width11 layer12 Width12 …`*`} {`*`site2 layer21 Width21 layer22 Width22 …`*`} …}`

Defines the followpin layer width for the specified site rail for followpin generation. The followpin width defined by this parameter has higher priority than the width of the same layer defined in the macro LEF, but lower than that defined by the `sroute -corePinWidth` parameter.

Following are the values used with this parameter:

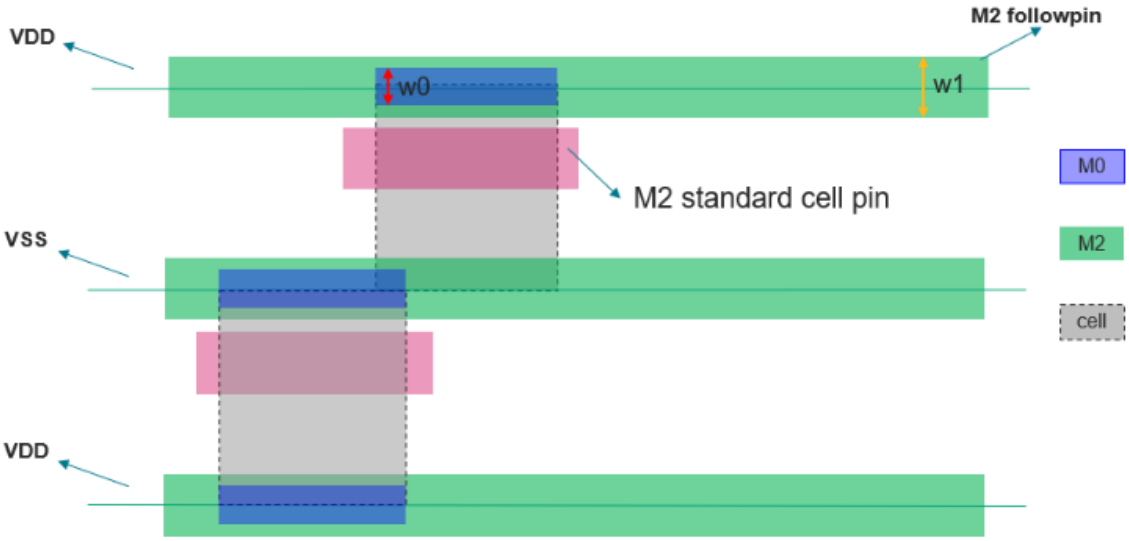
- `site`: Specifies the site name defined in the LEF file.
- `layer`: Specifies the name of the layer defined in the LEF file.
- `width`: Specifies the followpin width on the top and bottom sides of the defined site.

`-corePinSnapTo {M1_pin | opt_routing_track | grid | half_grid}`	
	Snaps metal2 followpins in the location to save routing tracks in a preventive manner. When set to: • `M1_pin`: Generated metal2 followpins are snapped to metal1 stdcell pin center. • `opt_routing_track`: Generated metal2 followpins are snapped to track or half track to save routing tracks. • `grid`: Generated metal2 followpins are snapped to the nearest routing track. • `half_grid`: Generated metal2 followpins are snapped to the nearest half routing track. *Default*: `M1_pin` **Note:** This option can only work when the option `-corePinReferToFollowPin` is set to `true`.
`-corePinStopRoute {RowEnd | CellPinEnd}`	
	Allows the command to extend the follow pin wire. Following are the parameter values: • `RowEnd`: Extends the follow pin wire to the row-end. • `CellPinEnd`: Extends the follow pin wire to the cell-end. *Default:* `RowEnd`
`-corePinReferToFollowPin {true | false}`	

If set to true, `sroute` generates followpins based on the standard followpins, whether or not there are standard cell pins on the defined metal layer. Standard followpins refer to the followpins on the first routing layer. This parameter can be used with any set of layers with same direction. Following is a usage example of this parameter:

```
setSrouteMode -corePinReferToFollowPin 1 …
sroute -corePinLayer M2 -corePinWidth w1 … #w0 is the standard
followpin's width
```

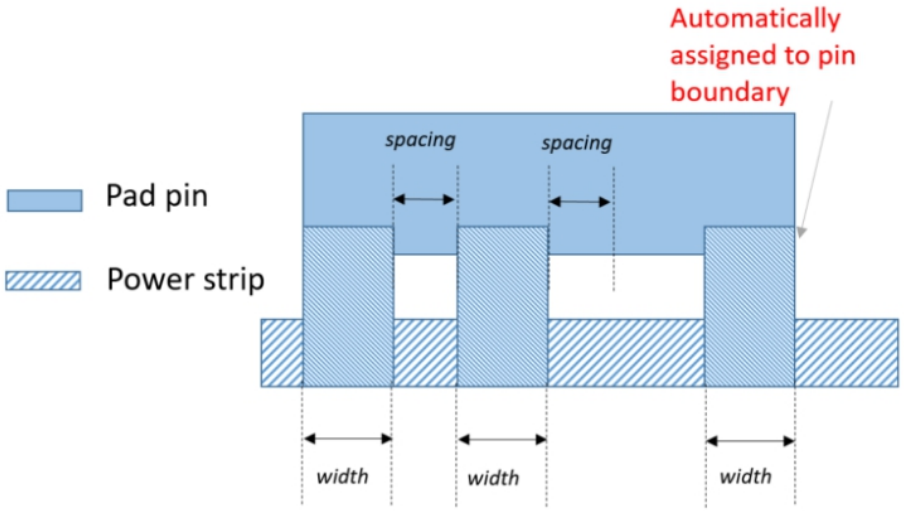
Following is the output of the above command:



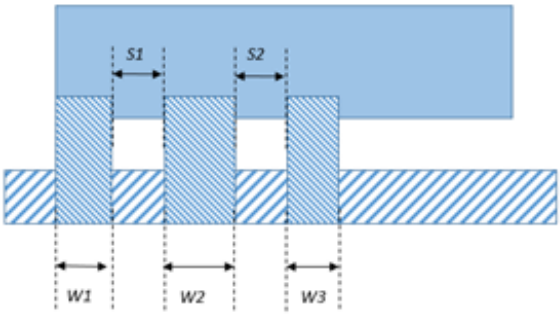
Default: `false`

`-extendNearestTarget {true | false}`

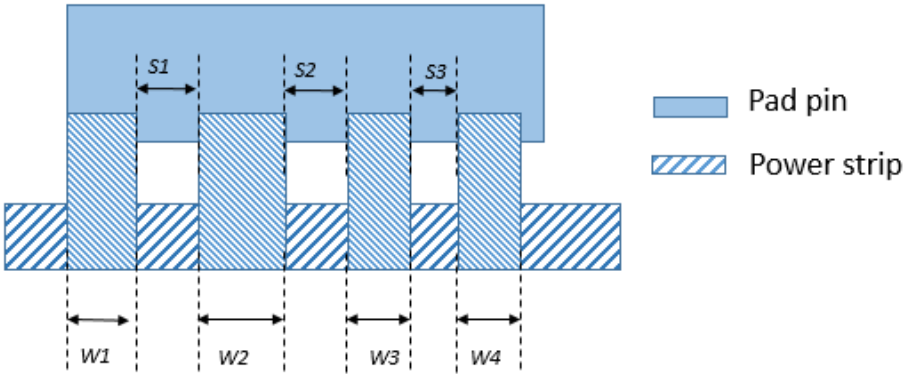
	Extends the nearest target so that it can be connected. The option is of type *bool*. *Default*: `false`
`-jogThresholdRatio` *value*	
	Defines the distance ratio between a jogging target and a straight target. The option is of type *float*. *Default:* 10
`-layerNormalCost` *layer1 cost1 layer2 cost2 ...*	
	Specifies layer cost of preferred direction. The option is of type: string. *Default*: ""
`-layerWrongWayCost` *layer1 cost1 layer2 cost2 ...*	
	Specifies layer cost of non-preferred direction. *Default:* ""
`-padPinMinViaSize viaSizePercent`	
	Permits the software to reduce the size of vias at pad pins when changing layers, if there is not enough room for a standard size via. *Default:* If you do not specify this parameter, the software uses a value of `20`, which permits vias that are 20% of the standard via size.
`-padPinSplit {`*width spacing* `|` *width1 spacing1 width2 spacing2 width3 spacing3 …*`}`	
	Splits the width and spacing to connect wide pad pins. When you use `{`*width spacing*`}`, `sroute` repeats it to connect the wide pad pins. It stops when the rest distance cannot put a full width wire. When you use {*width1 spacing1 width2 spacing2 width3 spacing3 …*}, `sroute` sets the connection for wide pad pins only once. It stops when the rest distance cannot put a full width wire. Refer to the command usage in various cases and corresponding outputs below: `setSrouteMode -padPinSplit {width spacing}`



```
setSrouteMode -padPinSplit {W1 S1 W2 S2 W3 S3}
```



```
setSrouteMode -padPinSplit {W1 S1 W2 S2 W3 S3 W4 S4 W5 S5 W6 S6}
```



Default: `""`

`-padRingLefConvention {true | false}`	
	Routes the pad rings based on the information specified in the LEF file. If set to 0, Innovus chooses the pad pin connection style (ABUTMENT or FEEDTHRU) when routing pad rings, disregarding what is specified in the LEF file. The option is of type *Boolean*. *Default:* `true`
`-reset`	
	Resets all or specified options to default value. Any values that do not already match the default value and are reset. will be reported.
`-secondaryPinMaxGap` *value*	
	Specifies variable value for gaps bigger than this value cause level shifter rail to break. The option type is *float*. *Default:* `0`
`-secondaryPinRailWidth` *value*	
	Specifies width of followpin rail. The option type is *float*. *Default:* `0`
`-signalPinAsPG {true | false}`	
	Specifies signal pins as PG pins in pad ring creation. When this parameter is set to `true`, the `sroute -nets` parameter supports wildcard characters (like * and ?). *Default*: `false`
`-splitLongVia {`*threshold_value step_value offset_value height_value*`}`	

	Splits vias longer than the specified length (`threshold_value`, in micrometers) into smaller vias with specified center-to-center spacing (`step_value`, in micrometers), left/bottom end offset (`offset_value`, in micrometers) and vertical/horizontal height (`height_value`, in micrometers) values . This is independent of the option `-split_via`. *Default:* If you do not specify this parameter, the software does not split vias. **Note:** If the offset_value is given as negative, the vias will be placed symmetrically on both ends. The default value of `offset_value` is `-1`.
`-srpgAonCellPin {`*`cellName: pinName`*`}`	
	Lists the cell/pin information NOT extracted from CPF. *Default:* `""`
`-targetNumber` *`value`*	
	Specify number of target to connect. The option type is *int*. *Default:* `0` (minimum). Maximum is `100000`.
`-targetSearchDistance` *`dist`*	
	Specifies target search distance. The option type is *float*. *Default*: 0
`-timeLimit` *`value`*	
	Specify time limit (in seconds) that the router is allowed in routing each port. The option type is *float*. *Default:* `0`
`-treatEndcapAsCore {true | false}`	
	Specifies to treat Endcap macro as core macro. The option type is *bool*. *Default*: false
`-treatWelltapAsEndcap` *`cell_name_list`*	

	Enables `sroute` to treat the `Welltap` cells as the `Endcap` cells. Additionally, the `ENDCAP` class cells are ignored by default, when generating the `followpin` wires. *Default*: ""
`-viaConnectToShape {padring | ring | stripe | blockring | blockpin | coverpin | noshape | blockwire | corewire | followpin | iowire}`	
	Specifies which shapes vias can connect to. The option type is *enum.* *Default:* `padring ring stripe blockring blockpin coverpin noshape blockwire corewire followpin iowire`
`-viaThruToClosestRing {true | false}`	
	Specifies that a via should connect only to the closest ring layer when multiple rings overlap. *Default:* If you do not specify this parameter, vias connect to all overlapping rings.

Examples

The following command defines followpin layer width for generating followpins:

```
setSrouteMode -corePinSiteRailWidth {{site1 layer1 w1} {site2 layer1 w2}}
```

Following is the output of the above command:

Routes power structures. Use this command after creating power rings and power stripes. Depending on the parameters you use, it can do any or all of the following:

- Create pad rings
- Connect pins on specified nets on the blocks
- Connect pads to nearby rings or stripes
- Extend unconnected stripes to make a connection
- Route standard cell pins

Note: To undo the `sroute` command, use the `defOut` command to save the design database before you issue the `sroute` command. Then you can use the `defIn` command to restore the design to its state before running `sroute`.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `sroute` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man sroute`
`-allowJogging {0 | 1)`	Specifies that jogs are allowed during routing to avoid DRC violations. **Note:** You can use `-allowJogging 1` and `-connect padRing` together to enable jog connection in pad ring connection.

`-allowLayerChange {0 | 1}`	Allows connections to targets on different layers. Default: **Note:** This parameter replaces the `-noLayerChangeRoute` parameters. If the 1 preferred routing direction is vertical and standard cells have their VDD and VSS pins on layer 1, sroute will change routing layers to continue extending the followpin connections to core rings by this option
`-area {`*`x1 y1 x2 y2`*`}`	Specifies the coordinates for the area in which power is to be routed. *Default:* If you do not specify this parameter, the entire design is routed. If you specify this parameter, existing routes are always preserved, even if you also specify the `-deleteExistingRoutes` parameter.
`-blockPin {useLef all onBoundary leftBoundary rightBoundary topBoundary bottomBoundary abutPins}`	

	Specifies which block pins to connect. **Note:** This parameter replaces the `-blockPin {useLefConvention | allPins | boundaryPins}`, `-blockPinBoundaryOnly`, and `-blockSides` parameters. Use one of the following options: • `abutPins`: Pins are abutted. • `all`: All pins on all ports are connected, regardless of how pins are specified in the LEF file. • `bottomBoundary`: Only pins on the bottom boundary are connected. • `onBoundary`: Connects *only* pins that abut block boundaries. • `topBoundary`: Only pins on the top boundary are connected. • `useLef`: Pins are connected exactly as specified in the LEF file. For example, if the LEF file has multiple ports with one geometry connecting to each port, then one pin per port is connected.
`-blockPinLayerRange {minLayerName maxLayerName}`	Specifies the layers on which the tool can make connections, between the bottom-most and top-most layers. A value of `1` indicates the lowest metal later, `2` indicates the next layer up, and so forth. • `maxLayerName`: Specifies the top-most block pin layer to connect to. • `minLayerName`: Specifies the bottom-most block pin layer to connect to.
`-blockPinTarget {nearestTarget | boundaryWithPin | farthestPadRing} | {[blockring] [padring] [ring] [stripe] [ringpin] [blockpin]}}`	

	Extends the block pin to targets of specified type. Multiple target types are allowed. The block pin will be open if no specified target is found: • `nearestTarget`: Extends the block pin to the nearest legal target. • `boundaryWithPin`: Extends the block pin to the design boundary and creates a new power pin along the design boundary. Any overlaps with existing I/O pins at the design boundary are flagged as violations after the extension. • `farthestPadRing` : Extends the block pin to the last pad ring that already exists on top of the I/O pad cells. • `blockring padring ring stripe ringpin blockpin` **Note:** • Specify either {`nearestTarget`}, `{boundaryWithPin}`, `{farthestPadRing}`, or a value from the following for which multiple keywords are allowed: {`blockring padring ring stripe ringpin blockpin`} • Shielding wire is not regarded as the target of the block pin.
`-blockPinWidthRange {min max}`	Specifies the allowable pin widths, between the maximum and minimum widths given. Specifies the maximum block pin width to connect to. *Default:* If you do not specify this parameter, the software uses a value of `100`. Specifies the minimum block pin width to connect to. The default value is `0.0`
`-connect {[blockPin] [corePin] [padPin] [padRing] [floatingStripe] [secondaryPowerPin] }`	

	Connects the specified objects to rings and stripes. If `-connect` is not provided, sroute connects `padPin`, `padRing`, `corePin`, `blockPin` and `floatingStripe` by default. If `-connect {}` is provided, sroute does nothing and exits. While connecting to the `padRing`, the connecting result may appear unexpected if the pads do not abut to the boundary. This is because in such cases, the direction calculation is inaccurate. Creating IO rows in consistency with the pad ring direction can guide the connecting direction. To connect `secondaryPowerPin`, you must explicitly use the combination of `-connect {secondaryPowerPin}` and `-secondaryPinNet {netname}`. **Note:** You can use `-allowJogging 1` and `-connect padRing` together to enable jog connection in pad ring connection.
`-connectAlignedBlockAndPadPin {blockPinAsTarget | padPinAsTarget}`	
	Specifies whether block or pad pins can be connection targets for aligned pad or block pins. **Note**: This parameter replaces -blockPinToAlignedPadPin and -padPinToAlignedBlockPin • `blockPinAsTarget`: Specifies that a block pin can be considered a connection target for a pad pin if the block pin is aligned with the pad pin. • `padPinAsTarget`: Specifies that a pad pin can be considered a connection target for a block pin if the pad pin is aligned with the block pin.

`-connectInsideArea`	Specifies that connections from all sources within the specified area can connect only to targets that are also inside that area. **Note:** This parameter is only available if you also specify the `-area` parameter. *Default:* If you do not specify this option the software makes connections from all sources within the specified area to targets both inside and outside the specified area.
`-corePinCheckStdcellGeoms`	Checks the standard cell geometries in the design for any spacing violations between the power rail to power stripe vias and cell blockages to repair any DRC violations. When detected, Innovus repairs these violations by trimming the via arrays as needed. Use this parameter after routing the power structures. *Default*: off
`-corePinLayer {`*`layerNumList`*`}`	Connects power pins only on the specified layers. A value of `1` indicates the lowest metal later, `2` indicates the next layer up, and so forth. If you specify more than one layer, you must enclose the list in curly braces. *Default:* If you do not specify this parameter, only pins on 1 or 2 will be connected. **Note:** Recommend to use LEF layer name.
`-corePinTarget {{[blockring] [ring] [stripe] [padring] [ringpin] [blockpin]}|{ firstAfterRowEnd | boundaryWithPin | farthestPadRing | none }}`	

	Specifies the extension target for followpins. • `firstAfterRowEnd`: Extends the standard cell pin to the first ring or stripe outside of the row. • `boundaryWithPin`: Extends the standard cell pin to the design boundary and creates a new power pin along the design boundary. Any overlaps with existing I/O pins at the design boundary are flagged as violations after the extension. • `farthestPadRing`: Extends the standard cell pin to the last pad ring that already exists on top of the I/O pad cells. • `none`: Unconnected standard cell pins are not extended, and connections may be left open. • `blockring ring stripe padring ringpin blockpin` **Note:** Followpin wire can be targets for stripe and secondary pin connection, but not for followpin connection. *Default:* `firstAfterRowEnd`.
`-corePinWidth real`	If `sroute -corePinWidth` is run prior to placement, then the standard cell rails are created with the specified width. If it is run after the placement, *sroute* will only route pins that have the specified width.
`-crossoverViaLayerRange {`*`bot top`*`}`	Specifies the highest and lowest layer that can be used for via stacking at the crossover point between power structures. **Note:** This parameter does not apply to T-pattern connections. *Default:* If you do not specify this parameter, all layers are used.

`-deleteExistingRoutes`	Specifies that the software remove existing connections when you use the `sroute` command multiple times. *Default:* The software maintains existing connections each time you issue the `sroute` command. **Note:** If you specify the `-area` parameter, existing routes are always preserved, even if you also specify the `-deleteExistingRoutes` parameter.
`-detailed_log`	Prints the detailed log file.
`-floatingStripeTarget {[blockring] [ring] [stripe] [padring] [ringpin] [blockpin] [followpin]}`	
	Specifies the target shape for floating stripes. *Default:* `{blockring ring stripe padring ringpin blockpin followpin}`
`-inst {`*`names_of_blocks`*`}`	Specifies the blocks to connect. **Note:** This parameter replaces the `-blocks` parameter.
`-layerChangeRange {bottomLayerName topLayerName}`	Allows routing between the specified bottom-most and top-most layer, inclusive. *Default*: If you do not specify this parameter, the tool can use any layer. **Note**: This parameter replaces -layerChangeBotLayer and `-layerChangeTopLayer`.
`-nets {names}`	Specifies the names of the nets to connect. If you connect to more than one net, you must enclose the net names in curly braces and separate the names with a space. This parameter supports wildcard characters (like * and ?), when the `setSrouteMode -signalPinAsPG` parameter is set to `true`. *Default:* If you do not specify this parameter, the software connects all power and ground nets in the design.

`-noBlockPinOneAmongOverlappedPins`	Specifies that all pins (including those that overlap) should be routed. **Note:** This parameter is effective *only* if `sroute -blockPin allPins` is specified. *Default*: If you omit this parameter, if multiple pins overlap either fully or partially, only one will be routed.
`-padCellSkipRoutingOnPadSide {top bottom left right}`	Specifies the pad pins of the pads should not be connected. • `bottom`: Specifies the pad pins on the bottom side of the pads should not be connected.. • `left`: Specifies the pad pins on the left side of the pads should not be connected. • `right`: Specifies that power pads along the right side of the chip should not be connected. • `top`: Specifies that power pads along the top side of the chip should not be connected.
`-padPinLayerRange {`*`minLayerName maxLayerName`*`}`	Specifies that routing is allowed between the bottom-most and top-most pad pin layers, inclusive. This parameter replaces `-padPinMaxLayer` and `-padPinMinLayer`. • `maxLayerName`: Specifies the top-most pad pin layer allowed for connection. • `minLayerName`: Specifies the bottom-most pad pin layer allowed for connection.
`-padPinPortConnect {[onePort | allPort ][ oneGeom |allGeom] | preferLayer}`	

	Specifies connections to pad pin ports. • `onePort`: Routes to only one port of a pad pin if multiple ports are defined in the LEF file. • `allPort`: Routes to all ports. • `oneGeom`: Routes to one geometry per port only. • `allGeom`: Routes to all geometries of the same port for each pad pin. • `preferLayer`: Routes to all geometries on the same port, but in the preferred routing direction only.
`-padPinTarget {nearestTarget | {[blockring] [ring] [stripe] [ringpin] [blockpin] [followpin]}}`	
	Specifies the target type.Extends the pad pin to targets of specified type. Multiple target types are allowed. The pad pin will be open if no specified target found. • `nearestTarget`: Extends the pad pin to the nearest legal target. • `blockring ring stripe ringpin blockpin`: *Default*: `nearestTarget`
`-padPinWidth` *real*	Routes only pad pins that have the specified width. If no width is specified, the software automatically calculates the width of the pad pins to use. It is usually not necessary to specify a pin width.
`-padRingLayer` *layerNumber*	Specifies which routing layer to use. A value of `1` indicates the lowest metal later, `2` indicates the next layer up, and so forth. The default is all layers. **Note:** Recommend to use LEF layer name.
`-padRingWidth` *real*	Specifies the width of pins to connect with. By default, the software automatically calculates this width.
`-powerDomains [`*powerDomainName1 powerDomainName2 …*`]`	

	Restricts `sroute` activity to the specified power domains. *Default*: All power domains **Note:** The `-deleteExistingRoutes` parameter will ignore the `-powerDomains` parameter while removing existing connections. To remove special nets in a power domain, run `editDelete` manually before `sroute`.
`-secondaryPinNet {`*`list_of_nets`*`}`	Connects voltage level shifter pins on the specified nets to the closest segment of the ring around the power domain. This option is available only if a power domain is defined. **Note:** This parameter replaces `-shifterPinConnection`.
`-secondaryPinRailLayer` *`layerName`*	Specifies connections to secondary pin rail layers. This is optional.
`-secondaryPinRailVerticalStripeGrid {topLayerNum width pitch}`	
	Specifies connections to secondary power pins. **Note:** This parameter replaces `-lsStripeLayer`, `-lsStripeWidth`, and `-lsStripePitch`. • `topLayerNum`: Specifies the top-most stripe layer on which the tool can route secondary power pins. • `width`: Specifies the width (in user units) of stripes that connect to secondary power pins. • `pitch`: Specifies the pitch (in user units) of stripes that connect to secondary power pins.
`-stripeLayerRange {`*`minLayerName maxLayerName`*`}`	

	Enables you to control the floating stripes (to be connected by `sroute`) by specifying a layer range helpful in case of advanced node designs. You need to specify the following values with this parameter: • `maxLayerName`: Specifies the top-most floating stripe layer allowed for connection. • `minLayerName`: Specifies the bottom-most floating stripe layer allowed for connection.
`-targetObjListFile` *`filename`*	Specifies a `.obj` file that contains a list of objects that the sroute software is to either consider as a target or remove from the list of available targets. **Note:** Cadence recommends that you use the Target List Editing page of the SRoute form to create this file. For more information, see "SRoute" in the Route Menu chapter of the *Innovus Menu Reference*.
`-targetViaLayerRange {`*`bot top`*`}`	Specifies the highest and lowest layer that can be used for via stacking at a target. *Default:* If you do not specify this parameter, all layers are used.
`-uda` *`subclass_string`*	Displays the user defined attribute attached to followpin, blockwire, core wires, iowires and padring.

Extra Configuration File Options for sroute

You should only use the extra configuration file if you are familiar with its use.

The following variables can be used in the extra configuration file:

- `srouteAlignViaOnStripe {true | false}`
- `srouteAutoRingPadBlockpinRoute {true | false}`
  Generates rings between pad pins and block pins. When this option is set to true, the Innovus software automatically generates the rings between pad pins and block pins to

be used as targets for pad pins and block pins.

The default is `false`.

- `srouteAutoRingLayer layer_number`
  Specifies the layer of the rings.
- `srouteAutoRingOffsetFromBlockPin db_unit`
  Specifies the clearance between the rings and the block pins.
- `srouteConnectAreaIO {true | false}`
- `srouteFollowPinOnShapePin {true | false}`
  The default is `false`.

Specifies whether the primary pins are O-shaped.

- `srouteForbidStackVia {true | false}`

  Note: This variable is obsolete and has been replaced by `srouteForbidStackVia`.
- `srouteMinRailLength minLength`
  Limits the creation of followpin rails to a length at or above the specified value. SRoute will not create followpin rails with a length less than the specified value. You can use this variable to restrict the creation of followpin rails where row spacing is limited. Units in database units.
- `srouteMinRailLength minLength`
  Limits the creation of followpin rails to a length at or above the specified value. SRoute will not create followpin rails with a length less than the specified value. You can use this variable to restrict the creation of followpin rails where row spacing is limited. Units in database units.
- `srouteRoutePowerBarPort {true | false}`
  The default is `true`.

When set to `false`, SRoute does not attempt to route outside the block after the power bars are routed.

- srouteAlignViaOnStripe {true | false}
  The default is `false`.

Controls the alignment of stacked cross vias between followpin rails and stripes. When a followpin rail passes through a pair of stripes, the power routing software generates stacked vias to connect the followpin rail to the stripe of the same net. The stacked via is created between the stripes and spans from the followpin rail layer to the layer just below the stripe layer. The via between the stripe layer and the layer below is placed at the intersection of the followpin rail and the stripe of the same net. The vias are connected with a wire from the layer just below the stripe layer.

The `srouteAlignViaOnStripe` configuration file option is enabled when set to `true` and only when the following conditions are met:

- When you specify two nets with the sroute command. For example:
  `sroute -nets {VDD GND}`
- When stripes are of the same layer and of the same width
- When the distance between the stripes is less than their width
- When there are only two stripe wires within the distance of the width (not split)

  Note: This variable replaces `srouteAlignViaOnStripe`.

- `srouteSecondaryPinIgnoreStandardCell {true | false}`
  In the previous release, if the followpins were on the `1` or the `2` layer, the command always treated the standard cells in the path of the followpin wires as blockages.

In this release, you can set the option to `true` to specify that the standard cells in the path of the followpin wires should not be considered as blockages even if the followpins are on the `1` or the `2` layer. This way, the secondary pin routing can route through these standard cells.

By default, the value is `false`. This means that the standard cells in the path of the followpin wires are treated as blockages if the followpins are on the `1` or the `2` layer.

- `srouteShifterPinObjListFile file_name`
  Specifies a file containing a list of secondary pins for sroute to ignore when routing. Use this variable when you have already routed certain shifter pins, if the shifter pins have different alignment, or if you want to use a different router (such as NanoRoute) to connect the pins, for example.

The file format is as follows:

```
delete pin pin_name macro macro_name layer layer_name
```

In the file, you can repeat this line for any pins as you want.

Currently, `layer` is ignored.

- `srouteForbidStackVia {true | false}`
  The default is `false`.

Note: This variable replaces `srouteForbidStack`.

- `srouteViaOnPadCorePin {true | false}`
  The default is `false`.

Earlier pad core pins were only considered for cross via generation. With the option `srouteViaOnPadCorePin`, pad core pins are considered as routing targets.

- `srouteTandemPadBlockpinRoute [1|2|0]`
  Controls the tandem route and routes block pin and pad pin in both preferred and non-preferred layers. Where,
  - 0 stands for do not do tandem route. This is the default.
  - 1 stands for preferred layer only.
  - 2 stands for all layers.
- `srouteTandemRouteReliefViaInterval dbunit`
  Creates stack via over tandem wires at specified intervals.

Prototyping Commands

- FlexModel Commands
- SoC Architecture Info (SAI) Commands

FlexModel Commands

- assemble_proto_model
- create_buffer_psPM_table
- create_flexfiller_route_blockage
- create_proto_model
- create_ps_per_micron_model
- get_proto_design_mode
- get_proto_mode
- get_proto_model
- hilite_proto_model
- identify_proto_model
- proto_design
- replace_proto_model
- report_proto_model
- set_proto_design_mode
- set_proto_mode
- set_proto_model
- set_proto_model_physical_constraint

- set_proto_timing_settings

assemble_proto_model

```
assemble_proto_model
-topdir {topDesignDir [protoModelDirName]}
[-blockdir {blockDesignDir [protoModeldirName]}]
-mmmc_file mmmcfileName
[-cpf_file cpfFileName]
[-help]
```

Generate full chip FlexModel netlist by assembling FlexModel partition netlists back to the top-level design for hierarchical FlexModel generation. It automatically creates a full chip FlexModel directory (proto_model) by merging back FlexModel information of all specified partition blocks and assembling back into the top-level design.

The purpose for this command is to get a FlexModel netlist DB in chip-level by assembling the block and top data. This command may be used to help memory usage by not loading a full chip netlist and can be run from where you will run top-down hierarchical flow. This flow should be used if there are partition block netlists.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `assemble_proto_model` parameter. For detailed description of the command and all its parameters, use the man command: `man assemble_proto_model` .
`-blockdir {blockDesignDir [protoModeldirName]}`	

	Specifies the path to block-level design. This directory should contain full netlist and FlexModel netlist of the block-level design and the corresponding proto model directory. If you specify more than one block-level design, then you must specify the `-blockdir` option separately for each block-level design. *protoModelDirName:* Optional. Specifies the directory name where FlexModel models can be found. The default directory name is retrieved from the setting of `set_proto_mode -create_dir` parameter that is specified before running `assemble_proto_model`. If `-create_dir` information is not available then the default directory name will be `proto_model` at the current run directory. It is recommended to specify *`protoModelDirName`* especially for -blockdir parameter. *Data_type*: string, optional
`-cpf_file`	Specifies chip level CPF file. This option should be specified for a design with power domain. *Data_type*: string, optional
`-mmmc_file`	Specifies chip level MMMC file. *Data_type*: string, optional
`protoModelDirName`	Optional. Specifies the directory name where FlexModel models can be found. The default directory name is retrieved from the setting of `set_proto_mode -create_dir` parameter that is specified before running `assemble_proto_model`. If `-create_dir` information is not available then the default directory name will be `proto_model` at the current run directory. It is recommended to specify *`protoModelDirName`* especially for -blockdir parameter. *Data_type*: string, optional
`-topdir {topDesignDir [`*`protoModelDirName`*`]}`	

	Specifies the path to the top-level design directory. This directory should contain top-level design netlist. If the design has Flexmodels then the top-level FlexModel netlist should also be found in this directory with the corresponding proto model directory. *protoModelDirName:* Optional. Specifies the directory name where FlexModel models can be found. The default directory name is retrieved from the setting of `set_proto_mode -create_dir` parameter that is specified before running `assemble_proto_model`. If `-create_dir` information is not available then the default directory name will be `proto_model` at the current run directory. It is recommended to specify *`protoModelDirName`* especially for -blockdir parameter. *Data_type*: string, optional

Examples

- The following command merges all models of partition block designs arb and tdsp_core to the top-level design DTMF_CHIP that does not have any FlexModels.
```
assemble_proto_model -topdir {PTN_dir/DTMF_CHIP} \
-blockdir { PTN_dir/arb/arb_modelgen.enc.dat PTN_dir/arb/proto_model } \
-blockdir { PTN_dir/tdsp_core/tdsp_core_modelgen.enc.dat
PTN_dir/tdsp_core/proto_model} \
-mmmc_file viewDefinition.tcl
```
- The following command merges model of partition block ptn_wrapper to the top-level design dtmf_recvr_core that has FlexModel(s)
```
assemble_proto_model -topdir {PTN/dtmf_recvr_core/modelgen.enc.dat proto_model} \
-blockdir { PTN/ptn_wrapper/modelgen.enc.dat PTN/ptn_wrapper/proto_model } \
-mmmc_file DBS/dtmf_recvr_core.enc.dat/viewDefinition.tcl
```

Related Information

- `create_proto_model`

create_buffer_psPM_table

```
create_buffer_psPM_table
[-help]
[-buffers string]
[-file string]
[-inverters string]
[-layer string]
-max_target_slew float
-min_target_slew float
[-rpt_file string]
[-slew_interval float]
```

Automatically calculates how much distance a specified list of buffers or inverters can drive across a set of routing layers and generates a rule file for the repeaters

For each repeater and routing layer a two pin net is created with given repeater as source and sink. Based on timing, the distance between source and sink is automatically adjusted until slew at the sink is close to the same as the input slew at the source. The command outputs a repeater rule file with one entry for each specified repeater with the distance value that gives the least total delay among all slews and layers. This repeater rule file can be used as an input to the repeater-by-rule commands: `addRepeaterByRule`

Here is a sample rule file:

```
SetBufferDrivingStrength bufferName maxDistanceInMicrons maxCapLoad
SetBufferDrivingStrength ...
SetDefaultDrivingStrength maxDistanceInMicrons maxCapLoad
SetDistLastRepToSink maxDistanceInMicrons
```

There is more information on repeater rule syntax here: `addRepeaterByRule`

Parameters

`-help`	Prints a brief description that includes the type and default information for each `create_buffer_psPM_table` parameter. For a detailed description of the command and all of its parameters, use the man command: `man create_buffer_psPM_table`

`-buffers` *string*	List of input buffers. Specified buffer should have only one input and one output. *Data_type*: string, optional
`-file` *string*	Specifies the `addRepeaterByRule` rule file name. *Default*: `<designName>_repeater.rule`. *Data_type*: string, optional
`-inverters` *string*	List of input inverters. Specified inverter should have only one input and one output. *Data_type*: string, optional
`-layer` *string*	Specifies the layer name. *Default*: All available routing layers. *Data_type*: string, optional
`-max_target_slew` *float*	Maximum target slew in picoseconds. *Data_type*: float, required
`-min_target_slew` *float*	Minimum target slew in picoseconds. *Data_type*: float, required
`-rpt_file` *string*	Report file name. *Default*: `<designName>_buffer_psPM.rpt`. *Data_type*: string, optional
`-slew_interval` *float*	Calculates the step and slew range interval. Specified value should be within [0.01 1.0]. The step is calculated using the following: `step = ($max_target_slew - $min_target_slew) * $slew_interval` *Default*: 0.1 *Data_type*: float, optional

Examples

- The following command reports distances and pico-second delay values per micron for specified buffers `buf2` and `oabuf1` with given minimum and maximum slews:

  ```
  create_buffer_psPM_table -buffers {buf2 oabuf1} -max_target_slew 100 -min_target_slew 70
  ```

- The following command reports distance and pico-second delay values per micron for specified buffers `TBUFX1`, `TBUFX3`, and `TBUFX20` with given minimum, maximum slews, and slew interval:
  ```
  create_buffer_psPM_table -buffers {TBUFX1 TBUFX3 TBUFX20} -min_target_slew 90 -max_target_slew 120 -slew_interval 0.8
  ```
- The following command reports distances and pico-second delay values per micron for specified inverter CLKINVX8 with given minimum, maximum slews, and slew interval:
  ```
  create_buffer_psPM_table -inverters CLKINVX8 -min_target_slew 70.0 -max_target_slew 80.0 -slew_interval 1.0
  ```

Related Information

- `addRepeaterByRule`
- Prototyping Methodologies chapter in the *Innovus User Guide*

create_flexfiller_route_blockage

```
create_flexfiller_route_blockage
[-help]
```

Generates default congestion model to estimate routing blockages over FlexFillers based on user-specified percentage value for characterizing. This command can handle both module-based and instance group-based FlexModels. Routing blockage value of an instance group-based FlexModels will be derived based on its parent module routing blockage value. You should run this command when models are already created.

Note: This command should be used for Active-logic Reduction technique (ART) based model generation flow. For non ART based flow, congestion model can be created during `create_proto_model` command.

Note: The FlexFillers generation capability supports hybrid rows and generates FlexFillers that can fit in the floorplan rows and can be placed legally in the floorplan.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `create_flexfiller_route_blockage` parameter. For a detailed description of the command and all its parameters, use the man command: `man create_flexfiller_route_blockage`.

Examples

- The following example indicates that 10% of created models will be used for routing blockage characterization:

  ```
  create_flexfiller_route_blockage
  ```

- The following example indicates that 80% of created flexmodels will be used for routing blockage characterization and `tdsp_core` and `alu` modules should be part of these 80% models:

  ```
  set_proto_mode -include_model_route_blockage {tdsp_core alu}
  set_proto_mode -characterize_percent_rt_blockage 0.8
  create_flexfiller_route_blockage
  ```

- ```
  Begin pinDensity
  # model_name pin_density flag
  # If flag is 1, use place_design and earlyGlobalRoute result for pin density.
  # If flat is 0, tool auto calculate it based on the pin area and total instance area.
  ```
  ```

```
MOUT_DT_CTL 1.952371 1
ZRAS_RZ 2.361781 0
End pinDensity
```

Related Information

- `create_proto_model`
- Prototyping Methodologies chapter in the *Innovus User Guide*

create_proto_model

```
create_proto_model
[-help]
[-keep_inst_file string]
[ [-out_dir string] [-module_model_tag string] ]
```

Creates prototyping models for the modules or instance groups that are marked as FlexModels on a disk. By default, ART based FlexModels are generated.

Note: To improve the usability, the `create_proto_model` command checks at the beginning if the current loaded design has any marking FlexModel. If the design has marked some modules as FlexModels, then the `create_proto_model` creates prototyping models for the modules or instance groups that are marked as FlexModels. If no FlexModel is marked, then it stops and displays a warning that no FlexModel will be created. Alternatively, if the design has existing FlexModels, which means the netlist has been reduced, then the `create_proto_model` command cannot be run and you need to switch to full netlist to re-generate it.

To generate prototyping models in a specific directory, type the following command:

```
set_proto_mode -create_dir directory_name
```

The default directory name is `proto_model`.

Note: This command supports multi-CPU settings and distributed processing.

```
setMultiCpuUsage -remoteHost 2 -cpuPerRemoteHost 1
setDistributeHost -local
create_proto_model -out_dir
```

Note: This command can handle only upto 1000 FlexModels in a design.

Note: Scan chains are supported during FlexModel creation.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `create_proto_model` parameter. For detailed description of the command and all its parameters, use the `man` command: `man create_proto_model`.

`-keep_inst_file` *string*	Specifies the name of the file that contains the list of instances to be kept specifically for FlexModel generation. **Note**: One instance name must be specified per line. *Data_type*: string, optional
`-module_model_tag` *string*	Specifies the module model tag to be used for ART based FlexModel generation in the iHDB directory structure. This module model tag is used in the Integrated Hierarchical Database (iHDB) flow. **Note:** This parameter is part of the iHDB flow. Before using this parameter, you must set the default central directory name (`set_module_model -default_dir` *default_model_data_directory*) where the module models data will be saved/loaded. For example: If there is a design `ptn_wrapper` and the default central directory is `/project/DATA` on specifying `create_proto_model -module_model_tag proto_model` a flexModel will be created in the following directory: `/project/DATA/ptn_wrapper/proto_model/pnr` **Note:** The structure followed here is: *<module_model_data_dir>/<design_name>/<tag_name>/<type>* *Data_type*: string, optional
`-out_dir` *string*	Specifies a directory name where ART based FlexModel design will be saved. *Default:* `DBS/model_gen.enc` *Data_type*: string, optional

Examples

- The following command creates FlexModels for all the identified modules in the `proto_dir` directory:

  ```
  set_proto_mode -identify_min_inst 2000 -identify_max_inst 5000
  identify_flexmodel
  set_proto_mode -create_dir proto_dir
  create_proto_model -out_dir DBS/model_design.enc
  ```

- The following command generates models using ART technique and save committed FlexModel design into DBS/model_design.enc.dat directory

  ```
  create_proto_model -out_dir DBS/model_design.enc
  ```

create_ps_per_micron_model

```
create_ps_per_micron_model
[-help]
[-overwrite]
```

Derives psPM.model as a separate command. This command is used for active logic flat top model generation. For non-ART model generation, psPM.model can still be generated during `create_proto_model` step. It supports MMMC where it can automatically generate a psPM model file for each delay corner. with this, you can do corner dependent psPM budgeting and generated hold budgeting that is accurate where correct corner is used for hold instead of using one corner for both hold and setup.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `create_ps_per_micron_model` parameter. For a detailed description of the command and all its parameters, use the man command: `man create_ps_per_micron_model`.
`-overwrite`	Overwrites an existing psPM.model. *Data_type*: bool, optional

Examples

The following commands generate psPM.model before running the `create_proto_model` command:

```
restoreDesign DBS/init_design.enc.dat dtmf_recvr_core

create_ps_per_micron_model
identify_proto_model
create_proto_model -flat_top DBS/model_gen.enc
```

Related Information

get_proto_design_mode

```
get_proto_design_mode
[-help]
[-effort]
[-cover_fixed_macros]
[-flexmodel_constraint_type]
[-keep_guide]
[-place_macro]
[-remove_overlap]
[-quiet]
[-nonDefault]
```

Returns information about a specified `set_proto_design_mode` parameter in the Innovus log file and the console. The following information is returned:

- Parameter name
- Current value
- Type (Boolean, string, and so on)
- Whether the current value was set by user

If you do not specify a parameter, the Innovus software returns values for all of the `set_proto_design_mode` parameters.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `get_proto_design_mode` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man` get_proto_design_mode
`parameter_names`	Returns information for the specified parameters. You can specify one or more parameters. See `set_proto_design_mode` for description of parameters.

Examples

- The following command returns the current setting of all proto_design modes:
  `get_proto_design_mode`

Related Information

- `proto_design`
- `set_proto_design_mode`

[-max_report_NDR_net]
[-route_net_NDR]
[-timing_net_delay_model]
[-timing_ps_per_micron]
[-verbose]
[-quiet]
[-nonDefault]
```

Returns information about a specified `set_proto_mode` parameter in the Innovus log file and the console. The following information is returned:

- Parameter name
- Current value
- Type (Boolean, string, and so on)

- Whether the current value was set by user

If you do not specify a parameter, the Innovus software returns values for all of the `set_proto_mode` parameters.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `get_proto_mode` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man get_proto_mode`
`parameter_names`	Returns information for the specified parameters. You can specify one or more parameters. See `set_proto_mode` for description of parameters.

Examples

- The following command retrieves the list of modules that have been excluded from being marked as FlexModels:

  ```
  get_proto_mode -identify_exclude_module
  ```

- The following command retrieves the name of FlexModel directory and estimated delay per micron for each layer:

  ```
  get_proto_model -create_dir -timing_ps_per_micron
  ```

Related Information

- `set_proto_mode`
- `identify_proto_model`
- `set_proto_model`

get_proto_model

```
get_proto_model
[-help]
[-committed]
[-create_optimize_effort]
[-exclude string]
[-file]
[-flip_table]
[-include_default]
[-tcl]
{-all | -model <string> | {[-type_match {flex_module flex_instgroup}] [-source_match {user auto}] }}
[-name | -type  | -create_total_area  | -create_gate_area  | -create_gate_count  | -create_area_per_gate  | -create_extra_macro | -planDesign_target_util | -flexfiller_route_blockage ]
```

Retrieves all the information that you specify on a model in a design. You can retrieve information on all the models or based on your search criteria and also on a specific module name. This commands returns the following information about `set_proto_model` parameters in the Innovus console:

- Parameter name
- Current value
- Type (Boolean, string, and so on)
- Whether the current value was set by user

If you do not specify a parameter, the Innovus software returns values for all of the `set_proto_model` parameters.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `get_proto_model` parameter. For a detailed description of the command and all of its parameters, use the man command: `man get_proto_model`
`-all`	Reports the attributes of all modules. *Data_type*: bool, optional

`-committed`	Reports attributes of committed models only. *Data_type*: bool, optional
`-create_area_per_gate`	Reports the specified area per gate value. *Data_type*: bool, optional
`-create_total_area`	Reports the total area including the standard cell area and the macro area. *Data_type*: bool, optional
`-create_extra_macro`	Reports the specified additional macros. *Data_type*: bool, optional
`-create_gate_area`	Reports the specified gate area value. *Data_type*: bool, optional
`-create_gate_count`	Reports the specified gate count value. *Data_type*: bool, optional
`-create_optimize_effort`	Reports the specified optimization setting. *Data_type*: bool, optional
`-exclude` *string*	Excludes specified option. *Data_type*: string, optional
`-file`	Allows you to output results to a file. *Data_type*: string, optional
`-flexfiller_route_blockage`	Reports percentages of flexFiller route blockage. *Data_type*: bool, optional
`-flip_table`	Flips orientation of the table. *Data_type*: bool, optional
`-include_default`	Includes public options with default parameters in parentheses (for non-tcl output). *Data_type*: bool, optional

`-model` *string*	Reports the attributes of specified models. *Data_type*: string, optional
`-name`	Reports the module name. **Note:** Does not support wildcards. *Data_type*: bool, optional
`-planDesign_target_util` *number*	Specifies the target utilization value to derive initial module size of a model. *Data_type*: bool, optional
`-source_match {user auto}`	Specifies source type for reporting. Valid values are `user` and `auto`. *Data_type*: enum_list, optional
`-tcl`	Reports the model as Tcl list. *Default*: table print *Data_type*: bool, optional
`-type`	Reports the module type. *Data_type*: bool, optional
`-type_match {flex_module flex_instgroup}`	Specifies the type match for reporting. *Default*: flex_module *Data_type*: enum_list, optional

Examples

- The following `get_proto_model` command retrieves the type, source, total area, and the target utilization of the `alu` and `crossbar` modules.

```
set_proto_model -model alu  -type flex_module  -create_total_area   1000  -
planDesign_target_util 0.75
set_proto_model -model crossbar -type full -create_total_area   3000
get_proto_model -all
Model     type          source     create_total_area    planDesign_target_util
alu       flex_module    user             1000                    0.75
crossbar  full           user             3000
```

- The following command returns the values of all models in the Tcl list format.

```
get_proto_model -all  -tcl
{{name alu}  {type flex_module}  {source user}  {create_total_area 1000}
{planDesign_target_util 0.75}}
{{name crossbar}  {type full}  {source user}  {create_total_area 3000}}
```

- The following command only returns flex module's information in Tcl list format

```
get_proto_model -type_match {flex_module}  -tcl
{{name alu}  {type flex_module}  {source user}  {create_total_area 1000}
{planDesign_target_util 0.75}}
```

Related Information

- `set_proto_model`
- Prototyping Methodologies chapter in the *Innovus User Guide*

hilite_proto_model

```
hilite_proto_model
[-help]
[-keep_existing_hilite]
[-type {flex_module flex_instgroup partition power_domain}]
[-reset]
[-level integer] | {[-min_level integer][-max_level integer]}
```

Highlights objects, such as, FlexModels, partitions, and/or power domains. This command automatically resets the list of used colors for each partition, so that the same color(s) can be re-used in different partitions.

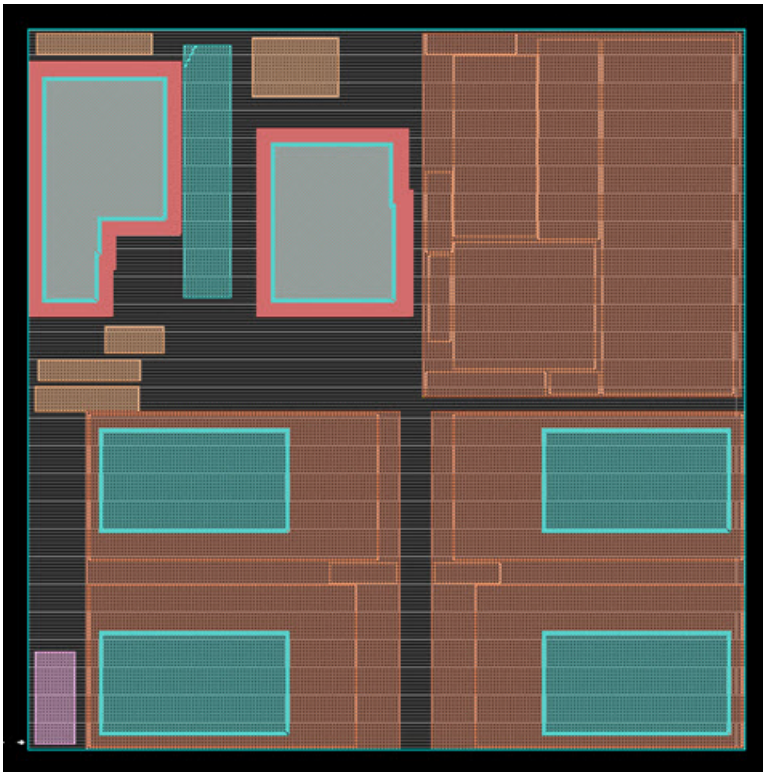
Parameters

`-help`	Prints out the command usage.
`-keep_existing_hilite`	Highlights new objects in addition to the existing highlighted objects. *Data_type*: bool, optional
`-level integer`	Specifies the level to highlight. *Data_type*: int, optional
`-max_level integer`	Highlights objects from level 0 to the specified level. *Data_type*: int, optional
`-min_level integer`	Minimum level to highlight. *Data_type*: int, optional
`-reset`	Resets all the previously highlighted models. *Data_type*: bool, optional
`-type {flex_module flex_instgroup partition power_domain}`	
	Allows you to specify which model type(s) to be highlighted. *Default*: `flex_module flex_instgroup` *Data_type*: enum_list, optional

Examples

The example below has the level range from 0 to 1. So we have `min_level` 0 and `max_level` 1. Default `hilite_proto_model` works levels from min to max.

Before `hilite_proto_model`

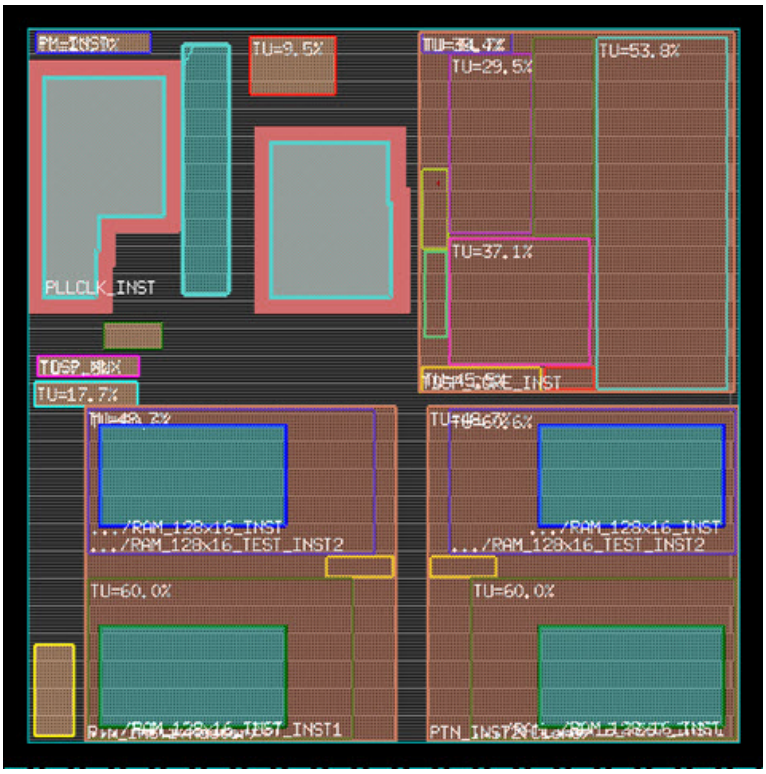


```
hilite_proto_model or <CMD>hilite_proto_model -min_level 0 -max_level 1
```

or

```
hilite_proto_model -min_level 0 #
```

These three usages have the same result on this design.



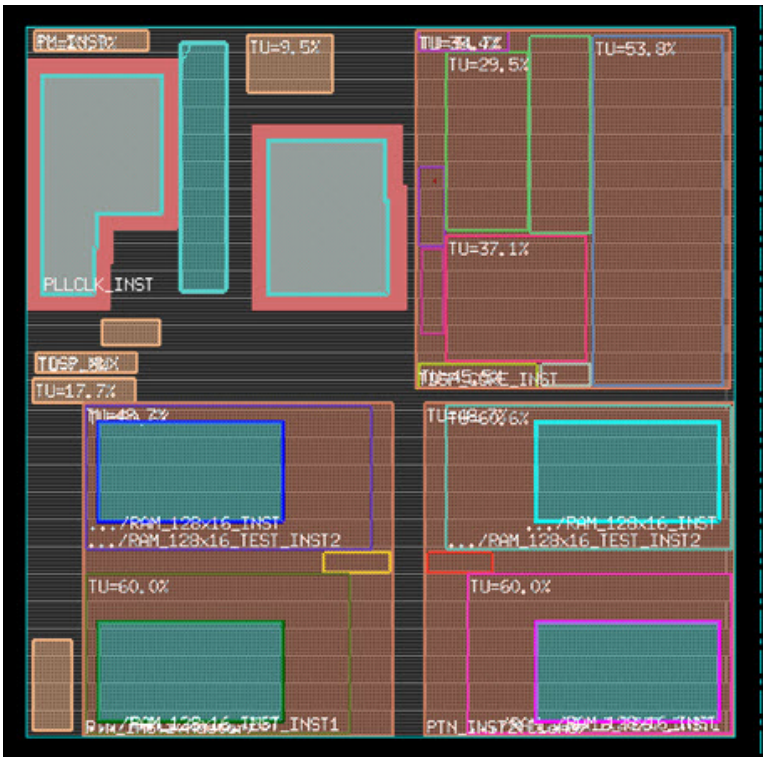
```
hilite_proto_model -level 1 #
```

Only display FlexModels on the specified level.

Or

```
hilite_proto_model -min_level 1 #
```

Display FlexModels upper or equal with level 1.



Related Information

- Prototyping Methodologies chapter in the *Innovus User Guide*

identify_proto_model

```
identify_proto_model
[-help]
[-skip_report]
```

Identifies the modules or instance groups of a design that will become FlexModels. This command supports either module-based or instance group-based FlexModels. If a design netlist has no logical hierarchy, the command will automatically create instance groups based on placement clustering algorithm and identify them as FlexModels.

The `identify_proto_model` command uses the parameters of `set_proto_mode` that have `-identify` as the prefix.

```
set_proto_mode -identify_min_inst number
set_proto_mode -identify_max_inst number
set_proto_mode -identify_exclude_module moduleName
set_proto_mode -identify_exclude_module_tree moduleTree
```

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `identify_proto_model` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man identify_proto_model`.
`-skip_report`	Skips reporting the list of identified flexModels at the end of the command. *Data_type*: bool, optional

Examples

- Consider the following design hierarchy that has 130000 instances at the top level. `MOD1` has 60000 instances, `MOD2` has 40000 instances and `MOD3` has 30000 instances.

```
TOP (130000)
          MOD1 (60000)
                MOD1a (20000)
                MOD1b (10000)
                MOD1c (30000)
          MOD2 (40000)
                MOD2a (20000)
                MOD2b (20000)
          MOD3 (30000)
                MOD3a (20000)
```

- The following commands identify the modules with minimum 20000 instances and maximum 50000 instances, and also excludes the module `MOD3` from being selected as flex_module.

```
set_proto_mode -identify_min_inst 20000 -identify_max_inst 50000
set_proto_mode -identify_exclude_module {MOD3}
identify_proto_model
get_proto_model -type flex_module -tcl -name
MOD1c MOD2 MOD3a
```

  In this example, MOD1a, MOD1c, MOD2, and MOD3a are being marked as flexModels. Here, MOD1 does not get marked as a flexModel because it is more than the maximum instance threshold. MOD1b is less than minimum instance threshold so it is also not marked as a flexModel. MOD3 is excluded because we want to exclude it as mentioned above. However its sub-module MOD3a is marked as a flexModel because it satisfies the minimum instance threshold.

proto_design

```
proto_design
[-help]
[-constraints name]
[-summary file_name]
```

Generates an initial floorplan for prototyping that can be used as a start point for making the final floorplan. It is a super command that places flexModels, power domains, and/or user-specified module seeds.

Note: The `proto_design` command supports multiple levels of hierarchy, such as nested partitions and nested power domains. To support this feature, you can use the `set_proto_mode -proto_design_level multi_level` option. You also have a choice to run proto_design to place FlexModels and/or macro blocks for each level of hierarchy for better placement QOR.

By default, the `proto_design` command makes settings internally so that FlexModel floorplans are available even though any user-defined settings are not made. However, if you make any changes, then the `proto_design` command settings will be overwritten. This feature helps to improve the usability.

Note: The `proto_design` command honors the fence spacing rules.

Parameters

`-constraints` *name*	Specifies the constraint file name (string). Uses the constraints specified in the constraint file for fence creation and module guide generation. A constraint file is a text file that can contain a list of seeds used when generating fences and module guides, and basic relative, spacing and orientation constraints to follow during macro placement. *Data_type*: string, optional
`-help`	Outputs a brief description that includes type and default information for each `proto_design` parameter. For a detailed description of the command and all of its parameters, use the man command: `man proto_design`
`-summary` *file_name*	Specifies the name of the file in which the summary output report with some checkPoints like violation summary, TU of modules, master/clones shape are written. *Data_type*: string, optional

Examples

The following example invokes `proto_design` with the specified constraint file `proto_user_constraint.txt` file with all the default settings:

```
set_proto_design_mode -timing_aware true
proto_design -constraints proto_user_constraint.txt
```

replace_proto_model

```
replace_proto_model
[-help]
[-out_dir string]
[-ptn_dir string]
[-module_model_tag string -full_module_model_tag string]
```

Converts flexmodel netlist back to the original full netlist with changes at the partition block level whenever feedthrough insertion step is needed in the flow. You can use this command after using the `savePartition` command. This command saves a directory under each partition directory with the default name *<designName>_proto_full.enc.dat* and you need to use this DB for block implementation.

To use this command in a FlexModel based partition flow:

1. Import a full chip FlexModel netlist design.
2. Floorplan the design.
3. Run the following commands to analyze the floorplan.
    a. `place_design`
    b. `earlyGlobalRoute`
    c. `timeDesign -proto`
    d. `load_timing_debug_report -proto`
4. Do feedthrough insertion .
5. Do pin assignment
6. Optionally optimize the design.
7. Budget the timing for blocks using the `deriveTimingBudget` command.
8. Partition the design using the `partition` command.
9. Save the partition using `savePartition -dir $ptnDir` (for placement and pin locations copy)
10. `replace_proto_model -ptn_dir $ptnDir -outdir $ptnDir`

Note: The `replace_proto_model` command only supports the netlist changes caused by feedthrough insertion, so `replace_proto_model` will have issues if there is some netlist change issued by other commands such as `createLogicHierarchy` before calling `replace_proto_model`. This is a limitation for the `replace_proto_model` command.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `replace_proto_model` parameter. For a detailed description of the command and all of its parameters, use the man command: `man replace_proto_model`.
`-full_module_model_tag` *string*	Specifies the module model tag for the original full netlist that is used in the iHDB directory structure for saving the full hierarchical DB (*output*) after eco. **Note:** The `-full_module_model_tag` and `-module_model_tag` parameters are part of the Integrated Hierarchical Database (iHDB) flow and are used by the `replace_proto_model` command to convert the FlexModel netlist back to the original full netlist in the iHDB directory structure. Before using these parameters, you must set the default central directory name (`set_module_model -default_dir` *default_model_data_directory*) where the module models data will be saved/loaded. *Data_type*: string, optional
`-module_model_tag` *string*	Specifies the module model tag for the hierarchical DB (*input*). This module model tag is used in the Integrated Hierarchical Database flow. **Note:** The `-full_module_model_tag` and `-module_model_tag` parameters are part of the iHDB flow and are used by the `replace_proto_model` command to convert the FlexModel netlist back to the original full netlist in the iHDB directory structure. Before using these parameters, you must set the default central directory name (`set_module_model -default_dir` *default_model_data_directory*) where the module models data will be saved/loaded. *Data_type*: string, optional

`-out_dir` *string*	Specifies the directory to save post ECO full top/block netlist partition data. *Data_type*: string, optional
`-ptn_dir` *string*	Specifies the partition directory for original full netlist. *Data_type*: string, optional

Example

The following command will read the FlexModel data with tag name “ptn” as input, and dump the original full netlist with tag name “full” in the iHDB directory structure.

```
replace_proto_mode  -module_model_tag ptn -full_module_model_tag full
```

report_proto_model

```
report_proto_model
[-help]
[-constraint]
[-file string]
[-min_inst integer | -identified | -created]
[-min_inst integer]
[-instance_ratio float | -min_inst integer]
```

Reports statistics information for models.

Note: The `report_proto_model` command takes the top-level cells in account while reporting the netlist reduction ratio at the end.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `report_proto_model` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_proto_model`
`-constraint`	Report physical constraint information. *Data_type*: bool, optional
`-created`	Reports the statistics, including reduction ratio of the models that have been created. *Data_type*: bool, optional
`-file` *string*	Specifies output report file name. *Data_type*: string, optional
`-identified`	Reports the statistics of the modules/instgroups that have been identified as models. *Data_type*: bool, optional
`-instance_ratio` *float*	Specifies ratio value where `report_proto_model` only reports flexModels that have instance ratio greater than or equal to this specified value. *Min:* 0 *Max:* 1.79769313486232e+308 *Data_type*: float, optional
`-min_inst` *integer*	Specifies the threshold of an instance count that is used to filter modules. *Data_type*: int, optional

Examples

- The following command reports modules or instance groups have been identified as FlexModels

```
report_proto_model -identified
```

```

Related Information

- set_proto_model
- Prototyping Methodologies chapter in the *Innovus User Guide*

set_proto_design_mode

```
set_proto_design_mode
[-help]
[-reset]
[-cover_fixed_macros {true | false}]
[-effort {low | high}]
[-flexmodel_constraint_type {guide |region |fence}]
[-keep_guide {true  | false}]
[-place_macro {true | false}]
[-remove_overlap {true | false}]
```

Controls certain aspects of how the `proto_design` command generates an initial floorplan. Use the `get_proto_design_mode` command to return the current settings for the `set_proto_design_mode` command.

Parameters

`-cover_fixed_macros {true|false}`	When enabled it forces flexModel to cover fixed macros that belong to it when using the `proto_design` command. *Default*: `false` *Data_type*: bool
`-effort {low | high}`	Specifies the effort level used by the `proto_design` command. *Default*: `low` *Data_type*: bool
`-flexmodel_constraint_type {guide | region | fence}`	
	Specifies the type of constraint the FlexModel is converted to after `proto_design`. *Default*: `region` *Data_type*: enums={guide region fence}
`-help`	Outputs a brief description that includes type and default information for each `set_proto_design_mode` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_proto_design_mode`

`-keep_guide {true|false}`	Retains module guides after the floorplan has been created. *Default*: `true` *Data_type*: bool
`-place_macro {true|false}`	Specifies if macro placement is done when using the `proto_design` command. *Default*: `true` *Data_type*: bool
`-remove_overlap {true|false}`	Specifies if overlap should be removed when using the `proto_design` command. *Default*: `true` *Data_type*: bool
`-reset`	Restores all parameters modified using `set_proto_design_mode` to their default settings. The `-reset` parameter must be the first parameter specified. If you specify `-reset` by itself, the software resets all `set_proto_design_mode` parameters to their default values. If you specify parameters after -reset, the software resets only those parameters to their default values. Any values that do not already match the default value and are reset will be reported.

Examples

The following command runs the prototyping module/macro placer with congestion aware setting:

```
set_proto_design_mode -effort low
proto_design
```

[-verbose]
```

Sets the mode for all the prototyping model commands as well as other commands, such as `place_design` and `timeDesign`. The parameters in this command having prefix as `identify` are used by the `identify_flexmodel` command and the ones with `create` prefix are used with the `create_proto_model` command.

Use the `get_proto_mode` command to return the current settings for the `set_proto_mode` command.

Parameters

`-allow_model_with_io {true|false}`	Allows modules with I/O to be selected as FlexModel. *Default*: `false` *Data_type*: bool
`-allow_powerdomain_in_flexmodel {true|false}`	Allows modules that contains power domain(s) to be selected as FlexModel. *Default*: `false` *Data_type*: bool
`-create_dir` *directoryName*	Specifies the directory to save created models. *Default*: proto_model *Data_type*: string
`-create_high_fanout_psPM {true|false}`	Creates high fanout psPM models. *Default*: `true` *Data_type*: bool
`-create_lib` *libraryName*	Specifies the OpenAccess library to save created models. *Default*: `proto_model_lib` *Data_type*: string
`-create_metal_fill_NDR` *double*	Creates metal fill that is used by `create_ps_per_micron_model` for creating psPM model for nets with non default rules. *Default*: 0 *Data_type*: float
`-create_metal_fill_nominal` *double*	Creates metal fill that is used by create_ps_per_micron_model for creating psPM model for normal nets. *Default*: 0.5 *Data_type*: float

`-create_multi_corner_psPM {true|false}`	Create multi corner psPM models. *Default*: `false` *Data_type*: bool
`-create_NDR_psPM_model {auto|on|off}`	Specifies whether `create_ps_per_micron_model` should generate psPM model for non default rule or not. *Default*: `auto` *Data_type*: enums={auto on off}
`-create_no_flex_filler {true|false}`	Specifies whether to create proto model without adding flex filler. *Default*: `false` *Data_type*: bool
`-create_partition_as_flexmodel {true|false}`	Creates partition specified as flexmodel automatically. *Default*: `false` *Data_type*: bool
`-create_pipeline_flop {*AB*}`	Specifies a list of pipeline flop instance patterns that are used in the design. The default value is an empty list. *Default*: `" "` *Data_type*: string
`-create_powerdomain_psPM {true|false}`	Creates power domain psPM models. *Default*: `false` *Data_type*: bool

`-create_timing_budget {true|false}`	When enabled, it uses Active-Logic Reduction Technology (ART) in timing budget mode during flexModel generation. The FlexModel creation uses the same settings as the `deriveTimingBudget` command to preserve logic paths so that they yield good timing budgets later on in the flow. **Note:** This option should only be specified if design has partitions defined. *Default*: `false` *Data_type*: bool
`-identify_algorithm {auto|module_based|instgroup_based}`	
	Identifies the proto algorithm. Specifying `instgroup_based` enables the instance group based `identify_proto_model`. *Default*: `auto` *Data_type*: enums={auto module_based instgroup_based},
`-identify_estimated_flexmodel_number` *number*	Specifies the estimated flexModel number to identify the design when using the instance group based `identify_proto_model`. *Default*: `20` *Data_type*: int
`-identify_exclude_module {`*module1 module2 ...*`}`	Excludes the specified module(s) but not its sub-modules for being marked as models. *Default*: `""` *Data_type*: string
`-identify_exclude_module_and_parent {`*module1 module2 ...*`}`	Excludes the specified module(s) and its parents for being marked as models. *Default*: `""` *Data_type*: string

`-identify_exclude_module_tree {`*`module1 module2 ...`*`}`	Excludes the specified module(s) and its sub-modules for being marked as flexModels. *Default*: `""` *Data_type*: string
`-identify_honor_objects_hierarchy {`*`object_list`*`}`	Specifies the hierarchy of the list of objects that the instance group based `identify_proto_model` will honor. *Default*: `""` *Data_type*: string
`-identify_max_inst` *number*	Specifies the maximum instance count threshold of a module to be marked as model. The default value is eight percent of the total instance count and goes no lower than 300000 instances. *Default*: -1 *Data_type*: int
`-identify_min_inst` *number*	Specifies the minimum instance count threshold of a module that is to be marked as a model. *Default*: `1000` *Data_type*: int
`-keep_inst_file_only {true|false}`	Specifies that the instance list for flexmodels should only be kept in the `keep_inst_file`. *Default*: false *Data_type*: bool
`-keep_instance_defined_in_sdc {true|false}`	Specifies that the flexmodel will keep the instance defined in the sdc file. *Default*: false *Data_type*: bool

`-keep_slack_improve_NDR {true|false}`	Specifies that report_NDR_WNS_gain will keep top critical nets as non default rule nets. *Default*: false *Data_type*: bool
`-max_report_NDR_net` *double*	Specifies that create_ps_per_micron_model creates psPM model for nets with non default rules. *Default*: 0.05 *Data_type*: float
`-route_net_NDR` *ruleName*	Specifies that create_ps_per_micron_model creates psPM model for nets with non default rules. *Default*: "" *Data_type*: string
`-timing_net_delay_model {best_layer_no_detour|best_layer_blockage_aware|use_actual_wire}]`	
	Allows you to the set mode of calculating wire delay. Note: Using the `best_layer_blockage_aware` option, Innovus uses an obstacle aware approach for estimating the channel-routing-wire-length between two timing points. The `timeDesign -proto` command is aware of routing blockages and other partition fences when the `best_layer_blockage_aware` option is specified. *Default:* `best_layer_no_detour` *Data_type*: enums={best_layer_no_detour best_layer_blockage_aware use_actual_wire}
`-timing_ps_per_micron {`*M<num1>[:M<num2>] psPerMicron ...}, {MetalLayerName1[:MetalLayerName2] psPerMicron ...} {1[:2] psPerMicron ...}, or {view {M<num1>[:M<num2>] psPerMicron ...} ...}, {view {MetalLayerName1[:MetalLayerName2] psPerMicron ...} ...} {view {1[:2] psPerMicron ...} ...}*	

	Specifies the estimated delay per micron for each routing layer (DB or LEF layer names). You can also specify layer pair value for each view. *Data_type*: " " *Data_type*: string
`-reset`	Restores all parameters modified using `set_proto_mode` to their default settings. The `-reset` parameter must be the first parameter specified. If you specify `-reset` by itself, the software resets all `set_proto_mode` parameters to their default values. If you specify parameters after `-reset`, the software resets only those parameters to their default values. Any values that do not already match the default value and are reset will be reported.
`-verbose`	Outputs detailed information into the log file. *Data_type*: false *Data_type*: bool

Examples

- The following command sets the prototyping mode to exclude the module `MOD1` and `MOD2` but not their children for being marked as flexModels:
  ```
  set_proto_mode -identify_exclude_module {MOD1 MOD2}
  ```
- The following command sets the prototyping model to exclude the modules `MOD3` and `MOD4` and their children for being marked as flexModels:
  ```
  set_proto_mode -identify_exclude_module_tree {MOD3 MOD4}
  ```
- The following command specifies the the estimated delay per micron for the routing layer `Metal1` as `0.50`, Metal`2` to Metal`5` as `0.25`, and Metal`6` to Metal`7` as 0.14:
  ```
  set_proto_mode -timing_ps_per_micron {Metal1 0.50 Metal2:Metal5 0.25 Metal6:Metal7 0.14}
  ```
- The following command specifies the estimated delay per micron values that will be used for all

timing views:

```
set_proto_mode -timing_ps_per_micron {M1 0.90 Metal2:Metal4 0.50 Metal5:Metal6 0.25}
```

- The following command specifies the estimated layer pair value for specific views:

```
set_proto_mode -timing_ps_per_micron {setup_func {M1 0.90 Metal2:Metal4 0.50
Metal5:Metal6 0.25} hold_func {Metal1 0.60 Metal2:Metal4 0.30 Metal5:Metal6 0.15}}
```

- The specified percentage of flexModels will be used to characterized for flexFiller routing blockage is 30%.

```
set_proto_mode -create_characterize_percent_rt_blkg 0.3
```

- The following command specifies that instance group based `identify_proto_model` will keep user-specified FlexModels Metal1 and Metal2 and identify all others as instance group based FlexModels.

```
set_proto_model -model Metal1 -type flex_module
set_proto_model -model Metal2 -type flex_module
set_proto_mode -identify_algorithm instgroup_based
identify_proto_model
report_proto_model -identified
```

- The following command ensures that the hierarchy under hinst1 is maintained and modules under hinst1 are not be mixed with other hierarchical modules.

```
set_proto_mode -identify_algorithm instgroup_based
set_proto_mode -identify_honor_objects_hierarchy {hinst1}
identify_proto_model
```

set_proto_model

```
set_proto_model
[-help]
-model name_list
[-type {full | flex_module | flex_instgroup}]
[-create_total_area number | -create_gate_area number |
{-create_gate_count number -create_area_per_gate number}]
[-create_extra_macro {macro_name number
[macro_name number] ...}
[-planDesign_target_util number]
[-reset]
```

The `set_proto_model` command specifies the model type of a specific module.

Note: Wildcards are not supported by this command.

Parameters

`-create_area_per_gate number`	Specifies the area per gate. *Data_type*: float, optional
`-create_extra_macro {macro_namenumber[macro_namenumber] ...}`	Specifies the additional macro(s) of a module that you want to add in the original netlist. If you wish to add extra macros, this option changes the netlist. For example, if your original netlist has macro `A` and you specify an additional macro named macro `B`, then the flexModel with have both macro `A` and macro `B`. *Data_type*: string, optional
`-create_gate_area number`	Specifies the total area of gates. This value does not include macro area. Its unit is square microns. The total area (equivalent to `-create_total_area`) is calculated as the sum of specified total gate area and macro area. *Data_type*: float, optional

`-create_gate_count` *number*	Specifies the number of gates. If you specify this parameter, you also need to specify area per gate value.Total gate area is equal to the product of gate count and area per gate. The calculated total gate area does not include the macro area. So, the total area (equivalent to `-create_total_area`) is equal to the sum of total gate area and the macro area. *Data_type*: int, optional
`-create_total_area` *number*	Specifies the module area of a model that includes the standard cell area and the macro area. **Note**: A warning message is issued when macro area is greater than the area specified using the `-create_total_area` parameter. **Note:** For `-create_area_per_gate number`, `-create_total_area number`, `-create_gate_area number` and `-create_gate_count number`; you can define the area instead of the value calculated by the tool (for times when you wish to specify larger area for the module to achieve better results). *Data_type*: float, optional
`-help`	Outputs a brief description that includes type and default information for each `set_proto_model` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man set_proto_model`.
`-model` *name_list*	Specifies a name for the model type. *Data_type*: string, required

`-planDesign_target_util` *number*	Specifies the target utilization value to derive initial module size of a model. This value is used by the `proto_design` command to derive the module size of a specified flexModel if its module is not placed yet. *Default*: current design utilization **Note:** You can reduce the target utilization value by 10 to 20 percent to account for 10 to 20 percent increase in instance count during optimization.  If the post-target utilization is 0.75, then Cadence recommends you to set the following: `set_proto_mode -model` *name_list* `-planDesign_target_util 0.55` *Data_type*: float, optional
`-reset`	Resets all the attributes of a module. *Data_type*: bool, optional
`-type {full | flex_module | flex_instgroup}`	
	Specifies the model type as full or a flex module or a flexInstgroup. You use this parameter when you want to convert a flex_module back to the original netlist or converse. *Data_type*: enum, optional

Examples

- The following command specifies the number of gates as 10000 and area per gate as 0.65 for the tdsp_core model:

  ```
  set_proto_model -model tdsp_core -create_gate_count 10000 -create_area_per_gate 0.65
  -type flex_module
  ```

- The following command specifies model alu as flex_module with total area `1000` and target utilization `0.75`:

  ```
  set_proto_model -model alu -type flex_module  -create_total_area   1000 -
  planDesign_target_util 0.75
  ```

- The following command specifies model crossbar as flex_module with total area `3000`:

  ```
  set_proto_model -model crossbar  -type flex_module -create_total_area   3000
  ```

- The following command specifies the extra macro `{pllclk 2 ram128x164}` of the `chico` model:

  ```
  set_proto_model -model chico -create_extra_macro {pllclk 2 ram128x164}
  ```

- The following command resets all the attributes of the `alu` model:

  ```
  set_proto_model -model alu -reset
  ```

set_proto_model_physical_constraint

```
set_proto_model_physical_constraint
[-help]
-type {guide | fence | region | soft_guide | none}
[-model string]
```

Sets FlexModels to specific physical constraints to guide placement. By default, all the FlexModels will be set to the specified type.

Parameters

`-help`	Prints out the command usage.
`-model` *string*	Specifies a list of flexmodels. *Data_type*: string, optional
`-type {guide | fence | region | soft_guide | none}`	
	Specifies the constraint type. You can select one of the following options: • `guide` • `fence` • `region` • `soft_guide` • `none` *Data_type*: enum, required

Examples

The following commands change physical constraint of all FlexModels to guide before running detailed placement:

```
set_proto_model_physical_constraint -type guide
set_proto_mode -effort high
place_opt_design
earlyGlobalRoute
timeDesign -proto
```

```
load_timing_debug_report -proto
```

set_proto_timing_settings

```
  set_proto_timing_settings
[-help]
[-reset]
```

Sets or resets the prototyping settings in the flow. The following variables are set by the command:

- `setInputTransitionDelay 80.0psps`
  (*Default:* `250.0ps`)
- `setDefaultNetLoad 0.0pf`
  (*Default:* `0.1pf`)
- `setDefaultNetDelay 0ns`
  (*Default:* `2.5ns`)
- `setUseDefaultDelayLimit 0`
  (*Default:* `300`)
- `setDelayCalMode -enable_high_fanout true`
  (*Default:* `false`)

Parameters

`-help`	Outputs a brief description that includes type and default information for each `set_proto-timing_settings` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_proto-timing_settings`.
`-reset`	Resets all prototyping settings. The settings are enabled by default. It resets the variables mentioned above and rebuilds the timing graph. It also resets the following setting: `setDelayCalMode -ignoreNetLoad false` The above is set to true by `timeDesign -proto`, and must be reset. *Data_type*: bool, optional

SoC Architecture Info (SAI) Commands

- add_sai_boundary_flops
- end_sai
- read_sai
- report_sai_constraint

add_sai_boundary_flops

```
add_sai_boundary_flops
[-help]
[-clock string]
[-delete_flops]
-hinsts string
-ports string
[-ref_flop string [-clock_input_pin string]
[-data_input_pin string]
[-data_output_pin string]]
```

Allows insertion of boundary flops for empty modules/blocks. The command options specify the clock net name, the module name and the module pin name.

Parameters

`-clock` *string*	Specifies clock net name. *Data_type*: string, optional
`-clock_input_pin` *string*	Specifies the cell CLK port name. *Data_type*: string, optional
`-data_input_pin` *string*	Specifies the cell D port name. *Data_type*: string, optional
`-data_output_pin` *string*	Specifies the cell Q port name. *Data_type*: string, optional
`-delete_flops`	Removes all the flops that have been added. *Data_type*: string, optional
`-help`	Outputs a brief description that includes type and default information for each `add_sai_boundary_flops` parameter.
`-hinsts` *string*	Specifies the module name. **Note:** While specifying multiple hinsts and multiple ports, ensure that the number of specified hinsts is the same as the number of specified ports. *Data_type*: string, optional
`-ports` *string*	Specifies the module pin name. *Data_type*: string, optional
`-ref_flop` *string*	Specifies the flop cell name to be inserted along the boundary. *Data_type*: string, optional

Related Information

- `read_sai`
- `end_sai`
- Prototyping Methodologies chapter in the *Innovus User Guide*
- Syntax and Scripts chapter in the *Innovus User Guide*
    - Supported SAI Commands

end_sai

```
end_sai
[-help]
```

Disables the SoC Architecture Information (SAI) mode.

Parameters

`-help`	Prints the command usage.

Related Information

- `read_sai`
- Prototyping Methodologies chapter in the *Innovus User Guide*
- Syntax and Scripts chapter in the *Innovus User Guide*
  - Supported SAI Commands

read_sai

```
read_sai
[-help]
[name]
[-partial]
[-reduce_by_flexfiller]
[-rule_only]
```

Enables the SoC Architecture Information (SAI) mode that allows the use of SAI commands interactively at the command line.

Parameters

`-help`	Prints out the command usage.
name	Specifies the SAI file name. *Data_type*: string, optional
`-partial`	When specified, it enables SAI to support designs loaded using the `restoreDesign` command. Use this option to enable partial netlist support in the SAI mode. *Data_type*: bool, optional
`-reduce_by_flexfiller`	When specified, it adds flexfillers in hinsts added by the `add_module` and `create_module` commands. Use this option to reduce the size of the generated SAI netlist using the FlexFiller technology that is same as the FlexModel methodology. This helps to address the capability and run-time limitations of a growing design size (10 or 100 of million instances). *Data_type*: bool, optional
`-rule_only`	When specified, the rules are imported only in the SAI file. *Data_type*: bool, optional

Example

The following command reads in the *example2.0.sai* file and reduces the SAI netlist while maintaining the module areas:

```
read_sai example2.0.sai -reduce_by_flexfiller
```

Related Information

- end_sai
- Prototyping Methodologies chapter in the *Innovus User Guide*
- Syntax and Scripts chapter in the *Innovus User Guide*
    - Supported SAI Commands

report_sai_constraint

```
report_sai_constraint
[-help]
[-area_weight float]
[-spacing_weight float]
[-order_weight float]
[-congestion_weight float]
[-rule {all | rule_name | rule_name_list}]
```

You can use the `report_sai_constraint` command to validate a floorplan result and to check whether the specified SAI constraints are met. This enables front-end designers to easily evaluate a floorplan provided by their physical designers against the specified floorplan rules without requiring them to have much knowledge about using the Innovus System. The `report_sai_constraint` command reports:

- The general floorplan violations such as macro-to-macro overlap, fence-to-fence overlap, macro overlaps with fence, and/or if macros are placed outside their parent module boundary.
- SAI 2.0 constraint violations
- The Floorplan Quality Index that enables you to estimate whether a floorplan is ready to be used. Floorplan Quality Index is similar to the total negative slack (TNS) concept of timing analysis
- Support area, spacing, net weight, order, and congestion quality indexes; and their index weights.

Besides generating a report, it also creates a violation marker if violations are detected. These violation markers will be displayed in the Innovus artwork window and can be queried from the Innovus violation browser.

Based on the reported floorplan quality index, you can decide whether this floorplan is good to go or not. If the floorplan quality index does not meet your requirements, you can further:

- Adjust the wire length, congestion, and/or overlap cost factors and rerun the `proto_design` command to produce new floorplan result(s).
- Improve the current floorplan by manual adjustment.

Note: Use this command in the SAI interactive mode or write in the SAI file.

Parameters

`-area_weight` *float*	Specifies the weight of the area index. *Default*: 1.0 *Data_type*: float, optional
`-congestion_weight` *float*	Specifies the weight of the congestion index. *Default*: 1.0 *Data_type*: float, optional
`-help`	Outputs a brief description that includes type and default information for each `report_sai_constraint` parameter.
`-order_weight` *float*	Specifies the weight of the order index. *Default*: 1.0 *Data_type*: float, optional
`-rule {all |` *rule_name* `|` *rule_name_list*`}`	
	Checks and reports the violation(s) of the specified rule(s). *Default*: all (All SAI rules of the current design) *Data_type*: string, optional
`-spacing_weight` *float*	Specifies the weight of the area index. *Default*: 1.0 *Data_type*: float, optional

analyze_esd_network

```
analyze_esd_network
[-help]
<run_name>
[-clamp_lowest_layer_taps {true | false}]
[-clamp_pin_short_file pin_shorting_file]
-config_file rule_filename
[-output directory]
[-remove_layers_below layer_name]
[-ta | -task_assistant]
-type {net | domain}
[-use_power_pad {true | false}]
```

Performs different types of effective resistance checks, such as bump to clamp, bump to bump, and clamp to clamp, and current density analysis during an ESD zap event. This command checks whether every power or ground bump has an ESD device, and the device is placed in such a way that it does not violate the effective resistance or current density limit.

The objective of ESD Checker is to easily identify the violations caused by high effective resistance or the current density above the specified threshold value.

Parameters

`-help`	Outputs the command usage and a brief description about the command parameters.
`<run_name>`	Mandatory parameter. Specifies the domain or net name. The result directory is prefixed with `<run_name>`.
`-clamp_lowest_layer_taps {true | false}`	
	Specifies to keep only the lowest layer of clamp taps for effective resistance analysis. The default value is `false`. • When set to `true`, the ESD pin nodes on the lowest layer are shorted, and effective resistance checks are performed to the shorted node on the lowest layer. • When set to `false`, the ESD pin nodes on all layers are shorted, and effective resistance checks are performed to the shorted pin nodes of clamps on different layers.
`-clamp_pin_short_file pin_shorting_file`	

	Specifies the list of pin layers to be shorted for bump-to-clamp and clamp-to-clamp resistance checks. If multiple layers for the same pin are specified, then these layers are shorted with each other.
	The format of the file is:
	`#Cell specification`
	`CELL <cell name> <pin> <layer>`
	`#Instance specification`
	`INST <instance name> <pin> <layer>`
	In this file, multiple layers for the same cell or instance can be specified by adding multiple rows for the same cell or instance name corresponding to each layer.
	If the `-clamp_pin_short_file` parameter is not specified, the software shorts all pin nodes of the lowest ESD cell pin layer, and performs effective resistance checks to the shorted node on the lowest layer.
	Note: If the `-clamp_pin_short_file` parameter is used in conjunction with `-clamp_lowest_layer_taps`, the `-clamp_pin_short_file` parameter will override the settings of `-clamp_lowest_layer_taps`.

`-config_file` *rule_filename*	
	Mandatory parameter. Specifies the name of the rule file that includes all the ESD checks to be performed as a set of rules. It also specifies the effective resistance threshold limit. For more information, refer to the **ESD Rule Specification** section in the "ESD Analysis" chapter of *Voltus User Guide*.
`-output` *directory*	
	Specifies the name of the output directory in which the ESD analysis results are saved.
`-remove_layers_below` *layer_name*	
	Specifies the layer name below which all layers are dropped from analysis. This parameter can be used in scenarios where the ESD cells connect to the PG grid at high layers, and therefore the impact of the lower PG layers is very small on effective resistance calculation and current density checks.
`-ta | -task_assistant`	
	Opens ESD Analysis Task Assistant, a task-based quick help functionality for the ESD analysis flow. The information in the Task Assistant is organized by topics relevant to the task you are performing. It answers frequently asked questions, such as format of the rule file, use model of the command, or supported ESD checks.
`-type {net | domain}`	
	Mandatory parameter. Specifies whether to run rail analysis on a domain or a net.
`-use_power_pad {true | false}`	
	Specifies that the x,y locations of the bump cells are to be obtained from the power pad file. This parameter can be used to support designs for which bump cells are not visible. The default value is `false`.

Examples

- The following commands specify to run ESD analysis on the domain `top`:

```
set_rail_analysis_mode -method static -accuracy hd -power_grid_library ./techonly.cl -ict_em_models ./Data/ESD_em.ict
analyze_esd_network top -config_file ./esd_new_rule.txt -type domain -output ESD_analysis -use_power_pad true
```

Related Information

- `set_rail_analysis_mode`
- `analyze_esd_voltage`

analyze_esd_voltage

```
analyze_esd_voltage
[-help]
-current_distribution_layer layer
-driver_receiver_file filename
-esd_pin_location_file filename
[-maximum_violations value]
-net NetName
[-report filename]
[-threshold value]
-total_current value
[-detailed_report {true | false}]
```

Performs IR Drop analysis for every driver/receiver pair and reports voltage drop above the given limit. Use this command to provide the current injection points (sinks), the current distribution layer (source), and the total ESD current to be distributed. The command generates a report containing all the violations where potential difference across driver/receiver is greater than the given threshold.

Parameters

`-help`	Outputs the command usage and a brief description about the command parameters.
`-current_distribution_layer` *layer*	
	Specifies to distribute current to all nodes of the given layer. This is the LEF/DEF layer name. This is a required parameter.
`-detailed_report {true | false}`	
	Specifies to report the differential voltage for each zap point above the specified threshold. It gives the x,y location of the zap point and the zap point name. Using this parameter, you can fix all the differential voltage violations in a single run. This parameter will generate the report file with the same name as specified using the `-report` parameter and with the `_detail.rpt` suffix. *Default* : `false` The following is an example of the parameter: `analyze_esd_voltage -net VSS -driver_receiver_file ./driverdb_railVSS -esd_pin_location_file VSS.pp -current_distribution_layer METAL5 -total_current 8 -report FULL_new_gnd_esd_cdm.rpt -detailed_report true -threshold 2`
`-driver_receiver_file` *filename*	
	Specifies the name of the driver/receiver file of the net. This file is created by the `-create_driver_db` parameter of the `set_power_analysis_mode`. This is a required parameter. The file has multiple columns, wherein the first column is the receiver, and the remaining columns are drivers to the receiver instance. The following is an example of the file content: **`padring/I_RCV_7`** `io_toplevel/padring/I_DECAP io_toplevel/padring/` In this example: `padring/I_RCV_7` is the receiver instance. `io_toplevel/padring/I_DECAP` and `io_toplevel/padring/` are driver instances.
`-esd_pin_location_file` *filename*	

	Specifies the name of the ESD pin location file. This is a required parameter.
	The format of the file is:
	`#Pin_name x coord y coord layer`
	`gnd_pin_1 2284.6 -2898.05 m4`
	`...`
	`...`

`-maximum_violations` *value*	

	Specifies the number of max worst violations to be reported. This is an optional parameter. When this value is specified, only the specified number of top violations will be reported. If a value is not specified, voltage drop for all driver/receiver pairs will be reported.
`-net` *`NetName`*	
	Specifies the name of the net to be analyzed. This is a required parameter.
`-report` *`filename`*	
	Specifies the name of the output report file in which details of the driver-receiver violation pair is written. This is an optional parameter. The report is filtered in descending order of differential voltage. The output file has four columns: • First column - `Differential voltage(V)` • Second column - `Driver name (node location(um) )` • Third column - `Receiver name (node location(um))` • Fourth column - `ESD pin name (location(nm))` The following is the sample ESD file format: **`14.1324 pmc/a_ip_pmc_chassis_c55fg ( 2050.875 -2760.085 ap ) io_toplevel/padring/I_ESDCLAMP_39 ( 1428.200 2884.250 m4 ) gnd_pin_22 ( 1458.200 2898.050 m4 )`**
`-threshold` *`value`*	
	Specifies the minimum allowed driver/receiver voltage for filtering the report. This is an optional parameter. When a threshold value is specified, driver/receiver pairs with differential voltage greater than the specified threshold value will be reported. If a threshold value is not specified, voltage drop for all driver/receiver pairs will be reported.
`-total_current` *`value`*	
	Specifies the total ESD current to be distributed. The default current unit is amperes. This is a required parameter.

Example

- The following example performs static IR Drop analysis to check the voltage drop between all driver and receiver pairs:

```
analyze_esd_voltage -net gnd -driver_receiver_file ./POWER/driverdb_railgnd  -esd_pin_location_file ./epinfile -
current_distribution_layer m1 -total_current 8 -report FULL_new_gnd_esd_cdm.rpt
```

Related Information

- `set_rail_analysis_mode`
- `analyze_esd_network`
- "ESD Analysis" in the *Voltus IC Power Integrity Solution User Guide*

analyze_joule_heat

```
analyze_joule_heat
[-help]
[-detail_delta_temperature_file filename]
[-detail_delta_temperature_region {x1 y1 x2 y2}]
[-domain rail_domain_name]
[-net pg_net_name]
[-report_conn_pin_wire filename]
[-scale_rms_limit value]
[-tile_delta_temperature_file filename]
[-tiles {n_tile_in_x m_tile_in_y}]
[-output_directory dir_name]
```

Specifies to perform joule heat analysis. This command will use the dynamic RMS current to compute delta-T RMS on the power and signal wires for all segments in the design. The `analyze_joule_heat` command is similar to the `analyze_self_heat` command, except that the `analyze_self_heat` command computes both delta-T FEOL (FEOL self heat) and delta-T RMS (BEOL self heat) whereas the `analyze_joule_heat` command computes only delta-T RMS.

Joule heat analysis (`analyze_joule_heat`) should be performed for the entire design, that is, you must use domain analysis with all PG nets (`-domain ALL`). The `-net <pgnet>` parameter should be used only for preliminary checking.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `analyze_joule_heat` parameter. For a detailed description of the command and all of its parameters, use the man command `man analyze_joule_heat`.
`-detail_delta_temperature_file filename`	
	Specifies the name of the generated BEOL detailed delta-temperature file.
`-detail_delta_temperature_region {x1 y1 x2 y2}`	
	Specifies the region coordinates for generating detailed delta temperature file.
`-domain rail_domain_name`	
	Specifies the domain name of the rail.
`-net pg_net_name`	
	Specifies a net for joule heat analysis.
`-output_directory dir_name`	
	Specifies the directory name for storing the joule heat analysis results. When you specify this parameter, the following result files are saved in the specified directory: • Rail analysis output directory • Detail delta temperature file If `-output_directory` is not specified, by default the joule heat analysis results are stored in the current working directory.
`-report_conn_pin_wire filename`	
	Reports results on wires connecting to cell pins.
`-scale_rms_limit value`	
	Specifies the scale factor for the root-mean-square (rms) limit relaxation factor during Electromigration current limit analysis.
`-tile_delta_temperature_file filename`	
	Specifies the name of the generated BEOL tile-based delta-temperature file.

`-tiles {n_tile_in_x m_tile_in_y}`	
	Specifies the number of tiles in the x and y directions in the tile-based delta temperature file.

Examples

- The following command is an example of `analyze_joule_heat` command:

```
analyze_joule_heat -domain ALL -tile_delta_temperature_file joule_ttm.txt -tiles {10 10} -detail_delta_temperature_file
joule_heat_detail.rpt -report_conn_pin_wire joule_heat.rpt
```

Related Information

- `set_rail_analysis_mode`
- `analyze_self_heat`
- "Self-Heating Effect Analysis" in the *Voltus IC Power Integrity Solution User Guide*

analyze_package

```
analyze_package
[-help] <domain>
[-computer_resources string]
[-output <directoryname>]
-pkg_bga_name <bga_circuitname>
-pkg_die_name <die_circuitname>
-pkg_pin_current_file <filename>
-result_name <filename>
[-spd_file filename]
-type <package_analysis_type>
-workspace <workspace_name>
```

Specifies how the package analysis will be performed, and to run package analysis.

Parameters

`-help`	Outputs the command usage and a brief description about the command parameters.
domain	Specifies the rail analysis domain name.
`-computer_resources` *string*	
	Specifies the computer resources for the package analysis run. This parameter allows you to customize the host distribution/CPU usage for package analysis. The default setting is "`-smt 0 -local -cn localhost -cpus 8`".
`-output <`*directoryname*`>`	
	Specifies the output directory name of the package analysis results. By default, the package model will be created in the specified workspace.
`-pkg_bga_name <`*bga_circuitname*`>`	
	Defines the ball grid array (BGA) circuit name in the package model.
`-pkg_die_name <`*die_circuitname*`>`	
	Defines the die circuit name in the package model.
`-pkg_pin_current_file <`*filename*`>`	
	Specifies the name of the generated pin current file from rail analysis that contains the package pin names and the current values. It is automatically generated after the package model is created.
`-result_name <`*filename*`>`	
	Specifies the name of the .xml result file.
`-spd_file` *filename*	
	Specifies an existing Sigrity .spd file for package analysis. This parameter allows you to specify a .spd file instead of the workspace name (package model database) of the package analysis (PowerDC) tool.
`-type <`*package_analysis_type*`>`	
	Specifies the type of package analysis. Currently, the software supports only DC package analysis.
`-workspace <`*workspace_name*`>`	
	Specifies the workspace name for package analysis (powerDC). The file name extension is `.pdcx`.

Example

- The following example specifies the package analysis details and starts package analysis:

```
analyze_package ALL \
-type dc \
-workspace /../sigrity/rak_pdc_irdrop/test.pdcx \
-pkg_bga_name FPBGA144_Signal02 \
-pkg_die_name CD1_Signal01 \
-output rak_pdc_irdrop_voltus_cpf \
-result_name rak_pdc_irdrop_voltus \
-pkg_pin_current_file /../spa_cpf/ALL_125C_avg_1/Reports/super_filter_pkg_iv.rpt
```

Related Information

- set_rail_analysis_mode

- "Package Analysis" in the *Voltus IC Power Integrity Solution User Guide*

analyze_rail

```
analyze_rail
[-help]
[-type {domain | net}]
[-output directory_name]
name
```

Runs rail analysis on a net or domain. This command must be specified after defining the rail analysis mode properties using the `set_rail_analysis_mode` command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `analyze_rail` parameter. For a detailed description of the command and all of its parameters, use the man command `man analyze_rail`.
name	Specifies the name of the domain or net that you want to analyze.
`-output` *directory_name*	
	Specifies the name of the directory in which to store the output directories created during the analysis. *Default*: Current working directory.
`-type {domain | net}`	
	Specifies whether to run rail analysis on a domain or a net. A domain is a list of power or ground nets to analyze together. See `set_power_pads` for more details. You can specify the variable "ALL" to analyze all domains.

Examples

- The following command performs an analysis for the `vdd` net and places the results directories in the `analysis_out` directory:
  ```
  analyze_rail -type net -output analysis_out vdd
  ```
- The next command performs rail analysis on TDSP power domain and writes the results in current working directory.
  ```
  analyze_rail -type domain -output ./ TDSP
  ```
- The following command performs rail analysis on all power domains and writes the results in the current working directory:
  ```
  analyze_rail -type domain ALL -output ./
  ```

Related Information

- `set_rail_analysis_mode`

analyze_resistance

```
analyze_resistance
[-help]
[-cell master_cell_name]
[-die_mode {3dic}]
[-force_reextraction {true | false}]
[-instance_list {instance1 pin1 instance2 pin2...}]
[-instance_list_file filename]
[-instance_pair_list {instance1 instance2 pin1  pin2 ...}]
[-instance_pair_list_file filename]
-net netName | -domain domainName
[-node_list {node1 node2.....  METAL_LAYER LABEL}]
[-node_list_file filename]
[-node_pair_list {node1X node1Y METAL_LAYER1 node2X node2Y METAL_LAYER2...LABEL}]
[-node_pair_list_file filename]
[-output filename]
[-output_dir directory_name]
[-region {x1 y1 x2 y2 layer number_of_nodes region_name}]
[-report_limit value]
[-threshold value]
[-print_cell_name]
[-domain_threshold value]
[-net_threshold value]
[-exclude_list_file filename]
```

Performs effective resistance analysis. Effective resistance computes effective resistance between two nodes on the power-grid, or from a node to all the voltage sources in the design, or from an instance to all the voltage sources in the design.

You can run this command without performing power calculation and IRdrop analysis. The flow requires you to load the design, set power nets, set power pads, and run resistance analysis. This command enables the tool to consider the entire power structure, including embedded ring structure within IO cells if any.

Note: The `analyze_resistance` full chip analysis supports running the `set_rail_analysis_mode -enable_rlrp_analysis` command to perform least resistance path analysis (RLRP) in conjunction with effective resistance analysis (REFF) in the DP mode. However, RLRP and REFF analysis should be done separately in the XP mode. When performing the point-to-point effective resistance analysis (`analyze_resistance`) for the power/signal nets in the XP mode, disable the RLRP analysis (`set_rail_analysis_mode -enable_rlrp_analysis false`).

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `analyze_resistance` parameter. For a detailed description of the command and all of its parameters, use the man command `man analyze_resistance`.
`-cell` *master_cell_name*	
	Reports effective resistance for all instances of the specified master cell name. The `-cell` parameter improves the usability of effective resistance ca specify only the cell name of the instances you want to analyze. You can specify multiple cells for performing effective resistance analysis of multipl
`-die_mode {3dic}`	
	Specifies to perform multi-die effective resistance analysis.
`-domain` *domainName*	
	Specifies the domain name that is to be analyzed.
`-domain_threshold` *value*	
	Specifies the minimum allowed effective resistance (effective resistance sum of each net) to instance. For specific instance list analysis, the instanc will be reported as “PASS”, while the instances above the threshold value will be reported as “FAIL”. For full chip analysis, the instances below the t reported in the domain report. The default value is 0.
`-exclude_list_file` *filename*	

Specifies the name of a file containing a list of cells or instances that will not be processed during the resistance analysis flow. The specified cells/ir report generation.
The use model of this parameter is:

```
analyze_resistance -exclude_list_file <file_name>
```

File Format:

```
<CELL | INST> <name>
```

Example:

```
CELL BUMP_MASTER
CELL ESD_MASTER
INST INSTA
```

`-force_reextraction {true | false}`

Specifies to force a re-extract of resistances.

`-instance_list {instance1 pin1 instance2 pin2...}`

Specifies the list of instances for which effective resistance is to be calculated. *pin* is an optional argument. By default, the tool will use the instance being analyzed. The *pin* argument can be used in special cases when two different pins of an instance are connected to the same net.

Note: The `-instance_list` and `-instance_list_file` parameters are mutually exclusive to the `-instance_pair_list` and `-instance_pair_list_fil` that you can specify `-instance_list` and `-instance_list_file` together but you cannot specify `-instance_list` and `-instance_list_pair` together.

`-instance_list_file filename`

Specifies the name of the instance list file. This file contains the list of instances in the same format as mentioned for the `-instance _list` paramete specify a large number of instances. `-instance _list_file` and `-instance _list` are mutually exclusive.

Note: The `-instance_list` and `-instance_list_file` parameters are mutually exclusive to the `-instance_pair_list` and `-instance_pair_list_fil` that you can specify `-instance_list` and `-instance_list_file` together but you cannot specify `-instance_list` and `-instance_list_pair` together.

`-instance_pair_list {instance1 instance2 pin1 pin2 ... }`

Specifies the instance pair list to enable effective resistance calculation between two instances in the design. *pin1* and *pin2* are pins of *instance1*

Note: The `-instance_list` and `-instance_list_file` parameters are mutually exclusive to the `-instance_pair_list` and `-instance_pair_list_fil` that you can specify `-instance_list` and `-instance_list_file` together but you cannot specify `-instance_list` and `-instance_list_pair` together.

`-instance_pair_list_file filename`

Specifies the name of the instance pair list file. This file contains the instance pair list in the same format as mentioned for the `-instance _pair_list` you to specify a large number of instance pairs. `-instance_pair_list_file` and `-instance_pair_list` are mutually exclusive.

Note: The `-instance_list` and `-instance_list_file` parameters are mutually exclusive to the `-instance_pair_list` and `-instance_pair_list_fil` that you can specify `-instance_list` and `-instance_list_file` together but you cannot specify `-instance_list` and `-instance_list_pair` together.

`-net netName`

Specifies the net name that is to be analyzed.

`-net_threshold value`

The effective resistance requirements for different power nets vary depending on the design. For example, an array or periphery supply to an SRAM lower effective resistance threshold compared to the core supplies. This parameter allows you to specify different threshold values for different nets.

The use model of this parameter is given below:

```
set_rail_analysis_domain -name ALL -pwrnets {vdd vddar vdda vdd1 vdd2} -gndnets vss
analyze_resistance -threshold 50 -net_threshold {{vdd 50} {vddar 20} {vdda 35} {vss 40}} -domain ALL -output_dir Reffective
```

In this example, the threshold value for different nets are:

vdd -> 50
vddar →20
vdda -> 35
vss -> 40
vdd1 -> 50
vdd2 -> 50

Here, for all the remaining nets for which a value is not specified using the `-net_threshold` parameter, the value specified with the `-threshold` parar

The different threshold values will have an impact on the list of instances reported in the `<state_dir>/Reports/<net>/<net>.effr` report.

`-node_list {node1 node2..... METAL_LAYER LABEL}`

Specifies the list of user-defined nodes for effective resistance calculation between the specified user-defined nodes and all voltage sources. You ca on the region on a given layer. `LABEL` is any name chosen by you to identify node entries in the list. This is optional but helps during debugging.

Note: The `-node_list` and `-node_list_file` parameters are mutually exclusive to the `-node_pair_list` and `-node_pair_list_file` parameters. This `-node_list` and `-node_list_file` together but you cannot specify `-node_list` and `-node_pair_list` together.

`-node_list_file filename`

Specifies the name of the node list file. This file contains the list of user-defined nodes in the same format as mentioned for the `-node_list` paramete specify a large number of nodes.

You can specify multiple nets for node list based resistance analysis. The use model for multiple nets is:
`analyze_resistance -domain <domain name> -node_list_file <filename>`

Here,

- the `-domain` parameter will specify the domain name, that is, the domain with nets that is required to be analyzed.
- the `-node_list_file` parameter will include the multiple net names

The format for specifying multiple nets is:

```
NET <netname1>
node1X node1Y METAL_LAYER [LABEL]
node2X node2Y METAL_LAYER [LABEL]

NET <netname2>
node1X node1Y METAL_LAYER [LABEL]
node2X node2Y METAL_LAYER [LABEL]
```

Note: The `-node_list` and `-node_list_file` parameters are mutually exclusive to the `-node_pair_list` and `-node_pair_list_file` parameters. This `-node_list` and `-node_list_file` together but you cannot specify `-node_list` and `-node_pair_list` together.

`-node_pair_list {node1X node1Y METAL_LAYER1 node2X node2Y METAL_LAYER2... LABEL }`

Specifies the node pair list for effective resistance calculation between two nodes on the power-grid. `You can add a list of nodes based on the LABEL` is any name chosen by you to identify node entries in the list. This is optional but helps during debugging.

Note: The `-node_list` and `-node_list_file` parameters are mutually exclusive to the `-node_pair_list` and `-node_pair_list_file` parameters. This `-node_list` and `-node_list_file` together but you cannot specify `-node_list` and `-node_pair_list` together.

`-node_pair_list_file filename`

Specifies the name of the node pair list file. This file contains the node pair list in the same format as mentioned for the `-node_pair_list` parameter. a large number of node pairs.

You can specify multiple nets for node pair list based resistance analysis. The use model for multiple nets is:
`analyze_resistance -domain <domain name> -node_pair_list_file <filename>`

Here,

- the `-domain` parameter will specify the domain name, that is, the domain with nets that is required to be analyzed.
- the `-node_pair_list_file` parameter will include the multiple net names

The format for specifying multiple nets is:

```
NET <netname1>
node1X node1Y METAL_LAYER1 node2X node2Y METAL_LAYER2 [LABEL]
node3X node3Y METAL_LAYER3 node4X node4Y METAL_LAYER4 [LABEL]

NET <netname2>
node1X node1Y METAL_LAYER1 node2X node2Y METAL_LAYER2 [LABEL]
node3X node3Y METAL_LAYER1 node4X node4Y METAL_LAYER4 [LABEL]
```

Note: The `-node_list` and `-node_list_file` parameters are mutually exclusive to the `-node_pair_list` and `-node_pair_list_file` parameters. This `-node_list` and `-node_list_file` together but you cannot specify `-node_list` and `-node_pair_list` together.

`-output filename`

Specifies the name of the output report file that contains the report header and the sorted list for resistance values.

Note: This parameter should not be specified in the XP flow as the XP reports are consolidated under the state directory by default.

`-output_dir` *directory_name*	
	Specifies the name of the directory in which the output report file is saved.
`-print_cell_name`	
	Specifies to print cell names in the effective resistance report. This parameter allows you to sort resistance values by cell names.
`-region {`*x1 y1 x2 y2 layer number_of_nodes region_name*`}`	
	Analyzes resistance in the specified region. You can draw a box on a specific layer, and specify the number of nodes to be selected (maximum limit parameter allows you to compute effective resistance on a given layer across the chip and determine how the resistance is changing for the design can assign a name for the region.
`-report_limit` *value*	
	Specifies the number of instances printed in the report to save disk space.
`-threshold value`	
	Specifies the minimum allowed effective resistance to display node/node-pair/instance/instance-pair that have a resistance value above this thresh threshold as a non zero value, then instances with resistance value above that threshold will be tagged as FAIL and the rest will be tagged as PASS

Examples

- The following command performs effective resistance calculation for the list of nodes and instances:
  ```
  analyze_resistance -net VSS -node_list { 231 1061.6 M1 } -instance_list_file instance.list
  ```
- The following command specifies a list of user-defined nodes and a node list file for effective resistance calculation:
  ```
  analyze_resistance -net VDD -node_list {{ 213.556 133.469 M1  I123 }} -node_list_file /../node_list.txt.1 -output reff_rpt
  ```
- The following is an example of specifying a list of instances for effective resistance calculation:
  ```
  analyze_resistance -instance_list {{INV11 vdd} {INV21 vdd}} -net VDD
  ```
- The following is an example of specifying a list of user-defined nodes for effective resistance calculation:
  ```
  analyze_resistance -net VDD -node_list {{800 11.88 M4} {999.768 11.88 M4} {1000.296 11.880 M4}} -output out.txt
  ```
- The following is an example of specifying node pair list for effective resistance calculation:
  ```
  analyze_resistance -net VDD -node_pair_list {195.728 133.369 M1 213.556 133.469 M1} -output out_nodelist.txt
  ```
- The following is an example of specifying instance pair list for effective resistance calculation:
  ```
  analyze_resistance -net GND -instance_pair_list {inst1 inst2 GND GND} -output outfile -threshold 100
  ```
- The following command performs effective resistance calculation for full chip analysis:
  ```
  analyze_resistance -threshold 13.0  -domain_threshold 25.0 -domain ALL
  ```

  Sample Report:

  ```
  NET: VSS VDD
  # Threshold:   25.000
  # Total Effective resistance for instances sorted from high to low
  # PASS/FAIL         REFF  INSTANCE                 PIN...

    FAIL            25.664  clk__L1_I1       VDD(51.52%)      VSS(48.48%)
    FAIL             25.35  clk__L2_I1       VDD(52.16%)      VSS(47.84%)
    FAIL            25.037  clk__L3_I1       VDD(51.56%)      VSS(48.44%)
  ```

- The following command performs effective resistance calculation for instance list analysis:
  ```
  analyze_resistance -domain ALL -threshold 13.0 -domain_threshold 25.0 -instance_list_file inst.list
  ```

  Sample Report:

  ```
  NET: VSS VDD
  # Threshold:   25.000
  # Total Effective resistance for instances sorted from high to low

  # PASS/FAIL         REFF  INSTANCE             PIN...
    FAIL            25.664  clk__L1_I1       VDD(51.52%)      VSS(48.48%)
    FAIL            25.35   clk__L2_I1       VDD(52.16%)      VSS(47.84%)
    FAIL            25.037  clk__L3_I1       VDD(51.56%)      VSS(48.44%)
    PASS            24.724  clk__L4_I1       VDD(52.21%)      VSS(47.79%)
    PASS            23.047  inst_pll         VDD(50.55%)      VSS(49.45%)
  ```

- The following command reports reff for all instances of the cell type CKBD8:
  ```
  analyze_resistance -net VDD -cell CKBD8
  ```
  The following is a sample reff report generated using the `-cell` parameter:

  ```
  ****************

  # Layer Representation: LEF
  # Coordinate Unit: um
  # Resistance Unit: Ohm

  NET: VDD
  # Threshold:    0.000
  # Effective resistance for instances sorted from low to high
  # PASS/FAIL       REFF        INSTANCE          PIN
    -             3.5752    add_94_37_I2/g695    VDD
    -             3.7521    add_94_37_I2/g694    VDD
  ```

analyze_self_heat

```
analyze_self_heat
[-help]
[-domain rail_domain_name]
[-output_directory   dir_name]
```

Runs Self-Heating Effect (SHE) analysis on a single die or multiple dies. This command must be specified after defining the SHE properties using the `set_self_heat_analysis_mode` command.

Self-heat analysis (`analyze_self_heat`) should be performed for the entire design, that is, you must use domain analysis with all PG nets (`-domain ALL`).

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `analyze_self_heat` parameter. For a detailed description of the command and all of its parameters, use the man command `man analyze_self_heat`.
`-domain rail_domain_name`	
	Specifies the domain name of the rail.
`-output_directory   dir_name`	
	Specifies the directory name for storing the self-heat analysis results. When you specify this parameter, the following result files are saved in the specified directory: • Rail analysis output directory • Detail delta temperature file • Instance delta temperature file • Tile delta temperature file If `-output_directory` is not specified, by default the self-heat analysis results are stored in the current working directory.

Examples

- The following command is an example of the `analyze_self_heat` command in the multi-die analysis flow:

```
set_self_heat_analysis_mode \
-die_instance_name die0 \
-alpha_parameters {{M1 0.74 0.85} {M2 0.62 0.85} {M3 0.53 0.85} ....} \
-beta_parameters {0.00423 -0.00045 0.81534}\
-instance_power_file ./dynamic_power.rpt \
-cell_thermal_resistance_file TRF.txt \
-instance_delta_temperature_file sh_itm.txt \
-tile_delta_temperature_file sh_ttm.txt \
-tiles {10 10} \
-detail_delta_temperature_file power_detail_die0.rpt

set_self_heat_analysis_mode \
-die_instance_name die1 \
-alpha_parameters {{M1 0.74 0.85} {M2 0.62 0.85} {M3 0.53 0.85} ...} \
-beta_parameters {0.00423 -0.00045 0.81534}\
-instance_power_file ./dynamic_power.rpt \
-cell_thermal_resistance_file TRF.txt \
-instance_delta_temperature_file sh_itm.txt \
-tile_delta_temperature_file sh_ttm.txt \
-tiles {10 10} \
-detail_delta_temperature_file power_detail_die1.rpt

set_self_heat_analysis_mode \
-die_instance_name die2 \
-alpha_parameters {{M1 0.74 0.85} {M2 0.62 0.85} {M3 0.53 0.85} ...} \
-beta_parameters {0.00423 -0.00045 0.81534}\
-instance_power_file ./dynamic_power.rpt \
-cell_thermal_resistance_file TRF.txt \
-instance_delta_temperature_file sh_itm.txt \
-tile_delta_temperature_file sh_ttm.txt \
-tiles {10 10} \
-detail_delta_temperature_file power_detail_die2.rpt

analyze_self_heat -domain core
```

analyze_signal_resistance

```
analyze_signal_resistance

[-help]
[-instance_pair_list_file filename]
-net net_name
[-output_dir directory]
[-report filename]
[-threshold value]
```

Computes effective resistance for signal nets from a given instance1/pin1 to instance2/pin2 accounting all applicable manufacturing effects. You can use the effective resistance output file to determine whether the critical routes are within the specified resistance limits.

Parameters

`-help`	Outputs the command usage and a brief description about the command parameters.
`-instance_pair_list_file filename`	
	Specifies the file name containing the signal net instance-pin pairs for which effective resistance needs to be computed. The format of the file is: `INST1 PIN1 INST2 PIN2`
`-net net_name`	
	Specifies the name of the signal net.
`-output_dir directory`	
	Specifies the name of the output directory.
`-report filename`	
	Specifies the name of the report file in which details of effective resistance between instance-pin pairs are written.
`-threshold value`	
	Specifies the minimum allowed effective resistance between instance-pin pairs.

Examples

- The following command computes effective resistance for the signal net `n_13190`:
  ```
  analyze_signal_resistance -net n_13190
  ```
- The following command computes effective resistance for the signal net `n_13190`, and writes the effective resistance details in the report `n_13190.rpt`:
  ```
  analyze_signal_resistance -net n_13190 -report n_13190.rpt
  ```
- The following command computes effective resistance for signal net instance-pin pairs specified in the file `instance.list`:
  ```
  analyze_signal_resistance -net n_0 -instance_pair_list_file instance.list
  ```

Related Information

- `set_rail_analysis_mode`
- `analyze_resistance`
- "Static Power, IRdrop and EM Analysis" in the *Voltus IC Power Integrity Solution User Guide*

calculate_didt

```
calculate_didt
[-help]
-net_name net_name
-nworst value
-state_directory dir
[-window_steps value | -window_size value ]
```

Generates the on-die di/dt information from an existing dynamic rail analysis run and saves it in a text file. This command allows you to determine the worst N di/dt events for each bump and for the sum of all bumps (vc_sum).

Parameters

`-help`	Prints a brief description that includes the type and default information for each `calculate_didt` parameter. For a detailed description of the command and all of its parameters, use the man command: `man calculate_didt`
`-net_name net_name`	
	Specifies a net for which the di/dt report is to be generated.
`-nworst value`	
	Specifies the number of worst windows with the largest di/dt values to be reported per bump.
`-state_directory dir`	
	Specifies the name of the state directory where the information on the bump-based di/dt information from the previous run resides.
`-window_steps value`	
	Specifies the transient time step size or resolution of the sliding window. The default value is `5`.
`-window_size value`	
	Specifies the duration of the sliding window in seconds. **Note**: The `-window_size` and `-window_steps` parameters are mutually exclusive. When both the parameters are specified, the `-window_size` parameter takes precedence. If you do not specify either of the two parameters, the results will be based on a default of 5 resolution steps.

Examples

- The following command generates the on-die di/dt information:
  ```
  calculate_didt -nworst 3 -window_steps 10 -net_name VDD10 -state_directory ./dynamic_rail/core_125C_dynamic_1
  ```

calculate_differential_voltage

```
calculate_differential_voltage
[-help]
-diffv_limit value
-power_directory directory_name
-state_directory directory_name
```

Determines the differential voltage between a receiver/driver pair during ramp-up analysis. This command can be used to mitigate the risk of high short-circuit current for a driver-receiver instance pair due to slow/fast (differential) ramp-up voltage at the output of the power-switch cell connected to the driver/receiver cell.

The `calculate_differential_voltage` command reports the differential potential for those receiver/driver pairs that are greater than the the specified differential voltage threshold, and the time interval at which the differential voltage remains greater than the threshold. You must specify the `set_power_analysis_mode -create_driver_db true` parameter before specifying this command.

The following is the format of the output report:

```
# <driverName>   <receiverName>   <peak_diffv>  <minT>   <maxT>
```

Parameters

`-help`	Outputs the command usage and a brief description about the command parameters.
`-diffv_limit value`	
	Specifies to report differential voltage for the receiver/driver pairs that exceed the specified threshold limit.
`-power_directory directory_name`	
	Specifies the path to the power directory to access the driver-receiver pairs.
`-state_directory directory_name`	
	Specifies the path to the state directory generated by rail analysis to access the EIV or timing database.

Examples

- The following command lists all the driver-receiver pairs that exceed the differential voltage limit of 0.001:

  ```
  calculate_differential_voltage -diffv_limit 0.001 -state_directory dynamic_rail/core_105C_dynamic_1 -power_directory dynamic_power
  ```

  The following is a snippet of the generated report:

  ```
  # <driverName>          <receiverName>        <peak_diffv>     <minT>     <maxT>
  column/MSV_I2         column/MULT8_reg_1_4     0.7382          5e-11    2.75e-09
  column/HIER_INST      column/MULT8_reg_1_4     0.7382          5e-11    2.75e-09
  ...
  ```

Related Information

calculate_noise_margin

```
calculate_noise_margin
[-help]
-noise_limit_file input_file
-power_directory dir
-state_directory dir
```

Specifies to calculate noise margins with worst voltages on the driver-receiver pins. To run this command, you need to specify the default or cell-specific noise limit, signal noise, guardband, rail directory, and power directory. Before running the `calculate_noise_margin` command, you need to specify the `set_power_analysis_mode -create_driver_db true` parameter to generate the driver-receiver database.

The use model of the command is:

```
set_power_analysis_mode ... -create_driver_db true
calculate_noise_margin -noise_limit_file input_file -state_directory dir -power_directory file
```

The command generates the noise margin output file in the state directory. The format of the noise margin output file (*powernetname_groundnetname*`.noise_margin`) is:

Margin_High(V)	Margin_Low(V)	NMH(V)	NMI(V)	Voh(V)	Vol(V)	Vih(V)	Vil(V)	Signal_Noise(V)	Guardband(V)	Dr Inst/pin	Rx Inst/pin
NMH - signal noise - guardband	NMI - signal noise - guardband	Voh - Vih	Vil - Vol	VDD_driver - VSS_receiver	VSS_driver - VSS_receiver	(1-noise_limit) * (VDD_receiver - VSS_receiver) noise_limit is the noise limit value specified in the noise limit file	noise_limit* (VDD_receiver - VSS_receiver) noise_limit is the noise limit value specified in the noise limit file	Signal noise value specified in the noise limit file	Guardband value specified in the noise limit file	Driver pin name	Receiver pin name

Parameters

`-help`	Prints a brief description that includes the type and default information for each `calculate_noise_margin` parameter. For a detailed description of the command and all of its parameters, use the man command: `man calculate_noise_margin`
`-noise_limit_file` *input_file*	

	Specifies the name of the input noise limit file that contains the default or cell-specific noise limit, signal noise, and guardband. The format of the noise limit file is:
	`default_noise_limit <value>`
	`default_signal_noise <value>`
	`default_guard_band <value>`
	`<cell_name> <noise_limit> <signal_noise> <guard_band>`
	The following is a snippet of the noise limit file:
	`default_noise_limit 0.46`
	`default_signal_noise 0.1`
	`default_guard_band 0.05`

`-power_directory` *dir*	

	Specifies the path to the power directory to access driver-receiver pairs.
`-state_directory` *dir*	
	Specifies the path to the state directory generated by rail analysis to access EIV database.

Examples

- The following command calculates noise margin:
  ```
  calculate_noise_margin -noise_limit_file ./noiselimit -state_directory dynamic_rail/core_105C_dynamic_1 -power_directory dynamic_power
  ```

convert_gds_to_def

```
convert_gds_to_def
[-help]
[-black_box_cell_file filename]
-gds_file filename
-gds_layermap filename
[-inst_name_file filename]
-net_location_file filename
[-output_components {ALL | NONE | CONN}]
-output_def_file filename
[-output_lef_macros filename]
-power_grid_library libraryname
-top_cell cellname
[-use_gds_label {ALL | TOP | <tech_layer_name> | <cell_name>:<tech_layer_name> | <cell_name>:ALL}]
[-verilog_file filename]
[-spef_file filename]
[-esd_marker_layer_file filename]
[-esd_cell_bbox_file filename]
[-inst_name_prefix prefix]
[-ignore_gds_inst_name]
[-print_complete_short_path]
[-extract_signal_net_logic_info_only]
[-zero_pin_size]
```

A GDS2DEF utility that converts a given GDSII file to a DEF file for power/rail signoff analysis. The utility can convert both cell-level GDS and full-chip level GDS to DEF. The generated DEF contains all the geometries for the P/G routing, the specified P/G pin information, component and logical connectivity information.

Parameters

`-help`	Outputs the command usage.
`-black_box_cell_file filename`	

	Specifies the name of a file containing a list of black box cells that the utility is to ignore. You can specify both exact string matches and wildcard searches in the specified file.
	For exact string matches, each cell name must reside on a separate line in the file, as shown below:
	`CellA`
	`CellB`
	The wildcard search feature allows you to search cell names that contain wildcard characters, such as square brackets and underscore. When you want to perform wildcard search, type the keyword `wildcard` first, followed by the cell name. For example, if you want to ignore cell names which contains CLK, add one line `wildcard .*CLK.*`.

`-esd_marker_layer_file filename`	

	Specifies a file that includes a list of ESD cell/instance names and their corresponding GDS marker layers that represent the bounding box of the ESD cells. The format of the file is:
	`<cell_name> <marker_layer> [top_layer] [bottom_layer]`
	Here,
	• `cell_name` is the ESD cell/instance name
	• `marker_layer` could contain multiple GDS layers, separated by ";"
	• The optional `top_layer` and `bottom_layer` specifies the top and bottom technology layers of the ESD cell pin shape. You can use these optional arguments to specify the top and bottom technology layers of the ESD cell pin shape. This provides you with the flexibility to specify the lowest layers to be used for creating pins in the LEF. In the following example, only the shapes between M3 and M1 layers are ESD cell pin shapes:
	Marker file example:
	`ESD_diode 168;255:3 M3 M1`
	`ESD_clamp 122 M3 M1`

`-esd_cell_bbox_file` *filename*

Specifies a file that includes the bounding box for each ESD cell. The format of the file is:
`<cell_name> <x1 y1 x2 y2> [top_layer] [bottom_layer]`

Here,

- `cell_name` is the ESD cell/instance name
- `x1 y1 x2 y2` are the bounding box coordinates
- The optional `top_layer` and `bottom_layer` specifies the top and bottom technology layers of the ESD cell pin shape. You can use these optional arguments to specify the top and bottom technology layers of the ESD cell pin shape. This provides you with the flexibility to specify the lowest layers to be used for creating pins in the LEF. In the following example, only the shapes between AP and M11 layers are ESD cell pin shapes:

Bbox file example:

```
ESD_diode_0 1281296 860923 1296972 895445 AP M11
ESD_diode_1 1281296 898651 1296972 933173 AP M11
```

`-extract_signal_net_logic_info_only`

Specifies to print only the logical connectivity for the signal nets in the `NETS` section of the output DEF file. If this parameter is not specified, the software prints both the logical connectivity and routing shapes for the signal nets in the `SPECIALNETS` section of the DEF file.

`-gds_file` *filename*

Mandatory parameter. Specifies the name of the input GDS file. The top cell name in the GDSII file is the design name in the generated DEF.

`-gds_layermap` *filename*

Mandatory parameter. The layer mapping file between GDS and tech layers. All the layers defined in a given mapping file is extracted. The layers not defined in the mapping file are ignored.

The format of the layer mapping file is:

`<layer_type> <tech layer name> <gds> <gds layer#> [gds layer data type] [PORT] [TEXT_ONLY] <mask keyword> [dummy]`

The format of the layer mapping file to identify the die area in the output DEF is:

`<layer> <prBoundary> <gds> <gds layer#> [gds layer data type]`

Format Description:

`<layer_type>` specifies the type of library layer. The various layer types are: `via`, `metal`, and `layer`.

`<tech layer name>` specifies the name of the library layer to map to the GDSII layer number. The library layers are technology layers which can be dumped using the `Techgen -techinfo` command.

`<gds>` specifies the keyword for the GDS layer mapping.

`<gds layer#>` specifies the layer number of the GDSII layer.

`[gds layer data type]` specifies the optional number of the subclass for the GDSII layer. If you do not specify a datatype, the software uses all datatypes for that GDSII layer. If GDS datatype is not defined, the software considers it as a regular layout routing layer where all the shapes will be extracted.

The GDS layer may have additional information/attribute assigned using the following keywords:

- `PORT`: Converts text labels in this layer to ports.
- `TEXT_ONLY`: Includes only the text in the named layer and ignores all geometries.

`<mask keyword>` keyword used to define the back-end metal layers with color masks (MASK A and Mask B).

`[dummy]` indicates that the layer is a metal fill layer. The `convert_gds_to_def` utility identifies these metal fill shapes and writes them to the `FILLS` section in the output DEF.

`<prBoundary>` specifies that the shapes on the `prBoundary` (Place-and-Route Boundaries) layer are used to determine the die area in the output DEF. This keyword can be used if you want to have the required die area in the output DEF file. If the `prBoundary` keyword is not specified, the die area is determined by the routing shapes specified in the GDS file, cell size, and the pin shapes of all the layers.

Example1:

```
metal METAL1 gds 15
via VIA1 gds 16
```

Example2:

The following is a sample layermap file with the mask keywords (`mask_a` and `mask_b`):

```
metal METAL1 gds 31 250
metal METAL1 gds 31 255 mask_a
metal METAL1 gds 31 256 mask_b
```

Here, the mask and main layers are defined using the same GDS layer number 31, but uses a different GDS data type (250, 255, and 256).

Example3:

The following is a sample layermap file with the `dummy` keyword:

```
metal  METAL5 gds 35 367 dummy
```

Here, the layer with the GDS layer ID `35` and data type `367` contains the metal fill shapes only.

Example4:
The following is a sample layermap file with the `prBoundary` keyword:

```
layer   prBoundary      gds     62 21
```

`-ignore_gds_inst_name`

Specifies to ignore the instance names from the specified GDS file, and the software will then automatically assign instance names to all the instances in the output DEF and Verilog files. This parameter can be used if instance names in the GDS file cannot be used, primarily in cases, such as duplicate instance names.

`-inst_name_file filename`

	Specifies the file name containing instance names for the generated DEF in the following format: `<x coord> <y coord> <instance name>` The x y coordinates are in the unit of micron. The priority of getting an instance name is: 1. instance name file 2. GDS label 3. internally assigned name The `-inst_name_file` parameter allows to provide user-specified instance names. The `convert_gds_to_def` utility reads the GDS label to decide the instance name. If there are no labels, the software internally assigns instance names.
`-inst_name_prefix` *prefix*	
	Specifies a prefix for all the instance names in the output DEF and Verilog files.
`-net_location_file` *filename*	

	Mandatory parameter. Specifies the name of the net location file containing a list of pin locations for nets that needed to be considered. All the geometries of the P/G nets as well as the instance pins connected to the specified P/G nets are included in the `SPECIALNETS` section of DEF. The instances connected to the P/G nets are included in the `COMPONENTS` section of DEF.
	The format of the net location file is:
	<net name> <x loc of pin> <y loc of pin> <layer> <POWER|GROUND|SIGNAL> [*pin name*]
	Example:
	`VDD 60 73 METAL3 POWER`
	`VSS 75 40 METAL2 GROUND`
	Here,
	• The x/y location in the file has the unit of micron.
	• The layer name is the tech layer name.
	• The type of a given net can only be POWER, GROUND, or SIGNAL. If the net type is marked as `SIGNAL`, the net will be traced from the GDS file and included in the `SPECIALNETS` section with "`USE SIGNAL`" in the output DEF file. In addition, the signal pin connectivity is specified for the net.
	• The pin name field is optional. If there is no pin name field, the pin name will be same as the net name.
	If you do not provide pin locations, the utility uses the GDS text labels in either the top-level cell or cells throughout the hierarchy to get the location. In such a case, the format of net location file is:
	<net name> <POWER|GROUND|SIGNAL>
	Example:
	`VDD POWER`
	`VSS GROUND`

`-output_components {ALL | NONE | CONN}`	
	Specifies the components to be printed in the DEF file `COMPONENTS` section during GDS to DEF conversion. The default is `ALL`. • `ALL`: Specifies to output all the instances in the DEF Components section. • `NONE`: Specifies not to print instances. • `CONN`: Specifies to output instances with logical connectivity only.
`-output_def_file` *filename*	
	Mandatory parameter. Specifies the name of the output DEF file. If the given DEF name is specified with "`.gz`", the software will gzip the DEF file to reduce the file size.
`-output_lef_macros` *filename*	
	Specifies the name of the file containing a list of macros for which LEF files are to be generated. One LEF file is generated for each macro. The generated LEF pin shapes are all shapes that connect to top-level nets on all metal/via layer shapes. The cell boundary of the LEF macro is derived by the bounding box of all shapes within the GDS cell.
`-power_grid_library` *libraryname*	
	Mandatory parameter. Specifies the name of the merged power-grid library (.cl). You can specify only a single .cl library.

`-print_complete_short_path`

Specifies to print the complete shorting path when there is a short between two nets. When this parameter is specified, the entire shorting path is assigned to one of the shorted nets and the path is printed in the generated DEF file. The shapes of the shorting path will be assigned to the net that is specified first in the net location file. For example, if a tracing point of VDD is shorted with a tracing point of VSS, the software honors the net that is defined first in the net location file.

If this parameter is not specified, the software assigns the shapes of the path to either of the shorted nets by default.

`-spef_file` *filename*

Specifies the name of the SPEF file that can be used to include the signal nets in the generated DEF file. The input SPEF file is required to have layer annotation in the `RES` statements to indicate the pin node layers.

For the signal nets, both the `*P` and `*I` nodes are used as the starting tracing points, and the SPEF file pins `(*P)` are honored as the top-level pins and are reported in the `PINS` section in the output DEF file. For the PG nets, the `*P` nodes and the user-defined locations in the net location file are used as the starting tracing points. The SPEF file connections (`*I` statements) are honored when generating the DEF logic connectivity for both the signal and PG nets. That is, the `convert_gds_to_def` utility relies on the SPEF file for logic connection if a SPEF file is specified. The instance and pin names are from the SPEF `*I` statements. The output DEF file includes all the signal net pins from `*P` in the `PINS` section, the signal routing shapes in the `NETS` section, and the PG net routing shapes in the `SPECIALNETS` section.

In addition to the SPEF file, you need to specify the following parameters for including the signal nets in the DEF file:

- `-gds_file`
- `-net_location_file`
- `-power_grid_library`
- `-gds_layermap`
- `-output_def_file`
- `-top_cell`

Notes:

- The `-net_location_file` parameter is used to identify the power and ground nets, and therefore the remaining nets are considered as signal nets.
- The `-power_grid_library` specifies the name of the power-grid library that includes the list of standard cells or macros that should be consistent with the SPEF file. That is, the cell of the instances in the SPEF file should be defined in the PGV.

`-top_cell` *cellname*

Mandatory parameter. Specifies the top cell name in the GDSII file.

`-use_gds_label {ALL | TOP |` *<tech_layer_name>* `|` *<cell_name>*`:`*<tech_layer_name>* `|` *<cell_name>*`:ALL>}`

Specifies the criteria for selecting text labels.

- `ALL`: specifies to honor all the text labels from GDS.
- `TOP`: specifies to honor just the top-level text labels.
- *<tech_layer_name>*: specifies to honor all the text labels on the specified layer.
- *<cellname>*`:`*<tech_layer_name>*: specifies to honor all the text labels of the specified GDS cell on the specified layer.
- *<cellname>*`:ALL`: specifies to honor all the text labels of the specified GDS cell.

The following example specifies to use the text labels of the cell "hierblock" on layer METAL10:

```
convert_gds_to_def -use_gds_label hierblock:METAL10
```

`-verilog_file` *filename*

Specifies the name of the output verilog file. This parameter allows you to use the GUI to display the rail analysis results of the GDS-only flow.

`-zero_pin_size`

Specifies to set the pin shape to size zero "(0 0)(0 0)" in the output DEF file. You can use this parameter when the port shape is outside the drawn shape (metal geometry) at places where the port label is defined near the edge of the geometry.

Examples

- The following command converts the specified GDS file `new.gds` to a DEF file `top.def`.

  ```
  convert_gds_to_def -net_location_file net.loc -gds_file new.gds -power_grid_library ../pv_library.cl -gds_layermap lmap -top_cell cella
  -output_def_file top.def
  ```

- The following command converts the specified GDS file `chip.gds` to a DEF file `my.def`:

  ```
  convert_gds_to_def -gds_file chip.gds.gz -power_grid_library  {pgv/techonly/techonly.cl   pgv/full.cl} \
                     -net_location_file netlocfile -gds_layermap  layermap -output_def_file my.def -top_cell chip -spef_file chip.spef.gz
  ```

  Here, the SPEF file `chip.spef` is specified to include the signal nets in the output DEF file.

- The following command specifies a marker layer file `esdcells` to enable ESD analysis using `convert_gds_to_def`:

  ```
  convert_gds_to_def -gds_file gw16_500_usr_test.gds  -power_grid_library { /../TECH/techonly.cl }  -net_location_file my.nlf -
  gds_layermap  gds_layer.map \
      -output_def_file my.def  -top_cell gw16_500_usr -use_gds_label ALL -esd_marker_layer_file esdcells
  ```

  `convert_gds_to_def` utility generates a LEF file for each ESD cell specified in the `esdcells` file to enable PGV generation. The output DEF includes the user-defined nets and the ESD instances based on the specified marker layer file.

create_current_region

```
create_current_region
[-help]
-reset | {-region x1 y1 x2 y2
[-current value | -current_pwl_file filename]
[-die_instance_name dieinstname]
[-file filename]
[-layer layername]
[-intrinsic_cap value]
[-loading_cap value]
[-series_resistance value]
[-net net_name]
[-polygon {x1 y1 x2 y2 x3 y3 ..x1 y1}]
[-pwrnet net_name]
[-gndnet net_name]
}
```

Specifies static or dynamic current regions on global power-grids over the placed macro to accurately capture high and low current consuming regions during rail analysis.

You can use this command prior to rail analysis to specify current regions or power distribution over the top of power-grid on a user-defined layer. These current regions are generally specified for a placed macro for which power-grid view library is not available, and power/current distribution inside this macro could possibly impact IRdrop in neighboring regions. These current regions can also be defined over top-level power-grid for an unplaced macro during early stages of power-planning.

Parameters

`-current value`	
	In the static mode (`set_rail_analysis_mode -method static`), the parameter specifies a single current value in mAmp. In the dynamic mode (`set_rail_analysis_mode -method dynamic`) the parameter specifies a PWL current waveform in time (in ns) and current (in mA) format. For example, 0ns 0mA 0.5ns 1mA 1ns 2mA 3ns 1mA 4ns 0.
`-current_pwl_file filename`	

	Specifies a PWL current file. The file has two columns, time (in ns) and current value (in mA), as shown below:
	`time1 value1`
	`time2 value2`
	The `-current_pwl_file` and `-current` parameters are mutually exclusive.

`-die_instance_name dieinstname`	
	Specifies the name of the die to which you need to apply a current region. This parameter is only applicable to the multi-die analysis flow (`set_rail_analysis_mode -die_mode multi-die`). The parameter allows you to accurately assign current to power and ground nets in specific geometric regions for individual dies during rail analysis in 3D-IC designs.
`-file filename`	

	Specifies the name of a file containing the list of current regions for each die. `-file` can be used only with the `-die_instance_name` parameter. The other parameters of the `create_current_region` command can be included within the specified file.
	Example:
	`create_current_region -file create_current_region_die0.tcl -die_instance_name Die0`
	`create_current_region -file create_current_region_die1.tcl -die_instance_name Die1`
	`###File content in create_current_region_die0.tcl`
	`-net VDD -current 50mA -layer M2 -region "10 10 100 100"`
	`-net VDD -current 50mA -layer M2 -region "100 100 200 200"`
	`-net VSS -current 100mA -layer M1 -region "10 10 200 200"`
	`###File content in create_current_region_die1.tcl`
	`-net VDD -current 150mA -layer M2 -region "10 10 50 50"`
	`-net VDD -current 50mA -layer M2 -region "100 100 200 200"`
	`-net VSS -current 200mA -layer M1 -region "10 10 200 200"`

`-help`	Outputs a brief description that includes the type and default information for each `create_current_region` parameter. For a detailed description of the command and all of its parameters, use the man command `man create_current_region`.
`-gndnet net_name`	
	Specifies a ground net name on which the specified current is to be applied.
`-intrinsic_cap value`	
	Specifies the cell intrinsic capacitance in pico farads (pf). This is required parameter when set in the dynamic mode (`set_rail_analysis_mode -method dynamic`). This parameter is disabled in static mode.
`-layer layername`	
	Specifies a layer name on which the scaling will be performed. Multiple commands can be issued to scale resistance on multiple layers. This is a required parameter.
`-loading_cap value`	
	Specifies the cell loading capacitance in pico farads (pf). This is required parameter when set in the dynamic mode (`set_rail_analysis_mode -method dynamic`). This parameter is disabled in static mode.
`-net net_name`	
	Specifies a net name on which the specified current is to be applied.
`-polygon {x1 y1 x2 y2 x3 y3 ..x1 y1}`	
	Specifies a rectilinear current region where the current will be distributed within. The rectilinear region enables you to specify multiple x,y points to add current regions in the areas that are not rectangular in shape. When specified, the last xy coordinate location will be the same as the first xy location. The xy coordinates will be in the counterclockwise sequence.
`-pwrnet net_name`	
	Specifies a power net name on which the specified current is to be applied.
`-region x1 y1 x2 y2`	
	Specifies the region on the layer across which the specified current and capacitance (in dynamic mode) is distributed by the rail analysis engine. The units of x and y should be in microns. This is a required parameter.
`-reset`	Resets all the previous `create_current_region` command settings.
`-series_resistance value`	
	Specifies the series resistance (ESR) value attached to each tap point in the current region definition.

Examples

- The following command specifies static current region:
  ```
  create_current_region -current 2mA -layer METAL_1 -region "100 100 200 200"
  ```
- The following command specifies dynamic current region:
  ```
  create_current_region -current {0ns 0mA 0.5ns 1mA 1ns 2mA 3ns 1mA 4ns 0} -layer METAL_1 -region "200 200 400 400" -intrinsic_cap 40 -loading_cap 20
  ```
- The following command resets all `create_current_region` parameters to their default values:
  ```
  create_current_region -reset
  ```
- The following command specifies rectilinear current regions for die instance `Die1`:
  ```
  create_current_region -net VDD -current 50mA -layer Metal5 -polygon "10 10 100 10 100 100 10 100 10 10 " -die_instance_name Die1
  create_current_region -net VDD -current 50mA -layer Metal5 -polygon "100 100 200 100 200 200 100 200 100 100" -die_instance_name Die1
  ```

create_die_model

```
create_die_model
[-accuracy {xd | hd }]
[-output_directory directory_name]
-state_directory directory_name
[-rail_analysis_domain domain_name | -net net_name]
[-repeat time]
[-probing_node_file file_name]
[-use_sigrity_repeat]
[-max_ports_per_net integer]
[-enable_reference_node]
[-enable_package_pin_map { true|false }]
[-disable_isrc_node_zero { true|false }]
[-disable_global_node_zero { true|false }]
[-multi_die {true | false}]
[-port_grouping_by_ploc_files { true|false }]
[-port_grouping_file filename]
[-temp_directory_name directory]
[-effective_rc]
[-probing_region_file filename]
[-effective_rc_deck]
[-port_grouping_tiles_file  filename]
[-enable_xp {true | false}]
[-ignore_port_grouping_conflict]
[-generate_sipi_port_definition_file {true | false}]
[-grid_reduction_cut_layer layer_name]
```

Specifies to generate a reduced n-port die model in the form of equivalent die parasitic and current profile after rail analysis to perform system-level analysis with extracted package and board models. Resonance and electro-magnetic interference like system-level analyses can be performed using this die-model in package designing software like Allegro Package Design and Sigrity.

ⓘ This command requires a VTS-XL license.

Parameters

`-accuracy {xd | hd }`	
	Specifies the accuracy mode for die-model generation. *Default* : `hd` • `xd`: xd or accelerated definition accuracy mode is used for faster die model generation with slight reduction in RC accuracy. • `hd`: hd or high definition accuracy mode is used for most accurate die model generation.
`-disable_isrc_node_zero { true|false }`	

	Specifies to disable node zero for current sources (isrc) in a generated die-model. The isrc node zero is used to connect decoupling capacitance and the current source in the generated die-model. This parameter is added to generate a die model without isrc node zero. By default, a virtual ground is used to connect decoupling caps and the current source in the generated die-model. When set to `true`, generates die model without the virtual ground and uses the ground network for connecting decoupling caps and current sources. It also creates the <BLOCK>_nportModel.sp.isrc_balanced file in the die-model directory. This file has information on the current sources and their port connections. The .subckt file generated for Spice simulation points to the .isrc_balanced file. *Default*: `false`
`-disable_global_node_zero { true|false }`	
	Specifies to disable the global node zero in a generated die model. • When set to `true`, generates die models without the virtual ground and uses the ground network for connecting decoupling caps and current sources. • When set to `false`, a virtual ground is used to connect decoupling caps and the current source in the generated die-model. *Default*: `true`
`-enable_package_pin_map { true|false }`	

	Specifies to support the 6-column style MCP format to map package pins to circuit ports. The following are the old and new MCP file formats:
	
	The original 5-column format is:
	<vsrc_name> <Ckt_port> <Net_name> <X coord> <Y coord>
	
	The new 6-column format is:
	<package_pin> <Ckt_port> <Net_name> <X coord> <Y coord> <vsrc_name>
	
	Example:
	
	Original format:
	`chip1/bmp_100_6_12 D1_bmp_100_6_12 VDDE 350.000 147.000`
	`chip2/bmp_122_3_15 D2_bmp_122_3_15 VDD2 321.000 983.800`
	
	New format:
	`bmp_100_6_12 D1_bmp_100_6_12 VDDE 350.000 147.000 chip1/bmp_100_6_12`
	`bmp_122_3_15 D2_bmp_122_3_15 VDD2 321.000 983.800 chip2/bmp_122_3_15`

`-effective_rc`	Generates an additional report file (.txt) containing the effective resistance and capacitance information. The parameter is used for generation of a table for effective resistance and capacitance across multiple operating frequencies.
	The following is a sample report format:
	`# Net:VDD_AO, Net:VSS`
	`# frequency  # rdie  # cdie`
	`1.0000000e+07  4.73148443  2.47034747e-11`
	`1.2589254e+07  4.90209173  2.46916698e-11`
	`....`
	`....`
	`# Net:VDD_external, Net:VSS`
	`# frequency  # rdie  # cdie`
	`1.0000000e+07  -183.231085  6.65466673e-12`
	`1.2589254e+07  -164.007129  6.55112569e-12`
	`....`
	`....`

`-effective_rc_deck`	

	Specifies to include the Rdie/Cdie (effective resistance/capacitance) calculation for the die-model frequency domain simulation setup in the Spice (.sp) format.
	The following is a snippet of the .sp file with the frequency-domain setup for Rdie/Cdie calculation:
	`**********`
	`* Frequency domain analysis to capture input impedance.`
	`.AC DEC 10 10Meg 5G`
	`.PRINT AC RDIE=PAR('VR(VSS_in,VDD_AO_in)') CDIE=PAR('1/(6.283185*freq*(VI(VDD_AO_in)-VI(VSS_in)))')`
	`**********`

`-enable_reference_node`	
	Specifies to replace the global node zero with the reference port in the generated die model.
`-enable_xp {true | false}`	
	Specifies to generate the die model in the Extensively Parallel (XP) mode in which processing is distributed over a large number of machines. *Default* : `false`
`-generate_sipi_port_definition_file {true | false}`	
	Generates a ports definition file during die-model creation. When set to `true`, the port definitions are output to the `port_defintion.txt` file, which is later used by Sigrity SystemPI for connecting the die model to the package design. *Default* : `false`
`-grid_reduction_cut_layer` *layer_name*	
	Specifies a cut via layer below which all the layers will be reduced. This feature minimizes data and enables efficient die model generation.
`-ignore_port_grouping_conflict`	

	Specifies to not generate an error message in case there is a conflict between the user-defined port grouping and the default port groups (voltage sources that are grouped by mapping to the same package terminal). For example, vsrcA and vsrcB are both mapped to the package terminal PKG_T, but in the user-specified grouping file, vsrcA and vsrcB belong to two groups. When this parameter is specified, the tool will not generate an error message if there is a conflict, but instead will group the voltage sources according to the user-specified port grouping file. If this parameter is not specified and there is a conflict in port grouping, an error will be generated.
`-max_ports_per_net` *integer*	
	Specifies the maximum number of ports allowed for each net in a generated die model. If you do not specify this parameter, the software by default enables port grouping with number of ports set to `200`. If the number specified through this parameter is `0`, port grouping will be disabled. The maximum number of ports per net should be `0` or a positive value. A negative value will be treated as 0. **Note:** The `-max_ports_per_net` parameter is only meaningful for N-port die model creation. The 2-port die model creation always groups all ports together.
`-multi_die {true | false}`	
	Specifies to generate a complete die model for a TSV/SiP design. *Default*: `false`
`-output_directory` *directory_name*	
	Specifies the directory in which you save the die-model files.
`-port_grouping_by_ploc_files {true | false}`	
	Specifies to read the PLOC group information from the user-defined PLOC files. You can specify the port information in the PLOC file, as shown below: `Vsource_5_VDD 21985.00 23785.00 AP VDD p18` # with net and group `Vsource_7_VDD 22385.00 23785.00 AP VDD p18 C=1e-09 L=1e-11` # with capacitance and inductance When `-port_grouping_by_ploc_files` is set to `true`, the die model flow will read the user-specified port grouping information and generate a reduced die model. This parameter is mutually exclusive with the `-port_grouping_file` parameter.
`-port_grouping_file` *filename*	

	Specifies a text file containing the user-defined pin grouping details on a per power/ground net basis. When this parameter is specified, a reduced die model is generated that honors the user-specified port grouping. This die model has a reduced RC netlist and `.isrc` when compared with the original un-grouped die model. The degree of reduction will depend on how many pins are being grouped.
	The format of the pin grouping file is as follows:
	`NET <netname>`
	`<grouped pin name> <vsrc names which have to be grouped>`
	`<grouped pin name> <vsrc names which have to be grouped>`
	`NET <netname>`
	`<grouped pin name> <vsrc names to be grouped>`
	`<grouped pin name> <vsrc names to be grouped>`
	`END`
	where,
	• `NET` is a keyword followed by the power or ground net name
	• *`grouped pin name`* is the user defined port name
	• *`vsrc names`* are the actual design voltage sources that need to be grouped

`-port_grouping_tiles_file` *`filename`*	

	Specifies to group power ground ports by a user-defined tile array. All the ports in a specific tile are grouped together.
	
	The use model of the parameter is:
	`create_die_model -port_grouping_tiles_file tiles.txt`
	
	The following is the format of the port grouping tiles format is:
	`NET <net>`
	`BBOX <x1 y1 x2 y2>`
	`ROWS <num rows>`
	`COLUMNS <num columns>`
	
	Here,
	• the keywords are highlighted in blue.
	• *<net>* is the power supply net name
	• *<x1 y1 x2 y2>* are the coordinates of the bounding box lower and upper corners. This is optional. If the bounding box is not specified, the default is the chip bounding box.
	• *<num rows>* is the number of rows in the tile array
	• *<num columns>* is the number of columns in the tile array
	This parameter allows you to partition the voltage sources of the die model in to several port groups. If the same grouping pattern is used for the voltage sources of the die model and the package pins, it will help in matching the die ports and package terminals, and connecting the die model to the package netlist.
	
	The grouping information is available in the MCP header of the generated die model file, as shown below:
	`* [REM]`
	`* [Power Nets]`
	`* vsrc_821 VDD2_GROUP_BUMP_tile01 VDD2 6316.25 20`
	`* vsrc_820 VDD2_GROUP_BUMP_tile01 VDD2 623.75 20`
	`* vsrc_822 VDD2_GROUP_BUMP_tile00 VDD2 5000 40`
	`* vsrc_823 VDD2_GROUP_BUMP_tile00 VDD2 5002 40`
	……
	`*[Ground Net]`
	`* vsrc_100 VSS_GROUP_BUMP_tile01 VSS 6300 25`
	`* vsrc_101 VSS_GROUP_BUMP_tile01 VSS 6250 25`
	`* vsrc_102 VSS_GROUP_BUMP_tile00 VSS 4000 40`
	`* vsrc_103 VSS_GROUP_BUMP_tile00 VSS 4002 40`
	Here
	• the first column is the voltage source name.
	• the second column is the port name under which the voltage sources are grouped. It also displays the tile number to check a specific tile's power and group port during simulation.
	• the third column is the net name.
	• the fourth and fifth columns indicate the X and Y coordinates, respectively. The unit of x/y coordinate location is micrometer (µm).

`-probing_node_file` *file_name*	

	Specifies the probe node file containing the probe point on a die. The file format for specifying probing nodes is as follows:
	`<user defined unique probe name> <location = x> <location = y> <layer> <Power/ground net name>`
	You can also specify the package node voltages and resistor currents that are to be probed in the following format:
	`<probe name> pkg ir <pkg circuit node name>`
	`<probe name> pkg rc <pkg circuit resistor name>`
	Example
	`probe_1 18 16 METAL_1 VDD`
	`# pkg node voltage`
	`probe_pkg_1 pkg ir GND.in0`
	`probe_pkg_6 pkg ir VDD.in2`
	`# pkg resistor current`
	`probe_pkg_cur_1 pkg rc R_1_1`
	`probe_pkg_cur_2 pkg rc R_5_2`
	Note: The units of x and y should be in microns.

`-probing_region_file` *filename*	
	Specifies a probe node region file to define a probe region and use all points in the region as probe contact points on the die. The file format for specifying a probing region is as follows: *region_label x1 y1 x2 y2 layer_name net_name*
`-rail_analysis_domain` *domain_name* | `-net` *net_name*	
	Specifies the domain name or net name for which the die-model is to be generated. When the domain name is specified, coupled die-model is generated and it includes all power and ground nets associated with the specified domain. When net name is specified, decoupled die-model is generated for the specified net. Before specifying this command parameter, the power net name must be specified using the `set_pg_nets` command. This is a required option and one of them must be specified.
`-repeat` *time*	Specifies the repeat time in ns. When this parameter is specified without the `-use_sigrity_repeat` parameter, the generated die model has the dynamic current profile of the die repeated to the specified time. By default, the die model consists of the default simulation period saved in dynamic current files during IR drop anlaysis. When this parameter is specified along with the `-use_sigrity_repeat` parameter, the software forces to write out repeating waveforms in the Sigrity specific format. If the `-use_sigrity_repeat` parameter is specified, the value specified through the `-repeat` parameter indicates the starting point of the repeating waveform.
`-state_directory` *directory_name*	

	Specifies the top-level state directory that is generated by the static or dynamic IR drop analysis. This state directory contains analysis of all nets associated with the power domain; For example, `core_25C_dynamic_1`. This is a required parameter.
`-temp_directory_name` *directory*	
	Specifies a directory to save temporary files for die-model generation.
`-use_sigrity_repeat`	When this parameter is specified along with the `-repeat` parameter of the `create_die_model` command, the software forces to write out repeating waveforms in the Sigrity specific format. If the `-use_sigrity_repeat` parameter is specified, the value specified through the `-repeat` parameter indicates the starting point of the repeating waveform. If `-use_sigrity_repeat` is specified without specifying `-repeat`, time `0` is used for the starting point. The default unit for the value is "ns". **Note:** When the `-use_sigrity_repeat` parameter is specified, the software will write the stimulus current in the specific Sigrity format, which cannot be used by other Spice like simulators.

Examples

- The following command creates an `n-port` die model having the dynamic current profile of the die repeated upto `50ns`, using the state directory `allDomains_25C_dynamic_1` and saves the generated n-port die-model file in the `n_port_diemodel` output directory:

```
create_die_model
-state_directory irdrop_allOn/allDomains_25C_dynamic_1
-rail_analysis_domain allDomains -output_directory n_port_diemodel -repeat 50
```

- The following example shows the use model of the `-effective_rc` parameter to create a report file containing the effective resistance and capacitance information:

```
create_die_model
  -effective_rc -state_directory staticRailResults/ALL_125C_avg_1/
  -output_directory static_die_model -rail_analysis_domain ALL
```

[-cluster_via_size value]
[-ignore_fillers {true | false}]
[-ignore_decaps {true | false}]
[-ignore_shorts {true | false}]
[-force_library_merging {true | false}]
```

Creates a hierarchical power-grid view. The hierarchical PGV generation of a block is part of the top-level Hierarchical Rail Analysis.

Parameters

`-block_lef lef_file`	
	Specifies the name of the block LEF file. The `lef_file` must have all power pin port geometries defined for the hierarchical block.
`-block_gds gds_file`	
	In absence of block LEF, you can specify block GDS and port label file to generate hierarchical power-grid view.
`-cell_name name`	Specifies the block cell name as specified in the block DEF file.
`-cluster_via1_ports {true | false}`	
	Designs with follow-pin routing on M1 and M2 layers have standard cells library LEF with M1, M2, and VIA1 ports. This parameter specifies to cluster VIA1 ports for such cells in order to improve overall extraction and rail analysis performance. *Default*: `true` This parameter is set to `true` by default to improve VIA1 port handling in designs with M1 and M2 follow-pin routing. This parameter gives significantly better performance by clustering equidistant VIA1 ports defined in cell LEF without significant loss of accuracy. However, if you specify a clustering rule, the user specification takes precedence over automated VIA1 clustering.
`-cluster_via_rule { {via_layer1 number_of_equidistant_vias}...}`	
	Controls the number of vias to cluster on a layer basis. The VIA clustering rule specified using this parameter will override the default clustering rule for a given accuracy mode. The following command will cluster 100 equidistant VIA1 cuts, 200 equidistant VIA2 cuts, and 300 equidistant VIA7 cuts: `create_hier_view -cluster_via_rule { {VIA1 100}} {VIA2 200} {VIA7 300}}` The rest of the VIAs will be clustered using the default clustering rule depending upon the rail analysis accuracy mode.
`-cluster_via_size value`	

	Specifies the size of the via array to cluster all via layers except VIA1 (layer between Metal1 and Metal2). The default value is `625` (25x25 via array), except when running static analysis using HD mode. The default for static HD mode is `16` (4x4), primarily to preserve more accuracy for EM analysis. *Default*: `625`
`-compress_powergrid_database {true | false}`	
	Specifies to compress the output files generated by extraction and rail analysis to save disk space usage. This parameter reduces disk space requirement from the extraction and rail analysis stages at approximately 5-10% performance penalty. *Default*: `false`
`-def` *list_of_DEF_files*	
	Specifies a list of block DEF files for hierarchical analysis.
`-extraction_mode {fast | accurate}`	
	Determines what power-grid views will be created, dependent on whether fast or accurate extraction is to be done. By default, hierarchical PGV generates both detailed and reduced views.
`-extraction_work_directory` *path_to_extraction_work_directory*	
	Specifies to re-use the extracted power-grid database to generate HPGV. This parameter is only supported to generate hierarchical extraction view of a block in the design. The specified extraction work directory must contain the extracted data for all the nets for which the hierarchical extraction view needs to be generated. This parameter is mutually exclusive with the `-state_directories` and `-def` parameters of the `create_hier_view` command.
`-force_library_merging {true | false}`	
	Specifies to force merge PGVs with different resistivity and layers. It uses the technology information of the first library. If multiple tech-only PGVs are specified, it will take the first tech-only PGV definition and the first cell definition. If you are merging a tech-only PGV with other PGVs, it will keep the tech-only technology definition and the first cell definition.
`-gds_port_file` *gds_port_file*	
	In absence of block LEF, you can specify block GDS and port label file to generate hierarchical power-grid view.
`-ground_nets {`*pin1pin2...pinN*`}`	
	Specifies a list of ground nets of the block.
`-help`	Outputs a brief description that includes the type and default information for each `create_hier_view` parameter. For a detailed description of the command and all of its parameters, use the man command `man create_hier_view`.
`-ignore_decaps {true | false}`	
	Ignores decap cells during rail analysis. It ignores cells that are tagged as DECAP cells during library characterization or set as decap cells using the `set_rail_analysis_mode -decap_cell_list` command parameter. If decaps are used to preserve connectivity on the follow-pin routing, you must set this parameter to `false`. Ignoring decaps during dynamic analysis is not recommended. *Default*: `true` for static, `false` for dynamic
`-ignore_fillers {true | false}`	
	Ignores filler cells during rail analysis if the list of filler cells are defined in PGV generation, or specified as fillers using the `set_rail_analysis_mode -filler_cell_list` command parameter. During rail analysis, ignore library cells that are tagged as FILLER cells and have no capacitance associated with the interface nodes. If fillers are used to preserve connectivity on the follow-pin routing, you must set this parameter to `false`. *Default*: `true`
`-ignore_shorts {true | false}`	

	Ignores shorts that are found during extraction and continues hierarchical PGV generation. However, `-ignore_shorts` cannot be applied if the design contains GDS. *Default*: `false`
`-libgen_command_file` *file*	
	Specifies the file name of a power-grid library generation (libgen) command file. When specified, it will be included in the auto-generated `libgen.cmd` file at the end as `include <file>`. This parameter allows you to provide a file that includes specific library generation options.
`-library_name` *name*	
	Specifies the name of the library that the block power-grid view will be placed in. A `.cl` extension will automatically be added to the name.
`-max_viacluster_mode {true | false}`	
	Specifies the extractor to cluster vias automatically to reduce the RC elements by clustering vias into one node, therefore reducing the IR drop analysis runtime in dynamic mode. It is based on the notion that current evenly distributes through all vias of an array via. *Default*: `true`
`-oaRef` *OA_Reference_libs*	
	Reads OpenAccess reference libraries.
`-output_dir` *dir*	Specifies the output directory that the results will be save in.
`-parasitic_extractor_command_file` *filename*	
	Specifies the name of the file input to the extractor invoked by the Library Generation engine. This file contains information about the cells in the design and is used for resistance and capacitance extraction. For variables and functions that can be placed in this command file, see *Extractor Options in Voltus Text Command Reference*. In general, this parameter is used for debugging purposes.
`-powergrid_view_libraries` *primitive_cells.cl*	
	Specifies a list of primitive cell libraries for hierarchical PGV generation.
`-power_nets {`*pin1value1pin2value2 ...pinN valueN*`}`	
	Specifies a list of power nets and the nominal voltage of those nets.

Examples

- The following command generates a hierarchical power-grid view for the hierarchical block using LEF and extraction directories for VDD and VSS nets:

  ```
  create_hier_view -block_lef blockA.lef -extraction_work_directory work -library_name blockA  -powergrid_view_libraries
  ./pgv/stdcells.cl  -power_nets {vdd 1.2} -ground_nets {gnd} -cell_name blockA
  ```

  The design.lef must have all power pin port geometries defined for the hierarchical block. The generated hierarchical PGV library is blockA.cl. The library is in binary format and it stores the block's connectivity to the top-level based on the provided LEF data. It stores the extracted power-grid network and current distribution from the provided directories.

- The following command specifies to force merge PGVs with different resistivity and layers:

  ```
  create_hier_view  \
    -force_library_merging true \
    -library_name lib1  \
    -view hier_extraction_view \
    -powergrid_view_libraries {../accurate_stdcells_A.cl ../accurate_stdcells_A.cl ... ../accurate_stdcells_AN.cl } \
    -def {../design.def.gz} \
    -cell_name  CELLA \
    -power_nets {VDD 1.32} \
    -ground_nets {VSS} \
    -block_lef {./design.lef}  \
    -extraction_mode accurate \
  generate_pg_library -output pgv
  ```

create_power_pads

```
create_power_pads
[-append_to_vsrc_file]
[-auto_fetch]
[-cell {cell_list} ]
[-cell_pin {{cellname1 pinname1}...{cellnamen pinnamen}+} ]
[-clear]
[-display]
[-format {padcell xy tsv}]
[-honor_pin_connection]
[-instance {inst_list} ]
[-instance_pin {{instname1 pinname1}...{instnamen pinnamen}+} ]
[-layer {layername}]
[-net netname]
[-package_resistance value ]
[-package_capacitance value ]
[-package_inductance value ]
[-region {x1 y1 x2 y2}]
[-region_pitch {xpitch ypitch}]
[-snap_distance { true|false }]
[-vsrc_file vsrc_filename]
[[-add | -delete] -loc {x y}]
[-list]
```

Returns a list of DC sources from your design. DC sources are identified in the LEF file as CLASS PAD POWER, or in the DEF file as PIN with +USE POWER/GROUND. If a single port shape is connected to N number of wires, N number of DC sources are reported for that port shape.

You can use one of the following three methods to fetch voltage sources into the database:

- fetch all voltage sources
- fetch the voltage sources within the specified region of the specified layer controlled by the specified xPitch/yPitch
  If the voltage sources with the specified xPitch/yPitch are not on the stripe, you can use the `-snap_distance` parameter to snap the voltage sources to the stripe. As a result, the voltage sources are generated only on the stripes and the xPitch/yPitch is honored. Use this feature to generate mesh type voltage sources on any process layer.
- fetch voltage source for the specified cell/cell pin/instance/instance pin

You can edit the fetched voltage sources before saving them to a voltage source file. To save the fetched list to a file, use the `-vsrc_file` parameter. By default, voltage sources will not be displayed on GUI after they are saved to file.

> The `create_power_pads` command supports hierarchical IR drop analysis for a TSV design. When you specify the `create_power_pads` command to fetch the voltage sources from the LEF file, the command not only searches for the P/G pin of the pad connected to the specified P/G net, but also fetches for the embedded bump TSV property definition for the P/G pin connected to the P/G net. The port that contains the point defined in the embedded bump property is considered as the embedded bump.

Parameters

`-add`	Adds the location of a new voltage source to memory.
`-append_to_vsrc_file`	Appends the fetched voltage sources to the existing voltage source file. You can use this parameter to fetch voltage sources in the incremental mode.
`-auto_fetch`	Specifies to fetch all voltage sources.
`-cell {cell_list}`	
	Specifies the cells from which voltage sources are determined.
`-cell_pin {{cellname1pinname1}...{cellnamenpinnamen}+}`	

	Specifies the cells and their pins from which voltage sources are determined.
`-clear`	Clears the display of the DC sources that were specified in the *Edit Pad Location* form.
`-delete`	Deletes the location of a voltage source from memory.
`-display`	Loads and displays the pad location data from the specified file.
`-format {padcell | xy | tsv}`	
	The format of the saved pad location file. The choices are Pad File (VoltageStorm), XY File (xy coordinates), and TSV. You can create and save the voltage sources location file with a unique name for the voltage sources (both VDD and VSS). *Default*: `xy`
`-help`	Outputs the command usage and a brief description about the command parameters.
`-honor_pin_connection`	
	Honors pin wire connection when fetching voltage source location from a power pad. When you specify this parameter, only pins with wire connection are output as voltage sources. You have the choice to specify whether real wire connection is to be honored or not. Typically, during the sign-off stage, power pads are already fully routed so the unconnected power pads should not be counted in as voltage sources. You can specify this using the -honor_pin_connection parameter. Alternatively, in the early stage, power pads may not have been fully routed so you do not need to set this parameter. **Note:** For a port with shapes at multiple layers, all layer connected shapes are fetched as voltage sources.
`-instance {inst_list}`	
	Specifies the instances from which voltage sources are determined.
`-instance_pin {{instnamelpinname1}...{instnamenpinnamen}+}`	
	Specifies the instances and their pins from which voltage sources are determined.
`-layer` *layerName*	
	Specifies the process layer in LEF on which the voltage sources are to be generated. When the `-layer` parameter is specified in conjunction with the `-region {x1 y1 x2 y2}` and `-region_pitch {xpitch ypitch}` parameters, the layer set here is the layer for which voltage sources are to be fetched. If the `-layer` parameter is not used together with the `-region {x1 y1 x2 y2}` and `-region_pitch {xpitch ypitch}` parameters, the layer set here is for the lowest layer to snap (the default value is `M5`).
`-list`	Loads and displays all voltage sources from memory.
`-loc {x y}`	Specifies the location at which the specified voltage source is to be added or deleted.
`-net` *netname*	Specifies the name of a power net for which to list DC sources. *Default:* If you do not specify a net name, the power analyzer automatically lists DC sources for all nets.
`-package_resistance` *value*	
	Specifies the resistance value of the package resistance-inductance-capacitance (RLC) model in Ohm.
`-package_capacitance` *value*	
	Specifies the capacitance value of the package resistance-inductance-capacitance (RLC) model in Farad (F).
`-package_inductance` *value*	
	Specifies the inductance value of the package resistance-inductance-capacitance (RLC) model in Henry (H).
`-region {x1 y1 x2 y2}`	
	Generates the voltage sources in the specified region.
`-region_pitch {xpitch ypitch}`	
	Specifies the region pitch in the x and y direction for the voltage sources.
`-snap_distance` *value*	

	Specifies the snapping distance constraint from IO/pad pins. If this parameter is not specified with a value, no snapping will be done. *Default:* 0 Specifies whether to snap DC sources from I/O pad pins to some location on the power structure. When set to true, the software performs autofetch with snapping. For I/O pad pins that are connected to core ring, the software selects the highest layer and center of the pin as the DC source location. When I/O pad pins are not connected to core ring, the software snaps the location of the I/O pad to somewhere on the core ring. The DC source location should be within the distance of snapping distance constraint from I/O pad pins, and the layer should not be lower than the lowest layer snap constraint.
`-vsrc_file` *vsrc_filename*	
	Specifies the name of the voltage source file that is required to save the auto fetched result.

Examples

- The following command fetches all voltage sources of the net `VDD`:
  ```
  create_power_pads -net VDD -auto_fetch
  ```
- The following command loads and displays all voltage sources from memory:
  ```
  create_power_pads -list
  ```
- The following command specifies the location at which the specified voltage source is to be added:
  ```
  create_power_pads -add -net VDD -layer METTOP -loc {500 500}
  ```
- The following command specifies the location from which the specified voltage source is to be deleted:
  ```
  create_power_pads -delete -loc {500 500} -layer METTOP -net VDD
  ```
- The following command fetches the voltage sources within the specified region of the layer `METAL6` controlled by the specified xpitch/ypitch, and saves the sources to the file `report2` in the xy format:
  ```
  create_power_pads -net VDD -region 100 100 3000 3000 -region_pitch 555 444 -layer METAL6 -format xy -snap_distance 100 -vsrc_file report2.pp
  ```
  > ⚠ In the first example, the output was not saved but it remains in the memory till you specify the second example. Before loading and saving the output of the second example, the first example output in the memory is saved to an auto generated dc source file incrementally, like pp.src, pp1.src, pp2.src, and so on.
- The following command fetches voltage source for the cell BUMPCELL in the xy format:
  ```
  create_power_pads -net VDD -cell BUMPCELL -format xy
  ```
- The following command clears the voltage sources displayed in the GUI and the fetched voltage sources in the database:
  ```
  create_power_pads -clear
  ```
- The following command displays the fetched and saved voltage sources for the net `VDD` in the file `report2` :
  ```
  create_power_pads -net VDD -auto_fetch -vsrc_file report2.pp -display
  ```
- The following command displays voltage sources in the GUI by loading the saved voltage source file `report1`:
  ```
  create_power_pads -vsrc_file report1.pp -display
  ```
- The following command saves the fetched voltage sources to the voltage source file `report1.pp`:
  ```
  create_power_pads -vsrc_file report1.pp
  ```

create_what_if_shape

```
create_what_if_shape
[-help]
[-area {llx lly urx ury}]
[-display]
[-direction {hor | ver}]
[-offset {X Y}]
[-add -method {auto | exact}]
[-layer layerName]
[-nets {net1 net2 net3…}]
[-spacing value]
[-objects {selected | all} ]
[-add  | -select | -deselect |
 -delete | -list  | -save filename | -load filename]
[-pitch pitch]
[-add -width width]
[-type {wire | via} ]
[-format {txt def}]
[-save filename -append ]
[-remove_existing_wires]
```

Specifies to add, select, deselect, delete, list, and display the what if wires/vias to a design.

Parameters

`-help`	
	Outputs the command usage.
`-add`	
	Specifies to add what-if wires/vias.
`-append`	
	Specifies to append all what-if wires/vias to the existing file specified with the `-save filename` parameter.
`-area {llx lly urx ury}`	
	Specifies the rectangular region in which the what if wires/vias are to be generated.
`-delete`	
	Specifies to delete all or selected what-if shapes by constraint `-net/-layer/-type`. You can use this parameter in conjunction with the `-objects` parameter.
`-deselect`	
	Specifies to deselect all what-if shapes by constraints `-net/-layer/-type`. Use this parameter in conjunction with `-area` to deselect what-if shapes overlapping with the specified area.
`-direction {hor | ver}`	
	Controls the direction of the wires added.
`-display`	
	Invokes the GUI to show what-if shapes and zooms to the selected shapes. It works only in the `-win` mode.
`-format {txt def}`	
	Specifies the output file format. The `def` format specifies to create incremental DEF to load into GUI using `read_def -top`. The default output format is `txt`.
`-layer layerName`	
	Specifies the LEF layer name for wires, or layer pair for via to be added.

`-list`

Specifies to list all or selected what-if shapes by constraint `-net/-layer/-type` . You can use this parameter in conjunction with the `-objects` parameter.

`-load` *filename*

Specifies to load the saved what-if shape file.

`-method {auto | exact}`

Specifies the method used to add vias:

- `auto`: When area and layer pair are specified, the tool automatically adds vias on all intersecting points on the specified layer pairs in the given area.
- `exact`: When an area and layer pair are specified, the tool adds a via of exact size of the specified area between the specified layer pair.

`-nets` *{net1 net2 net3…}*

Specifies the name of the nets for which what-if wires/vias is to be created. The what-if engine will create a shape based on the net pattern.

`-objects {selected | all}`

Specify `-objects` in conjunction with the `-delete` or `-list` parameters to delete or list the selected what-if shapes. You can also delete or list all what-if shapes. The default value is `all`.

For example, you can use the following command to delete the selected objects:

```
create_what_if_shape -delete -objects selected
```

`-offset {X Y}`

Specifies to create metal/via from the area + offset. This parameter is useful when you run multiple what-if shape creation commands and want to keep the same area but have different offset.

`-pitch` *pitch*

Specifies the distance between the centre line of two adjacent what-if wires (pitch) to be drawn in the specified `-area` in the preferred direction of the specified `-layer`. The direction of created wires can also be controlled using the `-direction` parameter.

If this parameter is not provided, a single rectangular shape of size {llx,lly,urx,ury} is created.

`-remove_existing_wires`

Specifies to remove a wire and connected vias from the specified layer and area before adding what-if shapes.

`-save` *filename*

Specifies to save all the in-memory what-if wires/vias to the specified file. The format of the file is:

```
type wire net netName area llx lly urx ury layer layer1
type via net netName area llx lly urx ury layer layer1 layer2
```

Following is an example of the file containing one wire and one via shape:

```
type wire net VDD area 191.000000 763.000000 207.000000 772.000000 layer METTOP
type via net VDD area 513.000000 497.700000 517.000000 499.100000 layer METG1 ME
```

`-select`

Specifies to select all what-if shapes by constrains `-net/-layer/-type`. Use this parameter in conjunction with `-area` to select what-if shapes overlapping with the specified area.

`-spacing` *value*

Specify the spacing between each net. Use this parameter to control the spacing between each net. The `-pitch` value specified should be greater than number of nets * (width+spacing).

`-type {wire | via}`

Specifies what kind of shape is to be created.

`-width` *value1 value2 ..valuen*

Specifies the width of what-if wires. You can use the `-width` parameter to specify a separate width value for each net.

Examples

- The following command adds a what-if wire for the net `VDD` and on the LEF layer `METTOP`:

```
create_what_if_shape -type wire -net VDD -area {391.000000 663.000000 407.000000 672.000000} -layer METTOP -add
create_what_if_shape -type wire -net VDD -area {191.000000 663.000000 207.000000 772.000000} -layer METTOP -add -pitch 9 -width 0.4
```

- The following command creates a what-if via for the net `VDD` and on the LEF layers `METG1 MET5`:

```
create_what_if_shape -type via -net VDD -area {513.000000 497.700000 517.000000 499.100000} -layer {METG1 MET5} -add -method exact
create_what_if_shape -type via -area {0 0 1000 1000} -method auto -layer {METTOP METG1} -add -net VDD
```

- The following command specifies to list selected what-if shapes:

```
create_what_if_shape -list -objects selected
```

- The following command specifies to select and highlight all wires in the win mode:

```
create_what_if_shape -select
```

- The following command specifies to select and highlight all what-if vias using area:

```
create_what_if_shape -type via -area {500 490 530 500} -select -net VDD
```

- The following command specifies to save what-if shapes into the file `whatif.shapes`:

```
create_what_if_shape -save whatif.shapes
```

- The following command specifies to delete all what-if shapes in memory:

```
create_what_if_shape -delete -objects all
```

- In the following example, for nets "`VDD VDD1 VDD2 VSS`", three spacing is possible (between VDD and VDD1, between VDD1 and VDD2, and between VDD2 and VSS), that is, spacing is "0.5 0.6 0.7" and width of what-if wires for all nets is "0.5":

```
create_what_if_shape -net {VDD VDD1 VDD2 VSS} -pitch 4 -width 0.5 -spacing {0.5 0.6 0.7 -area {0 0 12 12} -type wire -add -layer M10 -direction hor
```

- The following command will remove all wires on `M7` in the `0,0` to `100,100` region as well as any vias connected to the deleted wires:

```
create_what_if_shape -remove_existing_wires -layer {M7} -area { 0 0 100 100 }
```

debug_irdrop

```
debug_irdrop
[-help]
[-nworst_instances value]
[-output_directory dir]
-state_directory dir
[-net netname | -domain domainname]
[-region {x1 y1 x2 y2 }| -nregion value]
[-eco_report]
[-net_threshold value | -domain_threshold value]
[-summary_only]
[-tile_row_col {X Y}]
[-tile_size {X Y}]
[-non_violating_instslimit value]
[-enable_xp {true | false}]
```

Specifies to automatically identify the region with worst IRdrops and EM violations, and provide necessary information to determine and fix the root cause. The reports are consolidated for each region to find root-cause. Root cause analysis is done by identifying top 10 instances in each hotspot and report the following:

- Hotspot Region Coordinate
- Timing Library Analysis
- Power-Grid View Analysis
- Power-Grid Integrity Analysis
- IR-Drop Composition
- Root Cause Analysis

You must specify this command after running the `analyze_rail` command.

⚠ The `debug_irdrop` command requires a VTS-XL license.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `debug_irdrop` parameter. For a detailed description of the command and all of its parameters, use the man command man `debug_irdrop`.
`-domain domainname`	
	Specifies the name of the power domain.
`-domain_threshold value`	
	Specifies the minimum allowed voltage for the domain being analyzed. The value will be in percentage. This parameter behavior is same as the `set_rail_analysis_domain -threshold` parameter.
`-eco_report`	
	Specifies to generate a file with IR drop information that can be used by Tempus ECO to fix IR voltage drop for all instances in a design. The report (`eco.ird`) is generated in the specified output directory (`debug_irdrop -output_directory`).
`-enable_xp {true | false}`	
	Specifies to identify the worst IR drop and EM violations regions in the Extensively Parallel (XP) mode wherein processing is distributed over a large number of machines. *Default* : `false`
`-net netname`	
	Specifies the name of the power or ground net that you want to analyze.

`-net_threshold` *value*	
	Specifies the minimum allowed voltage for the power net being analyzed. The value must be an absolute number. This parameter behavior is same as the `set_pg_nets -threshold` parameter.
`-non_violating_instslimit` *value*	
	Reports non-violating instances within hotspots (violating tiles) that are close to the threshold value. This parameter allows you to define a limit (sub-threshold) that can be used to report the non-violating instances that are close to the threshold. For example, if the `-net_threshold` or `-domain_threshold` is `60mV`, and `-non_violating_instslimit` is `3mV` close to the threshold, the `debug_irdrop` command will report all the violating instances above the domain/net threshold and also the non-violating instances which are in the range of 60mV-57mV. This information about the non-violating instances can be used for IR improvement in the Timing-aware IR Drop Fixing flow.
`-nregion` *value*	
	Specifies the number of regions to be analyzed. The default value is `3`.
`-nworst_instances` *value*	
	Specifies the number of worst instances to be reported. The default value is 5.
`-output_directory` *dir*	
	Specifies the output directory in which the Irdrop and EM violation results will be saved in.
`-region {`*x1 y1 x2 y2* `}`	
	Specifies the region containing the worst instances. The default unit of *x1 y1 x2 y2* is in database units.
`-summary_only`	
	Specifies to generate a violation summary report that displays a summary of the IR drop violation distribution for all the cells. In addition, the report also displays the summary of the IR drop violation distribution for the standards cells. If this parameter is specified, the detailed IR report is not generated.
`-state_directory` *dir*	
	Specifies the top-level state directory that is generated by the dynamic IR drop analysis. This state directory contains analysis of all nets associated with the power domain. This is the output directory in which the results of the `analyze_rail` command is stored (for example, core_25C_dynamic_1).
`-tile_row_col {X Y}`	
	Specify the number of tiles in the x and y direction. The `-tile_row_col` and `-tile_size` parameters enable tile-based analysis of the hotspot regions. Tile-based analysis divides the design into user-defined tile size, and reports IR drop violations on each tile. The default value is `100um^2 (10x10 tiles)`.
`-tile_size {X Y}`	
	Specify the size of tiles in the x and y direction. The `-tile_row_col` and `-tile_size` parameters enable tile-based analysis of the hotspot regions. Tile-based analysis divides the design into user-defined tile size, and reports IR drop violations on each tile.

Examples

- The following command generates IR debug report for the `vss` net in the specified output directory:
  ```
  debug_irdrop -state_directory dynamic_rail/core_25C_dynamic_1/VSS -net VSS -output_directory IR_DEBUG_VSS -nworst_instances 10
  ```
- The following command generates a violation summary report that displays a summary of the IR drop violation distribution:
  ```
  debug_irdrop -summary_only
  ```

  The following is a sample summary report:

  ```
  Summary For All Cells:

  Worst IR drop: 0.123326V

  Specified IR drop threshold: 0.09V

  Worst IR drop violation: 0.033326V

  Total IR drop violation: 29.9416V

extract_package

```
extract_package
[-help] <domain>
[-output <directoryname>]
-pkg_bga_name <bga_circuitname>
-pkg_die_name <die_circuitname>
[-reference_net <netname>]
[-spd_file filename]
-workspace <workspace_name>
```

Specifies to start package model extraction.

Parameters

`-help`	Outputs the command usage and a brief description about the command parameters.
domain	Specifies the rail analysis domain name.
`-output <directoryname>`	
	By default, the package model will be created in the workspace. However, if you specify an output directory, then a copy of the result will be made in the new directory.
`-pkg_bga_name <bga_circuitname>`	
	Defines the ball grid array (BGA) circuit name in the package model. It is the PCB component in the package model, which eventually connects to the PCB model.
`-pkg_die_name <die_circuitname>`	
	Defines the die circuit name in the package model. When specified, the software automatically creates a mapping between the die name in the package extraction tool and the die name in the software.
`-reference_net <netname>`	
	Specifies the ground net that is selected as reference net for pin-based model generation. This is the ground net that is being referred to by the power nets.
`-spd_file filename`	
	Specifies an existing Sigrity .spd file for package extraction. This parameter allows you to specify a .spd file instead of the workspace name (package model database) of the package extraction tool (XtractIM).
`-workspace <workspace_name>`	
	Specifies the workspace name (package model database) of the package extraction tool (XtractIM). The file name extension is `.ximx`.

Example

- The following example specifies the package models details and starts extraction:

```
extract_package ALL \
  -workspace ../rak_xim_pkg_model/C1_Voltus_4L.ximx \
  -pkg_bga_name FPBGA144 \
  -pkg_die_name CD1 \
  -output rak_xim_pkg_model_voltus_cpf \
  -reference_net VSS
```

Related Information

generate_esd_rlrp_report

```
generate_esd_rlrp_report
[-help]
-net netname
[-instance_pair_list {{inst1 inst2 [pin1 pin2]}+} | -instance_pair_list_file filename]
[-number_threads value]
-state_directory directory
```

Reports the least-resistance path (RLRP) for the bump-to-clamp rule type in the ESD flow. This command helps to make debugging faster when a fail status is given for a bump-to-clamp pair. Using this command, you can:

- view the RLRP path for the selected bump-to-clamp pair in the GUI
- generate a point-to-point RLRP path report that displays the resistance between each node (resistor segment) pair along the RLRP path

Parameters

`-help`	Outputs the command usage and a brief description about the command parameters.
`-net` *netname*	
	Specifies the name of the net to be analyzed.
`-number_threads` *value*	
	Specifies the maximum number of threads to use when reporting the least-resistance path (RLRP) for the bump-to-clamp rule type in the ESD flow. Generally, using more threads decreases the run time. There is no absolute limit to the number of threads you can use, however, it is recommended that you do not specify more threads than the number of CPUs available. The default value is `1`, and the maximum value that can be specified is the total number of available CPUs.
`-instance_pair_list {{inst1 inst2 [pin1 pin2]}+}`	
	Specifies the instance pair list to enable effective resistance calculation between two instances in the design. *pin* is an optional argument. By default, the tool will use the instance pin associated with the net being analyzed. The *pin* argument can be used in special cases when two different pins of an instance are connected to the same net. *pin1* and *pin2* are pins of *inst2* respectively. If a pin name is not given, all pins associated to the specified instance are used.
`-instance_pair_list_file` *filename*	
	Specifies the name of the instance pair list file. This file contains the instance pair list in the same format as mentioned for the `-instance_pair_list` parameter. The file allows you to specify a large number of instance pairs. `-instance_pair_list_file` and `-instance_pair_list` are mutually exclusive.
`-state_directory` *directory*	
	Specifies the name of the state directory in which the ESD analysis results are saved.

Examples

- The following commands specify to generate point-to-point RLRP path report for net `VDD_AO`:

```
generate_esd_rlrp_report \
-state_directory /rak_for_esd/ESD/ALL_125C_esd_1 \
-net VDD_AO \
-instance_pair_list { {VDD_AO_vsrc1 u0} {VDD_AO_vsrc2 u0 NA VDD} }
```

generate_power_up_report

```
generate_power_up_report
[-help]
[-switch_net net_name]
-output_directory directory_name
-state_directory directory_name
```

Specifies to generate power-up statistics report to view the ramp up/inrush current, worst power switch voltage, and additional instance voltage data (average, median, max, and standard deviation voltage data versus time) for the powering-up rail. The following files are generated in the GIF and text formats:

- average voltage of instances (.avgV)
- max voltage of instances (.maxV)
- min voltage of instances (.minV)
- median of instance voltages (.medianV)
- standard deviation of instance voltages (.deltaV)
- total inrush current (.inrushI)
- average voltage of power gates (.avgV)
- max voltage of power gates (.maxV)
- min voltage of power gates (.minV)
- median of power gate voltages (.medianV)
- standard deviation of power gate voltages (.deltaV)

Parameters

`-switch_net net_name`	
	Specifies the name of the powering up rail for which you want to generate detailed power-up statistics.
`-output_directory directory_name`	
	Specifies the output directory in which the power-up statistics results will be saved in.
`-state_directory directory_name`	
	Specifies the top-level state directory that is generated by IR drop analysis. This state directory contains analysis of all nets associated with the power domain; for example, core_25C_dynamic_1.

Examples

- The following command generates power-up statistics for the `ABC_VDD_column` net:
  ```
  generate_power_up_report -switch_net ABC_VDD_column -state_directory core_25C_dynamic_1 -output_directory rpt
  ```

  The following is a snippet of the text and GIF formats with information on average voltage of instances:

Text Format (`ABC_VDD_column.avgV`)	**GIF Format (`ABC_VDD_column.avgV`)**

`#List average voltage of instances for net ABC_VDD_column`
`# 90% of nominal voltage at 2.1 ns`
`# 95% of nominal voltage at 2.2 ns`
`# 98% of nominal voltage at 2.6 ns`
 	
`#XLABEL# Time (ns)`

get_ir_insight

```
get_ir_insight
[-help]
-domain domainname
-domain_threshold value
[-eco_list list_of_instances ]
[-eco_mode {violation | aggressor | both}]
[-eco_report ]
-enable_xp {true | false}
[-lut_path directoryname]
[-nregion value]
[-nworst_instances value]
[-nworst_sensitivity value]
-output_directory directoryname
[-predict_eco]
[-predict_output filename]
[-reset_predict]
-state_directory directoryname
[-watch_box filename]
[-watch_inst filename]
```

The `get_ir_insight` command allows you do the following:

- IR drop distribution and summary reporting by the specified IR threshold - Worst Instance Voltage Drop (WIV), Total Instance Voltage Drop (TIV), and Number of Violation Instance Voltage Drop (NVIV)
- Aggressor IR impact analysis and reporting by the specified violation and aggressor limits
- Support various Tempus IR-ECO flows (violation or aggressor based flow with aggressor IR impact analysis and ECO IR estimation)
- IR drop prediction/estimation on input ECO changes
- IR violation reporting by regions

You must specify this command after running the `analyze_rail` command.

⚠ The `get_ir_insight` command requires the `invs_vi` (Innovus Voltus InsightAI Option) license.

Parameters

`-help`
Outputs a brief description that includes the type and default information for each `get_ir_insight` parameter. For a detailed description of the command and all of its parameters, use the man command man `get_ir_insight`.
`-domain domainname`
Specifies the name of the power domain.
`-domain_threshold value`
Specifies the minimum allowed voltage for the domain being analyzed. The value will be in percentage. This parameter behavior is same as the `set_rail_analysis_domain -threshold` parameter.
`-eco_list list_of_instances`
Specifies the list of instances which were changed for `-predict_eco`. The format of the file is: *<original x>,<original y>,<original orientation>,<original cell>,<x>,<y>,<orientation>,<cell>,<instance>*
`-eco_mode {violation | aggressor | both}`

Default: `violation`

Specifies the mode to be used for generating the ECO report with the `-eco_report` option. The possible options are:

- `violation`: Generates a list of violations in the report.
- `aggressor`: Generates a list of aggressors in the report.
- `both`: Generates a report that includes both the violations and aggressors.

`-eco_report`

Generates a file (`eco.ird`) that is used by the Tempus-ECO flow to fix IR drop violations in a design. The `eco.ird` file is located at: *output_directory/eco.ird*. The `-lut_path`, parameter must be specified with the `-eco_report` parameter. When the `-eco_report` is specified, it is recommended to also specify the `-eco_mode` parameter to support the required ECO flow.

`-enable_xp {true | false}`

Default : `false`

Specifies to identify the worst IR drop and EM violations regions in the Extensively Parallel (XP) mode wherein processing is distributed over a large number of machines.

`-lut_path` *`directoryname`*

Specifies the rail state directory containing the sensitivity database. You can enable sensitivity database generation by specifying `set_rail_analysis_mode -create_sensitivity_db true`. The `-lut_path` parameter must be specified with the `-predict_eco` and the `-eco_mode {aggressor | both}` parameters.

`-nregion` *`value`*

Default: 3

Specifies the number of regions to be analyzed.

`-nworst_instances` *`value`*

Default: 5

Specifies the number of worst instances to be reported.

`-nworst_sensitivity` *`value`*

Default: 50

Specifies the number of aggressors that should be reported for each violation.

`-output_directory` *`directoryname`*

Specifies the output directory in which the insight (IR drop and EM violation) results will be saved in.

`-predict_eco`

Specifies to generate the IR prediction for the ECO changes specified with the `-eco_list` parameter. Based on the list of instances specified with `-eco_list`, the tool performs IR prediction. You can also choose to use the `-watch_box` and `-watch_inst` parameters to specify either the area or instance you intend to observe and predict. You can specify multiple ECO change lists, and all the accumulated ECO changes are saved until you reset them using the `-reset_predict` parameter. This option is associated with `-predict_output`, `-eco_list`, `-watch_box`, `-watch_inst`, `-reset_predict`, and `-lut_path` parameters.

The format of prediction output is:

```
<instance_name1> <predicted_eiv_value1>
<instance_name2> <predicted_eiv_value2>
```

`-predict_output` *`filename`*

Specifies the output file where the prediction results for the `-predict_eco` parameter are saved.

The format of prediction output is:

```
instance_name1 predicted_eiv_value1
instance_name2 predicted_eiv_value2
```

`-reset_predict`

Specifies to reset all the previous ECO changes. If this parameter is not specified, the previous changes in `-eco_list` will be retained for the `-predict_eco` runs.
`-state_directory` *directoryname*
Specifies the top-level state directory that is generated by the dynamic IR drop analysis. This state directory contains analysis of all nets associated with the power domain. This is the output directory in which the results of the `analyze_rail` command is stored (for example, core_25C_dynamic_1).
`-watch_box` *filename*

Specifies a file containing the list of regions, wherein only the instances inside these regions will be reported for prediction. You can write multiple regions in the file. This parameter is used with the `-predict_eco` parameter.
The format of the file is:
`{{x1,y1}{x2,y2}}`
`{{x3,y3}{x4,y4}}`

`-watch_inst` *filename*

Specifies a file containing the list of instances to be reported for prediction. You can write multiple instances in the file. This parameter is used with the `-predict_eco` parameter.
The format of the file is:
`instance_1`
`Instance_2`

Examples

- The following command specifies to perform IR prediction/estimation:

```
get_ir_insight -predict_eco \
-state_directory Rail/latest \
-lut_path Rail/latest  \
-eco_list eco_five \
-predict_output predict.out \
-enable_xp true\
-domain PD \
-domain_threshold 0.1 \
-watch_box region_watch\
-watch_inst instance_watch\
-output_directory predictIR
```

  The generated report will be saved at: *predict.out*

  The following is the sample report:

```
CTS_buf_01236 0.828523
CTS_buf_01248 0.829177
CTS_buf_02745 0.817085
```

- Specifies to generate the eco.ird file for Tempus IR-ECO consumption:

```
get_ir_insight -eco_report \
-state_directory Rail/latest  \
-eco_mode both \
-enable_xp true\
-domain PD \
-domain_threshold 0.1 \
-lut_path Rail/latest  \
-output_directory debugIR
```

  The generated report will be saved at: *debugIR/eco.ird*

  The following is the sample report:

```
PGNET START
  NET   VDD  0.900
  NET   VSS  0.000
PGNET END

REGION START
  INST ua/FE_n10786  1
    IRDROP VDD:VSS  8.000e-11  0.1307  0.000e+00  7.029e-04  3.315e-03
  INST ua/FE_n6442  1
    IRDROP VDD:VSS  8.000e-11  0.1390  0.000e+00  7.452e-04  3.666e-03
```

Sample Summary Report

```
Found 8826 instances with IR-drop violations in design based on eiv_method: Worst and eiv_eval_window: elapse.

Summary For All Cells :
Worst IR drop : 0.12337V
Specified IR drop threshold : 0.09V
Worst IR drop violation : 0.033327V
Total IR drop violation : 48.94V

map_dies

```
map_dies
[-help]
-3dic_design_stack_file filename
[-component_config_file filename]
[-die_pad_file_pair {{<die_name1> <pad file1>} {<die_name1> <pad file2>}...}]
[-map_search_distance distance]
[-mode sanity_check]
[-output directory]
[-stacked_die_mapping filename]
```

A utility to generate the inter die data mapping file based on the design stack configuration file and die ploc files. This mapping file is required if there is a direct connection between dies. The generated mapping file defines the connection between dies (between interposer and logic die). This mapping file is then specified with the `set_multi_die_analysis_mode -stacked_die_mapping` command for multi-die analysis.

Parameters

`-help`	Outputs the command usage and a brief description about the command parameters.
`-3dic_design_stack_file filename`	
	Specifies the name of the XML file containing the design stack information. This file is from the Integrity™ 3D-IC product. It includes each die's tier level (Z direction), die instance name, size (post shrink size if there is a scale factor), flip, rotation (counter, clockwise), placement location, and contact layer.
`-component_config_file filename`	

	Specifies the name of the design configuration file. This file is used to define the power pad location files, and the power and ground net names.
	
	File Format:
	`COMPONENT IDIE`
	`Power_pad { {ldie_VDD.ploc VDD_AO} {ldie_VSS.ploc VSS} }`
	`[Power_net { VDD_AO}]`
	`[Ground_net {VSS}]`
	`END`
	`COMPONENT LDIE`
	`Power_pad { {ldie_ALL.ploc all} }`
	`[Power_net {VDD1}]`
	`[Ground_net {VSS2}]`
	`END`

`-die_pad_file_pair {{<die_name1> <pad file1>} {<die_name1> <pad file2>}...}`	
	Specifies the mapping between die instance names and their corresponding power pad file for the interposer die and logic dies.
`-map_search_distance distance`	
	Specifies the legal mapping distance range between the interposer and legal dies. The unit for distance is micrometer (um).
`-mode sanity_check`	
	Specifies to perform sanity checks for the generated mapping file.
`-output directory`	

	Specifies the output directory containing the mapping results. The output folder contains the generated mapping file (`die_die.map`).
	The format of the 6-column mapping file is:
	`IDIE_INST_NAME(idie_inst_name) Inet_name Ibump_name`
	`LDIE_INST_NAME(ldie_inst_name) Lnet_name Lbump_name`
	Here,
	• The first 3 columns are for the interposer die instance name, net name, and bump name(vsrc name), and the last 3 columns are for the logic die instance name, net name, and bump name.
	• The die instance names are written in upper case that is followed by the die instance names specified in the rail TCL for each die instance name.
	• The file is split in two sections, POWER and GROUND.

`-stacked_die_mapping` *filename*	

	Specifies the mapping file used to define the connection between dies (between interposer and logic die). This file provides the information on bump-to-bump mapping (one bump from interposer die and the other bump from logic die) to provide logical connectivity.
	The format of the 6-column mapping file is:
	`IDIE VDD_AO BUMP_PWR_1 LDIE1 VDD_AO LDIE_PWR_BUMP7`
	`IDIE VDD_AO BUMP_PWR_2 LDIE1 VDD_AO LDIE_PWR_BUMP8`
	`...`
	Here, the first 3 columns are for the interposer die instance name, net name, and bump name, and the last 3 columns are for the logic die instance name, net name, and bump name.

Output

The following is the list of reports that are generated for sanity checking:

- `die_map.summary` - This report has 2 sections:
  - Interface mapping summary - Lists all the die_inst1/net to die_inst2/net mapping pairs, and their matched bump mappings in the overlap region.
  - Die connect-terminal summary - Reports matched and total terminals for each die instance/net/layer group.
- `map_diagnosis.log` - Reports a list of unmapped bumps/terminals for a die-to-die pair list and the reasons for the unmapped bumps (For example, unknown die, unknown net, undefined terminal, power to ground short, and floating terminal).
- `terminal_map.rpt` - Lists mapping pairs (`die1:net1:bump1 :: die2:net2:bump2`) that pass the mapping and alignment checks, therefore are considered as legal mapping pairs.
- `terminal_offset.rpt` - Reports all mapping pairs where offset is greater than the specified `map_search_distance`.

Examples

- The following command generates a mapping file that includes the connection between dies (between interposer die INTERPOSER and logic dies DIE0, DIE1, DIE2, DIE3):

```
map_dies \
-output results \
-3dic_config_file ../data/design_stack.xml \
-die_pad_file_pair { {INTERPOSER ../data/Interposer_all.ploc} \
                     {DIE0 ../data/Die0_all.ploc} \
                     {DIE1 ../data/Die1_all.ploc} \
                     {DIE2 ../data/Die2_all.ploc} \
                     {DIE3 ../data/Die3_all.ploc} }
```

- The following command performs the sanity check for the generated mapping file:

```
map_dies \
-mode sanity_check \
-output Results \
-3dic_design_stack_file ./data/design_stack.xml \
-3dic_config_file ./data/design_stack.xml \
-component_config_file ./data/Components.config \
-stacked_die_mapping ./data/die2die_bump.map \
-map_search_distance 5 \
```

map_die_package

```
map_die_package
[-help]
[-output directory]
-package_model_file filename
{-die_mcp_header filename | -net_pad_file_pair {{<net1> <pad file1>} {<net2> <pad file2>}...}}
```

The command launches the *MCP Editor* GUI to make manual connections between package and die pins. It also performs the following functions:

- maps the voltage source files with the package model to check and correct mapping information before rail analysis.
- generates a mapping file that can be used in previous versions of the software in case there is no mapping between die and package pins.

The command has two types of inputs:

- Voltage source files in the xy format and a package model file with the MCP header.
- A circuit file with the MCP header and a package model file with the MCP header.

The output will be the same for both types of inputs:

- A ckt mapping file containing only the MCP header, with the name `pkg_model_base_name + "_map"+suffix`.
- The file named '`un_mapped_bumps.txt`' will contain all the bumps which cannot be mapped.

Parameters

`-help`	Outputs the command usage and a brief description about the command parameters.
`-die_mcp_header` *filename*	
	Specifies a circuit file with the MCP header containing the die abstract.
`-net_pad_file_pair {{<net1> <pad file1>} {<net2> <pad file2>}...}`	
	Specifies the voltage source files mapping to each net.
`-output` *directory*	
	Specifies the output directory containing the mapping results.
`-package_model_file` *filename*	
	Specifies the name of the package model file.

Examples

- The following command specifies a circuit file with MCP header and a package model file with the MCP header:
  ```
  map_die_package -die_mcp_header super_filter_mcp_ploc.ckt -package_model_file C1_Voltus_4L_C1_Voltus_4L_Final_PinBaseSPICE.ckt -output out_ploc
  ```
- The following command specifies voltage source files in the XY format and a package model file with the MCP header:
  ```
  map_die_package -output ./out_pad -net_pad_file_pair {{VDD VDD_AO_srcs.pp} {VDD VDD_external_srcs.pp} {VSS VSS_srcs.pp}} -package_model_file C1_Voltus_4L_C1_Voltus_4L_Final_PinBaseSPICE.ckt
  ```

Loading power/rail analysis results into GUI.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `read_power_rail_results` parameter. For a detailed description of the command and all of its parameters, use the man command: `man read_power_rail_results`.
`-cell_library { library1.cl}`	
	Specifies the single cell library that is required to load the state directory. The specified cell library must contain the technology layer information that is required to load the state directory. Therefore, you do not need to load all cell libraries used during analysis.
`-custom_value_inst_file_1 file`	

	Specifies the name of the custom value instance file (CVIF). This file can be used to display a user-specified instance voltage file in GUI.
	The format of the CVIF file is:
	`value1  instancename1`
	`value2  instancename2`
	`....`
	where, *value1* and *value2* are voltage values mapping to the specified instance.
	You can use the `cvil` argument of the `set_power_rail_display -plot` command parameter to view the EIV map in GUI.

`-data_type {rail | all}`	

	Controls the type of data to be loaded in the GUI. The possible arguments of this parameter are: • `rail` - Loads only the rail analysis results. • `all` - Loads both the power and rail analysis results. This is the default value.
`-detail_delta_temperature_file` *file*	
	Specifies the name of the detailed wire-based delta temperature file from self-heating analysis.
`-die_instance_name` *dieinstname*	
	Specifies the name of the die whose results you need to view. This parameter is only applicable to the multi-die analysis flow (`set_rail_analysis_mode -die_mode multi-die`). The `-die_instance_name` parameter must be specified with the `-rail_directory` parameter (multi-die rail directory).
`-effective_resistance_file` *file*	
	Specifies the result file from effective resistance analysis (only instance-based result is supported). When the rail analysis plot type `effr` is selected and a result file is specified, the layout shows effective resistance analysis result for each instance. **Note**: Currently, this feature only supports loading one net at a time.
`-enable_plots` *plot_names*	
	Specifies the list of power or rail plots names that are to be loaded.
`-esd_directory` *dir*	
	Specifies the ESD analysis directory.
`-esd_rj` *dir*	
	Specifies the name of the directory where the current density/EM results generated by a previous ESD analysis run reside. This parameter allows you to selectively load the required EM result directory if there are multiple ESD EM result directories under the `ESD` directory. You must either load the rail directory (`-rail_directory`) before running this command, or specify the rail directory with the `-esd_rj` parameter.
`-instances` *instancenames*	
	Specifies a list of instances to load in the GUI. This parameter loads only those partitions that include the specified instances. The `-instances` parameter allows you to analyze parts of the designs, thereby reducing the loading time and memory footprint. The `-instances` parameter is applicable to the Voltus-XP flow only.
`-instance_delta_temperature_file` *file*	
	Specifies the name of the instance-based delta temperature file from self-heating analysis. This is the device instance temperature.
`-instance_voltage_method { best | worst | avg | worstavg }`	
	Loads the instance voltage data for the specified EIV computing method. If this parameter is not specified (default), the instance voltage results for all the four methods are loaded.
`-instance_voltage_window { timing | whole }`	
	Loads the instance voltage data for the selected EIV window. If this parameter is not specified (default), the instance voltage results for both the timing and switching windows, and the entire rail simulation are loaded.
`-nets` *net_names*	
	Loads only the specified nets in the domain-based state directory to the GUI. If this parameter is not specified with the `-rail_directory` parameter, all the nets will be loaded.
`-physical_db` *dir_name*	
	Specifies the name of the hierarchical design directory to be loaded to the GUI along with the rail analysis results.
`-power_db` *file*	
	Specifies the power database file. This file was created by using the `-create_binary_db` option of the `set_power_analysis_mode` command.
`-power_directory` *power_output_directory*	

	Specifies to load the power analysis results and display the power plots without loading the rail analysis results.
`-profiling_power_file` *file*	
	Specifies to display the tile-based power density results generated from the vector profiling flow.
`-reset`	
	Frees the loaded analysis state directory or power database from the memory.
`-rail_directory` *dir*	
	Specifies the rail analysis directory. You can load all the domain results by selecting the automatically generated analysis directory under the output directory (`<domain>_<temp>_<dynamic/avg>_#`), or load individual nets by going one level further and selecting the net directory.
`-sem_db` *file*	
	Specifies to read the signal electromigration data from the specified database file generated by the `verifyACLimit -report_db` command parameter.
`-short_file` *file*	
	Specifies the path to the short violations report (`voltus_short.report`) . This file is generated using the `set_rail_analysis_mode -report_shorts true` command parameter, and is located in the work directory.
`-thermal_file` *filename*`.txt`	

	Specifies to load the tile-based temperature map file generated by Sigrity Celsius to be used for both power calculation and IR drop analysis.
	The following is an example of reading the thermal map file:
	`read_power_rail_results -rail_directory output/static_rail/core_25C_avg_1/ -thermal_file output/power_map_by_layer.txt`
	`set_power_rail_display -plot thermal`

`-tile_delta_temperature_file` *file*	
	Specifies the name of the tile-based delta temperature file of self-heating analysis. This is the worst instance temperature among all wire segments in a tile. This is also layer-based. The FEOL or cell layer is used to show the device instance temperature.
`-tile_thermal_config_file` *filename*	

	Specifies to load the configuration file that contains the mapping between the hierarchical levels with corresponding layer-based temperature map files generated by Celsius (system-level thermal analysis tool). When specified, you can view tile-based temperature distribution for each layer of the chip.
	The following is the format and example of the configuration file:
	<hierarchy> <block name> <X_tile_no,Y_tile_no> <LEF/DEF Flip/Rotation> <temperature map>
	`TOP DIE 0,0 N /thermal_data/DIE_TemperatureMap`
	`TOP/IP1 IP1 25,50 N /thermal_data/IP1_TemperatureMap`
	`TOP/IP1/B1 B1 50,125 N /thermal_data/B1_TemperatureMap`
	`TOP/IP1/B2 B2 200,125 S /thermal_data/B2_TemperatureMap`
	This is a mandatory parameter for the `tile_thermal` plot when loading hierarchical temperature maps.

`-top_cell_name` *topcell_name*	
	Specifies the name of the top module or top cell name to be loaded. This parameter must be specified with the `-physical_db` parameter.

Examples

- The following command specifies the appropriate files needed for viewing the instance voltage and power data:

```
read_power_rail_results\
   -rail_directory analysis/domain_25C_avg_1 \
   -power_db powermeter.db \
```

- The following command specifies to load the VDD and VSS nets for the worst and best EIV methods during the entire simulation:

```
read_power_rail_results -rail_directory dynamic_rail/core_25C_dynamic_1 \
    -nets { VDD VSS } -instance_voltage_window { whole } -instance_voltage_method { worst best }
```

- The following command specifies to load only the rail directory:

```
read_power_rail_results -rail_directory dynamic_rail/core_25C_dynamic_1 -data_type rail
```

- The following command specifies to load the hierarchical database and the rail analysis results to the GUI:

```
read_power_rail_results -rail_directory ./dynamic_rail/latest/ -physical_db /dma/Dynamic/saveDB -top_cell_name dma_mac
```

- The following command specifies to display the tile-based power density results in the GUI:

```
read_power_rail_results -profiling_power_file ./vectorProfileResults/profile.rpt.density
```

- The following command specifies to load the power analysis results and display the power plots directly by running the power analysis without loading the rail analysis results:

```
read_power_rail_results -power_directory ./dynamic_power
```

Related Information

report_power_rail_results

```
report_power_rail_results
[-help]
[-append]
[-enable_filter_summary]
[-filename file ]
[-filter_max max_value]
[-filter_min min_value]
[-ignore_limit_bound]
[-layers {All, layer_names } ]
[-limit N ]
[-nets {all | all_pwr | all_gnd | net_names}]
[-plot plot_type]
[-range_max max_value]
[-range_min min_value]
[-region x1 y1 x2 y2]
[-rlrp_inst {instance_name}]
```

Generates RLRP, region-based, and rail/power/capacitance reports.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `report_power_rail_results` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_power_rail_results`.
`-append`	Appends instance reports to the current report file.
`-enable_filter_summary`	
	Displays a summary of the filtered data in the histogram given in the *Summary* tab of the Result Browser form.
`-filename file`	
	Specifies the name of the text based violation report file to be created. The default file name is: • for region-based report: `region_x1_y1_x2_y2.rpt` • for RLRP report: `rlrp_instname.rpt` • for plot-based report: `power_rail_plot.rpt`
`-filter_max max_value`	
	Specifies the maximum value to include in the report. Use this option to further filter out the data within the range specified. This is used to obtain Optional, but if specified, the `-plot` option is required, and requires both `-filter_min` and `-filter_max` to be specified.
`-filter_min max_value`	
	Specifies the minimum value to include in the report. Use this option to further filter out the data within the range specified. This is used to obtain s Optional, but if specified, the `-plot` option is required, and requires both `-filter_min` and `-filter_max` to be specified.
`-ignore_limit_bound`	
	Specifies to ignore the maximum upper limit of `10000`, and instead use the higher value given with the `-limit` parameter for specifying the numbe in the power/rail report.
`-layers {all, layer_names }`	
	Specifies the layers to be reported. You can use `all` for reporting all layers, or list the specific layers that are to be reported. If this parameter is sp `-plot` parameter.
`-limit N`	

	Specifies the number of data points printed in the report. If this parameter is specified, you must specify the `-plot` parameter. *Default* : first `1000` data points
`-nets {all | all_pwr | all_gnd | net_names}`	

	Specifies the nets to be used for analysis reporting. You can use `all` for reporting all nets, `all_pwr` for reporting all power nets, `all_gnd` for reporti specific nets that are to be reported. If this parameter is specified, you must specify the `-plot` parameter.
	This parameter also allows you to specify the switched and always-on nets to be used for analysis reporting.
	The following is the use model to generate a report for the specified switched net:
	`report_power_rail_results -plot ir -nets {switchedNetName}`
	The following is the use model to generate a report for the specified always-on net, including its switched nets:
	`report_power_rail_results -plot ir -nets {alwaysOnNetName} -all`
	You must specify `-all` to include all switched nets associated with the specified always-on net.

`-plot plot_type`	
	Plots the specified plot type. See Plot Types for a description of each of the plot types.
`-range_max max_value`	
	Specifies the maximum value to report. Optional, but if specified, the `- plot` option is required, and requires both `-range_min` and `- range_max` to b
`-range_min min_value`	
	Specifies the minimum value to report. Optional, but if specified, the `- plot` option is required, and requires both `-range_min` and `- range_max` to be
`-region x1 y1 x2 y2`	
	Measures tap current and capacitance information in the specified region defined by x1, y1, and x2 y2 coordinates, and prints results in the log fil
`-rlrp_inst instance_name`	
	Reports the RLRP path for the specified instance. The default file name of the RLRP path report is `<rlrp_instname.rpt>`. You can modify the file parameter.

Plot Types

Plot Type	Description
`ac`	Available/feasible capacitance (Farad) Displays the feasible decoupling capacitance that can be added in the area. The feasible capacitance in the area is calculated based on the filler cells placement. The program matches the placed filler cells with the decap cells available in the power-grid library and computes the feasible capacitance. The capacitance of the decap cell is stored in the power-grid library.
`activity`	Displays the worst activity for the output and inout pins of every instance.
`cap`	Grid capacitance (Farad) Plots the capacitance of the extracted power-grid network.
`dd`	Decoupling capacitance (decap) density (Farad/um ^{2}) Plots decap density of the design. The decap density is the cell internal decoupling capacitance in the unit area (µm ^{2}).
`dr`	Decoupling capacitance required Reports the decoupling capacitance required to fix dynamic IR-drop violations. This option suggests how much decap needs to be added in a given area to fix the IR-drop violations. The voltage threshold used to determine the IR-drop violations for this analysis is the value specified by the `-threshold` option of the `set_pg_nets` command.

`ivdn`	Instance Voltage Drop (Volts) – net-based Plots the net-based instance voltage drop.
`ivdn`	Instance Voltage Drop (Volts) – domain-based Plots the domain-based instance voltage drop. For domain based, at least one power and one ground net must be selected.
`fd`	Filler cell density (1/μm^2) Displays the filler cell density per unit area (μm^2). The plot can be used to analyze the feasibility of adding decap cells by replacing the filler cells and not changing the placement of the logic cells.
`freq`	Frequency domain (Hz) Displays the associated clock frequency of all instances in the design. The instances associated with multiple clock domains are displayed using the fastest clock frequency. This plot can be used to analyze and debug the power distribution in the design.
`ip`	Instance total power (mW) The total power consumed by each instance is displayed. The total power is the sum of the internal, switching and leakage power of the instance. The power data is read from the power database and can be specified using the `-power_db` option or it is queried directly from memory, if power calculation is run during the session.
`ip_i`	Instance internal power (mW) The power consumed by charging and discharging of the internal interconnect and device capacitances of the instance.
`ip_l`	Instance leakage power (mW) The power consumed by devices when not switching.
`ip_s`	Instance switching power (mW) The power consumed by charging and discharging of the interconnect or output load.
`ipd_i`	Specifies internal power density in mW/um^2.
`ipd_l`	Specifies leakage power density in mW/um^2.
`ipd_s`	Specifies switching power density in mW/um^2.
`ipd_t`	Specifies total power density in in mW/um^2.
`ip_tr`	Displays toggle rates for all instances. The toggle rate for an instance is calculated as the average of toggle rates of all outputs of the instance. This plot allows you to determine the design area that toggles more than the others.
`ir`	IRdrop or voltage drop (Volts) Displays the IRdrop across each extracted power-grid segment in the design.
`jrms`	Specifies current density as j/jmax based on the Irms current. This plot is only supported for dynamic analysis. A jrms gif file will be saved in the state directory that shows where the Irms based EM violation occurred. This plot type allows you to verify the analysis results of "jrms" using the GUI.
`load`	Loading capacitance (Farad) Displays the output loading capacitance driven by the instance. This plot can be used to analyze and debug the regions with high switching power.
`pi`	Power-switch (gate) current violation: I/Idsat Displays the ratio of current through the power-switch and the saturation current (Idsat) of the power-switch. This plot can be used to analyze and debug whether the current through power-switches exceeds the saturation current characterized for the power-switch devices. The saturation current and on-resistance of the power-switches are characterized and stored inside the power-grid library of the power-switch cell. A ratio of greater than 1 means that the current requirement of the power-gated block can not be met with placed power-switch instance. Either the power-switch needs to be made larger or power-switch instances need to be added.

`pv`	Voltage drop across power-switch (Volt) Displays the IRdrop across power-switch instances. This plot can be used to analyze and debug the IRdrop inside the power-gated block, e.g. if the IRdrop across power-switches is already high, the IRdrop inside the power-gated block will be much higher. In this case, the power-switch placement will have to be refined in order to resolve the IRdrop problem.
`rc`	Resistor current (Amp) Displays the current across power-grid resistor segments. This plot can be used to analyze and debug how the current flows from the voltage sources into the rest of the design, e.g. high current should flow from pads to the top-level routing level layers and then to the lower level metal layers. This plot can also be used to debug current density violations (`rj`).
`rlrp`	The total resistance of the instance along the least resistive path. Displays the total resistance of the instance along the least resistive path, meaning the resistance of the instance along the path from where it gets the most amount of current. This plot can be used to analyze and debug the power-grid integrity early in the design stage. An instance with high resistance is likely to have high static or dynamic IRdrop depending on the vector that is simulated later in the design cycle. This plot can be also used during decap optimization, since regions with high dynamic IRdrop and high resistance may not be improved upon by adding decaps, because the effectiveness of decoupling capacitance depends on the resistance of the power-grid network. You can also highlight the least resistive path of the instance using the GUI and selecting the instance with left mouse button. The *RLRP Path* checkbox should be enabled.
`res`	Displays the total resistance of the least resistive path from each node to voltage source. This plot can be used to view high resistance regions of the power-grid. It is useful during IRdrop and decap analysis to identify weak power-grid connectivity.
`rj`	Resistor current density, J/Jmax. Displays the current density (current per unit area) violation on each power-grid segment using the ratio of calculated current density and maximum allowed current density. A ratio of greater than 1 means that the current density limit of the segment is violated. The current density limits are supplied by the foundry and can be read during analysis using the `set_rail_analysis_mode -em_models` command.
rs	Specifies the plot type for resistor sensitivity.
`slack`	Instance slack (Seconds) Displays worst instance slack. The slack data is queried from either the timing database or if the power database is specified using `-power_db` option, then the worst slack data is read from the power database. When using an external TWF, the slack data is read from the TWF.
`tc`	Tap current (Amp) Displays the current consumed by the instance devices or current taps. During rail analysis, it is based on the power consumption of the instance and is distributed inside the cell. The current distribution inside the cell is based on the extracted device netlist stored inside the power-grid library of the cell. The current distribution is generally based on the device width, length, and spice models. This plot can be used to analyze and debug IRdrop inside the macro.
`td`	Transition density (Hz) Displays the worst transition density (activity * frequency) of the instance. This plot can be used to analyze and debug activity distribution and high power density regions.
`tpd`	Displays power density map with user-specified grid size.
`unc`	Unconnected segments Displays power-grid segments that are disconnected from the voltage source (power pads). This plot can be used to debug unusually high IRdrop in the region.
`vc`	Voltage source current (Amp) Displays current through the voltage sources (power pads). This plot can be used to analyze the current carrying capacity of the power-pad.
`vu`	Voltage drop across package (Volt) Displays voltage drop across package. If analysis is run with package model attached to the power pads, this plot displays the IRdrop due to package RLCK elements.

Examples

- The following command will report the worst 100 IR segments on Metal 1 of the VDD net:
  `report_power_rail_results -plot ir -layers M1 -limit 100 -nets VDD`
- The following command will report the IR drop of the VDD_ring switched net:
  `report_power_rail_results -plot ir -net {VDD_ring}`
- The following command will report the IR drop of the VDD_AO always-on net, including its switched nets:
  `report_power_rail_results -plot ir -net {VDD_AO} -all`
- The following command filters the data such that it does not display the data points below 200 in the Result Browser histogram:
  `report_power_rail_results -plot ivdd -filter_min 200 -enable_filter_summary`

scale_what_if_capacitance

```
scale_what_if_capacitance
[-help]
-reset | {{-global | -region x1 y1 x2 y2 | -cell cell_name | -instance inst_name | -file filename}
[-instrinsic_cap value]
[-loading_cap value]
[-grid_cap value]
[-add]
[-layer name]
[-net net_name]
}
```

Scales the intrinsic cell capacitance value to determine how much additional capacitance can be added in a region to reduce dynamic IR drop.

Parameters

`-add`	
	Specifies to add capacitance (farads) on the power-grid on a specific layer and region. The parameter works in conjunction with the existing parameters, such as `-intrinsic_cap`, `-grid_cap`, and `-loading_cap`. When this parameter is specified, the value provided with the `-intrinsic_cap`, `-grid_cap`, and `-loading_cap` parameters will be treated as absolute value instead of a scale factor value, which is the default behavior.
`-cell cell_name`	
	Specifies to scale the capacitance value for the specified cell.
`-file filename`	

	Specifies a file containing the list of instances and cells that use the same scaling factor. The format of the file is:
	`CELL cellname`
	`INSTANCE instancename`

`-global | -region x1 y1 x2 y2`	
	You must specify either `-global` or `-region x1 y1 x2 y2`. The `-global` option scales the specified capacitances for the entire design. The `-region x1 y1 x2 y2` scales the specified capacitances in the region. The default unit of `x1 y1 x2 y2` is in database units
`-grid_cap value`	

	Scales power-grid capacitance of the design to the specified scale factor. The default scale value is 1. ⚠ The `-grid_cap` parameter can be specified either with the `-global` or the `-region` parameter. This parameter is not supported with the `-cell` and `-instance` parameters.
`-help`	Outputs a brief description that includes the type and default information for each `scale_what_if_capacitance` parameter. For a detailed description of the command and all of its parameters, use the man command: `man scale_what_if_capacitance`.
`-instance` *`inst_name`*	
	Specifies to scale the capacitance value for the specified instance.
`-intrinsic_cap` *`value`*	
	Scales instance internal gate capacitances to the specified scale factor. The default scale value is 1.
`-layer` *`layername`* `|` `all`	
	Specifies the LEF layer on which capacitance scaling is performed. Multiple commands can be issued to scale capacitance on multiple layers. You can specify the `all` argument to scale all the layers.
`-loading_cap` *`value`*	
	Scales loading capacitance of the instance to the specified scale factor. The default scale value is 1.
`-net` *`net_name`*	
	Specifies to scale the capacitance value for the specified net.
`-reset`	Resets all the previous `scale_what_if_capacitance` command settings.

Examples

- **Cell-based capacitance scaling** - The following command scales intrinsic capacitance on all instances of the cell *cellA* by 1e-10 (<*intrinsic_cap*> * 1e-10):
  ```
  scale_what_if_capacitance -cell cellA  -intrinsic_cap 1e-10
  ```
- **Pin-based capacitance scaling** - The following command scales intrinsic and loading capacitance on all instances of the cell *cellA* connected to the pin *vdd* by 1e-10 (<*intrinsic_cap*> * 1e-10 and <*loading_cap*> *1e-10):
  ```
  scale_what_if_capacitance -cell cellA -net vdd -intrinsic_cap 1e-10  -add -loading_cap 1e-10
  ```
- **Region-based capacitance scaling** - The following command scales capacitance in the specified region by 1e-10 (<*intrinsic_cap*> * 1e-10, <*loading_cap*> *1e-10, and <*grid_cap*> * 1e-10):
  ```
  scale_what_if_capacitance -region {896.877  937.661  1276.9365  1615.358} -intrinsic_cap 1e-10  -loading_cap 1e-10  -grid_cap 1e-10
  ```
- The following command scales grid capacitance in the specified layer by 1e-10:
  ```
  scale_what_if_capacitance -net VDD -region { 0 0 100 100 } -layer M2 -grid_cap 1e-10
  ```

Related Information

- `create_current_region`
- `scale_what_if_resistance`
- `scale_what_if_current`
- "What-If Rail Analysis" in the *Voltus IC Power Integrity Solution User Guide*

scale_what_if_current

```
scale_what_if_current
[-help]
[-hierarchy hier_name | -region x1 y1 x2 y2 | -global | -inst_list filename]
[-scale_clock_network]
[-scale value | -current value]
[-net net_name]
[-reset]
```

Scales current to do what-if analysis for a hierarchical partition and assess its effect on IR drop.

Parameters

`-current value`	
	Specifies current value in Amperes. This is used as target peak current for the given hierarchy and is then scaled appropriately. You cannot specify this option with `-region x1 y1 x2 y2` or `-global` options.
`-global`	Specifies current scaling to be applied to entire design.
`-help`	Outputs a brief description that includes the type and default information for each `scale_what_if_current` parameter. For a detailed description of the command and all of its parameters, use the man command `man scale_what_if_current`.
`-hierarchy hier_name`	
	Specifies the name of the hierarchical block. For example, `-hierarchy top/blockA`. To specify global scaling for the design use "`/`". For example, `-hierarchy /` `-hierarchy` is a required parameter. This parameter allows instance-based current scaling by the specified scale factor. The parameter can be used to scale down peak current values. The use model of instance current scaling is: `scale_what_if_current -hierarchy <instance_name> -scale <value>`
`-net net_name`	
	Scales current of the specified net.
`-inst_list filename`	

	Specifies to scale current for the specified nets. This parameter allows you to specify a file containing the list of instances and their scale factor.
	Use Model
	`scale_what_if_current -inst_list filename -scale val`
	The format of `filename` is:
	`instanceName scaleFactor`
	`instanceName scaleFactor`
	Here,
	• `val` means the global scale factor. This value will be used if the local or instance-specific scale factor is not specified.
	• `scaleFactor` means the local scale factor. If both global and local scale factors are specified, the local scale factor takes precedence.
	Default scale factor value is `1`.

`-region x1 y1 x2 y2`	
	Specifies a region where current scaling is to be applied. The default unit of `x` and `y` coordinates is in microns (um).
`-reset`	Resets all the previous `scale_what_if_current` command settings.
`-scale value`	

	Specifies any value greater than `0`. For example, a value of `0.5` will scale the current in half. This is a required parameter.
`-scale_clock_network`	
	When specified, scales current for all instances within the given hierarchy. When not specified, the software does not scale the instances that belong to the clock network. It scales current for the rest of the instances within the given hierarchy to the specified value. You cannot specify this option with `-region x1 y1 x2 y2` or `-global` options. This is an optional parameter.

Examples

- The following command scales current for the hierarchical block `BLOCK_C`:
  ```
  scale_what_if_current -hierarchy top/BLOCK_C -current 0.5
  ```

Related Information

- `scale_what_if_capacitance`
- `scale_what_if_resistance`
- `create_current_region`
- "What-If Rail Analysis" in the *Voltus IC Power Integrity Solution User Guide*

scale_what_if_resistance

```
scale_what_if_resistance
[-help]
-reset | {-net netname
{-global | -region x1 y1 x2 y2 | -instance instancename | -cell cellname | -file filename}
[-scale value | -scale_ron {R_ON_scale_factor | R_OFF}]
[-auto_scale_adjacent_via_layers {true | false}]
[-layer {layername | all} ]
}
```

Scales resistance globally or in a region to determine how much resistance can be modified in a region to reduce the entire IR drop. In designs with power switches, the scaling of resistance will be applied to always-on net as well as its switched nets in a given region. Currently, it is not possible to apply different scaling factors for always-on and switched nets.

Parameters

`-auto_scale_adjacent_via_layers {true|false}`	
	Specifies to use auto via scaling for what-if resistance analysis. When scaling resistance on a specific metal layer, via resistance on the adjacent via layers are automatically scaled with the same scaling factor. The default value is `true`. Use `-auto_scale_adjacent_via_layers false` to keep via resistances un-scaled.
`-global | -region x1 y1 x2 y2 | -instance instancename | -cell cellname | -file filename`	

	You must specify either `-global`, `-region`, `-cell`, `-instance`, or `-file`.
	• When the `-global` parameter is specified with the `-scale` parameter, it scales resistance by the specified value globally for a given layer. If the `-global` parameter is specified with the `-scale_ron` parameter, it scales the resistance value of all power switch cells globally for a given layer. This is the default.
	• When the `-region` parameter is specified with the `-scale` parameter, it scales the grid resistance in the specified region. If the `region` parameter is specified with the `-scale_ron` parameter, it scales the resistance of all power switch cells in the specified region. The default unit of x1 y1 x2 y2 is in database units.
	• The `-instance instancename` or `-cell cellname` parameter specifies to scale the internal resistors from the PGV for the specified instance or cell.
	• The `-file filename` parameter specifies a file containing the list of instances and cells that use the same scaling factor. The format of the file is:
	`CELL cellname`
	`INSTANCE instancename`
	This is a required parameter. Default is `-global`.
	The precedence for resistance scaling is as follows:
	1. Instance
	2. Cell
	3. Region
	4. Global

`-help`	Outputs a brief description that includes the type and default information for each `scale_what_if_resistance` parameter. For a detailed description of the command and all of its parameters, use the man command `man scale_what_if_resistance`.
`-layer layername | all`	
	Specifies the layer name (LEF layer or technology layer) on which the scaling is performed. Multiple commands can be issued to scale resistance on multiple layers. You can specify the `all` argument to scale all the layers. When the `all` argument is used, the `-auto_scale_adjacent_via_layer` parameter is disabled. This is a required parameter.
`-net netname`	

	Scales resistance of the specified net in the domain which is being analyzed. This is a required parameter.
`-reset`	Resets all the previous `scale_what_if_resistance` command settings.
`-scale` *value*	
	Specifies any value greater than 0. For example, a value of 0.5 will scale the resistance in half. This is a required parameter.
`-scale_ron {`*R_ON_scale_factor* `| R_OFF}`	
	Specifies the value used to scale the RON of the power-gate instance/cell. The default value is `1`. You can also specify the "`R_OFF`"(case insensitive) keyword to apply the off state power-gate resistance for the specified instance/cell.

set_advanced_package_options

```
set_advanced_package_options
[-help]
-reset  |
{[-tool_path <binary_path>] [-net_mapping_file <filename>]}
```

Specifies the path to the bin folder of package extraction and analysis tools. Also, a net mapping file needs to be specified. The mapping file is a simple two column format containing the die net name and the corresponding package net names. After running this command, use the `extract_package` command to start package model extraction.

Parameters

`-help`	Outputs the command usage and a brief description about the command parameters.
`-tool_path <binary_path>`	
	Specifies the full path to the bin folder of the package extraction and analysis tools (XtractIM and PowerDC).
`-net_mapping_file <filename>`	
	Specifies the name of the two column mapping file that contains the mapping between the net names of package with the net names of die.
`-reset`	
	Resets all specified options back to default values.

Example

- The following example specifies the path to the bin folder of package extraction and analysis tools:

```
set_advanced_package_options \
   -tool_path /home/sigrity/tools/bin/ \
   -net_mapping_file net_mapping.txt
```

Related Information

- `extract_package`
- "Package Analysis" in the *Voltus IC Power Integrity Solution User Guide*

set_advanced_rail_options

```
set_advanced_rail_options
[-help]
[-reset] | [[-voltus_rail_include_file_begin file_name1]
[-voltus_rail_include_file_end file_name2] ]
```

Provides the ability to include a file that provides a list of additional rail options that should be used for rail analysis. If you do not specify values to the set_advanced_rail_options command parameters, the parameter values are set to the default value, that is, empty file name.

For more information on the `vstorm2` commands, refer to the "Rail Analysis Options" section in the *Voltus IC Power Integrity Solution Text Command Reference.*

Parameters

`-help`	Outputs the command usage and a brief description about the command parameters.
`-reset`	Resets parameters to their default values. This means that an extra include file is not required.
`-voltus_rail_include_file_begin file_name`	
	Provides the ability to provide a file that includes additional rail options that will be run prior to the analyze command. This can be used for those legacy rail analysis commands that do not have a Voltus equivalent.
`-voltus_rail_include_file_end file_name`	
	Provides the ability to provide a file that includes additional rail options that will be run after the analyze command. This can be used for those legacy rail analysis commands that do not have a Voltus equivalent.

Examples

- The following command needs to be set to override the default precision digits:
  ```
  set_advanced_rail_options -voltus_rail_include_file_begin vstorm.file

  <vstorm.file>
  setvar precision_digits 10
  ```
  With this variable, you will get IR with 10 precision digits (10 includes all digits before and after the decimal point).

Related Information

- `set_rail_analysis_mode`

set_die_model

```
set_die_model
[-help]
[-subckt subcircuitname]
{-reset  | [[-die_instance_name dieinstname [-spice model_file [-mapping mapping_file]]] ]
}
```

Specifies to import a die model on die Interposer or on package netlist.

This command gives information about the die model that will be used in the rail analysis of another die, wherein the two die are connected through die Interposer die or package netlist. For example, if you are performing IR drop analysis for a die (**die2**) on an Interposer/package design that is connected to another die (**die1**), and if the two die share the power/ground network, it is imperative to import the die model of **die1** during IR drop analysis of **die2**.

You can import multiple die models by specifying multiple `set_die_model` commands.

Parameters

`-die_instance_name` *dieinstname*	
	Mandatory parameter. Specifies the die instance name for die model. This is the die model of the die that needs to be imported.
`-help`	Outputs a brief description that includes the type and default information for each `set_die_model` parameter. For a detailed description of the command and all of its parameters, use the man command `man set_die_model`.
`-mapping` *mapping_file*	

	Mandatory parameter. Specifies the name of the mapping file that contains the port connection mapping between the die model and voltage source of the chip to be analyzed.
	The two mapping file formats are:
	• **Mapping when die model on LEF/DEF-based Interposer Die**
	`#port_of_die_model  cell  die_name/VSRC_pad_name`
	`VDD_Bump_VDD_9_0  cell  Interposer/Bump_DIE0_VDD_0`
	`VDD_Bump_VDD_9_0  cell  Interposer/Bump_DIE0_VDD_1`
	...
	• **Mapping when die model on Package Design**
	`#port_of_die_model  pkg  port_of_pkg_netlist`
	`VDD_Bump_VDD_9_0  pkg  VDD_3`
	`VDD_Bump_VDD_9_0  pkg  VDD_4`

`-reset`	Resets all the previous `set_die_model` command settings to the default settings.
`-spice` *model_file*	
	Mandatory parameter. Specifies a file containing a SPICE subcircuit describing the die model.
`-subckt` *subcircuitname*	
	Defines the top-level subcircuit in package files. When this parameter is not specified, the first circuit in the Spice file is used as the default top circuit.

Examples

- The following command imports two die models `Die1` and `Die2`:

```
set_die_model -die_instance_name Die1 -spice die1_model.ckt -mapping die1_port.txt
set_die_model -die_instance_name Die2 -spice die2_model.ckt -mapping die2_port.txt
```

Related Information

set_dynamic_rail_simulation

```
set_dynamic_rail_simulation
[-help]
[-start value]
[-stop value]
[-resolution value]
[-reset]
[-auto_repeat]
```

An optional command to set the parameters for dynamic rail analysis. By default, dynamic rail analysis uses the start time, stop time, and resolution from current data file. To analyze fewer clock cycles, you can choose different start and stop times using the `-start` and `-stop` options. It is recommended that at least one or two full cycles are simulated to fully charge and discharge the on-chip capacitance.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `set_dynamic_rail_simulation` parameter. For a detailed description of the command and all of its parameters, use the man command `man set_dynamic_rail_simulation`.
`-auto_repeat`	

	Specifies to repeat the dynamic current waveform till the `-stop` time specified. If `-stop` is not specified, all the waveforms will repeat till the longest waveform duration. The `-auto_repeat` parameter can be used when multiple dynamic current files have different simulation periods or when IR drop analysis needs to be run for longer duration.
	The following command sets the dynamic simulation time from 20ns to 100ns in which the current data will be repeated until 100ns is reached:
	`set_dynamic_rail_simulation -start 20ns -auto_repeat -stop 100ns`
	The `-repeat` parameter of the `set_power_data` command has higher priority than `set_dynamic_rail_simulation -auto_repeat`, as shown in the following example:
	`set_power_data VDD1.ptiavg -repeat 50`
	`set_power_data VDD2.ptiavg`
	`set_dynamic_rail_simulation -auto_repeat -stop 100`
	In this example, VDD1 waveform will repeat till 50ns, while VDD2 waveform will repeat till 100ns.

`-reset`	Resets all the previous `set_dynamic_rail_simulation` command settings to the default settings.
`-resolution value`	
	By default rail analysis picks up the resolution (or step size) saved in the dynamic current files. To achieve better rail analysis performance, you can increase the step size using this option. However, using larger than two times the step size of current data file is not recommended as it can impact accuracy of dynamic IR drop analysis. You can specify the units with the value. If you do not specify a unit, the software uses the default unit. *Default*: Picoseconds (ps).
`-start value`	
	Defines the start time to be used for dynamic rail analysis. This option is used with the `-stop` option and enables you to perform a more detailed analysis in specific time ranges. You can specify the units with the value. If you do not specify a unit, the software uses the default unit. *Default*: The default unit is nanoseconds (ns). The default value is the start time from current data file. The start time in the current data file is usually 0ns.
`-stop value`	
	Defines the stop time to be used for dynamic rail analysis. This option is used with the `-start` option and enables you to perform a more detailed analysis in specific time ranges. You can specify the units with the value. If you do not specify a unit, the software uses the default unit. *Default*: The default unit is nanoseconds (ns). The default value is the end of the current data. If multiple current files are specified and they all have different simulation periods, the largest simulation period is used to decide the stop time.

Examples

- The following command sets the dynamic simulation time from 2ns to 12ns with a resolution of 100ps:
  ```
  set_dynamic_rail_simulation -start 2ns -stop 12ns -resolution 100ps
  ```

set_multi_die_analysis_mode

```
set_multi_die_analysis_mode
[-help]
-name analysis_name
-die_list {die_instance_name1 die_instance_name2}
[-report_rlrp_path_instance_list filename]
[-stacked_die_mapping Innovus_map_file]
```

Specifies how the multi-die analysis will be performed.

Parameters

`-die_list` *die_instance_name1 die_instance_name2*	
	Specifies the die instance names.
`-help`	Outputs a brief description that includes the type and default information for each `set_multi_die_analysis_mode` parameter. For a detailed description of the command and all of its parameters, use the man command `man set_multi_die_analysis_mode`.
`-name` *analysis_name*	
	Specifies the name of the analysis.
`-report_rlrp_path_instance_list` *filename*	

	Specifies a file containing a list of die instances (one per line) for which the RLRP path should be reported. This parameter is used to generate the l die.
	The format of the specified input file is:
	<die_name> <net_name>
	The `-report_rlrp_path_instance_list` parameter generates a report `mdie_inst_rlrp_path.rpt` at the following location: *<output_dir>/<state_di*
	The format of the report is:
	`Die Name: <die_name>`
	`Net Name: <net_name>`
	`Pin Name: <pin_name>`
	`Instance Name: <inst_name>`
	`Die Layer/Via Resistance(cumulative) Ohm Length Node1#(X,Y) Node2#(X,Y) Net`
	Example of an Output File:
	`Die Name: LDIE1`
	`Net Name: VDD_AO`
	`Pin Name: TVDD`
	`Instance Name: ring/PSO_RING_78`
	`Die Layer/Via Resistance(cumulative) Ohm Length Node1#(X,Y) Node2#(X,Y) Net`
	`LDIE1 METAL_1 0.1238(3.4182) 2.210 169.28500,233.27500 167.07500,233.27500 VDD_AO`
	`LDIE1 METAL_1 0.1302(2.7137) 2.035 169.28500,221.89000 169.28500,223.92500 VDD_AO`
	`LDIE1 VIA_1 0.0269(2.5835) 0.140 169.28500,221.89000 169.28500,221.89000 VDD_AO`
	`LDIE1 METAL_2 0.0070(2.5565) 0.145 169.28500,221.74500 169.28500,221.89000 VDD_AO`
	`LDIE1 VIA_2 0.0875(2.5496) 0.140 169.28500,221.74500 169.28500,221.74500 VDD_AO`
	`LDIE1 VIA_3 0.0875(2.4621) 0.140 169.28500,221.74500 169.28500,221.74500 VDD_AO`
	...

`-stacked_die_mapping` *Innovus_map_file*	
	Specifies the name of the inter die data mapping file from Innovus. The mapping file is a virtual mapping that provides the connections between any communication directly between the die (master/slave configuration).

Examples

- The following command specifies an analysis name called `tsv`, two die instances called `mother_die` and `daughter_die`,and a stacked mapping file `pwr.mapping`:

```
set_multi_die_analysis_mode -name tsv -die_list {mother_die daughter_die}
-stacked_die_mapping ../data/pwr.mapping
```

Related Information

- `set_rail_analysis_mode`
- `create_die_model`
- "Through-Silicon Via and System-in-Package" in the *Voltus IC Power Integrity Solution User Guide*

set_net_group

```
set_net_group
[-help]
-reset | {-name group_name
-type [power | ground]
-nets {net_list}
}
```

Specifies the list of either power or ground nets that are isolated but need to be analyzed together as a single net. The results are generated for the new grouped net. The new grouped net name must be one of the net names in the group. To analyze the grouped net, you must also specify power pads for the grouped net name.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `set_net_group` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_net_group`.
`-name group_name`	
	Name of the net group. **Note:** The name of the net group must be one of the net names in the group. Using a net name that is not in the net group will trigger error when displaying results in the flow.
`-nets {net_list}`	
	Specifies a list of power or ground nets.
`-reset`	Resets all previously created net name(s) with the new grouped net name(s).
`-type [power | ground]`	
	Specifies whether it is a power or ground net.

Examples

- The following example groups the power nets that will be analyzed together as a group called VDD.

```
set_net_group -name VDD -type power -nets { VDD VDD1 VDD2 VDD3 }
set_power_pads -net VDD -format xy -file VDD.pp
analyze_rail -type net VDD
```

Related Information

- `set_rail_analysis_mode`
- `set_power_pads`
- "Static Power, IRdrop and EM Analysis" in the *Voltus IC Power Integrity Solution User Guide*

set_offchip_package_trace

```
set_offchip_package_trace
[-help]
-mapping mapping_file
-name switched_name
-ploc_file_list list_of_bump_location_files
[-reset]
-spice spice_model_name
[-subckt subcircuitname]
```

Specifies to include RDL0 (off-chip package trace) resistance effects during the static and dynamic rail analysis. This flow allows you to analyze switched net bumps that are marked as RDL0 bumps. When this command is specified, the software automatically generates switched net bump current and bump voltage waveforms in the `voltus_rail_pad.tran.ptiavg` file created in the new switch net directory located under the rail state directory.

You can specify multiple `set_offchip_package_trace` commands to define connectivity of different bump nets.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `set_offchip_package_trace` parameter. For a detailed description of the command and all of its parameters, use the man command `man set_offchip_package_trace`.
`-mapping mapping_file`	
	Specifies the name of the mapping file that contains the mapping between the package port and switched net bump names. The format of the file is: `<spice_circuit_port_name> pin <vsrcName_in_switch_net's_ploc>`
`-name trace_model_name`	
	Specifies the trace model name or switched net bump of RDL0.
`-ploc_file_list list_of_bump_location_files`	

	Specifies the name of a file containing switched net names and associated ploc/power pad files. The format of the file is:
	`SWITCHED_NET1 plocfile1`
	`SWITCHED_NET2 plocfile2`
	`…..`
	The format of plocfile (power pad) is:
	`<voltage_source_name> <x> <y> <metal_layer>`
	The format of this file is same as specified for the `set_power_pads -format xy` format.

`-reset`	Resets all the previous `set_offchip_package_trace` command settings to the default settings.
`-spice model_file`	
	Specifies a file containing a SPICE subcircuit (RDL0 netlist or full-chip package netlist) for off-chip package trace.
`-subckt subcircuitname`	
	Defines the top-level subcircuit for off-chip package tracing.

Examples

- The following command specifies to analyze the switched net `VDDau`:

```
set_offchip_package_trace -name VDDau  -ploc_file_list  ploc_file_list.txt -spice pkg.ckt -mapping pkg_mapping.file
```

Related Information

- `set_package`
- `create_die_model`
- "Package Analysis" in the *Voltus IC Power Integrity Solution User Guide*

set_package

```
set_package
[-help]
-reset | {-spice model_file
[-mapping mapping_file]
[-offset {x y}]
[-die_instance_name dieinstname]
[-rotate rotation_angle_in_degrees]
[-flip {true | false}]
[-subckt subcircuitname]
[-scale scaling_factor_number]
[-mapping_type { distributed | lumped }]
}
```

Specifies the package model information to be used in power rail analysis.

Parameters

`-die_instance_name` *`dieinstname`*	
	Specifies the die instance name for multi-die analysis. This option is only available in multi-die analysis (`set_rail_analysis_mode -die_mode multi-die`).
`-flip {true | false}`	
	Specifies to flip the die along the Y axis. *Default*: `false`
`-help`	Outputs a brief description that includes the type and default information for each `set_package` parameter. For a detailed description of the command and all of its parameters, use the man command `man set_package`.
`-mapping` *`mapping_file`*	
	Specifies the name of the package terminal mapping file, which contains the mapping of the terminals of the SPICE subcircuit in the package model file (Specified by the `-spice` *`model_file`* parameter) to the locations at the grid or top-level pins. The mapping file formats supported by the software are: • Model Connection Protocol (MCP) • Voltus-specific Format For more information on the mapping file formats, refer to the *Package Model and Mapping File* section in the "File Formats" chapter of *Voltus User Guide*.
`-mapping_type { distributed | lumped }`	

	Specifies the type of mapping to be used in the Voltus-specific terminal mapping file that will be added in the rail analysis flow. The possible arguments are:
	• `distributed` – A distributed mapping file lists out the mapping for each bump on the die to its corresponding package port. The mapping file is specified with the `set_package -mapping` parameter.
	• `lumped` - A lumped mapping file allows for auto-grouping of the die bumps to the lumped package ports. When `lumped` is specified, the software implements a lumped package by internally creating a lumped package model and its mapping file.
	
	The format of the lumped mapping file is:
	`<terminal_name>  <die | vsrc>  <net_name>`
	`vddcore_in  die  vddcore`
	`vddcore_out  vsrc  vddmpu`
	
	In this format:
	◦ the software connects "`<terminal_name> die <net_name>`" to the bumps belonging to `<net_name>` on the die
	◦ the software connects "`<terminal_name> vsrc <net_name>`" to the voltage source of `<net_name>`
	◦ The number of lines in the lumped mapping file are few and are equal to the number of terminals on the package model
	Default: `distributed`

`-offset {x y}`	
	Specifies to adjust and shift the X Y coordinates in the MCP header for each pin. When performing package analysis, the MCP is used to map the terminals of the SPICE subcircuit in the package model file to the locations at the grid or top-level pins in DEF. The die origin specified in MCP must be same as specified in DEF. If the die origin is not the same, you can use the `-offset` parameter to modify the XY location specified in the MCP file.
`-reset`	Resets all the previous `set_package` command settings to the default settings.
`-rotate` *rotation_angle_in_degrees*	
	Specifies the rotation angle of the die. The possible values are: `0/45/90/135/180/225/270/315`. Rotation is always in the counter clockwise direction from the original point. Default value is `0`. This information is required to do coordinate conversion for xy based pin mapping.
`-scale` *scaling_factor_number*	
	Specifies to scale the package model.
`-spice` *model_file*	
	Specifies a file containing a SPICE subcircuit describing the package model.
`-subckt` *subcircuitname*	
	Defines the top level subcircuit in package files.

- `create_die_model`
- "Package Analysis" in the *Voltus IC Power Integrity Solution User Guide*

set_pg_nets

```
set_pg_nets
[-help]
-net net_name
-voltage value
[-threshold value]
-tolerance value
-force
[-die_instance_name dieinstname]
[-pkg_net_name package_net_name]
[-lib_binding_voltage value]
[-vu_limit value]
```

Specifies the power grid nets. Using this command, you can specify power/ground net voltages in the static and dynamic power analysis flow, and the rail analysis flow.

For the power analysis flow, you must specify the `set_pg_nets` command before `report_power`.

Note: When specifying a ground net with a non-zero nominal operating voltage value, a threshold greater than the ground value must be specified in order for the net to be treated as the ground net.

Parameters

`-die_instance_name dieinstname`	
	Specifies the die instance name for multi-die analysis. This option is only available in multi-die analysis (`set_rail_analysis_mode -die_mode mult`
`-force`	Skips the validity check on power nets.
`-help`	Outputs a brief description that includes the type and default information for each `set_pg_nets` parameter. For a detailed description of the command and all of its parameters, use the man command `man set_pg_nets`.
`-lib_binding_voltage value`	
	Specifies the voltage to be used for library binding in power analysis. This parameter binds the instances to the library that is closest to the user-sp voltage.
`-net net_name`	
	Specifies the name of the power or ground net that you want to analyze.
`-pkg_net_name package_net_name`	
	Specifies the net name on the package side. By default, the package net name is same as the net name.
`-threshold value`	
	Specifies the minimum allowed voltage on the power net or the maximum rise on the ground net, depending on the setting of the `-voltage` parame parameter is used to verify that the power grid passes the limit check and to set the filters for an IR plot.
`-tolerance value`	
	Specifies the tolerance range of the voltage value. Specify a value from 0 to 1 (not including 1). A value of 0.2 results in a range of "voltage +20%" *Default*: 0.3.
`-voltage value`	
	Specifies the voltage on the power rail to be analyzed.
`-vu_limit value`	

	Specifies the voltage drop limit for a net. This parameter allows you to specify the voltage threshold value for each net separately. The specified tl the rail reports, histograms, and plots. If the threshold value is not specified for some of the nets being analyzed, the default range will be applied to *Default Range*: 0mV to max VU

Examples

- The following command specifies a `VDD_TDSPCore` value of 0.9 volts with a threshold of 0.89V and a tolerance of 0.3:

  ```
  set_pg_nets -net VDD_TDSPCore -voltage 0.9 -threshold 0.890 -tolerance 0.3
  ```

- The following command specifies to use the library binding voltage for binding the libraries to the instances instead of "`-voltage`":

  ```
  set_pg_nets -net vdd -voltage 0.90 -lib_binding_voltage 0.75
  ```

Related Information

- `set_rail_analysis_mode`
- `set_rail_analysis_domain`
- "Static Power, IRdrop and EM Analysis" in the *Voltus IC Power Integrity Solution User Guide*

set_power_data

```
set_power_data
[-help]
-reset | {-format {current | ascii | area | ascii_current}
[-instance instance_name]
[-offset offset_value]
[-power value]
[-scale factor]
[-repeat time]
[-bias_voltage value]
[-die_instance_name dieinstname]
[-power_output_directory dir]
[-repeat_window {start end}]
[-strip_hier_instance instance]
[filename]
}
```

Specifies the static and dynamic power or current files for IRdrop and EM analysis. The power data for the design can be generated using the `report_power` command. This command also has ability to read external ASCII static power files to do static rail analysis. For dynamic analysis, you must use the `report_power` command to generate dynamic current files.

This command should be specified prior to the `analyze_rail` command. You must specify the `set_power_data` command after the `report_power` command in the flow script if power data is not available.

Parameters

`-bias_voltage value`	
	Specifies the value of the bias voltage. This parameter must be set if -format is set to ascii or area.
`-die_instance_name dieinstname`	
	Specifies the die instance name for multi-die analysis. This option is only available in multi-die analysis (`set_rail_analysis_mode -die_mode m`
filename	Specifies the name of the power data files. The file is optional if -format area is specified.
`-format {current | ascii | area | ascii_current}`	
	Specifies the format of the power data. The power data format can be `current, ascii`, or `area`. The parameter `-bias_voltage` must be set if `area` or `ascii` is specified. • When using the current format option, specify the current file (*.ptiavg) that is generated by the power analysis software within Voltus . For ex `set_power_data -format current static_VDD.ptiavg`

	• When using the `ascii` format option, specify the ascii instance based power file, generated by PowerMeter or CPE software within Voltus. F
	`set_power_data -format ascii -bias_voltage 1.08 powermeter.pwr`
	Note: The command accepts an ASCII power file in three-column format consisting of *instance/cell name*, *power* in W,and *power pin name*. are treated as comment lines.
	The format of the three-column input file is as follows:
	`<instance/cell name> <power in Watts> <power pin name>`
	Example:
	`top/inst1 0.001 vdd`
	`top/inst2 0.001 vdd1`
	`top/inst3 0.003 vdd3`
	where vdd, vdd1, and vdd3 are power pin names of the instance
	ⓘ Although `-bias_voltage` is a required argument with `-format ascii`, when 3-column power file format is specified, the program will ignore rely on associated net voltages to determine current for the pins.

	• When using the `area` format option, specify the total power of the chip in Watts. This power is distributed based on cell area. Optionally, you for macro cells using a file, for example, `set_power_data -format area -bias_voltage 1.08 -power 10 cell_power.file` where, `-bias_voltage` is the voltage at which power was characterized; If the analysis voltage is different, this power will be scaled accordingly. `cell_power.file` is in two column format with *`cell_name`power_in_watts*.
	• When using the `ascii_current` format option, specify an ASCII instance current file for static analysis. The format of the three-column input fi *`<instance/cell name> <current in Ampere> <power pin name>`*
`-help`	Outputs a brief description that includes the type and default information for each `set_power_data` parameter. For a detailed description of the command and all of its parameters, use the man command `man set_power_data`.
`-instance` *`instance_name`*	
	Specifies the hierarchical instance name for which the current files are included. This option is useful when power is calculated for hierarchical partitions of the design, enabling you to read power for the hierarchical partitions For example, `set_power_data -format current -instance xy {dynamic_VDD.ptiavg dynamic_VSS.ptiavg}`
`-offset` *`offset_value`*	
	Specifies the start time offset for current waveforms saved inside the current files. The default unit is in seconds; However, you can also specify the unit with the offset time value. This option is useful in the hierarchical flow to align current waveforms of various partitions. It can be also used to shift power-up rush current w UltraSim software. For example, `set_power_data -format current -offset 1ns -instance xy {dynamic_VDD.ptiavg dynamic_VSS.ptiavg}`
`-power` *`value`*	
	Specifies the total power of the chip in Watts and is used with -format area option.
`-power_output_directory` *`dir`*	
	Specifies the name of the directory that contains the current files required to run power analysis in parallel with rail analysis.

`-repeat time`	
	Repeats the dynamic current waveform for the specified time. You must ensure that `set_dynamic_rail_simulation -stop` is also specified and duration. This option is only available for current format files during dynamic analysis. The repeat option can be used when multiple current files periods or when IR drop analysis needs to be run for longer duration. See example below. *Default units*: ns.
`-repeat_window {start end}`	
	Specifies to extract the given window from the current waveform and repeat it. You can pick a window such that the current at the `start_time` ar parameter allows you to identify and repeat windows where the start and end time have similar values to ensure that the repeated waveform is no high current values. The unit for the start and end time is ns. The following command specifies that the pattern between {20ns 80ns} will be repeated until simulation stops: `set_power_data -repeat_window {20ns 80ns}`
`-reset`	Overwrites previously specified current data.
`-scale factor`	
	Specifies a scale factor to apply to the current data. You can use this parameter to scale currents to a more optimistic or pessimistic power-consumption estimate. This parameter is only for `-format current` and `-format ascii`.
`-strip_hier_instance instance`	
	Specifies to use power generated from the top-level rail analysis for block-level rail analysis. This parameter allows you to specify the top-level for which the current files are to be included. When the parameter is specified, the tool removes the prefix from the top-level and reads the top-le during the block-level analysis. The parameter is useful when top-level power data is already available, therefore, you do not need to re-run blo

Examples

- The following command specifies a format of type current and a scale of 1 for the three given files.:
  ```
  set_power_data -format current -scale 1 {static_VDD_TDSPCore.ptiavg \ static_VDD_TDSPCore_R.ptiavg static_VSS.ptiavg}
  ```
- The next example specifies two current data files. The first file specifies vdd_vdd.ptipeak. The second one specifies dynamic_VDD.ptiavg and this current data will be repeated every 100ns, which is the stop time specified for the dynamic analysis.
  ```
  set_power_data -format current vdd_vdd.ptipeak
  set_power_data -format current -repeat=100ns dynamic_VDD.ptiavg
  set_dynamic_rail_simulation -stop 100ns
  analyze_rail ...
  ```

Related Information

- `set_rail_analysis_mode`

set_power_pads

```
set_power_pads
-reset |{
[-auto_voltage_source_creation {true|false}]
[-def_shape_only {true | false}]
[-die_instance_name dieinstname]
[-enable_switchnet_ploc_generation {true | false}]
[-format {defpin | padcell | xy | boundary | xyiv}]
[-layer vialayername]
-net net_name
[-number_of_voltage_source value]
[-file file]
[-region {x1 y1 x2 y2}]
[-short_pin_nodes {true | false}]
[-tile {x y}]
}
```

Specifies power pad information.

You can specify multiple power pad formats (`xy` coordinates, pad cell, or power pin) for the same power net, in both, net-based and domain-based rail analysis.

Note: All voltage source names in the power pad location file must be unique for all nets in the domain, e.g. if voltage source name vsrc1 is used in pad location file of net VDD as well as VSS in domain based analysis, program will issue error and exit. In addition, the names of voltage sources in the power pad location file must be different from the names in the DEF pin section.

Parameters

`-auto_voltage_source_creation {true|false}`	
	Specifies to automatically create voltage sources either for all nets (`-net ALL`) or for a specific net (`-net net_name`). The voltage sources are created on the top metal of all via cuts located either on the user-specified via layer or the design top via layer (default). Default: `false`.
`-def_shape_only {true | false}`	
	Specifies to generate voltage sources only on the DEF routing shapes. This parameter controls the generation of voltage sources on the cell instance shapes. When this parameter is set to `false`, voltage sources are created for both the DEF routing shapes and shapes inside cell instances. This parameter is specified with the `-auto_voltage_source_creation` parameter. Default: `true`
`-die_instance_name dieinstname`	
	Specifies the die instance name for multi-die analysis. This option is only available in multi-die analysis (`set_rail_analysis_mode -die_mode multi-die`).
`-enable_switchnet_ploc_generation {true | false}`	
	Specifies to generate voltage sources on all switched nets. This parameter is specified with the `-auto_voltage_source_creation` parameter. Default: `false`
`-file file`	Specifies the name of the file containing the voltage source information. Not required for `-format defpin` option.
`-format {defpin | padcell | xy | boundary | xyiv}`	
	Specifies how the voltage source is determined. Required for `xy`, `padcell`, or `boundary`.
	`defpin` - Specifies that voltage sources will be determined by power pins.
	`padcell` - Specifies that voltage sources will be determined by pad cells.

	`xy` - Specifies that voltage sources will be specified by x y coordinates. You can also specify a PWL function on the X,Y location for a voltage source. When specified, Rail Analysis will read the power pad file and use the PWL waveform for the voltage source.
	Example:
	`set_power_pads -format xy -file <xy_plocFile>`
	
	Add the PWL option in the xy file:
	`*vsrc_name x y layer_name [pwl=]`
	`vsrc3 8.39 370.35 Metal5 pwl=(t1,v1,t2,v2,t3,v3…)`

	`boundary` - Specifies that voltage source locations will be used for instances in the design.
	`xyiv -` Specifies whether the voltage sources specified in the xy power pad location file are current source or reference voltage source. The format is the same as the xy file, except the additional first and last columns to indicate the current/voltage source and current/voltage value.
`-layer` *`vialayername`*	
	Specifies the via layer on which the voltage sources are to be generated. If this parameter is not specified, the voltage sources will be generated on the top via layer of the design. This parameter is specified with the `-auto_voltage_source_creation` parameter.
`-net` *`net_name`*	Specifies the name of the power net.
`-number_of_voltage_source` *`value`*	
	Specifies the number of voltage sources to be generated. You can adjust either `-tile` or `-number_of_voltage_source` to reduce the number of voltage sources created. This parameter is specified with the `-auto_voltage_source_creation` parameter. Default: `1 million`.
`-region {`*`x1 y1 x2 y2`*`}`	
	Generates the voltage sources in the specified region. If this parameter is not specified, the software uses the entire design/layout size as the region. This parameter is specified with the `-auto_voltage_source_creation` parameter.
`-reset`	Resets all the previous `set_power_pads` commands
`-short_pin_nodes {true | false}`	
	Specifies to short all interface nodes on a pad cell pin to a single node and create voltage source for that node. ***Default***: `false` **Example**: `set_power_pads -net vdd -format padcell -short_pin_nodes -file pad_cell.file`
`-tile {`*`x y`*`}`	
	Defines the number of tiles in the X and Y direction for automatic creation of voltage sources. When `-tile` is specified, the area (`-region` or default design area) will be tiled vertically and horizontally per the given tile size (x*y). For each tile, one voltage source will be created on the top metal of the biggest via array. If `-tile` is not specified, the software creates voltage sources on the top metal of all via cuts located either on the user-specified via layer or the top via layer of the design. You can adjust either `-tile` or `-number_of_voltage_source` to reduce the number of voltage sources created. The `-tile` parameter is specified with the `-auto_voltage_source_creation` parameter.

Examples

- The following command specifies the power pad information for the `VDD_TDSPCore_R` net in the file `dtmf_chip.VDD_TDSPCore_R.vsr`c. The voltages sources are specified by x y coordinates.
  `set_power_pads -net VDD_TDSPCore_R -format xy -file dtmf_chip.VDD_TDSPCore_R.vsrc`
- The following command specifies `xy`, `padcell`, and `defpin` formats for a single net (`VDD`) as follows:

```
set_power_pads -net VDD -format xy -file VDD.pp
set_power_pads -net VDD -format padcell -file VDD.padcell
set_power_pads -net VDD -format defpin
```

- The following command specifies power pad information using a combination of user-specified and automatic voltage source creation methods:
  # Specific setting for net VSS using automatic voltage source creation
  ```
  set_power_pads -net VSS -auto_voltage_source_creation true -layer VIA_6
  ```

  # Global setting for all nets using automatic voltage source creation
  ```
  set_power_pads -auto_voltage_source_creation true -net ALL -layer VIA_5
  ```

  # User-specified power pad file for net `VDD_AO`, therefore automatic voltage source creation feature will not be enabled for this net
  ```
  set_power_pads -net VDD_AO -format padcell -file padcell.file -short_pin_nodes true
  ```

Example of power pad location file with XY coordinates for net VDD

```
*-------------------------------------------------------------------------------------------------------------------------------------------------------
----
* XY power pad location file
* vsrc name X(um) Y(um) LEF/Tech Layer <R=value ohm> <C=value F> <L=value H>
* Package R,L and C parameters are optional
*-------------------------------------------------------------------------------------------------------------------------------------------------------
-----
VDD100 5.000 793.500 M7
VDD101 1187.835 293.500 M7
VDD102 695.000 5.000 M6
VDD103 1187.835 493.500 M7
VDD104 595.000 1293.800 M6
VDD105 595.000 5.000 M6
```

Example of pad cell file for VDD net,

```
*-------------------------------------------------------------------------------------------------------------------------------------------------------
----
* Pad cell file for Voltus
* cellname <r=value> <l=value> <c=value>
* Package parameters are optional
*-------------------------------------------------------------------------------------------------------------------------------------------------------
-----
PVDD1 r=2.5e-3 l=2.5e-11 c=120e-12
PVDD2 r=2.5e-3 l=2.5e-11 c=120e-12
```

set_rail_analysis_domain

```
set_rail_analysis_domain
[-help]
-name domain_name
-pwrnets power_net_list
-gndnets ground_net_list
[-threshold value]
```

Specifies a rail analysis power domain.

Note: For a power-gated domain, you should only specify the "always on" net. The switched net should not be specified as part of power domain definition, because it is traced by the program automatically.

Parameters

`-gndnets ground_net_list`	
	Specifies a list of ground nets that are in the domain.
`-help`	Outputs a brief description that includes the type and default information for each `set_rail_analysis_domain` parameter. For a detailed description of the command and all of its parameters, use the man command `man set_rail_analysis_domain`.
`-name domain_name`	
	Specifies the name of the power domain.
`-pwrnets power_net_list`	
	Specifies a list of power nets that are in the domain.
`-threshold value`	
	Specifies the minimum allowed voltage on the power net or the maximum rise on the ground net, depending on the setting of the`-voltage` parameter. The `-threshold`parameter is used to verify that the power grid passes the limit check and to set the filters for an IR plot. **Note:** This parameter does not support domains with MSMV power nets. If you have specified both net (`set_pg_nets -threshold`) and domain-based (`set_rail_analysis_domain -threshold`) thresholds, the net-based threshold will be honored. The valid value for threshold is between 0 and 0.5 (50%). For example, `set_rail_analysis_domain -threshold 0.1` indicates that 0.1 is 10% IRdrop. If a power net in the domain has nominal voltage of 1v, 10% of threshold will translate to 100mV of maximum effective IRdrop between the power and ground net.

Examples

- The following command sets the power domain `TDSP` to include `VDD_TDSPCore_R` and `VSS` nets:
  ```
  set_rail_analysis_domain -name TDSP -pwrnets VDD_TDSPCore_R -gndnets VSS
  ```

```

Specifies how the rail analysis will be performed.

Parameters

`-accumulate_overlapping_ddv_pwl_waveforms {true | false}`	
	Specifies to accumulate the current values of Dynamic Detailed View (DDV) PWL waveforms from different trigger events when the PW are overlapping with each other. If set to `true`, the current values of the overlapping PWL waveforms are added together for rail analysis. The default value is `false`.
`-accuracy {xd | hd }`	
	Specifies the accuracy mode of analysis. *Default* : `hd`
	• `xd`: xd or accelerated definition accuracy mode is used for early implementation stage IR/EM analysis.
	• `hd`: hd or high definition accuracy mode is used for final verification stage IR/EM analysis.
`-analysis_view view`	
	Specifies analysis view created in a CPF (Common Power Format) file. Optional.
`-avg_em_analysis {true | false}`	
	Specifies to calculate the average EM in the dynamic rail analysis run. This parameter generates the `<net_name>.rj.avg.rpt` report. *Default* : `false`
`-block_powerup_rail netname`	
	Specifies a net for block power-up analysis. You can specify only one net for block power-up analysis at a time.
`-cell_ignore_file filename`	
	If specified, excludes all references to the named cells in the specified file, from the design database.
`-check_current_balanced_power_grid_em {true | false}`	

	Specifies to check the power-grid EM rules (power-rail terminal-via EM rule). This parameter allows EM comparison with/without this E is only applicable in TSMC N20 process nodes where the EM limit may be relaxed if certain constraints are met. Refer to TSMC DRM f
`-check_thermal_aware_em {true | false}`	
	Specifies to use the thermal map for EM checks. The thermal map file is specified using the `-read_thermal_map` parameter. The Rail Ar temperature specified in the thermal map file for EM analysis. EM limit has a strong temperature dependency. For a chip that has substa variation across the chip, the Rail Analysis engine can use the temperature specified in the thermal map file to perform accurate EM an
`-check_vsrc_placement_on_switched_net {true | false}`	
	Specifies to check voltage source placement on switched nets. When this parameter is set to `true`, the software checks whether the specified voltage source location file places any voltage sources o the power-gated domain, and disables voltage source placement on the switched net. It also detects shorts and generates an error mes
`-cluster_via1_ports {true | false}`	
	Designs with follow-pin routing on M1 and M2 layers have standard cells library LEF with M1, M2, and VIA1 ports. This parameter spec ports for such cells in order to improve overall extraction and rail analysis performance. *Default* : `true` This parameter is set to `true` by default to improve VIA1 port handling in designs with M1 and M2 follow-pin routing. This parameter giv performance by clustering equidistant VIA1 ports defined in cell LEF without significant loss of accuracy. However, if you specify a clus specification takes precedence over automated VIA1 clustering.
`-cluster_via_rule { {`*`via_layer1 number_of_equidistant_vias`*`}...}`	
	Controls the number of vias to cluster on a layer basis. The VIA clustering rule specified using this parameter will override the default cl given accuracy mode. The following command will cluster 100 equidistant VIA1 cuts, 200 equidistant VIA2 cuts, and 300 equidistant VIA7 cuts: `set_rail_analysis_mode -cluster_via_rule { {VIA1 100} {VIA2 200} {VIA7 300}}` The rest of the VIAs will be clustered using the default clustering rule depending upon the rail analysis accuracy mode.
`-cluster_via_size` *`value`*	
	Specifies the size of the via array to cluster all via layers except VIA1 (layer between Metal1 and Metal2). The default value is `625` (25x25 via array), except when running static analysis using HD mode. The default for static HD mode is `16` (4x preserve more accuracy for EM analysis. *Default* : `625`
`-common_res_inst_pair_file_name` *`file`*	

	Specifies to calculate common resistance along the least resistance path (RLRP) between a pair of cells having the same voltage sour allows you to check RLRP along cell instance pairs from multiple voltage source locations.
	The format of the specified file is:
	`inst_name1 inst_name2`
	`inst_name3 inst_name4`
	`...`
	The `-common_res_inst_pair_file_name` parameter generates a report `<`*`net_name`*`>.common_res` in the following location:
	`<`*`output_dir`*`>/<`*`state_dir`*`>/Reports/<`*`net_name`*`>/`
	The format of the report is:
	`inst_name1 inst_name2 common_res1 pad1`
	`inst_name3 inst_name4 common_res2 pad2`
	`...`
	The following is a snippet from the report:
	`inst_name1 inst_name2` 13.4315 PAD_VDD2

`-compress_powergrid_database {true | false}`	
	Specifies to compress the output files generated by extraction and rail analysis to save disk space usage. This parameter reduces disk from the extraction and rail analysis stages at approximately 5-10% performance penalty. *Default* : `false`

`-decap_cell_list { cell1 cell2 ... celln }`

Specifies a list of decap cells. This option is used when the decap cells are not tagged in the power-grid library. A cell characterized as
power-grid view generation with LibGen does not need to be specified.

For dynamic only.

`-def_based_hierarchical_reports {true | false}`

Specifies to generate separate rail reports for each DEF instance. The net-based effective instance voltage, RLRP, and effective resista
generated hierarchically.

Reports will be generated for every net in each DEF hierarchy using the following directory structure:
`<output_dir>/<state_dir>/Reports/HIER/hier_<HIER_ID>/<domain_name | net_name>.<report_type>`

In the `Reports` folder, the Rail Analysis engine will generate a hierarchical map (`def_hierarchy.map` file) during DEF parsing to associa
with each DEF instance, as shown below:

```
#hier_id   hier_name   #def_name

   0        chip        chipCore
```

Default : `false`

`-default_package_inductor value`

Specifies the default inductance value of the package resistance-inductance-capacitance (RLC) model to use when you specify voltag

If the power-grid views contain area-based voltage source locations, the following equation is used to define the inductance applied to

```
Li = L * number_of_sources
```

where:

`Li` is the inductance on an individual voltage source.

`L` is the default inductance set by `-default_package_inductor`.

`Number_of_sources` is the number of voltage sources in the power-grid view.

The default inductance value is specified in `henrys`.

`-default_package_resistor value`

Specifies the default resistance value of the package resistance-inductance-capacitance (RLC) model to use when you specify voltage

If the power-grid views contain area-based voltage source locations, the following equation is used to define the resistance applied to t

```
Ri = R * number_of_sources
```

where:

`Ri` is the resistance on an individual voltage source.

`R` is the default resistance set by `-default_package_resistor`.

`Number_of_sources` is the number of voltage sources in the power-grid view.

The default resistance value is specified in `ohms`.

`-default_package_capacitor value`

Specifies the default capacitance value of the package resistance-inductance-capacitance (RLC) model to use when you specify voltag

If the power-grid views contain area-based voltage source locations, the following equation is used to define the capacitance applied to

```
Ci = C/number_of_sources
```

where:

`Ci` is the effective capacitance on an individual voltage source.

`C` is the default capacitance set by `-default_package_capacitor`.

`Number_of_sources` is the number of voltage sources in the power-grid view.

The default capacitance value is specified in `farads`.

`-design designname`

	Specifies the DEF or GDS design name for multi-die analysis. This option is only available in multi-die analysis (`-die_mode multi-die`)
`-die_mode {single|multi-die|3dic}`	
	Specifies whether single or multi-die analysis will be performed. The `3dic` option is used for performing multi-die rlrp analysis. *Default* : `single`
`-die_instance_name` *dieinstname*	
	Specifies the die instance name for multi-die analysis. This option is only available in multi-die analysis (`-die_mode multi-die`).
`-disable_analysis_types` { *list of analysis types* }	
	Disables specific analysis types during rail analysis. For example, `set_rail_analysis_mode -disable_analysis_types { rlrp vu pi pv }` disables `rlrp`, `vu`, `pi`, and `pv` analysis types du By default, the disable list is empty. The following analysis types can be disabled: `ir tc iv vc dd pi pv javg rj jrms rc node_effr`
`-disable_em_split_ac_dc_rules {true | false}`	
	Specifies to use the same AC/DC rules for the EM analysis of the signal and PG nets. When this parameter is set to `true`, the software handling of the AC/DC rules. By default (when set to `false`), the software uses separate EM rules for the signal and PG nets.
`-disable_parallel_extraction`	
	Specifies to use a single processor for extracting resistance or capacitance. If this parameter is not specified, the software uses parallel extraction.
`-dynamic_trigger_file` *filename*	
	Specifies a dynamic trigger file. When a Macro EM view with current signature is used in a design, it needs to be determine when this b The dynamic trigger file is used to determine this. At the trigger time, the dynamic current waveforms of the EM view block will be applie **Note**: If you specify trigger for cells or instances using this parameter, the tool would give higher precedence to this user-defined trigger generated trigger files in the power analysis directory (`power_output_dir/trigger*.txt`).
`-eiv_average_per_window_list` *filename*	

	Specifies to generate a report containing different sets of Effective Instance Voltage (EIV) for each timing/switching window for a list of
	The format of the specified file is:
	`INST xxx`
	`CELL xxx`
	The report contains a set of average EIVs for each instance based on the timing/switching window in the current files. The report file na `name.win_avg.rpt`.
	Example:
	`set_rail_analysis_mode -eiv_average_per_window_list ./clock_network.insts`
	File format:
	`INST clk__L2_I1`
	`INST clk__L11_I2`
	`INST clk__L13_I4`
	`INST clk__L13_I3`
	`INST clk__L13_I2`
	Output EIV report format:
	`#INST_NAME START_TIME:END_TIME EIV_AVG`
	`clk__L15_I4 1.32e-09:1.78e-09 1.06354 6.38e-09:6.8e-09 1.06217`
	`clk__L15_I3 1.32e-09:1.68e-09 1.06273 6.38e-09:6.72e-09 1.06854`
	`...`

`-eiv_eval_gnd_window {true | false}`	
	Specifies that the ground net switching window should also be considered for the EIV computation. The switching windows from the pc will be merged into a single switching window.
`-eiv_eval_layers {`*layerlist*`}`	

	Specifies to report the EIV of nodes only on the specified layers. When this parameter is not specified, the software reports the EIV valu across all layers. The parameter allows you to analyze the EIV values for the user-defined layers. **Example**: `set_rail_analysis_mode -eiv_eval_layers B_M0 -eiv_eval_nodes port` This command reports only the EIV values of nodes on the `B_M0` layer.
`-eiv_eval_nodes {tap | port}`	
	Specifies to report EIV based on the instance nodes (tap or port). By default, the software uses the tap nodes for EIV reporting.
`-eiv_eval_window {switching | timing | both | elapse}`	
	Controls the window where EIV is evaluated. EIV is obtained by processing the voltage waveforms and finding the worse-case effectiv power and ground pins during a specific window. There are four possible windows to evaluate EIV: • `switching` – any switching activity (current is non-leakage) reported in power analysis • `timing` – timing window information from TWF or embedded timing engine • `both (Default)` – both switching or timing window • `elapse` – entire rail simulation not filtered to a specific window **Note**: Although power analysis uses timing window information to generate switching activities, it is possible that switching window wil timing window if the instance is scheduled to switch at the very beginning or the very end of the timing window. Current waveform may than the time of switching.
`-eiv_histogram_max` *value*	
	Specifies the maximum voltage value of the user-defined voltage range for EIV histogram generation.
`-eiv_histogram_min` *value*	
	Specifies the minimum voltage value of the user-defined voltage range for EIV histogram generation.
`-eiv_histogram_number_of_bucket` *value*	
	Specifies the number of buckets/ranges to be used for EIV histogram generation. The default number of buckets is 8. The data points a based on the range specified.
`-eiv_max_instances` *value*	
	Specifies the maximum number of instances to be included in the .iv files.
`-eiv_method {worst best avg worstavg bestavg}`	
	Allows different methods of computing EIV during rail analysis. Using this parameter, you can write out the best, worst, or average effec between power and ground nets. The `worstavg` EIV method computes the average instance voltage during each evaluation window defined by the `-eiv_eval_window` pa the worst average instance voltage out of all the windows. Similarly, the `bestavg` EIV method computes the average instance voltage d window defined by the `-eiv_eval_window` parameter, and reports the best average instance voltage out of all the windows. If `-eiv_meth` and `-eiv_eval_window elapse` (i.e. 1 evaluation window) are specified, then this method will report average voltage across all time step *Default*: `worst`
`-eiv_pin_based_report {true | false}`	

	Specifies to report an individual pin's instance voltage for each instance. When enabled, the format of the instance voltage file (.iv file) v instance pin per line with pin name added to the last column. If an instance has multiple pins connected to the same net, it will have mu file.
	The format of the report is:
	<Instance Name> <Instance Voltage> <Cell Name> <Pin Names>
	The following is a snippet of the report from the .iv file:
	`NET`
	`INSTANCESUPPLY 18118 VDD 1.08 POWER`
	`BEGIN`
	`- inst1  1.0798 CKND12 VDD`
	`- inst2  1.0799 INVD6LVT VDD`
	`DOMAIN`
	`INSTANCESUPPLY 18118 VDD 1.08 DIFFERENTIATE`
	`- clk__L13_I3  1.0767 CKND12 VDD VSS`
	`- clk__L13_I4  1.0767 CKND12 VDD VSS`

`-eiv_pin_location {true | false}`	
	Specifies to report an individual pin's location for each instance. This parameter works only with the `-eiv_pin_based_report` parameter format of the instance voltage file (.iv file) will be changed to one instance pin per line with the pin location added to the last column. Th works for `ivdn` (net-based instance voltage drop). It is not supported for `ivdd` (domain-based instance voltage drop). That is, the pin loca only in the net-based iv report file (for example, VDD.iv file) and not in the domain-based iv report file (for example, VDD-VSS_div.iv). The default value of the `-eiv_pin_location` parameter is `false`. The format of the report is: *<Instance_Name> <PWR_IV> <Cell_Name> <Pin_Names> <X Y Coordinates>* The following is a snippet of the report from the .iv file: `- INST1 1.13831 MUX2_F8_75LL VDD met1` **`<6152370, 5708640>`** `- INST1 1.13831 ENOR4_F4_75LL VDD met1` **`<6153420, 5714520>`** `- INST2 1.13831 BUF_F1_1SR_75LL VDD met1` **`<6147330, 5708640>`**
`-eiv_print_time {true | false}`	
	Prints the time stamp for the worst voltage in the switching window of the instance, and for the whole (elapse) window. The time stamp the detailed EIV report. The default value of this parameter is `false`. Using the time stamp information, you can determine the current signature related to the worst EIV for easy debugging. The default unit
`-eiv_report {auto | netonly | all}`	
	Specifies the type of EIV report to be generated. The possible options are: • `auto` - generates net-based .iv report for net analysis, and domain-based .iv report for domain analysis. • `netonly` - generates net-based .iv report. • `all` - generates both net and domain .iv reports, if available.
`-eiv_threshold` *value*	
	Specifies the EIV drop threshold in mV for reporting. Only voltage drop above the threshold will be saved into the report.
`-em_cdf_percentage` *value*	
	Specifies to calculate the Cumulative Distribution Factor (CDF) derating factor based on the EM rules specified in the ICT EM file, given `ict_em_models` parameter. This parameter is used to calculate the fail rate and reliability of a design. The `-em_cdf_percentage` paramet the ICT EM file with the `cdf_percentage` keyword. The value of the CDF percentage should be between 0 and 100. The default value is `1e-9`. The use model of the new parameter is: `set_rail_analysis_mode -em_cdf_percentage 5` When the CDF related rule exits in the ICT EM file, the software uses the default value `1e-09` for `-em_cdf_percentage` if it is not specifie
`-em_ignore_pgv_resistors {true | false}`	
	Specifies to filter out all the EM violations of resistors inside a macro (resistors coming from PGV).

`-em_limit_scale_factor {{avg value} {rms value} {peak value}}`	
	Scales the calculated EM limits by the respective factor for avg, rms or peak current limit specified by `{avg value} {rms value} {peak` compares the current through the net against the scaled EM limit to report violations in power EM.
`-em_models file`	Specifies the name of a file that includes the electromigration (em) models. The `-process_techgen_em_rules` and `-em_models` parameters are mutually exclusive. In the static mode, if `-em_models` is not specified, `process_techgen_em_rules` is not set to `true`, current density (RJ) analysis will be disabled due to lack of EM models.
`-em_peak_analysis {true | false}`	
	Specifies to perform peak EM analysis. When this parameter is specified with `-process_techgen_em_rules true` or `-em_models`, both Rl be reported in the same run.
`-em_report_line_threshold value`	
	Controls the size of the EM (`rj.avg.rpt`) text report by limiting the number of lines written to the report file. This feature is useful in limiti you specify a very low EM threshold. **Example**: The following command reports only the top 18 lines: `set_rail_analysis_mode -em_report_line_threshold 18` The truncated EM report file has the following note: # NOTE: Aborting EM Report printing as total number of lines has exceeded the Line Threshold "em_report_line_threshold = 18"
`-em_rms_delta_t temp`	
	Specifies the delta temperature for the EM RMS current limit analysis. Default is 5C.
`-em_rms_delta_T_layer_list {{<LEF_layer_name> <delta_T_in_C>}+}`	
	Specifies the delta temperature for specific LEF layers during power EM RMS current limit analysis.
`-em_temperature <string>`	Sets a different temperature for EM analysis. As a result, you can use a different but higher t temperature for conservative EM analysis.
`-em_temperature_layer_list {{<LEF_layer_name> <em_temperature_in_C>}+}`	
	Sets a different temperature for specific LEF layers during power EM AVG current limit analysis.
`-em_threshold value`	
	Specifies to set EM analysis threshold value for the resistors being reported. Using this parameter, you can control the reporting thresh By default, rail analysis generates EM report for any resistor having current above `0.9` of its limit. Changing the value to `0` will show eve limit to the failed resistors only.
`-enable_2d_partition_extraction {true | false}`	
	Specifies to enable the upgraded extraction algorithm that allows 2D partitioning. The 2D extraction algorithm uses an updated capacit qrcTechFile that provides better accuracy for capacitance calculation. The resistance accuracy level of the 2D extraction algorithm is th extraction algorithm. It is recommended to use 2D partitioning as it improves the parallelism of the extraction jobs for large designs. The parameter is `false`. When the `-enable_2d_partition_extraction` parameter is set to `true`, you must provide the complete qrcTechFile using the `set_rail_extraction_tech_file` parameter. This parameter does not support the 3DIC, inductance extraction, and full-chip GDS flows.
`-enable_ccs_analysis {true | false}`	
	Specifies to enable constant current source analysis. The default value is `false`.
`-enable_distributed_processing_in_solver {true | false}`	
	Specifies to enable distributed processing for Matrix Solver. When set to `true`, Matrix Solver will be able to use multiple hosts across th power-grid. *Default* : `true` You can specify this parameter when peak memory of the analysis exceeds machine memory in the local multi-threaded mode. In the d memory on the local machine will be reduced as child processes will be executed on network hosts. However, the master thread on the continue to consume majority of peak memory even in the distributed mode.

`-enable_instance_powergate_report {true | false}`

Specifies to generate a report (`powergate.inst.rpt`) that summarizes information about each power gate instance.

The default is `false`.

The format of the report is:

```
<inst_name> <cell_name> <Inst X> <Inst Y> <V_Ref> <Ion(total)> <PI(Ipeak/Iavg)> PV(IR)>
```

Here,

- <`inst_name`> is the power gate instance name
- <`cell_name`> is the name of the power gate cell
- <`Inst X`> is the x coordinate of the power gate instance
- <`Inst Y`> is the y coordinate of the power gate instance
- <`V_Ref`> is the rail voltage
- <`Ion(total)`> is the total current for enabled powergate instance
- <`PI(Ipeak/Iavg)`> is the worst Idsat ratio out of all the Ron values
- <`PV(IR)`> is the voltage across the power switch using the combination for the worst V(AON Pin)-V(SW Pin)

`-enable_manufacturing_effects {true | false}`

Specifies to honor manufacturing effects during static or dynamic analysis.

Default : `false`

The manufacturing effects are enabled by default in the hd accuracy mode. That is, if you specify `set_rail_analysis_mode -accuracy` `enable_manufacturing_effects` parameter is set to `true` by default.

`-enable_multi_die_connectivity_check {true | false}`

Specifies to check if voltage sources with `type=nonvsrc` have resistance path to any voltage source with `type=vsrc` inside each die. Thi you to determine if the non-real voltage source (type=`nonvsrc`) is floating or does not have any resistance path to an ideal voltage sourc ignore floating voltage sources during rail analysis.

The "`vsrc`" and "`nonvsrc`" types are given in the .ploc file specified with the `set_power_pads` command. When the `-enable_multi_die_connectivity_check` parameter is specified, the log file displays the list of disconnected terminals for each net. This used in both the single-die and multiple-die analysis flows.

`-enable_package_battery_current_probing {true | false}`

Specifies to include the battery current waveform data in the `tran_<net>_pad.ptiavg` file. This file includes the voltage of all battery side ground_pin mapped pins.

Default : `false`

`-enable_rc_analysis {true | false}`

Enables the Resistor Current (RC) analysis. This parameter supports designs without EM rules/analysis to generate the RC plot for IR

`-enable_reff_analysis {true | false}`

Specifies to run full-chip effective resistance analysis as part of the static or dynamic IR drop analysis. Effective resistance analysis will domain specified with `analyze_rail`. This parameter allows you to run both resistance and IR drop analyses in a single session.

The use model of this parameter is:

```
set_rail_analysis_mode -enable_reff_analysis  true
analyze_rail -output <dir_name> -type domain <domain_name>
```

Default : `false`

`-enable_rlrp_analysis {true|false}`

Specifies to enable least resistance path analysis for all the instances in the design. The RLRP path can be displayed in the GUI using `set_power_rail_display -enable_rlrp` command.

`-enable_scheduler {true | false}`

	Controls the advanced scheduler that improves data handling and multi-CPU scalability of rail analysis . When set to `true`, the schedul improve performance and memory consumption, especially when running on large number of processors. The default value is `true`.
`-enable_seb {true | false}`	
	Specifies to enable the Statistical ElectroMigration Budgeting (SEB) analysis. *Default* : `false`
`-enable_sensitivity_analysis {true | false}`	
	Only available in the static mode. When set to `true`, the software performs sensitivity analysis on all power-grid segments and highlights those which can be optimized to IRdrop profile of the design. The power-grid segments can be optimized using the `scale_what_if_resistance` command. *Default* : `false`
`-enable_voltage_across_vias {true|false}`	
	Specifies to report voltage across vias.
`-enable_vsrc_in_gif {true|false}`	
	Specifies to enable or disable the display of voltage sources in the generated IR drop plot GIFs. When set to `false`, disables voltage sources (power pads) from the *Layout* tab during IR drop analysis. This parameter allows you to co voltage sources in the generated IR drop plot GIFs so that the plot is easily interpreted. *Default* : `true`
`-enable_xp {true | false}`	
	Specifies to run rail analysis in the Extensively Parallel (XP) mode. When this parameter is set to `true`, the rail analysis engine distributes processing over a large number of machines in every stage of th extraction, reporting, GUI, and simulation) to reduce the processing time. *Default* : `false`
`-enable_xpgv_scaling {true | false}`	
	Specifies to enable xPGV current scaling that is calculated as a ratio of voltages. If PGV voltage is V1 and analysis voltage is V2, then would be V2/V1. This factor is applied to each power net. In case there are multiple power nets and a single ground net, the tool will us factor from the power rails and apply it to the ground net. This parameter is used for scaling of currents stored in xPGV. The parameter allows you to use the same xPGV in different designs, irre at which the xPGV is generated. `-enable_xpgv_scaling` and `-static_trigger_file` are mutually exclusive. *Default* : `false`
`-enlarge_vsrc_in_vuvc {true | false}`	
	Specifies to increase the size of voltage sources represented for the voltage source current (vc) and voltage drop across package (vu) p visibility.
`-env_temperature <`*`temperature in °C`*`>`	
	Specifies the ambient temperature used to calculate S_{DC} for SEB analysis. *Default* : `25`
`-era_check_wires_for_generated_current_regions {true | false}`	
	Specifies to generate unplaced current regions only in areas where actual net wires are present. The default value is `false`. The curren generated from the power domain information present in the design.
`-era_current_distribution_factor_for_placed` *`value`*	

	When you use `-era_current_distribution` and set to distribute current for placed blocks/macros, the ratio of power allocated to each p calculated based on its total area. Using this parameter, you can control the current distribution factors for the placed blocks/macros, he for area-based power calculation. For example, if you specify `0.5`, the tool will assume all placed blocks/macros to be 50% of its actual current accordingly. *Default* : `1`
`-era_current_region_file` *filename*	

	Specifies a file that includes a list of regions and the amount of current to be distributed within them for the power-grid. Default units in f specify rectilinear current regions in the file.
	#Format:
	`LABEL` *name* `NET` *netName* `AREA` *x1 y1 x2 y2* `LAYER` *layername* `<CURRENT` *value* `| PWL (`*t1 i1 t2 i2 …*`)> INTRINSIC_CAP <`*value*`> LO` `[ADD_OVERLAP | SUBTRACT_OVERLAP]`
	#Unit:
	current mA, cap pf, time ns, coordinate um
	• `ADD_OVERLAP`: Honors all overlapping regions, and adds current in the overlapped regions.
	• `SUBTRACT_OVERLAP`: Specifies that if two XY regions overlap, the first specified region will be honored, and the subsequent region wil overlapped area to apply the region current to the remainder area.
	Static Example :
	`label test1 net VDD area 100 200 400 500 layer M1 current 10`
	Dynamic Example :
	`label test1 net VDD area 100 200 400 500 layer M1 pwl (0ns 0mA 1ns 0mA 1.9ns 0mA 2ns 10mA) intrinsic_cap 10 loading_ca`

`-era_current_distribution_layer` *layer_name*	
	Specifies the layer name for distributing unplaced current in the early rail analysis mode.
`-era_current_distribution { unplaced | placed | all | none }`	
	This parameter controls the behavior of era current distribution. `set_power_data` area based power, or `current_region_file` need to be current distribution to work. Placed instanced without uti or ascii based power can also be considered for era current distribution. • Unplaced: Enable current distribution only for unplaced instances. If `set_power_data` area based power is specified, `-era_current_` will be required. • Placed: Enable current distribution for placed instances without any power specified. • All: Both unplaced and placed instances without power specified; will have ERA current. • None: Disable ERA current distribution.
`-era_current_distribution_nets {`*net1 net2* `...}`	
	Specifies to distribute current for unplaced instances by total die area on specified nets only. The default behavior is to distribute curren parameter will be required when `-era_current_distribution_unplaced_area diearea` is used. For single net analysis, you can either specify a single net (for example, `-era_current_distribution_nets {VDD_AO}`) or perform the ar parameter.
`-era_current_distribution_unplaced_area {instance | diearea}`	
	Specifies to distribute current for unplaced instances by total die area or actual instance area. The default value is `instance`. When `diearea` is specified, the entire unplaced die area is considered for computation of current distribution. The die area considered e current regions, placed instances, and placement blockages.
`-era_insert_virtual_followpins { standard | extended | none }`	
	Specifies to generate virtual followpins. The `extended` followpins will create followpins that extend from one stripe to another. The `stan` extend to previous stripe but does not reach the next stripe. *Default*: `none`
`-era_insert_virtual_followpin_for_io {true | false}`	

	By default, ERA virtual follow pin insertion only works in the core area. When this parameter is set to `true`, ERA follow pin routing is ext as well.
`-era_insert_virtual_via_on_layers` *value*	
	Enables you to control on which layers virtual via can be inserted in early rail analysis. Using this parameter, virtual via can only be ins pair of layer names provided in the design. Alternatively, you can provide wildcard, '*', as the second layer name and virtual via will be from the first layer to any layers in the design. For example, `-era_insert_virtual_via_on_layers { {M1 *} }` will allow virtual via to be inserted from M1 to any layers in the design. This parameter does not have a default value but ERA will insert virtual via for all layers if -era_skip_virtual_via parameters are not pro
`-era_instance_dynamic_current_file` *filename*	

	Specifies an instance/cell based PWL file in the dynamic ERA flow (`set_rail_analysis_mode -era_dynamic`). This feature allows you ERA without having to specify the dynamic .ptiavg/.ptiavk current files (`set_power_data`).
	The specified PWL should cover the entire simulation period. If the simulation period is longer than the specified PWL, the software wil the remaining period (`set_dynamic_rail_simulation -stop <time>`). You can also use the `set_dynamic_rail_simulation -auto_repea` the dynamic current waveform till the `-stop` time specified, instead of assuming 0 current for the remaining period.
	The format of the file is:
	`INSTANCE | CELL <NAME> PWL { <time> <current> } <PG_PIN> [ADD_OVERLAP | SUBTRACT_OVERLAP]`
	• Default time unit = `ns`.
	• Default current unit = `mA`
	• `<PG_PIN>` is optional. If it is not specified, the software mirrors the current on VSS pins.
	• `ADD_OVERLAP` keyword indicates to honor all overlapping instance currents, that is, instance to instance overlap and instance to regio
	• `SUBTRACT_OVERLAP` keyword indicates to honor instance current, and subtract its area from the overlapped X-Y region to apply the X- remainder area. `SUBTRACT_OVERLAP` is default. This keyword is not applicable for instance to instance overlap.
	The following is a snippet of the specified file:
	`INSTANCE top/instA PWL { 0ns 0mA 0.1ns 1mA 0.2ns 0.5mA } VDD`
	`INSTANCE top/instA PWL { 0ns 0mA 0.1ns -1mA 0.2ns -0.5mA } VSS`
	`CELL macro_A { 0 0 0.1ns 1 0.2 0.5 }`
	`...`
	If you have specified both the `-era_instance_dynamic_current_file` and `-era_current_region_file` parameters, and there are overla the specified current region, the `SUBTRACT_OVERLAP` behavior is implemented by default.

`-era_lef_layermap` *filename*	

	If a technology library or an extraction techfile is not provided, ERA can automatically create a technology library and the layermap nee library. If the automatic layer map generation fails, you can use this parameter to manually specify a layer map file.
	The format of the layer map file is:
	File Format:
	`Layer Type tech_layername lefdef lefdef_layername`
	`metal METAL_1 lefdef M1`
	`via VIA_1 lefdef VIA1`
	`metal METAL_2 lefdef M2`
	`via VIA_2 lefdef VIA2`
	`metal METAL_3 lefdef M3`

`-era_power_gate_file` *filename*	

	If a power gate PGV is not provided, this parameter specifies the name of the power gate (power switch) file that will be used to perform state analysis.
	File format:
	`CELL <CELLNAME> SUPPLY <SUPPLY_PIN> SWITCHED <SWITCHNET_PIN> RON <VALUE> IDSAT <VALUE> ILEAK <VALUE>`
	`CELL HDRSID0 SUPPLY TVDD SWITCHED VDD RON 500 IDSAT 1 ILEAK 0.001`

`-era_skip_virtual_via_by_type {whatif | def | all | none}`	

	Specifies to skip a given via type. By default, ERA generates all virtual via layer types. • `whatif` vias are virtual vias that have connectivity to user-defined what if shapes. • `def` vias are virtual vias between two metal shapes defined in DEF. • `all` will skip all virtual via generation. • `none` will insert both what-if and DEF vias. It will insert vias on all layers, unless the layers are controlled by other parameters. *Default*: `all`
`-era_skip_virtual_via_on_layers {{ layer1 layer2 } { layer3 layer4 } ... }`	
	Skips via insertion between stripes and non-stripes, on the specified LEF layer pairs.
	{ layer1 layer2 } { layer3 layer4 } ...: Specifies the LEF layer names.
`-era_techlib_generation {true | false}`	
	Specifies to skip technology PGV generation in the early rail analysis mode. This parameter skips technology PGV generation even if t `extraction_tech_file` parameter is specified. The default value is `true`.
`-extractor_include filename`	
	Specifies extractor (ZX) commands and variables in the form of an include file.
`-extract_subconductor_layers {true | false}`	
	Specifies to perform extraction of the sub-conductor layers. The default is `false`.
`-extraction_tech_file filename`	
	Specifies the extraction technology file to be used for top-level power-grid extraction. If you do not specify this parameter, the software v technology file stored inside the power-grid view library.
`-feol_scale_factor non_negative_integer_number`	
	Specifies to scale the front-end-of-line (FEOL) self-heat value for all instances in the self-heating analysis flow. The delta T FEOL will b the static power, thermal resistance, and FEOL scale factor.
`-filler_cell_list { cell1 cell2 ... celln }`	
	Specifies a list of filler cells. This option is used when the filler cells are not tagged in the power-grid library.
`-finegrain_powergate_ron {min avg max}`	
	Specifies whether the minimum, maximum, or average Ron will be used for a powergate cell in finegrain memory characterization with The default value is `max`.
`-finegrain_powergate_ron_list filename`	

	Specifies the name of a file containing the powergate cell names and their corresponding Ron values (minimum, maximum, or average finegrain memory characterization with multiple Ron values. The format of the file is:
	`CELL cell1 min/max/avg`
	`CELL cell2 min/max/avg`
	`INST inst1 min/max/avg`
	Note: The `-finegrain_powergate_ron` and `-finegrain_powergate_ron_list` parameters allow you to specify multiple Ron values in a Ron value can change with respect to different modes of simulation.

`-fine_pre_simulation_period value`	
	Specifies the fine-grain pre-simulation period that rail analysis will use. The supported time units are s, ms, us, ns, and ps. If no explicit the default ns (nanosecond) will be applied. The time step in the fine-grain pre-simulation period will be the same as the simulation per Pre-simulation allows you to determine the current profile and analyze IRdrop of the circuit when power supply is in steady state. **Note**: When both the coarse-grain (`-pre_simulation_period`) and fine-grain pre-simulation periods are specified, the fine-grain pre-sim after the coarse-grain pre-simulation period. The simulation phase starts after the fine-grain pre-simulation period. Both fine-grain pre-si grain pre-simulation can be specified just by themselves without requiring the other one to be specified. In the case where fine-grain pr specified, the simulation will start right after the coarse-grain period.
`-flatten_xpgv_block_instances filename`	

	Specifies a file that includes a list of block instances that use DEF instead of xPGV for rail analysis, that is, specify the instances that ar xPGV. This parameter allows you to specify a few instances of the same block that will use DEF, and the others that will use xPGV at th not specify this parameter, and if both DEF and xPGV are given for a block, xPGV takes precedence over DEF.
	Instance List File Format:
	`<block_name> <block_instance_name|All|None>`
	In this file, you can specify if a block is using a DEF by specifying the block instance name, or with the `All` or `None` keywords. `All` indica are using DEF, and `None` indicates that none of the instances are using DEF.
	Example:
	`CORE /top/x1/x12/instA`
	For a design with three blocks, if you want to use the DEF and xPGV as following:
	Block_1 - > A1 (xPGV) & A2 (DEF)
	Block_2 - > B1 & B2 (xPGV for both instances)
	Block_3 - > C1 & C2 (DEF for both instances)
	The specified file will contain the following information:
	`Block_1 A2`
	`Block_2 None`
	`Block_3 All`

`-force_extraction {true | false}`	
	Specifies whether the existing work directory extracted data should be used, or the design needs to be re-extracted during rail analysis *Default* : `false`
`-force_library_merging {true | false}`	
	Specifies to force merge PGVs with different resistivity and layers during rail analysis, wherein the first library definition will be used. *Default* : `false`
`-gds_file` *file*	Specifies a GDS file. Partial (RDL GDS in flip-chip) or full-chip GDS can be specified. You can view extracted parasitic network for GDS GDS layout it needs to be imported as an OA database.

`-gds_map` *file*	Specifies the GDS layermap for the GDS file specified using `-gds_file` parameter. The GDS layermap file format is as follows:
	`#layer gds layer_name gds_layer_number`
	`<gds_data_type><[port|text]>`
	`layer gds via8 85`
	`layer gds metal9 74`
	`layer gds metal9 126 1 text`

`-gds_offset` { *x y* }	
	Specifies the offset value used to adjust and shift the GDS of a Redistribution Layer (RDL) cell in the mixed DEF+GDS flow. This parameter is available only when the `-gds_file` parameter is specified.
`-gds_purpose {metalFill | flipChip | fullChip}`	
	Specifies the data type of the GDS provided. • `metalFill`: The GDS data will be used as fill metals for manufacturing effects calculation but the physical shapes will not be extracte • `flipChip`: The GDS data contains only the RDL layers, and the extracted physical shapes will be merged with the DEF netlist. • `fullChip`: The GDS data contains physical shapes for the entire design.
`-gds_top_cell` *cell_name*	
	Specifies the name of the GDS top cell.
`-generate_hier_bbv {true | false}`	

Specifies to control the generation of block boundary voltage (BBV) for all hierarchical block instances that use xPGVs. The xPGVs for generated using the xPGV flow (Refer to "Hierarchical Power Integrity Analysis with Extreme Modeling" in the *Voltus User Guide*). The parameter is `false`. The BBV file contains realistic static or dynamic voltages for all nodes in the xPGVs starting where the top-level po the xPGVs. Since the BBV file is generated in context of full-chip analysis, running block-level analysis using this file gives insight to IF lower layers not included in the xPGV. This top-down flow can be used to identify and fix IR drop problems at the partition level without expensive fullchip analysis.

`generate_hier_bbv` is a global parameter so all instances of xPGV will be generated. The output is written to the state directory for each analyzed as '`instance_name.pp`'. The file contains '`putvsrc`' commands. You can output on a per-instance basis using the '`write block` command in an include file, as shown below:

```
set_advanced_rail_options -voltus_rail_include_file_begin voltus_begin.inc
```

voltus_begin.inc:

```
write block_boundary_voltage instance_name output_file_name
```

For dynamic analysis, add `-watch`:

```
write block_boundary_voltage instance_name output_file_name -watch
```

The dynamic flow is recommended since transient information is not saved by default.

To use the output BBV file at the block level, return to the block-level execution script and change `set_power_pads -format` to `boundary` file:

```
set_power_pads -net net_name -format boundary -file bbv_file
```

Example of a BBV file for dynamic analysis:

```
* Boundary conditions for instance sample_instance
# putvsrc vsrc_# IR/Bounce x y PWLFILE pwl_file_for_node_location
putvsrc K4 Vbc_VSS_1 1.210359e-01 247.296 179.712 PWLFILE sample_instance.pp.ptiavg 1
putvsrc K3 Vbc_VSS_2 1.210360e-01 247.296 179.712 PWLFILE sample_instance.pp.ptiavg 2
putvsrc K4 Vbc_VSS_3 1.210097e-01 247.296 175.104 PWLFILE sample_instance.pp.ptiavg 3
…
```

`-generate_instance_effr_report file`

Generates a layer-based instance effective resistance report for specified cells/instances. The specified file contains the list of cells or i Reff report is to be generated. The format of the input file is:

```
CELL cell1
CELL cell2
INST inst1
```

The output file will be stored under each net's report folder `<net>.instance_effr.rpt`. For example, `Reports/VDD/VDD.instance_effr.r`

For each cell or instance specified in the input file, the report has information such as layer-based effective resistance ranges, worst no statistics, and interface node resistances. This feature is applicable for both net-based and domain-based analysis.

`-generate_instance_ir_report file`

Specifies to generate a layer-based IR drop report for a set of cells/instances. The *`file`* contains the list of cells or instances for which t be generated. The format of the file:

```
CELL cell1
CELL cell2
INST inst1
```

The output file will be stored under each net's report folder `<net>.instance_ir.rpt`. This feature is applicable for both net-based and d

`-generate_instance_pin_ir_report file`

	Specifies to generate a detailed report containing boundary node IR information for a set of cells/instances.
	The file contains the list of cells or instances for which the IR drop report is to be generated. The format of the file is:
	`INST <instance_name>`
	`CELL <cell_name>`
	The instance pin IR report will list all the pins' node information (layer, location) and the worst IR drop value.
	The output file will be stored under each net's report folder `NET/<net>.instance_pin_ir.rpt`. The following is a snippet of the IR drop re
	`instance: <NAME>`
	`cell: <CELL>`
	`pin name: <PIN>`
	`# pin nodes: <total count>`
	`Min/Avg/Max: <min/avg/max interface node IR>`
	`For each of the interface node:`
	`IR X Y Layer`
	`......`
	The interface node output is sorted in the descending order of IR drop (that is, worst IR drop first).

`-generate_combined_ivd_gif {true | false}`	
	Specifies to generate a combined instance voltage drop GIF file for all the nets specified in the domain. This GIF allows you to see the instance voltage plot. The GIF file displays color scaling based on voltage drop as percent of different domain thresholds (print threshol domains), as shown below:  The file location of this GIF file is `<rail_dir>/Reports/ALL_violations_ivd.gif`.
`-generate_multi_voltage_library {true | false}`	
	When this parameter is specified, all the PGVs for each cell will be considered, and voltage-dependent capacitance information will be analysis, similar to the multi-voltage PGVs. The `-generate_multi_voltage_library` parameter is used in a scenario when you have generated multiple PGVs for different voltages a single multi-voltage PGV that has voltage-dependent capacitance. The default value of the parameter is `false`.
`-generate_package_pin_current_voltage {true | false}`	

	Specifies to generate a file containing transient current and voltage information of the package pins for the package analysis flow. This dynamic rail analysis. The default value is `false`. This parameter is used in both the Sigrity Package Analysis (SPA) and non-SPA package analysis flows: • SPA flow - used in Sigrity tools to do chip-aware package analysis. This parameter is enabled by default (set to `true`) in the SPA flo • Non-SPA flow - allows you to check the current on package pins. The format of the generated report in the static analysis mode (3 column format) is: *pin_name1 current1 voltage1* *pin_name2 current2 voltage2* ... The format of the generated report in the dynamic analysis mode is: .SUBCKT *Subcircuit_Name <list of pins for power and ground nets>* *MCP header with package pin name IA1 A1 0 PWL t1 i1 t2 i2 t3 i3 t4 i4 t5 i5 +t6 i6 … .ENDS *Subcircuit_Name* Here, • `IA1` (first item) is the current source element name • `A1` (second item) and `0` (third item) are the power and ground nodes • `PWL` keyword is followed by the time and current values
`-gif_iv_threshold` *value*	
	Specifies the instance voltage threshold for the combined instance voltage drop GIF for all the nets specified in the domain. The thresh voltage drop value. Any instance voltage drop value greater than the threshold will be put into the red bucket range in GIF, and the rest linearly distributed down to the minimum instance voltage drop.
`-gif_new_color_scale {true | false}`	
	Specifies to change the color scheme of the GIF file generated in the state directory during the static and dynamic rail analysis flow to n scale.
`-gif_resolution {low | medium | high}`	
	Controls the resolution of the generated GIFs after rail analysis. This option can have the following values: `low`, `medium`, and `high`. The d
`-gif_zoom_area { x1 y1 x2 y2 }`	
	Specifies to set the GIF generation bounding box to the given area (in microns).
`-gif_zoom_topcell_diearea {true | false}`	
	Specifies to set the GIF generation bounding box to the topcell DIEAREA listed in the DEF file, instead of the total design size includin used, this parameter has no effect. This parameter will change the bounding box of all the GIFs generated in rail analysis. **Note:** The `-gif_zoom_area` and `-gif_zoom_topcell_diearea` parameters are mutually exclusive. If both the parameters are specified, th parameter takes precedence.
`-hier_delimiter` *character*	
	Specifies the hierarchical delimiter in the DEF file. The default hierarchical delimiter is a forward slash (/) but can be changed by settin parameter. You can use this parameter to override the existing hierarchical delimiter.
`-honor_negative_static_current {true | false}`	
	Specifies to honor negative current value in the current file (`.ptiavg`) during static rail analysis. The default is `false`.
`-hpgv_block_lefs` *list_of_files*	
	Specifies the block LEF file for all hierarchical DEF blocks in the design. This will trigger automatic hierarchical PGV generation for the software will error out if any of the LEF files are missing for a DEF hierarchy.
`-hpgv_generate_view {ir | em | all}`	

	Specifies the view type to generate for the hierarchical PGV. The allowed values are "ir", "em" and "all". "all" means both ir and em vie you choose to only generate ir or em view, disk consumption can be reduced since only one view will be generated. *Default*: all
-ict_em_models *file*	
	Specifies the ICT-EM file which only contains the EM rules and excludes the RC extraction data in ICT. The software will use the EM ru ICT-EM file to calculate EM limits for power net EM analysis even if there are embedded EM rules in the Quantus tech file.
-import_what_if_shapes {true | false}	
	Specifies to import the what-if shapes created by the add_what_if_shapes command for rail analysis. **Note**: If both the -import_what_if_shapes and -what_if_shapes_file parameters are specified, union of two sets of what-if shapes is c
-ignore_decaps {true | false}	
	Ignores decap cells during rail analysis. It ignores cells that are tagged as DECAP cells during library characterization or set as decap c set_rail_analysis_mode -decap_cell_list command parameter. If decaps are used to preserve connectivity on the follow-pin routing parameter to false. Ignoring decaps during dynamic analysis is not recommended. *Default*: true for static, false for dynamic
-ignore_duplicate_vsrc {true | false}	
	Specifies to check for multiple voltage sources with the same name in the power pad (.ploc) file. When set to true, the duplicate voltag When this parameter is set to false and duplicate voltage sources are present in the .ploc file, an error will be generated. If there are duplicate voltage sources, rail analysis will report an error message like the following: `** ERROR: (VOLTUS_RAIL-3647): Failed to run rail analysis due to redefined voltage source name in power pin location f /vsrc_same_name/PADs/VDD_AO.pp.` *Default*: true
-ignore_fillers {true | false}	
	Ignores filler cells during rail analysis if the list of filler cells are defined in PGV generation, or specified as fillers using the set_rail_an filler_cell_list command parameter. During rail analysis, ignore library cells that are tagged as FILLER cells and have no capacita the interface nodes. If fillers are used to preserve connectivity on the follow-pin routing, you must set this parameter to false. *Default*: true
-ignore_from_reporting *filename*	

	Specifies the name of a file containing a list of cells and instances that are not to be included in the EIV report.
	A sample file is given below:
	`INST AO2/MULT16_reg_2_6`
	`CELL BUFX*`

-ignore_incomplete_net {true | false}	
	Specifies to skip power and ground nets that are not defined in the design, or have been defined but with no instance connection.
-ignore_nets_without_vsrc {true | false}	
	Specifies if Rail Analysis should continue or exit with an error message if there are nets with no voltage sources. The possible argumer • true: prints an error message only but will allow the Rail Analysis run to continue. • false: exits immediately and returns to the Tcl prompt. If all the VDD/VSS nets have no voltage sources attached, the Rail Analysis run will error out and exit even if -ignore_nets_without_v *Default*: false
-ignore_shorts {true | false}	
	This parameter allows you to ignore shorts that are found during rail extraction and continue rail analysis. However, -ignore_shorts ca design contains GDS.

`-ircx_models {RC.ircx EMIR.ircx}|{RC.ircx}`	
	Specifies an encrypted or unencrypted RC/EM technology (.ircx) file. The foundry-specific IRCX file, which contains the process inform EM modeling, can be used when the ICT-EM file is not available for electromigration analysis. You can either specify two IRCX files, one file containing the RC process data (`RC.ircx`) and the other file containing EM rules (`EM.ircx` that includes both the RC and EM sections (`RC.ircx`). A single IRCX file is used for the mature nodes, and separate RC and EM IRCX f advanced process nodes.
`-lef_map` *`lefMappingFile`*	
	Specifies the LEF layermap file, which contains the mapping of the LEF layer and the technology layer. The LEF layermap file format is as follows: `layer map lef_layer_name tech_layer_name`
`-lifetime` *`value`*	
	Specifies the lifetime value in hours. *Default* : 87,600 hours (= 10 years)
`-limit_number_of_steps {true | false}`	
	Specifies to limit the number of steps (simulation period, and resolution or step size) during dynamic IRdrop analysis or power-up analy The default value of this parameter is `true`. If the number of steps during dynamic IRdrop analysis or power-up analysis exceeds `1000`, the tool gives an error message and exits ar ensures that you are aware that there could be a problem in how the analysis is set up. If the performance risks are understood, you car `false` and re-run the analysis. The step-size and simulation period for the analysis is derived from current files generated by power analysis. You can explicitly set the simulation period during power analysis using the `set_dynamic_power_simulation` command. During power-up analysis, the simulation is derived based on the turn-on time of the last power-switch in the power-up domain. If this time is too large, you may want to check if t power-gates are correctly captured in the timing window file. Optionally, you can reduce the number of steps by explicitly specifying the analysis using the `set_dynamic_rail_simulation` command.
`-lowest_layer_for_em_check` *`layer_name`*	
	Specifies the layers that should not be displayed in the EM plots (such as, rj, jrms, and javg) and reports. *`<layer_name>`* is the layer below which the EM plots and reports will not be generated. The default value is `false`.
`-mcp_model_mapping {{`*`<mcp model name1> <die DEF name1>`*`} {`*`<mcp model name2> <die DEF name2>`*`} ...}`	
	Specifies to set the mapping between the package model and die name.
`-method {static | dynamic | era_static | era_dynamic}`	
	Specifies whether static or dynamic rail analysis, or static or dynamic early rail analysis will be performed. *Default* : `static`
`-off_rails` *`net_name_list`*	
	Specifies a list of nets to exclude from analysis. Used in designs with power switches.
`-override_set_power_data {true | false}`	
	Default: `false` Specifies to override the previous settings of the `set_power_data` command and use the last specified setting of `set_power_data` when t design object using the same current file. This feature is convenient when many `set_power_data` commands have been set and you wa them with a new scaling factor or other options. **Example**: In the following example, the first command will be discarded and the second command will be honored: • `set_power_data -format current -instance XYZ dynamic_VDD.ptiavg` • `set_power_data -format current -instance XYZ dynamic_VDD.ptiavg -scale 2.0`
`-package_trace_connectivity {true | false}`	

	When `-package_trace_connectivity` is set to `true`, connectivity tracing is enabled from the die pins to the board pins of all the element file. When this parameter is set to `false`, connectivity tracing is disabled. *Default* : `false`
`-peak_em_analysis {true | false}`	
	Specifies to calculate the peak EM in the dynamic rail analysis run. This parameter generates the `<net_name>.rj.peak.rpt` report. *Default* : `false`
`-power_grid_library` *dir_list*	
	Specifies the name of the power-grid view library directories.
`-powerup_fast_mode {true | false}`	
	Specifies to enable fast mode simulation for native power-up analysis. When the fast mode is enabled, the software uses lumped paras instances connected to the powering up net. The fast mode native power-up analysis allows you to quickly estimate turn-on time and rush current injected in the global power-grid a is powering up. The fast-mode power-up analysis gives faster turn-around time and similar accuracy as accurate power-up analysis. *Default* : `true`
`-powerup_sequence_file` *filename*	

	Specifies the name of the file containing the firing time for each power gate instance. The power-up sequence file format is as follows:
	`<power gate instance name> <pin name> <always- on net> <switched net> <rise_time> <rise_slew> <fall_time> <fall_slew> <`
	`<control pin voltage>` is optional.
	A sample power-up sequence file is given below:
	`inst_name E VCC_NORMAL VCC_SWITCHED 5.50E-09 2.90E-10 5.50E-09 2.90E-10 0.84`
	`inst_name E VCC_NORMAL VCC_SWITCHED 5.93E-09 7.23E-10 5.93E-09 7.23E-10 0.84`

`-powering_up_rails` *net_name1* ... *netname_n*	
	Specifies a list of powering up nets.
`-powering_down_rails` *net_name1... netname_n*	
	Specifies a list of powering down nets.
`-pre_simulation_period` *value*	
	Specifies the pre-simulation period that rail analysis will use. The supported time units are s, ms, us, ns, and ps. If no explicit time unit is ns (nanosecond) will be applied. The pre-simulation period include the coarse-grain and fine-grain pre-simulation periods. If `-fine_pre_simulation_period` is not speci pre-simulation period will do coarse pre-simulation.
`-pre_simulation_resolution` *value*	
	Specifies the transient time step size or resolution. The supported time units are s, ms, us, ns, and ps. If no explicit time unit is specified (picosecond) will be applied.
`-prechain_powerup_sequence_file` *filename*	

	Specifies a power-up sequence file that contains the pre-chain start/end and mother (data) chain start/end timing information. In the pov specify this pre-chain sequence file instead of a complete power-up sequence file to modify the ramp-up timing of different power switcl constraint in the specified file. The timing information for the other power-gate instances is calculated using the pre-chain sequence file The format of the file is:
	`Prechain_start <pggate_instance_name> <pin_name> <d_time> <d_delay> <d_slew>`
	`Prechain_end <pggate_instance_name>`
	`Datachain_start <pgagate_instance_name> <pin_name><m_time> <m_delay> <m_slew>`
	`Datachain_end pggate_instance_name`

`-print_gif_range_percentage {true | false}`	

Specifies to display the plot title and voltage drop percentage (`Drop%`) for the following GIF files:

- **IR** (File Location: `<rail_dir>/Reports/<power_net>/`)

  `ir_linear.gif`

  `ir_limit.gif`

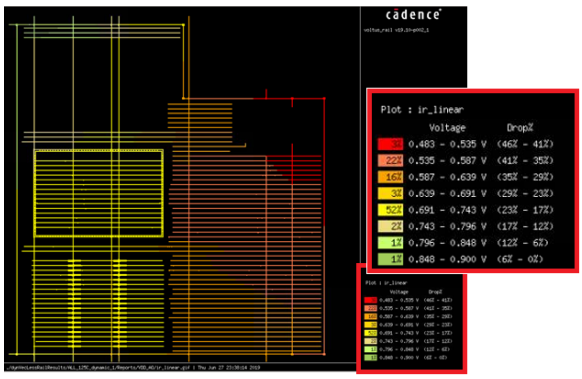
- **EIV** (File Location: `<rail_dir>/Reports/`)

  `<pg_pair>.<eiv_method>_eiv.gif`

  `<pg_pair>.<eiv_method>_limit_eiv.gif`

`IR Drop%` is calculated by 1-(voltage/ideal_voltage), and `EIV Drop%` is calculated by 1-(effective_voltage/ideal_effective_voltage)

The following image shows the voltage drop percentage for the `ir_linear` plot:



Default : `false`

`-probe_instance_pin_waveforms {true | false}`

Specifies to probe current and voltage waveforms for all the pins belonging to probing instances. When `-probe_instance_pin_waveforr` writes all the voltages and currents of the pins of probing instances to the waveform files.

The use model of this parameter is:

```
set_rail_analysis_mode -method dynamic -probe_instance_pin_waveforms true
```

The watched instance has the pin names in the waveform file, as shown below:

Voltage waveform name: `<instance_name>:ir`
Current waveform name: `TC_<instance_name>:ir`

Default : `false`

`-probe_instance_tap_waveforms {true | false}`

Specifies to probe current and voltage waveforms for all tap nodes belonging to probing instances. When `-probe_instance_tap_wavefo` writes all the tap node voltages and currents of the instances from `-probe_waveform_list` to the waveform files. The default value of the `false`.

The use model of this parameter is:

```
set_rail_analysis_mode -method dynamic -probe_instance_tap_waveforms true -probe_waveform_list instance_list_file
```

The instance's tap nodes are named based on instance name, and its node ID and location in the waveform file, as shown below:

Voltage waveform name: `<instance_name>:N_...:X_..:Y_:ir`
Current waveform name: `TC_<instance_name>:N_...:X_..:Y_...`

`-probe_package_interface_ports {true | false}`

Specifies to probe voltages for all the ports of the top-level subcircuit and the interfaces within the package. When this parameter is spe engine retrieves the package interface ports from the package model and writes them into a probing node file to watch their voltage wa

Default : `false`

`-probe_pin_voltage_list filename`

	Writes the voltage of the interface nodes for the specified instance/cell to a block boundary voltage file. The software generates a block with file name based on the block instance name, `<instance_name>.pp` for every instance/cell in the list.
`-probe_waveform_list` *filename*	

	Specifies the name of a file containing the instance and cell name(s) for which you want to capture voltage and current waveforms. This to control whether to probe voltage or current waveforms or both.
	You can specify the optional parameter `PROBE <VOLTAGE|CURRENT|ALL>` in the file. Default is `ALL`. When `VOLTAGE` or `CURRENT` is specified, current waveforms will be probed.
	The format of the file is:
	`CELL/INST <name>`
	Following is an example of the file:
	`INST I1_1`
	`INST I2_1`

`-probing_node_file` *file_name*	

	Specifies the probe node file containing the probe point on a die. The file format for specifying probing nodes is as follows:
	`<user defined unique probe name> <location = x> <location = y> <layer> <Power/ground net name>`
	You can also specify the package node voltages and resistor currents that are to be probed in the following format:
	`<probe name> pkg ir <pkg circuit node name>`
	`<probe name> pkg rc <pkg circuit resistor name>`
	Example
	`probe_1 18 16 METAL_1 VDD`
	`# pkg node voltage`
	`probe_pkg_1 pkg ir GND.in0`
	`probe_pkg_6 pkg ir VDD.in2`
	`# pkg resistor current`
	`probe_pkg_cur_1 pkg rc R_1_1`
	`probe_pkg_cur_2 pkg rc R_5_2`
	Note: The units of x and y should be in microns.

`-process_techgen_em_rules {true | false}`	
	Processes the EM rules defined in the extraction technology file. When `-process_techgen_em_rules` is specified with `-extraction_tec` technology file will be processed. If `-process_techgen_em_rules` is specified without `-extraction_tech_file`, the .cl model will be proc *Default* : `false` The `-process_techgen_em_rules` and `-em_models` parameters are mutually exclusive. In the static mode, if `-em_models` is not specified, `process_techgen_em_rules` is not set to `true`, current density (RJ) analysis will be disabled due to lack of EM models.
`-process_bulk_pins_for_body_bias {true | false}`	
	When set to `true`, rail analysis will process current sinks on the cell's bulk pin connections. This parameter is used during body bias an bias net is connected to bulk pins of the cell. The bulk pins for a cell is defined in the cell library using the `set_pg_library_mode -bulk_power_pins -bulk_ground_pins` command p If bulk pins are defined using `set_pg_library_mode -power_pins -ground_pins`, then the `-process_bulk_pins_for_body_bias` paramet *Default* : `false`
`-promote_pin_shapes_only {filler | decap | both}`	
	Specifies to promote either only filler shapes, only decap shapes, or both types of pin shapes during rail analysis. When this parameter interface nodes for the filler and decap cells are ignored. The `-promote_pin_shapes_only` parameter helps to reduce the resistor and no designs without affecting connectivity. This parameter must be specified with `set_rail_analysis_mode -enable_2d_partition_extraction true` (enabled by default for the X
`-rdl_def` *def_file*	

	Specifies to instantiate the RDL instance/DEF at the top level and merge it with the DEF of the top level block being analyzed.
	The following is the usage model:
	`set_rail_analysis_mode -rdl_def <def_file> -rdl_placement { X Y }`
	For GUI display, the same parameters also work for `read_def`:
	`read_def -rdl_def <def_file> -rdl_placement { X Y }`

`-rdl_def_list {{rdl_filename1 x1 y1 orient1} {rdl_filename2 x2 y2 orient2} ...}`	
	Specifies to import the list of the RDL DEF files for the top-level rail analysis. This parameter allows to import multiple RDL DEFs with t rotation information in the top level. Example: `-rdl_def_list { {RDL1.def 0 0 N} {RDL2.def 100 200 N}}`
`-rdl_placement {X Y}`	
	Specifies to place the RDL at a given X,Y location (in micron).
`-rdl_orientation { N|S|W|E|FN|FS|FE|FW }`	
	Specifies the orientation of the RDL DEF file.
`-read_thermal_map thermal_map_file`	
	Specifies to process the thermal map file to calculate resistance based on uniform temperature. Resistor scaling is supported for the tile-based power map file. Using the tile-base thermal map from Sigrity PowerDC, the software will value based on the temperature of the resistor's physical location, which provides more accurate IR and EM results with thermal impac *Default* : `None` For more information on the thermal map file format, refer to the Thermal Map File section in the "File Formats" chapter of the *Voltus Us*
`-record_inst_peak_current {true | false}`	
	Specifies to save the instance peak current during rail analysis in the rail state directory. This parameter allows you to check and debug abnormal instance peak current, which may result in high IR drop. The default value of this parameter is `false`.
`-record_results_start_time time`	
	Records rail analysis results based on the specified start time. The default unit of this parameter is `ns`. The software will use the specified time for all types of analysis, for example, instance voltage calculation, dynamic waveforms, and po
`-reff_detail_report {true|false}`	
	Specifies to include the following additional columns for instance pins in the effective resistance (`effr.rpt`) report: • `X` and `Y`: location (x/y coordinates) • `LAYER`: layer name • `PIN_NODES(FLOAT/TOTAL)`: number of floating nodes per total number of nodes of the instance By default, these columns are not included in `effr.rpt`.
`-reff_domain_report_format {1 | 2 | 3 | 4}`	

Controls the format of the effective resistance analysis domain report (`domain_effr.rpt`). This parameter allows you to specify the level displayed in the domain-based analysis report.

The following table gives the report format for the four format values:

Format Value	Format
1 (1 is the default format)	# PASS/FAIL REFF INSTANCE PIN(Pin REFF Percentage) **Example**: FAIL 10.0 instanceName VDD1(50.00%) VDD2(30%) VSS1(10.00%) VSS2(10%)
2	# PASS/FAIL REFF INSTANCE POWER-PIN GROUND-PIN (Pin REFF Percentage) **Example**: FAIL 6.0 instanceName VDD1(83.33%) VSS1(16.67%)
3	# PASS/FAIL REFF INSTANCE PIN (Pin Absolute REFF Value, Pin REFF Percentage) **Example**: FAIL 10.0 instanceName VDD1(5.0, 50.00%) VDD2(3.0, 30%) VSS1(1.0, 10.00%) VSS2(1.0 10%)
4	# PASS/FAIL REFF INSTANCE PWRNET PIN Layer X Y % GNDNET PIN Layer X Y % **Example**: FAIL 22.709 instanceName VDD pinName layerName 571.340 473.060 value(37.49%) VSS pinName Layername 571.340 471.800 value(62.51%)

`-reff_eval_nodes {port | tap}`

Default: `port`

Reports effective resistance based on the port (pin) or tap nodes. By default, the software uses the port nodes for REFF reporting.

`-reff_pin_report_layer { top | bottom | all }`

Specifies which layer of the pin shapes are to be reported in the EFFR report. This parameter allows you specify which cell boundary p for the resistance report.

The possible arguments of this parameter are:

- `top`: Specifies to report only the pin shapes located on the highest pin layer.
- `bottom`: Specifies to report only the pin shapes located on the lowest pin layer.
- `all`: Specifies to report the pin shapes located on every layer.

The default value is `all`.

`-reff_pin_report_method { best | worst }`

Specifies whether to report the best or worst effective resistance value of an instance pin with multiple nodes.

The possible arguments of these parameters are:

- `best`: Reports the smallest resistance value among the nodes of instance pin shapes for REFF.
- `worst`: Reports the largest resistance value among the nodes of instance pin shapes for REFF.

The default value is `worst`.

`-reff_report_all {true | false}`

	Default: `false` Reports both fail and pass instance pins in the REFF report. By default, only the "FAIL" instance pins are reported.
`-remove_duplicate_inst {true | false}`	
	Specifies to remove duplicate cell instances during the DEF parsing stage of the rail analysis run. These duplicate cell instance names DEF file, and are also printed in a warning message so that you are not required to debug these disconnected instances. When this pa the duplicate cell instances within the same DEF file will not be reported as disconnected instances in the *Physically Disconnected Ins* power-grid integrity report. The default value is `false`.
`-report_instances_missing_current_data {true | false}`	
	Specifies to generate a report that includes a list of all instances with missing current data. This parameter is supported in both the net-l based analyses. When this parameter is specified, the `<net_name>.nocurrentdata.inst.rpt` file is created in the `<state directory>/<net_name>/` direc file includes the annotation statistics for instances with current data available on a per-net basis, as shown below: `#Instances missing current data: #count/#total_instances (%#percent value)` *Default* : `false`
`-report_layer_based_ir_average {true | false}`	
	Specifies to add the average IR drop value to the layer-based IR drop report and log file.
`-report_layers_above_pin_for_instance_ir {true | false}`	
	Specifies to report nodes above the pin layer. With this parameter set to `true`, the report will also contain layers above the pin nodes to layer. The reporting will be based on the largest rectangular bounding box of the instance.
`-report_power_options option_names`	
	This parameter is used when `-report_power_in_parallel` is set to `true`. When the `-report_power_in_parallel` parameter is specified, you will not run the `report_power` command, therefore the reporting para specified. Using the `-report_power_options` parameter, you can specify the required `report_power` command parameters that are to be with rail analysis.
`-report_msmv_format {true | false}`	
	When set to `true`, the software generates an instance voltage file for each MSMV power domain in the design, e.g. VDD_VSS.iv and V VDD and VDDm are MSMV power nets with common VSS net. *Default* : `true`
`-report_power_in_parallel {true | false}`	
	Enables power analysis in parallel with rail analysis to improve the overall turnaround time. For information on the parallel flow setup, refer to the "**Run Dynamic Power Analysis and Rail Analysis in Parallel**" section in the *Dy IRDrop Analysis chapter* of the *Voltus User Guide*.
`-report_shorts {true | false}`	

Specifies to check for power and ground shorts between two geometries belonging to different nets. The parameter performs power and for the following:

- PG and PG nets
- PG and signal nets
- All extracted nets

When the parameter is set to `true`, if shorts are detected, the file "`voltus_short.report`" will be generated in the extraction work directo report file is:

LayerName X-coord Y-coord NetName1 NetName2

If one of the net is not an extracted net (that is, signal net or non-extracted PG net), it will be marked as N/A in the report.

The following is the use model of the parameter:

```
set_rail_analysis_mode -report_shorts true
```

The following is a snippet from `voltus_short.report`:

```
# Layer   X          Y       NET         NET

   AP  98.500    211.000   VSS         N/A
   AP  98.500    219.550   VSS         N/A
   AP  98.500    301.000   VDD25_LVTL N/A
   AP  98.500    309.550   VDD25_LVTL N/A
   M8  13007.800 2267.200  VSS         VDD
...
```

`-report_voltage_drop {true | false}`

When set to `true`, instead of reporting the actual (effective) instance voltage, all the values will be reported in terms of voltage drop/bou full pwr-gnd is 1V, pwr is 0.9 and gnd is 0.1, the IV file will report 0.8 (0.9-0.1) if this parameter is set to `false`, or 0.2 (0.1drop+ 0.1bounc set to `true`.

`-reset`

Specifies to reset all the `set_rail_analysis_mode` command parameters to their default values.

`-reuse_state_directory` *dir_name*

Specifies an existing state directory. The software assumes that the design data (DEFs and GDS) and power-grid libraries are not char analysis of the design using power-grid database inside the specified state directory. If the state directory does not contain the necessa files, it will issue an error message and provide information on the missing files.
For net based analysis, you should specify net-based state directory, as shown below:

- `set_rail_analysis_mode -reuse_state_directory` *VDD_25C_avg_1*

For domain based analysis, you should specify the domain's state directory, as shown below:

- `set_rail_analysis_mode -reuse_state_directory` *domain_25C_dynamic_1*

A new state directory will be generated for the new analysis with soft links to the old state directory files that were reused.

`-rlrp_cell_report_layer` *filename*

Specifies the cell names and layer of the pin shapes that are to be reported in the RLRP report. This parameter allows you to perform c reporting for the instance RLRP report.

The format of the specified input file is:

```
#cell_name #netname #pinlayer
```

`netname` is either a netname or "`ALL`". If you specify `ALL` for a net name, all the nets in the analysis domain will be considered for RLRP r

Example of an Input File

```
PDVDD_18_18_NT_DR_V ALL {M9,M1}
PDVDD_18_18_NT_DR_V DVDD_D1 {M9,M1}
PDVDD_18_18_NT_DR_V DVDD_D1 {M9,M1} VSS_D1 {M2}
```

`-rlrp_detail_report {true | false}`

	Specifies to trace and report the total power gate resistance along the RLRP path for each instance. The RLRP report (`<netName>.rlrp` following additional columns for each instance: • `RLRP_TOTAL` - Total RLRP resistance including the power gate path (from the always-on and switched nets) • `NET_RES` - Total RLRP resistance excluding the power gate path • `PGATE_RES` - RLRP resistance for the power gate path • `PGATE_RON` - Number of power gate RON resistors The report allows you to trace the Ron resistors in each power gate instance and generate the RLRP report based on power gate instar The default value of this parameter is `false`.
`-rlrp_eval_nodes {port | tap}`	
	Reports RLRP based on the port (pin) or tap nodes. By default, the software uses the port nodes for RLRP reporting.
`-rlrp_percentage_threshold` *value*	
	Specifies to output top x% of the instances with large RLRP.
`-rlrp_pin_based_report {true | false}`	
	Specifies to generate a pin-based RLRP report. When specified, a new column "*Pin*" is included in the RLRP report.
`-rlrp_pin_report_layer { top | bottom | all }`	
	Specifies which layer of the pin shapes are to be reported in the RLRP report. This parameter allows you specify which cell boundary p for the resistance report. The possible arguments of this parameter are: • `top`: Specifies to report only the pin shapes located on the highest pin layer. • `bottom`: Specifies to report only the pin shapes located on the lowest pin layer. • `all`: Specifies to report the pin shapes with best or worst resistance value among all layers. The default value is `all`.
`-rlrp_pin_report_method { best | worst | eiv_best | eiv_worst}`	
	Specifies whether to report the best or worst effective resistance value of an instance pin with multiple nodes. The possible arguments of these parameters are: • `best`: Reports the smallest resistance value among the nodes of instance pin shapes for RLRP. • `worst`: Reports the largest resistance value among the nodes of instance pin shapes for RLRP. • `eiv_worst`: Reports the RLRP of the node that has the worst EIV value among the tap nodes of instance pin shapes. • `eiv_best`: Reports the RLRP of the node that has the best EIV value among the tap nodes of instance pin shapes. The default value is `worst`.
`-rlrp_threshold` *value*	
	Specifies to ignore instances with RLRP less than the specified threshold value.
`-rms_em_analysis {true | false}`	
	Specifies to calculate the RMS EM in the dynamic rail analysis run. When not specified, it will be enabled automatically if the EM mode You can set this parameter to `false` to skip the RMS EM analysis even if the EM models are provided. This parameter generates the `<n` report. *Default* : `false`
`-save_voltage_waveforms {true | false}`	
	When set to `true`, instance voltage waveforms are saved in the state directory (.ptiavg). This waveform file can be loaded in the `view_dy` command to probe voltage waveform for desired instances. This waveform file can be fed to Tempus to perform SPICE critical path ana waveforms. It can be used in Substrate Noise Analysis as well.
`-scale_initial_condition_current` *filename*	

	Specifies a file containing the current scale factor for the initial condition of the specified nets. The parameter allows you to increase/de current at time 0 to minimize oscillation in the package and to shorten the settling time.
	The format of the file is:
	`default <default scale factor for all nets>`
	`<net name> <scale factor for this net>`
	`...`
	The use model of this parameter is:
	`set_rail_analysis_mode -method dynamic -scale_initial_condition_current scale_factor.file`
	The content of *scale_factor.file* is:
	`default 1.0`
	`VDD 0.8`
	`VSS 0.7`

`-seb_lifetime value`	
	Specifies the life time of product in hours. *Default* : `43800` hours (that is, 5 years)
`-seb_table table_filename`	
	Specifies the file name of the Failures in Time (FIT) table. This file is provided by the foundry. The file has the following columns: • Layer • MTF • Sigma • Activate energy • Current density exponent
`-seb_temperature temperature`	
	Specifies the temperature used to update the median time to failure (MTF) with respect to the ambient temperature. • If this temperature is specified, it would be used globally for all the resistors. • If this temperature is not specified, the seb_temperature may take the following possible values depending on the specific circumsta ◦ If detailed delta temperature file is not used for SEB, the `seb_temperature` always takes the same value as that used for EM analy ◦ If detailed delta temperature file is used for SEB, the seb_temperature is calculated by the following equation: `seb_temperature = env_temperature + delta_T` Where delta_T is the maximum temperature rise, including joule heat and coupling heat from FEOL, in the resistor's bounding bo
`-set_analyze_bbox {xmin ymin xmax ymax}`	
	Specifies the X, Y, min and max coordinates of the bounding box in which the instances can be analyzed. The values of the coordinate microns (um).
`-shorting_resistance value`	
	Specifies the minimum shorting resistance value (in ohm) assigned to resistors. When specified, those resistors with resistance equal c specified value are merged to reduce the size of the R network. *Default* : `0`
`-skip_extraction {true | false}`	
	Specifies to reuse a work directory. It is recommended to use this parameter when you want to reuse the previous extraction work direc net rail analysis flow. *Default* : `false`
`-snap_layer_for_current_taps` *file_name*	

Specifies the layer file name for adaptive current modeling. It snaps current taps from lower via layers to higher via layers for better perf is supported for EM view of both macro PGV and hierarchical PGV. The current taps from lower layers will be processed based on the redistributed equally across all the vias within the tile at the higher via layers. The default tile size is `5umx5um (25 um2)` for macro PGV, a `um2`) for hierarchical PGV.

For example, when running full chip analysis, you already have detailed analysis on the sub-blocks or hierarchical blocks so you might the analysis by merging the current taps from lower layer to spread it across higher via layers. The current drawn from within the PGV w same so the accuracy at the top level will not be affected.

The format of the file is:

#Instance Based
```
INST <inst_name> <via_layer_name> <tile_size>
```

#Cell Based
```
CELL <cell_name> <via_layer_name> <tile_size>
```

`via_layer_name` is the layer name used in the LEF file.
`tile_size` is optional.

`-static_multi_mode_analysis {true | false}`

Specifies to analyze the worst-case static IR drop across multiple functional modes of operation for macros. When this parameter is spe will use the multi-mode static current file (`set_power_analysis_mode -static_multimode_scenario_file`) to iterate over multiple scenar instances, and output the worst-case IR and EM report. The generated report identifies the worst Differential Instance Voltage (DIV) and produces worst DIV across all instances.

Default : `false`

This parameter generates the following report in the Reports folder:

`State_dir/Reports/powerNetName_gndNetName``.worst_scenario_div.rpt` - this file reports each instance's worst scenario. It lists the ins DIV in the ascending order to determine the worst among all worst instance DIVs.

The following is a snippet from the worst scenario report:

```
#INST_NAME      SCENARIO_ID   DIV
block19/ICG4/ICG    12     -0.107583
block19/ICG3/ICG    12     -0.107557
...
```

Here, `SCENARIO_ID` is the worst time in the current file.

`-static_trigger_file` *`filename`*

Specifies a file containing user-defined xPGV current scaling information on a per PG net basis for static analysis. This parameter is us currents stored in xPGV.

You must provide scaling for all PG nets associated with the xPGV in the trigger file. The parameter allows you to use the same xPGV i irrespective of the voltage at which the xPGV is generated.

The format of the user-specified trigger file for a net is:
```
<INSTANCE|CELL>   inst_name/cell_name  time  scale_factor   mode  ref   net
```

Instance-based scale factors get higher precedence than the cell- based scale factors.

Example of a Trigger File:
```
INSTANCE    inst_C1    0   3   IPPGV::DEFAULT::super_filter   0   VDDD1
INSTANCE    inst_C1    0   2   IPPGV::DEFAULT::super_filter   0   VDDC1
INSTANCE    inst_C1    0   3   IPPGV::DEFAULT::super_filter   0   VSSA1
```

`-enable_xpgv_scaling` and `-static_trigger_file` are mutually exclusive.

`-suppress_message` **{** *`message_id`* **+ }**

The messages with the specified message ids will not be output.

Default : No messages are suppressed.

`-switchbit_file_for_eiv_calculation` *`filename`*

	Specifies the file that includes the cell or instance based switch-bit information. This parameter allows you to override the switch-bit in a switch-bit for a specific cell or instance.
	Note: The switch-bit information is defined for memory cells to distinguish between the pre-charge and functional mode (read/write) ope charge, the memory cells may have large IRdrops due to large demand current in a short period of time. However, these cells can tolera because word-lines are shut-off. To accurately measure the effect of IRdrop on the operation of a memory, the instance voltage should the functional mode. The switch-bit signal is used by the software to calculate the instance voltage when memory is in the functional mo
	The format of the specified file is:
	`CELL | INST <cell_name | instance_name>`
	`<MODE_NAME> <Tmin1> <Tmax1> <Tmin2> <Tmax2>`
	where,
	• *cell_name*/*instance_name* must have a PGV with the dynamic current waveform.
	• `MODE_NAME` must match one of the mode names in the PGV for the cell.
	• `Tmin` and `Tmax` is the window when the switch-bit is ON, and when EIV will be calculated. The default time unit is ns.
	The Rail Analysis engine reads this switch-bit information, and reports the elapsed and worst instance voltage drop (IVD) when the swi Analysis will generate two IVD values for a given instance in the EIV report:
	• Worst IVD across simulation (`ELAPSE_EIV`)
	• Worst IVD in switching window (`WIN_EIV`)

`-temp_directory_name` *directory*	
	Specifies a directory to use for temporary files. You can also use the global environment variable `TMPDIR` to specify an alternative location for the temporary data. If both are specified, using the `-temp_directory_name` parameter will take precedence. Following is an example for setting the TMPDIR environment variable: `setenv TMPDIR ./temp_directory`
`-temperature` *value*	
	Specifies the temperature in degree celcius during rail analysis. The default temperature is 25 degree celsius. This is an optional parameter.
`-topcell_placement {X Y}`	

	Specifies to place the top DEF block at a given X,Y location (in micron) with respect to virtual top (0,0).
	The following is the usage model:
	`set_rail_analysis_mode -topcell_placement { X Y } -topcell_orientation { N|S|W|E|FN|FS|FE|FW }`
	For GUI display, the same parameters also work for `read_def`:
	`read_def -topcell_placement { X Y } -topcell_orientation { N|S|W|E|FN|FS|FE|FW }`

`-topcell_orientation { N|S|W|E|FN|FS|FE|FW }`	
	Specifies the orientation of the top DEF block.
`-tsv_subckt_modelfile_list` *filename*	

	Specifies the name of the external Through Silicon Via (TSV) subckt model files to be used for 3D-IC extraction. You can specify a list space. Each file contains the subckt model information for TSV. The specified file has the Spice format.
	A sample file is shown below.
	`.subckt TSV top bottom`
	`R1 top n2 0.03075`
	`R2 n2 bottom 0.03075`
	`C1 n2 0 28f`
	`.ends`

`-unconnectedcell_ignore_file` *filename*	

	Specifies the name of a file containing the list of cells and instances to be ignored while reporting connectivity issues in the .rpt files, log parameter allows you to filter out the cells/instances that are known to have connectivity related issues and are not to be fixed. The format of the file is: `CELL/INST  Cell Name/Instance Name  Pin Name` Here: • `CELL` and `INST` are keywords • Pin names are not mandatory. If pin names are not given, the corresponding cell/instance is ignored. **Example**: `CELL AND` => ignore all AND cell(s) `INST INST1` => ignore instance INST1 `CELL BLOCK2*` => Ignore all blocks with the name starting with BLOCK2 `CELL *` => ignore all cells `INST *` => ignore all instances `CELL AN1 VDD*` => ignore AN1 cells's VDD* pins `INST INST2 {VDD1 VDD2}` => ignore multiple pins of instance INST2 `INST INS* VDD` => ignore VDD pin of all instances with the name starting with INS
`-unconnected_die_pkg_pins {ignore | error | edit}`	
	Specifies whether or not to ignore unconnected pins between die and package (if any), and consequently if the simulation should be pa continued. This option enables the manual connection between package and die through the *MCP Editor* utility if any disconnects are p The default value is `ignore`.
`-unified_power_switch_flow {true | false}`	
	Specifies to enable the unified analysis of the always-on and switch nets. When set to `true`, the power-up and always-on analyses are flow, wherein the switch nets and always-on nets are simulated together resulting in improved performance and accuracy. **Use Model**: • Always-on Flow: `set_rail_analysis_mode -unified_power_switch_flow true` • Power-up Flow: `set_rail_analysis_mode -unified_power_switch_flow true` and `-powering_up_rails <powerup_rail_list>`
`-use_early_view_list` *filename*	
	Specify cells in the file for which you want to use Early power-grid views. The file format accepts cell name in each line. You can specif cell names.
`-use_em_view_list` *filename*	
	Specify cells in the file for which you want to use EM power-grid views. The file format accepts cell name in each line. You can specify names.
`-use_ir_view_list` *filename*	
	Specify cells in the file for which you want to use IR power-grid views. The file format accepts cell name in each line. You can specify w names.
`-use_rms_delta_t {true | false}`	
	When this parameter is set to `true`, the `delta_T` used to calculate `seb_temperature` would be based on the RMS delta T (joule heat only If this parameter is set to `false`, the `delta_T` used to calculate `seb_temperature` would be based on the sum of self-heat delta T and RM *Default* : `false`
`-verbosity {true | false}`	
	Specifies to get side logs for extraction and rail analysis. The default value of this parameter is `false`.
`-verify_logical_connectivity {true | false}`	
	Specifies to report the list power and ground pins of each cell instance that do not have logical connectivity. The list of pins are reported report.
`-vsrc_search_distance` *value*	

	Specifies the search distance in microns for adding voltage sources at power pin locations. *Default* : `50`
`-watch_location_waveform { {`*layerName xCoord yCoord*`}+ }`	
	Specifies to perform node based voltage probing for rail analysis. You can use this parameter to observe voltage waveform at a given l x,y coordinates and the metal layer. The unit of x,y coordinates is um, and the layer name should be a LEF/DEF layer.
`-what_if_shapes_file` *filename*	
	Specifies to take the what-if shape specification from a file. This file is the file created with the `-write` parameter of the `add_what_if_sha` **Note**: If both the `-import_what_if_shapes` and `-what_if_shapes_file` parameters are specified, union of two sets of what-if shapes is c
`-work_directory_name` *directory*	
	Specifies the work directory location for extraction data. When you specify this parameter, the software generates extraction temporary directory.
`-write_demand_current_region_file` *filename*	

	Specifies a file that contains regions for custom demand current generation. This parameter allows to compute the total current within e sum up all tap currents that are outside the specified regions as a global port.
	The format of the region file is:
	`<REGION_PORT_LABEL> <XL YL XR YR> <NET>`
	here,
	• `REGION_PORT_LABEL` specifies a name for the region.
	• `XL YL XR YR` specifies the enclosing region coordinates in microns.
	• `NET` specifies the power/ground net name for analysis.
	Example file:
	`A 0 0 100 100 VDD_AO`
	When specified, one demand current waveform "`tran_<netname>_region.ptiavg`" will be generated per net in the rail output directory a
	• For DP: `./Reports/Waveforms/tran_<netname>_region.ptiavg`
	• For XP: `./reports/rail/waveforms/tran_<netname>_region.ptiavg`

`-xpgv_config_file` *filename*	

	Specifies block details, such as, cell name for which xPGV is generated, via layer at which current is saved, block LEF file names, and for which xPGV is generated. This parameter is specified during block-level analysis.
	Configuration File Format:
	`CELL <`*block_name*`>`
	`CUT_LAYER <`*cut_via_layer_name*`>`
	`Lef <`*tech_lef_name block_lef_name*`>`
	`END`
	Note: This parameter is not supported with the `analyze_resistance` command.

`-xp_cpu_per_job_power` *value*	
	Specifies the number of CPUs per power analysis job in the XP mode (`-enable_xp`). The specified value must be greater than `0`. This value should not exceed the value specified with `set_multi_cpu_usage -cpuPerRemot` is not specified, the value will be determined automatically based on the number of host resources.
`-xp_cpu_per_job_simulation` *value*	
	Specifies the number of CPUs per simulation job in the XP mode (`-enable_xp`). The specified value must be greater than `0`. This value should not exceed the value specified with `set_multi_cpu_usage -cpuPerRemot` is not specified, the value will be determined automatically based on the number of host resources.
`-xp_host_allocation_method {on_demand | at_startup}`	

	Specifies the method for remote host allocation during distributed processing. The possible arguments are: • `at_startup` – Specifies to wait for all available remote hosts before starting rail analysis. This parameter allocates all available remo `set_multi_cpu_usage` at startup. • `on_demand` - Allocates the available remote hosts based on demand. *Default* : `on_demand`
`-xp_purge {full}`	
	Specifies to clean up disk after run completion to delete temporary directories created for each analysis step (data generated in the volt this parameter is specified, the reuse parameters (`-reuse_state_directory and -xp_reuse_extraction_directory`) will not work for th in the future runs. This parameter is applicable only in the XP mode (`-enable_xp`).
`-xp_resume {true | false}`	
	Specifies to resume from the failed step, and skip the previously successful run steps. This parameter is applicable only in the XP mod *Default* : `false`
`-xp_reuse_extraction_directory` *directory_name*	
	Specifies the path to the state directory that contains the extraction power-grid database. This parameter allows you to skip extraction a data from a previous run in the XP mode.
`-xp_simulation_cpu_timeout` *value*	
	Specifies the time limit to either acquire the number of CPUs requested at the start of the run or acquire the number of CPUs specified v `xp_simulation_min_cpu` parameter in the XP mode. When this parameter is specified, the tool will wait for the given time limit to acquire simulation before exiting. The unit for timeout is seconds. If a timeout value is not specified, the tool will wait for 7200 seconds (two hours) to acquire the CPUs. *Default* : `7200`
`-xp_simulation_min_cpu` *value*	
	Specifies the minimum number of CPUs required for the rail simulation stage in the XP mode. The specified value must be greater than When this parameter is specified, the tool waits to acquire the specified number of CPUs before performing simulation. This parameter want to perform simulation with the minimum number of CPUs required to proceed with simulation instead of waiting for all the CPUs n If this parameter is not specified, the tool performs simulation with the available number of CPUs.

Examples

- The following command sets the rail analysis mode to static and xd accuracy, along with some other parameters:

```
set_rail_analysis_mode \
-method static \
-accuracy xd \
-power_grid_library fast_library/fast_allcells.cl \
-vsrc_search_distance 50
```

- The following command is an example of setting up rail analysis in the XP mode:

```
#resume previously failed XP run
set_rail_analysis_mode -enable_xp true -xp_resume true

set_rail_analysis_mode -method dynamic -accuracy hd \
...
-enable_xp true \
-xp_host_allocation_method at_startup \
-xp_reuse_extraction_directory dynamic_rail/core_125C_dynamic_1 \
-xp_cpu_per_job_power 2 \
-xp_cpu_per_job_simulation 8 \
-xp_purge full
```

- The following is an example of net-based early rail static analysis on an unplaced or partial placed design where virtual via/followpin would be created.

The power would be distributed to placed instances on the basis of area. For unplaced instances, current region would be created on the M1 layer.

```
set_pg_nets -net vdd -voltage 0.998 -threshold 0.99301
set_power_pads -net vdd -format xy -file vdd.pp
set_power_data -format area -bias_voltage 0.998 -power 2.15
set_rail_analysis_mode -method era_static -accuracy xd -extraction_tech_file ./qrcTechFile -era_current_distribution_layer M1 -
era_current_distribution unplaced
analyze_rail -type net vdd
```

- The following is an example of domain-based early rail static analysis with virtual via/followpin. Here, user-specified instance current files are used.

```
set_pg_nets -net VSS -voltage 0 -threshold 0.18
set_pg_nets -net VDDm -voltage 1 -threshold 0.856
set_pg_nets -net VDD -voltage 0.84 -threshold 0.756
set_power_pads -net VDD -format xy -file vdd.pp
set_power_pads -net VDDm -format xy -file vddm.pp
set_power_pads -net VSS -format xy -file vss.pp
set_power_data -format current {instance_current_files/static_VSS.ptiavg instance_current_files/static_VDD.ptiavg
instance_current_files/static_VDDm.ptiavg  instance_current_files /static_VDDlu.ptiavg instance_current_files/static_VDDau.ptiavg}
set_rail_analysis_mode -method era_static -accuracy xd -extraction_tech_file typical.tch -era_power_gate_file pwrgates_port.txt
set_rail_analysis_domain -name PD -pwrnets {VDD VDDm} -gndnets VSS
analyze_rail -type domain PD
```

- The following is an example of net-based early rail analysis with user specified ASCII instance and current region file. Here, all virtual vias and followpin creation have been skipped.

```
set_pg_nets -net vss -voltage 0.0 -threshold 0.01
set_power_pads -net vss -format xy -file vss.pp
set_power_data -format ascii -bias_voltage 1 -power 1.5 instance_power_file.txt
set_power_data -bias_voltage 1 -power 1.5

set_rail_analysis_mode -method era_static -accuracy xd -extraction_tech_file ./qrcTechFile -era_current_region_file
./cur_region_file  -era_insert_virtual_followpins none -era_skip_virtual_via_on_layers MI M2

analyze_rail -type net vdd
```

- The following is an example of static early rail analysis with current distribution for unplaced instances by total die area:

```
set_rail_analysis_mode -power_grid_library fast_library/fast_allcells.cl -extraction_tech_file typical.tch -accuracy hd -ignore_shorts
true  -method era_static -enable_rlrp_analysis true -vsrc_search_distance 50  -era_current_distribution unplaced -
era_current_distribution_layer Metal1 -era_current_distribution_unplaced_area diearea -era_techlib_generation false -
era_check_wires_for_generated_current_regions true
```

- Let us consider a design with cell type A that has the M1 and M2 PG pin shapes, and cell type B that has the M3 and M4 PG pin shapes.
  The following command calculates the reff values of the interface nodes on the M2 pin shapes for the cell type A and on the M4 pin shapes for the cell type B, and reports the worst (biggest) value among them. Similarly, it calculates the rlrp values of the interface nodes on the M1 pin shapes for the cell type A and on the M3 pin shapes for the cell type B, and reports the best (smallest) value among them.

```
set_rail_analysis_mode \
      -reff_pin_report_layer top \
      -reff_pin_report_method worst \
      -enable_rlrp_analysis true \
      -rlrp_pin_report_layer bottom \
      -rlrp_pin_report_method best \
…

analyze_resistance
```

- The following command reads the switch-bit information in the specified memory cells:

```
set_rail_analysis_mode \
  -power_grid_library "${Libgen_Golden_Pgv}" \
  -accuracy hd \
  -ignore_shorts true \
  -method dynamic \
  -enable_rlrp_analysis true \
  -eiv_eval_window switching  \
  -limit_number_of_steps false \
  -watch_location_waveform u0 \
  -switchbit_file_for_eiv_calculation  sw.list
```

The following is a snippet of the sw.list file:

```
CELL MEM128Kx32
READ 0.1ns 0.13ns
WRITE 0.1ns 0.15ns
CELL MEM64Kx32
READWRITE  0.1ns 0.2ns 0.3ns 0.4ns
```

The following is a snippet of the report:

```
INST_NAME WIN_EIV PWR_WIN_IV GND_WIN_IV WIN_TIME ELAPSE_EIV PWR_ELAPSE_IV GND_ELAPSE_IV ELAPSE_TIME CELL_NAME
*"NA" means the instance is disconnected from the net or the instance does not have timing/switching window
BEGIN
- external/MULT8_reg_3_6 0.75841 0.85220 0.09379 48.470 0.75841 0.85220 0.09379 48.470 SDFFQXL
```

- The following command specifies the instance-based PWL current file in the dynamic ERA flow:

  ```
  set_rail_analysis_mode -method era_dynamic -accuracy hd -vsrc_search_distance 500 -era_instance_dynamic_current_file
  ./inst_cell_pwl_file -power_grid_library ./../techonly.cl
  ```

  The following is a snippet of the PWL file:

  ```
  instance ram/ram3 net VDD pwl (0ns 0mA 0.1ns 1mA 0.2nA 0.5mA) intrinsic_cap 10pf loading_cap 60pf
  instance ram/ram2 net VDD pwl (0ns 0mA 0.1ns 1mA 0.2nA 0.5mA) intrinsic_cap 10pf loading_cap 60pf
  ...
  ```

- The following command specifies different temperature values to the layers M1, M2, M3, VIA1, VIA2, and VIA3 for average current limit analysis:

  ```
  set_rail_analysis_mode
  ...
     -em_temperature 110 \ #temperature for the remaining layers
     -em_temperature_layer_list {M1 125 M2 115 M3 105 VIA1 115 VIA2 105 VIA3 120} #layer-based temperature
  ```

  The log file will display the following info message:

  ```
  Layer specific EM temperature will be used for AVG check for layer M1(125C), M2(115C), M3(105C), VIA1(115C), VIA2(105C), VIA3(120C).
  ```

  The header of the power EM report displays the layer-based temperature, as shown below:

  ```
  # Temperature: 110.0 (C)
  # Jmax_factor:
  # ……
  #   M2  0.981000 @ 115.0 (C)
  #  ……
  ```

- The following command specifies to perform unified power switch flow:

  ```
  set_rail_analysis_mode -method dynamic -accuracy hd \
  ....
  -powering_up_rails "VDD_sw1 VDD_sw2" \
  -enable_xp true \
  -unified_power_switch_flow true
  ```

set_self_heat_analysis_mode

```
set_self_heat_analysis_mode
[-help]
[-alpha_parameters {{<layer_name> < α_overlapping > < α_connecting >}+}]
[-beta_parameters {C1 C2 C3}]
[-cell_thermal_resistance_file filename]
[-detail_delta_temperature_file filename]
[-detail_delta_temperature_region {x1 y1 x2 y2}]
[-die_instance_input_signal_em filename]
[-die_instance_name dieinstname]
[-instance_delta_temperature_file filename]
[-instance_power_file filename]
[-report_conn_pin_wire filename]
[-scale_rms_limit value]
[-tile_delta_temperature_file filename]
[-tiles {n_tile_in_x m_tile_in_y}]
```

Specifies the number of tiles, layer-based α coefficients, β coefficients, and list of cells with cell thermal resistances. This command will use the static power data to compute delta T FEOL for all instances in the design. This command:

- computes the RMS currents on signal wires
- computes the RMS currents on power network wires
- generates Detail Delta Temperature File (ddt), Instance Delta Temperature File (idt), and Tile Delta Temperature File (tdt)

The command supports both single-die and multi-die flows.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `set_self_heat_analysis_mode` parameter. For a detailed description of the command and all of its parameters, use the man command `man set_self_heat_analysis_mode`.
`-alpha_parameters {{<layer_name> < αoverlapping > < αconnecting >}+}`	
	Specifies the alpha parameters for all layers. It is the metal layer effect.
`-beta_parameters {C1 C2 C3}`	
	Specifies the thermal coupling effect coefficient Value.
`-cell_thermal_resistance_file filename`	
	Specifies the name of the cell's equivalent thermal resistance file. The specified file contains the list of cells and their corresponding thermal resistance value. The unit of thermal resistance is in °C/W (temperature rise per unit rate of heat dissipation). The format of the file is: `<cell_name> <thermal_resistance_in_C/W>` To get instance deltaT, use half of the instance power multiplied by the cell thermal resistance.
`-detail_delta_temperature_file filename`	
	Specifies the name of the generated BEOL detailed delta-temperature file.
`-detail_delta_temperature_region {x1 y1 x2 y2}`	
	Specifies the region coordinates for generating detailed delta temperature file.
`-die_instance_input_signal_em filename`	
	Specifies the setup Tcl script for each die instance.
`-die_instance_name dieinstname`	
	Specifies the die instance name for multi-die analysis. This option is only available in multi-die analysis (`set_rail_analysis_mode -die_mode multi-die`).

`-instance_delta_temperature_file` *filename*	
	Specifies the name of the generated FEOL instance-based delta-temperature file.
`-instance_power_file` *filename*	
	Specifies a file for instances and their corresponding static power. It is a two column format of <*instance_name*> and <*total_power*>.
`-report_conn_pin_wire` *filename*	
	Reports results on wires connecting to cell pins.
`-scale_rms_limit` *value*	
	Specifies the scale factor for the root-mean-square (rms) limit relaxation factor during Electromigration current limit analysis.
`-tile_delta_temperature_file` *filename*	
	Specifies the name of the generated FEOL/BEOL tile-based delta-temperature file.
`-tiles` *{n_tile_in_x m_tile_in_y}*	
	Specifies the number of tiles in the x and y directions in the tile-based delta temperature file.

Examples

- The following command is an example of `set_self_heat_analysis_mode` command:

```
set_self_heat_analysis_mode \
-die_instance_name die0 \
-alpha_parameters {{M1 0.74 0.85} {M2 0.62 0.85} {M3 0.53 0.85} {M4 0.42 0.85} {M5 0.32 0.85} {M6 0.26 0.85} {M7 0.26 0.85} {M8 0.26
0.85} {M9 0.26 0.85} {M10 0.26 0.85} {M11 0.26 0.85} {M12 0.26 0.85}} \
-beta_parameters {0.00423 -0.00045 0.81534}\
-instance_power_file ./dynamic_power.rpt \
-cell_thermal_resistance_file TRF.txt \
-instance_delta_temperature_file sh_itm.txt \
-tile_delta_temperature_file sh_ttm.txt \
-tiles {10 10} \
-detail_delta_temperature_file power_detail_die0.rpt
```

```
set_self_heat_analysis_mode \
-die_instance_name die1 \
-alpha_parameters {{M1 0.74 0.85} {M2 0.62 0.85} {M3 0.53 0.85} {M4 0.42 0.85} {M5 0.32 0.85} {M6 0.26 0.85} {M7 0.26 0.85} {M8 0.26
0.85} {M9 0.26 0.85} {M10 0.26 0.85} {M11 0.26 0.85} {M12 0.26 0.85}} \
-beta_parameters {0.00423 -0.00045 0.81534}\
-instance_power_file ./dynamic_power.rpt \
-cell_thermal_resistance_file TRF.txt \
-instance_delta_temperature_file sh_itm.txt \
-tile_delta_temperature_file sh_ttm.txt \
-tiles {10 10} \
-detail_delta_temperature_file power_detail_die1.rpt
```

```
set_self_heat_analysis_mode \
-die_instance_name die2 \
-alpha_parameters {{M1 0.74 0.85} {M2 0.62 0.85} {M3 0.53 0.85} {M4 0.42 0.85} {M5 0.32 0.85} {M6 0.26 0.85} {M7 0.26 0.85} {M8 0.26
0.85} {M9 0.26 0.85} {M10 0.26 0.85} {M11 0.26 0.85} {M12 0.26 0.85}} \

set_voltage_regulator_module

```
set_voltage_regulator_module
-component_list {VRM_DEF_component_list}
-ground_pin_mapping {{spice_pin_name[DEF_net_name]}+}
-input_pwr_pin_mapping {{spice_pin_name[DEF_net_name]}+}
-name vrm_name
-netlist vrm_spice_netlist_file_name
-output_pwr_pin_mapping {{spice_pin_name[DEF_net_name]}+}
-reset
-subckt_name vrm_subckt_name
```

Analyzes voltage regulator effects. Use this command to enable the Vreg flow.

You must specify this command before running the `analyze_rail` command.

Parameters

`-component_list {VRM_DEF_component_list}`
Specifies the names of the DEF instances which comprise the VRM. The component name must be the instance name used for the specified VRM. If this parameter is not specified, it is assumed that VRM is represented as a single MACRO on the die.
`-ground_pin_mapping {{spice_pin_name[DEF_net_name]}+}`
Specifies the mapping between the ground pin name in the SPICE netlist and the corresponding DEF net name for the same power pin.
`-input_pwr_pin_mapping {{spice_pin_name[DEF_net_name]}+}`
Specifies the mapping between the input power pin name in the SPICE netlist and the corresponding DEF net name for the same power pin.
`-name vrm_name`
Specifies the VRM name assigned to a voltage regulator. You need to specify this parameter for each voltage regulator in the design.
`-netlist vrm_spice_netlist_file_name`
Specifies the VRM netlist file in the SPICE format that is encapsulated in a single sub-circuit. This should also include SPICE models and testbench for each voltage regulator.
`-output_pwr_pin_mapping {{spice_pin_name[DEF_net_name]}+}`
Specifies the mapping between the output power pin name in the SPICE netlist and the corresponding DEF net name for the same power pin.
`-reset`
Resets all specified parameters back to default values.
`-subckt_name vrm_subckt_name`
Specifies the subcircuit that corresponds to the VRM. This parameter is specified when the specified SPICE netlist has multiple subcircuit definitions. If this optional parameter is not specified, the first subcircuit found in the netlist file will be used.

Examples

- The following command performs Vreg analysis for the VRM `vrm1`:

  ```
  set_voltage_regulator_module -name vrm1 -netlist ./TEST.spi -input_pwr_pin_mapping {{VCC VCC}} -output_pwr_pin_mapping {{VDD VDD}} -
  ground_pin_mapping {{ VSS VSS }} -subckt_name LDO_MODEL -component_list { vmesh_reg_1 }
  ```

- "Dynamic Power and IRDrop Analysis" in the *Voltus IC Power Integrity Solution User Guide*

view_dynamic_movie

```
view_dynamic_movie
[-help]
[-type [ir|tc] ]
[-movies_directory dir]
```

Provides the ability to view movies created during dynamic analysis. Movies are sequences of analysis plots displayed over a specific simulation time.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `view_dynamic_movie` parameter. For a detailed description of the command and all of its parameters, use the man command `man view_dynamic_movie`.
`-movies_directory dir`	
	Specifies the movie directory that was generated during dynamic rail analysis (that is, `state_directory/movie_analysis`)
`-type [ir | tc]`	
	Specifies the movie type. `ir`: IRdrop `tc`: Tap current

Examples

- The below command views the dynamic movie of type `ir` in the specified state directory:

```
view_dynamic_movie -type ir -movies_directory \ dynamic_rail/TDSP_25C_dynamic_1/VDD_TDSPCore_R/movie_analysis
```

Related Information

- `set_rail_analysis_mode`
- `view_dynamic_waveform`
- "Dynamic Power and IRDrop Analysis" in the *Voltus IC Power Integrity Solution User Guide*

view_dynamic_waveform

```
view_dynamic_waveform
[-help]
[-type [current | voltage | profile]]
[-waveform_files {file1 file2 ... fileN}]
[-instance_name instance_name]
[-composite_waveform_type [hierarchy | clock | clock_with_seq
    | total_current]
[-composite_waveform_name [hierarchy_name | clock_name]]
[-power_db [powermeter.db]]
[-effective_voltage_waveform]
[-free_data]
[-state_directory directory_name]
[-hier_block_file filename]
[-clear_hier]
```

Provides the ability to view dynamic current or voltage waveforms generated during analysis.

Parameters

`-clear_hier`	Specifies to clear the hierarchical block data that was loaded using the `-hier_block_file` parameter.
`-composite_waveform_name [hierarchy_name | clock_name]`	
	Only available for `-type current`. If `hierarchy_name` is specified, plots total current waveform for the specified hierarchy. If `clock_name` is specified, plots current waveform for the selected or all clocks. If `-composite_waveform_type clock_with_seq` is specified, plots total current waveform for all sequential cells. If `-composite_waveform_type total_current` option is specified, plots total current waveform for all instances in the current file.
`-composite_waveform_type [hierarchy | clock | clock_with_seq | total_current]`	
	You can specify to view a waveform for a specific hierarchy, a clock, clock with sequential cells, or total current.
`-effective_voltage_waveform`	
	Plots the effective voltage waveform (i.e. VDD - VSS). You must specify the voltage for two nets to generate the effective waveform.
`-free_data`	Frees the memory but leaves the menu entries.
`-help`	Outputs a brief description that includes the type and default information for each `view_dynamic_waveform` parameter. For a detailed description of the command and all of its parameters, use the man command `man view_dynamic_waveform`.
`-hier_block_file filename`	

	Specifies to analyze the multiple (top/block-level) current (.ptiavg) files of a hierarchical design in the SimVision waveform viewer interface. This parameter can be used to easily find an instance of a specific block when there are multiple blocks with the same instance name.
	`-hier_block_file` specifies a text file that contains the list of blocks. For example, if the block name `BLOCK_A` is specified in the text file, you can match the instance named `BLOCK_A/Instance_A` and `Instance_A` in the `BLOCK_A`'s .ptiavg file.
	When specifying multiple block names in the text file, one block name should be given per line.
	The following is a snippet from the `block_hier` file:
	`u_top/vcore3`
	`u_top/vcore2`
	`u_top/vcore1`

`-instance_name instance_name`	

	Plot the waveform for the specified instance.
`-power_db [`*`powermeter`*`.db]`	
	Specifies the power database. Must be specified if `-composite_waveform_type` is `clock` or `clock_with_seq`.
`-state_directory` *`directory_name`*	
	Specifies to load the state directory where the current or voltage waveform files have been saved. The current and voltage waveforms are saved in the state directory generated during rail analysis. If you specify this state directory when viewing dynamic waveforms, the generated waveform file is automatically populated in the GUI.
`-type [current | voltage | profile]`	
	Specifies to display either current (power) or voltage waveform. The `profile` option displays the profiling db and the SimVision interface to view the histograms.
`-waveform_files {`*`file1 file2 ... fileN`*`}`	
	Specifies one or more current or voltage waveform files generated with a `.ptiavg` extension.

Examples

- The following command views dynamic composite total current waveforms from the file vddm_vddm.ptipeak:

```
view_dynamic_waveform -type current -composite_waveform_type total_current \
    -waveform_files vddm_vddm.ptipeak
```

- The following command views the dynamic current waveform for instance inst1:

```
view_dynamic_waveform \
    -type current \
    -waveform_files dynamic_vss.ptiavg \
    -instance_name inst1
```

- The following command is for viewing the total current waveform:

```
view_dynamic_waveform \
    -type current \
    -waveform_files dynamic_vss.ptiavg \
    -composite_waveform_type total_current
```

- The following command plots a clock domain composite waveform:

```
view_dynamic_waveform \
    -type current \
    -waveform_files dynamic_vss.ptiavg \
    -power_db power.db \
    -composite_waveform_type clock \
    -composite_waveform_name clk
```

- The following command plots a hierarchical composite waveform:

```
view_dynamic_waveform \
    -type current \
    -waveform_files dynamic_vss.ptiavg \
    -composite_waveform_type hierarchy \
    -composite_waveform_name ethernet_mac_2
```

view_package_results

```
view_package_results
[-help]
[-result_file <filename>]
-type <package_analysis_type>
[-workspace <workspacename>]
```

Specifies to view the package IR drop analysis results in the PowerDC GUI which will be invoked from within Voltus/Innovus.

Parameters

`-help`	Outputs the command usage and a brief description about the command parameters.
`-result_file <filename>`	
	Specifies the name of the .xml result file.
`-type <package_analysis_type>`	
	Specifies the type of package analysis. Currently, the software supports only the `dc` package analysis type.
`-workspace <workspace_name>`	
	Specifies the workspace name for package analysis (powerDC). The file name extension is `.pdcx`.

Example

- The following example specifies to view the package analysis results

  ```
  view_package_results -type dc
  ```

create_parasitic_coordinate_transform

```
create_parasitic_coordinate_transform
[-help]
{-inst inst_name
[-x_block_origin value]
[-x_offset value]
[-y_block_origin value]
[-y_offset value]
[-orient {R0 R90 R180 R270 MY MX90 MX MY90}]
[-relative_to_parent]} | {-reset}
```

Determines accurate location information of nodes during SPEF reading.

In case of hierarchical designs, there can be multiple blocks in a design that are implemented separately. During Top level STA analysis, SPEFs of these blocks are stitched together with top for flat STA analysis. This works well if pin location of blocks is not required. In case of AOCV analysis, when spatial analysis is enabled, accurate location of all nodes (pin/net) in the design is required for calculating accurate derates in the design. This makes it necessary to determine accurate nodes location during SPEF reading. This can be achieved by transforming SPEF coordinates as per their physical locations.

Note:

- This command works with all possible SPEF and RCDB input combinations with `read_parasitics` command, which means for only RCDB(s) as input, mix of SPEF(s) and RCDB(s) as input and only SPEF(s) as input.
- If this command is not specified, the `spefIn` command tries to automatically find the orientation and origin of the hierarchical SPEF blocks and applies those identified transforms to the parasitic co-ordinates.
- The `create_parasitic_coordinate_transform` command settings remain in effect for all the subsequent `spefIn` and `read_parasitics` until they are reset using the `-reset` option.
- Whenever the block's origin (in block SPEF/DEF) is non-zero, the x and y coordinates need to be specified for applying the transform. The last two parameters, `-x_block_origin` and `-y_block_origin` in the following command use-model are only required to be specified for the case of non-zero block origin.

  ```
  create_parasitic_coordinate_transform -inst inst_name
  -x_offset x-offset of block origin in top-level DEF/SPEF
  -y_offset y-offset of block origin in top-level DEF/SPEF
  -orient orientation
  -x_block_origin x-coord of non-zero block origin
  -y_block_origin y-coord of non-zero block origin
  ```

  For example:

  - **For Non-Zero Origin Block**: Specify the block origin as shown below:
    ```
    create_parasitic_coordinate_transform -inst eco_inst1
    -x_offset 421.6
    -y_offset 485
    -orient R180
    -x_block_origin 3.4
    ```

```
-y_block_origin 9.7
```

- **For zero origin block**: No need to specify the block origin as shown below:

  ```
  create_parasitic_coordinate_transform
  -inst controller
  -x_offset 16.8
  -y_offset 205
  -orient R0
  ```

  or

  ```
  create_parasitic_coordinate_transform
  -inst controller
  -x_offset 16.8
  -y_offset 205
  -orient R0
  -x_block_origin 0
  -y_block_origin 0
  ```

  Both the above commands are equivalent.

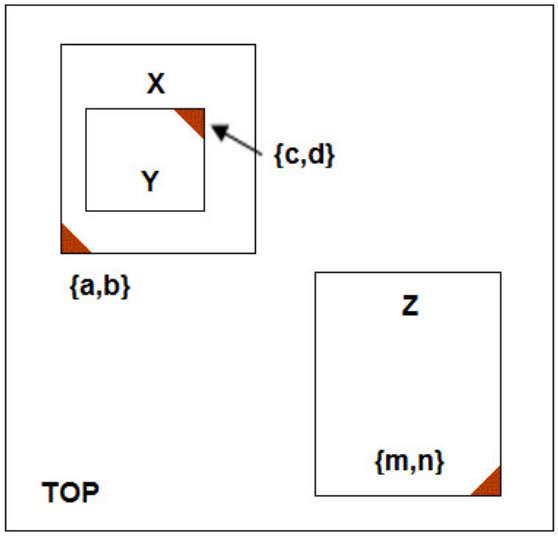
- The impact of this command is valid till first `spefIn` command is read (in case of MMMC, till all corners SPEFs have been read). If you want to read SPEF again, this command needs to be applied once again. These transformations will be applied during `spefIn` command.

Parameters

`-help`	Prints out the command usage. For a detailed description of the command and all of its parameters, use the `man` command: `man create_parasitic_coordinate_transform`
`-inst` *`inst_name`*	Indicates the hierarchical name of the instance for which SPEF is being read.
`-orient {R0 R90 R180 R270 MY MX90 MX MY90}`	Indicates orientation change of instances. The valid values are `R0`, `R90`, `R180`, `R270`, `MX`,`MX90`, `MY`, and `MY90`.
`-relative_to_parent`	When this parameter is specified, the software considers block offsets for the specified instance relative to the immediate parent. By default, the software considers the offset value relative to the top hinst.
`-reset`	Resets SPEF transform values.
`-x_block_origin` *`value`*	Specifies that in case of non-origin block, offset x-coordinate in microns
`-x_offset` *`value`*	Indicates the actual x-coordinate as exists in the physical floor plan, corresponding to the specified instance.
`-y_block_origin` *`value`*	Specifies that in case of non-origin block, offset y-coordinate in microns.
`-y_offset` *`value`*	Indicates the actual y-coordinate as exists in the physical floor plan, corresponding to specified instance.

Examples

Consider the following hierarchical design where X and Z are two blocks inside TOP, and Y is another hierarchical block in X:



Here, X,Y, and Z have the following physical locations in the floor plan:

X - (a,b)
Y- (c,d)
Z- (m,n)

You can apply transformations to all blocks with respect to TOP, by using the following commands:

```
create_parasitic_coordinate_transform -inst X -x_offset a -y_offset b

create_parasitic_coordinate_transform -inst Z -x_offset m -y_offset n -orient MY

create_parasitic_coordinate_transform -inst X/Y -x_offset c -y_offset d -orient R180
```

These transformations will be applied when spefIn command is issued.

Related Commands

- set_analysis_view
- redirect
- read_parasitics
- spefIn

extractRC

```
extractRC
[-help]
```

Extracts resistance and capacitance for the interconnects and stores the results in an RC database. Optionally, an ASCII report file can be generated. Use this command after performing early global routing or final routing, and after using the `setExtractRCMode` command.

Parameter

`-help`	Outputs a brief description of the `extractRC` command. For a detailed description of the command, use the `man` command: `man extractRC`

Example
The following command extracts interconnect resistance and capacitance:

```
extractRC
```

RC database is created.

The `extractRC` command can be followed by the `rcOut` command to extract the parasitics from the RC database, and to generate an ASCII report containing the database information.

Related Information

- `setExtractRCMode`
- The following topic in the *Innovus User Guide*
  - Performing Extraction in Innovus

generateCapTbl

```
generateCapTbl
[-help]
[-cap totalCapFactor]
[-encrypt]
-output fileName
[-res resistanceFactor]
[-xcap crossCouplingFactor]
[-lef fileName [-shrinkFactor value]]
{-ict fileName | -incaptable fileName}
```

Reads in the interconnect technology (ICT) process file and generates a Capacitance table file. The Capacitance table file contains a header having a summary of process information and manufacturing effects followed by tables containing coefficients used during RC extraction.

The capacitance table is used both for preRoute extraction (above 32nm) and postRoute extraction `-effortLevel low`.

Note: For TQuantus, IQuantus, preRoute extraction (32nm and below), and Standalone Quantus, a Quantus Techfile is needed instead of a Capacitance table.

The `generateCapTbl` command automatically omits the creation of coefficients for the poly layers, local interconnect layers, and mimcap layers. The `generateCapTbl` command recognizes poly layers by the `gate_forming_layer true` statement.

Note: The command accepts ICT files that contain the `gate_forming_layer true` construct in multiple `conductor` sections to allow handling of diffusion models as a conductor. In this case, the Innovus captable generation process ignores all but the last `gate_forming_layer true` construct. The last one is considered as `poly` and is used as the ground plate level for the metal layers above.

The command does not support `grown_from_conformal` (non-planar stack) construct defined in the ICT file.

You can use the multi-CPU processing commands to generate a capacitance table in the parallel mode. However, this functionality is only available when invoking `generateCapTbl` from the software prompt, and not from the standalone utility `generateCapTbl`.

To generate a capacitance table file in the parallel mode, you must first set up the multiple-CPU processing mode using the multiple-CPU processing commands.

See the following multiple-CPU processing commands for more information:

- `setDistributeHost`
- `setMultiCpuUsage`

For more information, see Distributed Processing in Extraction in the *Innovus User Guide*.

Examples

- To run the `generateCapTbl` command in the parallel mode on different hosts, specify the following commands:

  ```
  setDistributeHost -rsh -add { host1 host2 host3 }
  setMultiCpuUsage -remoteHost 3
  generateCapTbl -ict sample.ict -output sample.capTbl
  ```

- To run the `generateCapTbl` command with three threads, specify the following commands:

  ```
  setDistributeHost -local
  setMultiCpuUsage -localCpu 3
  generateCapTbl -ict sample.ict -output sample.capTbl
  ```

Parameters

`-help`	Outputs a brief description that includes type and default information for each `generateCaptbl` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man generateCaptbl`
`-cap` *totalCapFactor*	Specifies the capacitance scale factor. Use this parameter with the -incaptable parameter to generate a capacitance table with capacitance values scaled by the specified scale factor.
`-encrypt`	Encrypts the generated capacitance table to protect the process information in the capacitance table header. When you use the `create_rc_corner -cap_table` command to read the encrypted capacitance table, the software writes the version number that was used to generate the file, and the name of the process to the log file.
`-ict` *fileName*	Specifies the name and path to the ICT (interconnect technology) process file. To support multiple process corners, a capacitance table should be created for each corner from the matching corner ICT file.
`-incaptable` *fileName*	Specifies the name of an existing capacitance table in ASCII format. You use this parameter along with the `-encrypt` parameter to create an encrypted version of an existing capacitance file. **Note**: The `-ict` and `-incaptable` parameters are mutualy exclusive. One of the two parameters must be specified.
`-lef` *fileName*	Specifies the name and the full path to the process LEF file for optimal accuracy. With the LEF file, this parameter generates a capacitance table by using the actual wire widths as specified in the non-default rules defined in the LEF. Without the LEF, the software uses generic widths and spacings, which might increase the need for interpolation during extraction.
`-output` *fileName*	Specifies the output filename that contains the capacitance table. This is a required parameter.

`-res` *resistanceFactor*	Specifies the resistance scale factor. Use this parameter with the -incaptable parameter to generate a capacitance table with resistance values scaled by the specified scale factor.
`-shrinkFactor` *value*	Specifies the value by which the measurements in the optional LEF file have to be shrunk for the technology used with this design. Use this parameter only with the `-lef` parameter and when the LEF technology does not match the target technology in the ICT file. Innovus scales the dimensions when reading the LEF file using the shrinkFactor specified. The ICT file should always refer to the target technology (min width and min spacing). **Note**: When working on a design that needs to be scaled down in Innovus, you must also set the shrinkfactor in *Design Import*. This tells the extractor to scale down all geometries before processing. When the ICT file contains a `layout_scale` in the process declaration part, you do not need to specify the shrink factor. In this case, the embedded shrink factor will also be written in the captable header. Also, there is then no need to set the shrink factor in the *Design Import* form. The embedded `layout_scale` is used to support half nodes such as 40nm technology. *Default:* 1.0
`-xcap` *crossCouplingFactor*	Specifies the cross-coupling capacitance scale factor. Use this parameter with the `-incaptable` parameter to generate a capacitance table with cross-coupling capacitance values scaled by the specified scale factor.

Example

The following command reads in the ICT file `test.ict`, and generates a `new.capTbl` output file:

```
generateCapTbl -ict test.ict -output new.CapTbl
```

Related Information

- The following topic in the *Innovus User Guide*
  - Generating a Capacitance Table

generateRCFactor

```
generateRCFactor
[-help]
[-outputFile file_name]
[-preroute {true | false}]
[-postroute {low | medium}]
[-reference {low | medium | high | signoff | externalSpef}]
[-spefMapFile file_name]
[-use_ostrich_filters file_name]
```

Generates the resistance and capacitance scale factors for optimal RC correlation by comparing the SPEF files generated by native extraction either with the user-specified reference RC data or with the automatic running of extraction in the higher accuracy mode. After generating the scale factors, the command prints a summary of the scale factors to a file. You can use this file to set the actual scale factors.

This command allows you to generate scale factors for one engine or multiple engines, depending on the parameters you specify. You can run preRoute (`-preroute`), or postRoute (`-postroute`) or both types of extraction to generate scale factors. For postRoute extraction, you can run extraction with effortLevel low or with effortLevel low and medium. The reference for comparison can be either an external SPEF or a SPEF generated from the postRoute extraction engine with the specified effortLevel.

When using an external SPEF as reference, use the `-spefMapFile` parameter to specify the name of a file containing multiple SPEF files for use in an MMMC setup.

Note: A Standalone Quantus extraction licence is required to run sign-off extraction in this command. Specify the Quantus path in the path setup. If you do not have a Standalone Quantus extraction license, you can use the `-spefMapFile` parameter to specify the signoff SPEF file(s). In addition, a proper setup of Quantus technology file(s) is required when specifying `-reference medium, high` or `signoff`.

Parameters

`-help`	Outputs a brief description that includes type and default information for the `generateRCFactor` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man generateRCFactor`
`-outputFile file_name`	
	Specifies the name of the file in which the command will save the new RC factor setting. You can use this file to set the actual scale factors.
`-preroute {true | false}`	
	Generates the scale factor for preroute extraction. When set to `true`, generates optimal scale factors for both signal nets and clock nets for preroute extraction. *Default*: `true`
`-postroute {low | medium}`	

	Specifies whether scale factors are to be generated for postRoute extraction. It also specifies whether scale factors are to be generated for engine with effortLevel low only, or for both engines with effortLevel low and medium. If the `-postroute` parameter is not specified, scale factors are not generated for postRoute extraction. When you use the `-postroute low` parameter, the software generates different scale factors for signal nets and clock nets.
`-reference {low | medium | high | signoff | externalSpef}`	
	Specifies the postRoute engine or external SPEF that you want to use as reference for comparison. *Default*: `signoff` If you specify `externalSpef`, you should use the `-spefMapFile` parameter to specify the third party SPEF file(s) to be used for comparison.
`-spefMapFile` *`file_name`*	

	Specifies the SPEF map file to be used for comparison when using MMMC designs. When you use this parameter, the design must be placed and fully routed, and the referenced SPEF file must be the one generated from the same routed design.
	The map file has a list of RC corners and the corresponding SPEF file for each RC corner, as shown in the following example:
	`rcmin design_rcmin.spef`
	`rcmax design_rcmax.spef`

`-use_ostrich_filters file_name`	

	Specifies the filename containing user-specified ostrich filter values for Tcap, res, and Xcap. These user-specified values are applied during the Ostrich run.
	In case this parameter is not specified by the user, default ostrich filter values will be used.
	The format of the file to be specified by the users for ostrich filters is:
	`-tcap {-min_data <value> -max_data <value> -min_fanout`
	`<value> -max_fanout <value> -max_perc_dev <value>}`
	`-res {-min_data <value> -max_data <value> -min_fanout <value>`
	`-max_fanout <value> -max_perc_dev <value>}`
	`-xcap {-min_data <value> -max_data <value> -min_fanout`
	`<value> -max_fanout <value> -max_perc_dev <value>}`

Examples

- The following command generates the resistance and capacitance scale factors for the postRoute engine with effortLevel low in an MMMC design by comparing the parasitics with the SPEF file from signoff extraction:

  ```
  generateRCFactor -preroute false -postroute low -reference signoff -outputFile low_signoff.tcl
  ```

  Following are some sample sections in the log file for the above command:

  ```
  ======================================================
  Summary of scale factor generation
  ======================================================
  RC-Corner Name: rc_typical
  Extraction Engine "Postroute", Effort Level "low"
  Cap scale factor : 0.973457
  Res scale factor : 1.015816
  XCap scale factor : 0.91458
  Clock Cap scale factor : 1.031517
  Clock Res scale factor : 1.000277
  RC-Corner Name: rc_best
  Extraction Engine "Postroute", Effort Level "low"
  Cap scale factor : 1.087774
  Res scale factor : 0.843309
  XCap scale factor : 1.137418
  Clock Cap scale factor : 1.11112
  Clock Res scale factor : 0.827263
  RC-Corner Name: rc_worst
  Extraction Engine "Postroute", Effort Level "low"
  Cap scale factor : 0.92273
  Res scale factor : 1.186163
  XCap scale factor : 0.809296
  Clock Cap scale factor : 0.994961
  Clock Res scale factor : 1.170787
  Finished correlation ......................
  ```

- The following command generates scale factors for preroute and postroute -effortLevel low engines in an MMMC design by comparing the parasitics with an external supplied list of SPEF files:

  ```
  generateRCFactor -preroute true -postroute low -reference externalSpef -spefMapFile
  preRoute_mapFile
  ```

  In this example, the SPEF files specified in the file referenced in the `-spefMapFile` parameter must be generated using a postroute extraction tool on the same routed design.

```

Returns information about the specified `setExtractRCMode` parameter in the Innovus log file and the console. The following information is returned:

- Parameter name
- Current value
- Type (Boolean, string, and so on)
- Whether the current value was set by user

If you do not specify a parameter, the software displays information for all the `setExtractRCMode` parameters.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `getExtractRCMode` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man getExtractRCMode`
`parameter_names`	Displays information for the specified parameters. You can specify one or more parameters. See `setExtractRCMode` for descriptions of the extraction setup parameters you can specify.
`-quiet`	Displays the current settings for the specified parameters in Tcl list format only. If you specify `-quiet` without any parameters, the software displays the current settings of all `setExtractRCMode` parameters in Tcl list format.

Examples

- The following command displays the current setting for the `-viaCap` parameter:
  ```
  getExtractRCMode -viaCap
  ```
  The software displays the following information:
  ```
  -viaCap true # bool, default=true
  true
  ```
- The following command displays the current settings for the `-viaCap` and `-engine` parameters:
  ```
  getExtractRCMode -viaCap -engine
  ```
  The software displays the following information:
  ```
  -viaCap true # bool, default=true
  -engine preRoute # enums={preRoute postRoute}, default=preRoute, user setting
  {viaCap true} {engine preRoute}
  ```
- The following command displays the current setting for the `-viaCap` parameter in Tcl list format only:
  ```
  getExtractRCMode -viaCap -quiet
  ```
  The software displays the following information:
  ```
  true
  ```
- The following command displays the current settings for the `-viaCap` and `-engine` parameters in Tcl list format only:
  ```
  getExtractRCMode -viaCap -engine -quiet
  ```
  The software displays the following information:
  ```
  {viaCap true} {engine preRoute}
  ```
- The following command displays the current settings for all `setExtractRCMode` parameters in Tcl list format only:
  ```
  getExtractRCMode -quiet
  ```

Related Commands

- extractRC
- setExtractRCMode

rcOut

```
rcOut
[-help]
[-excludeIlm]
[-noRes]
[-useEEQCellWithLibertyInfo]
{{{-spef fileName}[-excNetFile fileName | -net fileName | -netName list_of_nets]}}
[-view viewName | -rc_corner rcCornerName]
[-cUnit {pF fF}]
```

Reads the parasitic database and outputs the parasitics in the Standard Parasitic Exchange Format (SPEF).

Parameters

`-help`	Outputs a brief description that includes type and default information for each `rcOut` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man rcOut`
`-cUnit` *unit*	Specifies the unit of capacitance as `fF` or `pF` in the output SPEF file. *Default:* `pF`

`-excludeIlm`	Writes out only the top-level SPEF while excluding the ILM parasitics.
	Note: When this parameter is specified, the top cell-name is suffixed in the SPEF output filename.
	For example, if `test.spef` is the name of the SPEF file and `top_cell_name` is the cell-name, then when you run below command:
	`rcOut -spef test.spef -excludeIlm`
	The output SPEF filename will be:
	`test.spef.top_cell_name`

`-excNetFile` *fileName*	Specifies the name of the file that contains nets to be excluded from the output file.
`-net` *fileName*	Specifies the name of the input file that contains the net names to be extracted. *Default:* Extracts all net names
`-netName` *list_of_nets*	Specifies the names of the nets to be written in the SPEF file. *Default*: Writes all nets

`-noRes`	Generates a SPEF file without the resistance information. The SPEF file generated by this parameter can only be used to improve the performance of third-party simulator tools in early stages of the design. **Caution**: Most tools expect the resistance information to be present in the SPEF file for performing extraction. Therefore, SPEF files with no resistance information should not be used with Ostrich for RC correlation.
`-rc_corner` *rcCornerName*	Specifies the RC corner that is used to generate the parasitic output file in the multi-corner flow.
`-spef` *fileName*	Specifies the name of the SPEF output file. If you add `.gz` as a suffix, the `rcOut` command automatically compresses the generated file.
`-useEEQCellWithLibertyInfo`	Writes EEQ master cell in case the EEQ cells are present.
`-view` *viewName*	Specifies that the RC corner associated with the specified view is used to generate the output SPEF file in the multi-corner flow.

Examples

- Use any of the commands listed below to read the parasitic database created during RC extraction and write parasitic information for two nets for `corner1` in SPEF format to the specified file:

```
rcOut -spef spefFile -rc_corner corner1 -netName [ list net1 net2 ]
```
OR
```
rcOut -spef spefFile -rc_corner corner1 -netName {net1 net2}
```
OR
```
rcOut -spef spefFile -rc_corner corner1 -netName "net1 net2"
```

Related Information

- `spefIn`
- The following topics in the *Innovus User Guide*
  - Performing Extraction in Innovus
  - Correlating Native Extraction With Sign-Off Extraction

read_parasitics

```
read_parasitics
[-help]
[-force]
[-rc_corner_map rc_corner1:spef_field1 rc_corner2:spef_field2 ...]
[-starN]
{[{{[-rc_corner <string>]}}]}
[-via_variation_file viaVariationFile]
```

Reads the SPEF and RCDB-based RC parasitics information and information from the RCDBs already created in Innovus. For hierarchical designs, use this command to read top-level as well as block-level parasitic information.

Note: The following are important aspects to be considered for using this command:

- The RCDB parasitic file must have the `.rcdb.d` extension.
- The RCDB-based parasitic data that is provided as input to this command must be the one that was saved in the same major release of the software. The command will not read the RCDB data saved in a previous release. For example, if you provide RCDB saved in the software's 10.1.x release as input to the `read_parasitics` command in the software's 11 release, then it cannot be read.
- Only the RCDB parasitic data on systems that are same as those used for saving the data can be read. For example, if the data is saved on Linux in 64-bit mode, you can only restore it on Linux 64-bit mode.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `read_parasitics` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man read_parasitics`
`-force`	Allows reading of parasitic data even when block level RCDB/ SPEF is missing for a corner. **Note:** This parameter is only applicable for hierarchical designs. It is required that the top cell should have parasitic data specified for all the active RC corners.
`-rc_corner` *list of RCcorner specific RCDBs/SPEFs for hierarchical design | RCcorner specific RCDB/SPEF*	
	Specifies the RC corner name along with a corner-specific RCDB or SPEF for both top and block levels. For hierarchical designs, this parameter lists the corner-specific SPEFs/RCDBs for both top and block levels. **Note:** A corner-specific RCDB parasitic file can only be provided as input to the RC corner for which it was generated. It cannot be provided as input to other RC corners.
`-rc_corner_map` *rc_corner1:spef_field1 rc_corner2:spef_field2 ...*	
	Provides a mapping of RC corners to the SPEF fields of multi-value SPEF files.
`-starN`	Specifies whether or not to read the *N statements in the SPEF file. The *N statements define the location of the RC nodes. When this parameter is specified, the *N statements are read, otherwise the *N statements are ignored.
`-via_variation_file` *viaVariationFile*	

	Specifies the name of the file for modeling via variation. The contents of the file include all the via layer names with the corresponding MEAN_SHIFT and STDDEV so that all the VIA resistance in SPEF can be mapped to their own variation multiplier. This option is used to specify the via_variation file only when the design has a single corner.
	For example,
	`read_parasitics`
	`-rc_corner rcCornerName \`
	`-via_variation_file` *viaVariationFileName*

Examples

- The example below is for hierarchical design with Top (T), Block 1(B1) and Block 2(B2), and two active RC corners, C1 and C2.
  - The following command specifies the RC corner names along with corner-specific RCDB and SPEF for both top and block levels:

    ```
    read_parasitics \
    -rc_corner C1 Top_C1.spef Block1_C1.spef Block2_C1.spef.gz \
    ```

```
-rc_corner C2 Top_C2.rcdb.d Block1_C2.spef Block2_C2.rcdb.d
```

Related Commands

- `extractRC`
- `setExtractRCMode`
- RC Extraction chapter in the *Innovus User Guide*

report_net_parasitics

```
report_net_parasitics
net_name
[-help]
-rc_corner rc_corner_name
[-file_name output_file_name]
```

Reports the RC parasitics of the specified net.

The `report_net_parasitics` command reports a list of attackers in the order of worst coupling capacitance by default. The software determines and reports the probable top N worst attackers for a victim. The command output will show worst coupling capacitance, in addition to RC parasitics.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `report_net_parasitics` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man report_net_parasitics`
`-file_name` *output_file_name*	Specifies the name of the output file.
`-` `rc_corner` *rc_corner_name*	Specifies the RC corner name for which the RC parasitics are to be reported.
net_name	Specifies the name of the net for which the RC parasitics are to be reported.

Example

- The following command reports the RC parasitics for net, NET1 for RC corner, `rc_best`:

```
report_net_parasitics -rc_corner rc_best NET1

Net: NET1
RC Corner: rc_best
Total Cap = 0.473082 ff
Total Res = 2.104041 ohms
Total XCap = 0.334035 ff
Cap Distribution:

Total Ground Cap = 0.139046 ff
XCap With Nets:

NET3 = 0.059964 ff
NET4 = 0.040277 ff
NET5 = 0.233794 ff
```

Related Commands

- extractRC
- setExtractRCMode

report_rcdb

```
report_rcdb
[-help]
rcdb_dir_name
```

Displays the contents of the RCDB being read.

Note:

1. This command is supported only for reading flat single RCDB. Multiple RCDB's cannot be read simultaneously using this command.
2. The RCDB being read must be generated on the same platform and architecture on which it is being read. For example, if you have generated the RCDB on Linux platform, then the `report_rcdb` command cannot report its content on the IBM AIX platform. Similarly, an RCDB generated on a 64-bit system cannot be reported on a 32-bit system.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `report_rcdb` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man report_rcdb`
`rcdb_dir_name`	Specifies the location of the RCDB directory.

Example

- The following command reports the contents of the RCDB being read in the `test.rcdb.d` directory:

```
report_rcdb test.rcdb.d
Opening parasitic data file 'test.rcdb.d/header.da' for reading.
RCDB VERSION           : 11.1
OS-bit                 : 64
OS-endianness          : little-endian
RCDB Compression       : on
RCDB Source            : Innovus
DESIGN                 : test
RC-Corners:            : typical
Coupled                : yes
Node-loc               : no
Statistical            : no
```

Related Commands

- extractRC
- setExtractRCMode

report_unit_parasitics

```
report_unit_parasitics
[-help]
-layer metal_layer_name
-rc_corner rc_corner_name
[-space wire_space_in_um]
[-via_res via_resistance]
[-width wire_width_in_um]
```

Reports unit parasitics for individual metal layers and vias. The report prints the per unit resistance and capacitance for the specified layer. The resistance values are reported in ohms per micron for min width and min spacing of the layer. The capacitance values are reported in femtofarad (fF) per micron for min width and min spacing of the layer.

Via parasitics are printed considering the layer mentioned in the command as the lower layer of the via. The default via specified in the LEF file will be considered in this case.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `report_unit_parasitics` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man report_unit_parasitics`
`-layer` *`metal_layer_name`*	Specifies the name of the metal layer for which the unit parasitics are to be reported.
`-rc_corner` *`rc_corner_name`*	Specifies the name of the RC corner for which the unit parasitics are to be reported.
`-space` *`wire_space_in_um`*	Specifies the wiring space in microns. *Default*: minimum spacing
`-via_res`	When this parameter is specified, the resistances of all vias, whose upper layer is specified using the `-layer` parameter, are reported.
`-width` *`wire_width_in_um`*	Specifies the wiring width in microns. *Default*: minimum width

Examples

- The following command reports the unit parasitics for metal layer, `Metal5`, for the specified RC corner, `rc_worst`:

  ```
  report_unit_parasitics -layer Metal5 -rc_corner rc_worst
  ```

  The software gives the following information:

  ```
  Unit parasitics for layer Metal5 (in fF,ohm)
      RC-Corner = rc_worst
        Cap = 0.213204
        Res = 0.900873
  ```

```
Parasitics for default Via "VIA5_0_VH"
      Via Cap = 0.017901
      Via Res = 8.859576
```

- The following commands reports the unit parasitics for `Metal5` with spacing two times the minimum spacing:

  ```
  report_unit_parasitics -layer Metal5 -rc_corner rc_worst -space [expr 2 * [dbGet [dbGet
  head.layers.extName Metal5 -p].minSpacing]]
  ```

  The software gives the following information:

  ```
  Unit parasitics for layer Metal5 (in fF,ohm)

      RC-Corner = rc_worst

          Cap = 0.188657
          Res = 0.900873

  Parasitics for default Via "VIA5_0_VH"

          Via Cap = 0.017901
          Via Res = 8.859576
  ```

- The following commands reports the unit parasitics for Metal5 with width two times the minimum width:

  ```
  report_unit_parasitics -layer Metal5 -rc_corner rc_worst -width [expr 2 * [dbGet [dbGet
  head.layers.extName Metal5 -p].minWidth]]
  ```

  The software gives the following information:

  ```
  Unit parasitics for layer Metal5 (in fF,ohm)

      RC-Corner = rc_worst
      Cap = 0.198657
      Res = 0.555333

  Parasitics for default Via "VIA5_0_VH"

      Via Cap = 0.017901
      Via Res = 8.859576
  ```

- The following commands reports the unit parasitics for vias with top layer of Metal5:

  ```
  report_unit_parasitics -layer Metal5 -rc_corner rc_worst -via_res
  ```

  The software gives the following information:

  ```
  Unit parasitics for layer Metal5 (in fF,ohm)

      RC-Corner = rc_worst
      Cap = 0.213204
      Res = 0.900873

  Parasitics for default Via "VIA5_0_VH"

      Via Cap = 0.017901
      Via Res = 8.859576
      Other Via res
      VIA45_1C 8.859576
      VIA45_1C_H 8.859576
      VIA45_1C_V 8.859576
      VIA45_1ST_N 8.859576
  ```

```
VIA45_1ST_S 8.859576
VIA45_2C_E 4.429788
VIA45_2C_W 4.429788
VIA45_2C_N 4.429788
VIA45_2C_S 4.429788
VIA45_2ST_N 4.429788
VIA45_2ST_S 4.429788
VIA45_4C 2.214894
```

Related Commands

- extractRC
- setExtractRCMode

reset_parasitics

```
reset_parasitics
[-help]
```

Deletes the parasitic database without resetting the extraction modes specified using the `setExtractRCMode` command.

Parameter

`-help`	Outputs a brief description of the `reset_parasitics` parameter.

Related Commands

- `extractRC`
- `setExtractRCMode`

restoreRC

```
restoreRC
[-help]
dirName
```

Restores the RC extraction data that was previously saved either with the `saveDesign name -rc` or the `saveRC` command.

Note: The systems you use to save and restore RC extraction data must match (32-bit or 64-bit data models).

Parameters

`-help`	Outputs a brief description that includes type and default information for the `restoreRC` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man restoreRC`
dirName	Specifies the location of the RCDB directory. The syntax of the directory name is `*.rcdb.d`. For example, you can restore the parasitic data in `test.rcdb.d`.

Related Commands

- `saveRC`
- `saveDesign`

saveRC

```
saveRC
[-help]
dirName
```

Saves the RC extraction data in the specified directory. Use the `restoreRC` command to restore the parasitic data. Use this command after running either `extractRC` or `spefIn` to ensure that the parasitic data is available in Innovus database.

Note: You can restore the parasitic data on systems that are same as those used for saving the data. For example, if the data was saved on Linux in 32-bit mode, you can restore it on Linux 32-bit mode only.

Parameters

`-help`	Outputs a brief description that includes type and default information for the `saveRC` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man saveRC`
`dirName`	Specifies the location of the RCDB directory. The directory name should follow the `*.rcdb.d` format.

Related Commands

- `restoreRC`
- `extractRC`
- `spefIn`

setExtractRCMode

```
setExtractRCMode
[-help]
[-reset]
[-assumeMetFill scalevalue]

[-turboReduce {true | false | auto}]
[-useQrcOAInterface {true | false}]
[-useShieldingInDetailMode {true | false}]
[-viaCap {true | false}]
[-writeDefOptionsForSignoffExtract list_of_def_options]
```

Sets the native RC extraction mode. Use this command before using the `extractRC` command. You can use the `setExtractRCMode` command multiple times during an Innovus session to specify additional parameters or change the previously defined values for the extraction mode. You can perform RC extraction during preRoute and postRoute stages, and select an extraction engine based on the expected run time and accuracy level. Each extraction engine supports a specific set of `setExtractRCMode` command parameters. The following table lists the engine support for each parameter.

Note: In previous releases, the `setExtractRCMode` command accepted incomplete parameter names. Now, only complete parameter names are recognized by the software. If you enter an incomplete parameter name, the software will return an error that the given parameter is not a legal argument. To avoid this error, update your scripts to use the legal (documented) parameter syntax.

setExtractRCMode Parameters	PreRoute Extraction Engine	PostRoute Extraction Engine low	PostRoute Extraction Engine Medium & high	PostRoute Extraction Engine signoff
-assumeMetalFill	X	X		
-capFilterMode		X	X	X
-compressOptMemRCDB		X	X	
-coupling_c_th (-coupled true only)		X	X	X
-coupled		X	X	X
-defViaCap	X			
-effortLevel		X	X	X
-extraCmdFile			X	
-extractionFillStreamMapFile				X
-hardBlockObs		X		
-pvs_fill				X
-qrcCmdFile				X
-qrcCmdType				X
-relative_c_th		X	X	X
-reset	X	X	X	X
-signoff_stream_layer_map				X
-specialNet	X	X		
-total_c_th		X	X	X
-turboReduce {true | false}			X	X
-useShieldingInDetailMode		X		
-viaCap		X		

Parameters

`-help`	Outputs a brief description that includes type and default information for each `setExtractRCMode` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setExtractRCMode`

`-assumeMetFill` *scalevalue*	Takes into account the metal fill in the design. For postRoute extraction, only extraction engine with `-effortLevel low` supports this parameter. In postRoute extraction with `-effortLevel low`, *scalevalue* is not required and will be ignored. Detail extraction uses the `FILLACTIVESPACING` values from LEF to account for metal fill in the design. If the `FILLACTIVESPACING` values are not specified in the LEF file, the software uses the default value, which is `0.6um`. In preRoute extraction, when calculating the capacitance of a wire segment in layer *N*, this parameter always assumes layer *N-1* and layer *N+1* to be filled. Specify one of the following values: • `0`: Assume no metal fill in layer *N*. ▪ When you do not specify this parameter, the software assumes no metal fill in layer *N*. This is equivalent to setting the *scalevalue* parameter to `0`. • `1`: Assume full metal fill at minimum spacing distance. ▪ Where there is a minimum of signal-to-signal spacing, the cross-coupling capacitance will be extracted and reported. ▪ Where there is no wire within the minimum spacing, a capacitance to ground will mimic minimum-spaced metal fill in that location. • x: Capacitance value is calculated once with full metal fill and once without metal fill. The user-specified scale value (decimal value between 0 and 1) determines the interpolation point between the two calculated values, for example, `0.5` *Default:* 0
`-capFilterMode { relOnly | relAndCoup | relOrCoup }`	

	Specifies the capacitance filtering mode. The filtering modes are conditions which define how to use the `-coupling_c_th` and `-relative_c_th` values, or their combination. Based on the filtering mode specified, the software determines the nets in the design, which will have their coupling capacitance lumped to the ground. **Note**: TQuantus only supports the `relandCoup` mode of this parameter. It does not support the `relOnly` and `relOrCoup` modes as they are for old nodes only. **Note:** The behavior of the `-total_c_th` filter is independent of the `-capFilterMode` parameter setting. Nets that have a total capacitance value lower than the value specified with the `-total_c_th` parameter will have their coupling capacitances grounded regardless of the `-capFilterMode` setting. You can use one of the following modes: • `relOnly`: Grounds the coupling capacitance of nets based on the threshold value set by the `-relative_c_th` parameter. • `relAndCoup`: Grounds the coupling capacitance of nets only when it is lower than the threshold value specified with the `-relative_c_th` parameter as well as the `-coupling_c_th` parameter. In this mode, you enforce maximum restriction on grounding the coupling capacitances. • `relOrCoup`: Grounds the coupling capacitance of nets if it is lower than the threshold value specified with one of the `-relative_c_th` or `-coupling_c_th` parameters. *Default*: For TQuantus, IQuantus, and Standalone Quantus extraction, the default value is `relAndCoup`. For postRoute extraction with `-effortLevel low`, the default value is dependent on the process node specified with the `setDesignMode -process` command. If the process node is 130nm or below, the default value is `relAndCoup` and if the process node is above 130nm, the default value is `relOnly`.
`-cerebrus_license_only {true | false}`	This parameter is applicable to the Cerebrus-Quantus flow. When set to `true`, only the Cerebrus license will be considered and Innovus will not fall back to use Quantus license when Cerebrus license(s) is/are not available. By default, the option is set to `false`, which means the regular Quantus license will be considered when Cerebrus license(s) is/are not available. *Default*: `false`
`-compressOptMemRCDB {true | false }`	

	Generates compressed RCDB data. *Default*: `false` **Note:** This functionality reduces the disk usage but leads to marginal increase in run time.
`-coupled {true | false}`	Separately outputs grounded and coupling capacitance. The `-coupled` false value is typically used for static timing analysis. Signal Integrity analysis requires the coupled mode. *Default:* `true` (for postRoute extraction) **Note**: The TQuantus extraction engine supports this parameter.
`-coupling_c_th` *value_in_fF*	Specifies the threshold value that determines when the extractor lumps a net's coupling capacitance to ground. This parameter is applicable only when the `-coupled` parameter is set to `true`. The software decouples the coupling capacitance of nets when the total coupling capacitance between the pair of nets is lower than the threshold specified with this parameter. The actual decoupling also depends on the setting of the `-capFilterMode` parameter. *Default:* `0.2fF`. If the `setDesignMode -process` *process_node* command is used, the software assigns the recommended default value for this parameter based on the process node specified. **Note**: See the `setDesignMode` command for the list of default values that are applied based on the process node setting. **Note**: The TQuantus extraction engine supports this parameter.
`-defViaCap {true | false}`	Takes into account the via capacitance in the preRoute RC extraction results. Specify a value of `true`, if you are experiencing correlation issues caused by deviations in clock latency when running preRoute RC extraction. *Default*: `false` **Note**: For 20nm and below nodes, the default value of this parameter is set to `true`.
`-effortLevel { low | medium | high | signoff }`	

	Specifies the postRoute engine variant that you want to use for performing RC extraction. *Default*: `low` **Note**: TQuantus (`-effortLevel medium`) is the default extraction engine in the postRoute flow for 65 nm and below designs. However, TQuantus and IQuantus require a Quantus Techfile. Therefore, Native Detailed (`-effortLevel low`) engine remains the default engine if no Quantus Techfile has been defined. This parameter supports the following values: • `low`: Invokes the native detailed extraction engine. This is the same as specifying the -engine postRoute setting. • `medium`: Invokes the TQuantus extraction engine. This engine supports distributed processing. TQuantus engine is recommended for process nodes < 65nm. For this effort level, specify the extra command file using the `-extraCmdFile` parameter. • `high`: Invokes the Integrated-Quantus (IQuantus) extraction engine. IQuantus provides superior accuracy compared to TQuantus. IQuantus is recommended for extraction after ECO. In addition, IQuantus supports distributed processing. For this effort level, specify the extra command file using the `-extraCmdFile` parameter. **Note**: IQuantus requires a Quantus-XL license. • `signoff`: Invokes the Standalone Quantus extraction engine. This engine choice provides the highest accuracy. The engine has several runModes, thereby, providing maximum flexibility. For this effort level, specify the extra command file using the `-qrcCmdFile` parameter.
`-engine { preRoute | postRoute }`	Specifies the extraction engine to use. • `preRoute`: Uses preRoute engine. RC extraction is done by the fast density measurements of the surrounding wires; coupling is not reported. Use this mode to perform extraction on pre-routed designs after clock tree synthesis. • `postRoute`: Uses postRoute engine. RC extraction is done by the detailed measurement of the distance to the surrounding wires; coupling is reported. The `-effortLevel` parameter further specifies which postRoute engine is used for balancing performance versus accuracy needs. *Default:* `preRoute`
`-extraCmdFile` *fileName*	

Specifies the Quantus extra command file for TQuantus/IQuantus extraction. The extra command file supports the following variables:

- `log_file -dump_options {`**`true`** `| false}`
- `extraction_setup -copy_port_to_obs {`**`true`**`|false}`
- `extraction_setup -remove_net_pin_overlap {true |`**`false`**`}`
- `metal_fill -type {grounded |` **`floating`** `| virtual}`
- `output_setup -compress_temporary_files {true |` **`false`**`}`

Notes:

- TQuantus only supports advanced virtual metal fill in `metal_fill` in the extra command file. It does not support the grounded and floating options.
- When the `metal_fill` type is virtual, provide the absolute paths to the vmf rule file and the metal schema file. For example,

```
metal_fill \
     -type virtual \
     -enable_advanced_virtual_fill true \
     -vmf_metal_scheme_file
     .../saveTestcase_vmf/missing_vmf_files/abc.vmf_metal_scheme
     \
     -vmf_rule_file
     .../saveTestcase_vmf/missing_vmf_files/abc.vmf_rule
```

- The `-extraCmdFile` parameter becomes “non-portable” if the vmf rule file and/or schema file have been specified. This means that the two file paths will not be automatically modified or ported. You can modify the file paths, if required. To make the extra command file portable, ensure that the vmf rule file and schema files are available at the locations specified in the extra command file.
- The **bold** text in the above example indicates that these values are used by default when the commands are not explicitly specified in the extra command file. For example, IQuantus extracts the “**`floating`**” metal fills by default when either the `-extraCmdFile` option is not specified or the `metal_fill` variable is not specified in the extra command file.
- This parameter is only valid if `-effortLevel medium` or `high` is specified.
- This parameter is not available on the IBM platform.

Default: `" "`

`-extractionFillStreamMapFile` *`fileName`*	This parameter is specified only when `-pvs_fill` parameter is set to `true`. When the `-pvs_fill` parameter is set to `true`, a Quantus stream/oasis map Tcl command is required to map the PVS layer/dtype data to the corresponding Quantus layers.
	If the `pvs_fill.data` is generated based on stream (GDS), the map file should be in the following format:
	`#layer gds_layer gds_dtype`
	`<layer_name> <layer_number> <data_type>`
	…
	If the `pvs_fill.data` is generated based on OASIS, the map file should be in the following format:
	`#layer oasis_layer oasis_dtype`
	`<layer_name> <layer_number> <data_type>`
	…
	Where,
	• `layer_name` is the layer name in the design
	• `layer_number` is the layer ID in the GDS/OASIS file
	• `data_type` is the datatype specified in the GDS/OASIS file
	For example,
	`M1 31 0`
	`M1 31 1`
	`M2 32 0`
	`M2 32 1`
	Note: This parameter only affects signoff Quantus extraction.
	Default: `" "`

`-hardBlockObs {true | false}`	Makes cell geometries on metal layers from obstruction, and power and ground pin shapes visible to the extractor for hard blocks only. The software recognizes the following three types of hard blocks: • Hard macro (`CLASS BLOCK` in LEF file) • Blackbox (`CLASS BLACKBOX` in LEF file) • Partition (Committed during the Innovus session) Specify a value of `true` when routing goes over the listed hard blocks. A value of `true` removes the optimism for such routes, and provides better correlation with sign-off extraction without significantly impacting runtime. **Note**: This parameter is not supported when the extraction engine is TQuantus. *Default:* `false`
`-incremental {true | false}`	Uses incremental IQuantus extraction mode. If the incremental mode is set after performing initial extraction on full design, extraction checks for design changes, and if the amount of changes are below threshold, extraction is rerun in incremental mode on the modified areas only. Incremental mode can provide significant performance improvement during signal integrity optimization phase. *Default:* `true`
`-layerIndependent {0 | 1}`	
	By default, this parameter is set to `1`. In this mode, layer-independent extraction is enabled. This mode of extraction is recommended for designs with layer stacks that have significant variations in RC characteristics. This mode uses advanced techniques to avoid timing jumps due to differences in routing-layer assignments between preRoute and postRoute stages. When set to `0`, layer-independent extraction is disabled. **Note**: PreRoute extraction scale-factors should be computed without setting this mode. *Default*: `1`

`-lefTechFileMap` *`fileName`*	Specifies the location of the optional layer map file for the IQuantus and Standalone Quantus engines.
	
	Note: For IQuantus, layer mapping between the LEF or DEF file and the Quantus technology file is done automatically. This parameter is only necessary if this mechanism fails. If necessary, you can use a copy of the automatically generated layer map file `extLogDir/IQRC_*/<design>.layermap.log` and modify it for your own use.
	
	Layer map file is required for use with Standalone Quantus.
	
	For TSV designs, you are required to provide the name of the layer map file for IQuantus and Standalone Quantus.
	
	Note: If used, the layer map file must be in the Common Command Language (CCL) format.
	
	The following is an example of the layer map file format:
	
	`extraction_setup \`
	`-technology_layer_map \`
	`# <LEF/DEF Name> #<Tech File Name>`
	`M1 METAL_1 \`
	`VIA1 VIA_1 \`
	`M2 METAL_2 \`
	
	Note: For cell-level IQuantus layer map, the DEF/LEF layer names are case sensitive, but ICT layer names are case-insensitive.
	
	Note: TQuantus is not impacted by this parameter because it always automatically generates the layer map.
	
	Default: `" "`

`-localCpu` *`number_of_cpus`*	Specifies the number of CPUs to be used for IQuantus extraction. **Note**: • This option is only applicable for IQuantus extraction engine. • When specified, it overrides the `setMultiCpuUsage -localCpu` option for IQuantus. *Default*: As specified in the `setMultiCpuUsage -localCpu` setting.
`-pvs_fill`	When set to `true`, the PVS fill data attached to the Innovus database is sent to Quantus so that the effects of the fill data are extracted. This parameter only affects signoff Quantus extraction. It has no effect on tQuantus or iQuantus extraction done inside Innovus. This parameter requires that either the `-extractionFillStreamMapFile` parameter or the `-signoff_stream_layer_map` parameter is specified. *Default*: `false`

`-qrcCmdFile` *fileName*	Specifies the user created Quantus command file to be used for running Standalone Quantus. This command file should be in the new CCL syntax. **Note:** This parameter is only valid if `-effortLevel signoff` and `-qrcCmdType` partial or custom is selected. *Default*: `" "`
`-qrcCmdType {auto | partial | custom}`	
	Specifies whether to derive the settings for running Quantus from the Innovus settings, or from user-created command file using the `-qrcCmdFile` parameter. The `-qrcCmdType` parameter is only valid if `-effortLevel signoff` is selected. This parameter supports the following values: • `auto`: Derives the Quantus settings automatically from the Innovus parameter settings. **Note**: In this mode, the `-lefTechFileMap` parameter is required to be specified. • `partial`: Appends user commands from the qrcCmdFile to the settings derived from the Innovus parameter settings. You must provide the partial mode command file in CCL syntax. Use the `partial` command file only when you add extraction directives for those options that cannot be set in Innovus. Following are some important restrictions: ◦ Do not specify the following options in the partial mode command file: ▪ Threshold setting ▪ Coupled/decoupled mode ▪ Quantus Techfile (s) ▪ Operating Temperature ◦ Do not specify the "`-directory_name`" and "`-temporary_directory_name`" in the `output_setup` section of the command file ◦ Do not specify output file using `output_setup -file_name` command in the partial command file **Note**: The multi-temperature multi-corner extraction (MTMC) feature is enabled in the partial mode only if process technology is not specified in the user command file. In MTMC extraction, for RC corners with same Quantus technology file but different temperatures, resistance is extracted for multiple corners while capacitance is extracted only for a single corner.

	Note: There is no checking for syntax or content of this file. This file is appended as is to the automatically created Quantus command file. • `custom`: Gets the complete Quantus settings from the user-created command file. Except for input and output, no settings from Innovus parameters are used. You must provide the complete Quantus command file in CCL syntax. Following are some important restrictions for using custom command file: ◦ Do not specify an input DEF/OA DB in the custom mode command file ◦ Do not specify the "`-directory_name`" and "`-temporary_directory_name`" and "`-file_name`" in the `output_setup` section of the command file. ◦ Specify the output SPEF file with the following convention for the name:`<design.spef>`. In the MMMC mode, the output SPEF files will be named: `<design>_<corner>_<Temperature>.spef`. Here "design" refers to the top cell name. **Note:** Do not prefix or postfix the output file name. ◦ Specify the Quantus Techfile(s) to be used. In the MMMC mode, the corner names should match the names used in the `create_rc_corner` command ◦ Provide Quantus Techfile layermapping information in the custom command file ◦ If GDS is provided for cell contents, provide a Quantus Techfile to GDS layer number matching **Note**: The MTMC extraction feature is not enabled in the custom mode of Quantus extraction. **Note:** There is no checking for syntax or content of this command file prior to running the extraction. The command file will be used as is. If the output file is not specified correctly, the resulting parasitic file will not be read into the Innovus RC database. *Default*: `auto`
`-qrcOutputMode {rcdb | spef}`	
	Sets the Quantus output write mode to RCDB or SPEF. **Note:** This parameter is only valid if `-effortLevel` is `signoff`. *Default:* `spef`
`-qrcRunMode {concurrent | sequential}`	

	Specifies the Quantus run mode in MMMC designs. Note*:* For MMMC designs, in Quantus partial command type, do not specify the output SPEF file name and RC corner name in the command file to run Quantus in concurrent or sequential mode. For MMMC designs, in Quantus custom command type, do not specify the output SPEF file name and RC corner name together in the command file. Quantus sequential mode is not supported in custom command type. This parameter supports the following values: • `Concurrent`: Runs Quantus for all active corners concurrently. • `Sequential`: Runs Quantus for all active corners sequentially. *Default*: `concurrent`
`-relative_c_th` *value*	Sets a ratio threshold value that determines when the extractor lumps a net's coupling capacitance to ground. This parameter is applicable only when the `-coupled` parameter is set to `true`. If the total coupling capacitance between a pair of nets is less than the percentage (specified with this parameter) of the total capacitance of the net with the smaller total capacitance in the pair, the coupling capacitance between these two nets will be considered for grounding. The actual decoupling also depends on the setting of the `-capFilterMode` parameter. The range of this value is 0 to 1. If the `setDesignMode -process` *process_node* command is used, the software assigns the recommended default value for this parameter based on the process node specified. **Note**: See the `setDesignMode` command for the list of default values that are applied based on the process node settings. **Note**: The tQuantus extraction engine supports this parameter. *Default:* 0.03
`-reset`	Resets the extraction status of the loaded design and the `setExtractRCMode` parameters to their default values. The `-reset` parameter *must* be the first parameter specified. If you specify `-reset` by itself, the software resets all `setExtractRCMode` parameters to their default values. If you specify parameters after `-reset` , the software resets only those parameters to their default values. Any values that do not already match the default value and are reset will be reported.

`-signoff_stream_layer_map` *fileName*	This parameter is specified only when the `-pvs_fill` parameter is set to `true`. When the `-pvs_fill` parameter is set to `true`, a Quantus stream/oasis map Tcl command is required to map the PVS layer/dtype data to the corresponding Quantus layers.
	If the `pvs_fill.data` is generated based on stream (GDS/OASIS), the map file should be in the following format:
	`#layer gds_layer gds_dtype use-type color-ID`
	`<layer_name> <layer_number> <data_type> <use-type> <color-ID>`
	…
	Where,
	• `layer_name` is the LEF layer name in the design
	• `layer_number` is the layer ID in the GDS/OASIS file
	• `data_type` is the datatype of the layer in the GDS/OASIS file
	• `use_type` is the keyword for identifying the use of the data. The valid values are:
	  ◦ `gray`: library data in the GDS/OASIS file
	  ◦ `fill`: regular metal fill data in the GDS/OASIS file
	  ◦ `active`: active metal fill data in the GDS/OASIS file
	• `color-ID` is the color ID. Use “`1`” or “`2`” if the layer is colored, or use hyphen “`-`” if the layer is not colored
	For example,
	`M1  31  0 gray -`
	`M1  31  1 fill -`
	`M2  32  0 gray -`
	`M2  32  1 fill -`
	Note: This parameter only affects signoff Quantus extraction.
	Default: `""`

`-total_c_th` *value_in_fF*	Specifies the threshold value (femtoFarads) that determines when the extractor lumps a net's coupling capacitance to ground. This parameter is applicable only when the `-coupled` parameter is set to `true`. The software grounds the coupling capacitances for the nets which have a total capacitance value less than the value specified with this parameter. If the `setDesignMode -process` *process_node* command is used, the software assigns the recommended default value for this parameter based on the process node specified. **Note**: See the `setDesignMode` command for the list of default values that are applied based on the process node settings. **Note**: The TQuantus extraction engine supports this parameter. *Default:* `5 fF`
`-tQuantusModelFile` *fileName*	
	Specifies the name of the tQuantus model file to be used for postRoute effort-level medium extraction. You can specify the model file as follows: `setExtractRCMode -engine postRoute -effortLevel medium -tQuantusModelFile tQuantus_model.bin` For details of the use model, see Creating RC Model Data in TQuantus Model File in the *Innovus User Guide*. *Default*: `""` **Note**: If this file is not specified, it will be generated automatically by the software.

`-tsvSubcktFile` *file_name*	Specifies the name of the Through Silicon Via (TSV) subckt file to be used. The file contains the .subckt model information for TSV. The file has a Spice format. A sample file is shown below.
	`.subckt TSV top bottom`
	`R1 top n2 0.03075`
	`R2 n2 bottom 0.03075`
	`C1 n2 0 28f`
	`.ends`
	Where,
	`top` and `bottom` refer to the terminal nodes on the top and bottom layers of the TSV
	`n2` is the internal node between the top and bottom layers
	`R1 top n2 0.03075` means that a resistor with a resistance of `0.03075 Ohms` is added between the `top` and `n2` nodes
	`R2 n2 bottom 0.03075` means that a resistor with a resistance of `0.03075 Ohms` is added between the `bottom` and `n2` nodes
	`C1 n2 0 28f` means that a ground capacitance of `28 fF` is added on the `n2` node
	Note: The IQuantus engine might not keep the subckt connectivity as it is. The optimization of RES network will remove node n2 (if there is no other connections) and keep a single resistor between the top and bottom nodes with an accumulated resistance. For example, in the above example, the accumulated resistance will be `0.0615 Ohms`. Capacitance will also be moved to a “higher layered node”. In the above example, this layer is `top`.
	Default: `""` (empty string)

`-turboReduce {true|false|auto}`	

	Controls the turbo reduction feature for tQuantus/IQuantus, and Standalone Quantus extraction. It has no effect on tQuantus. This is a cell-level reduction that provides a complimentary reduction capability and only affects the coupling capacitors. It has no effect on lumped capacitor extraction. When set to `auto`, the software automatically turns `on` turbo reduction and proceeds when the required Quantus license is available. However, if the required Quantus license is not installed in the license server, the software automatically turns off Turbo reduction and proceeds with a warning message. If the license is installed in the license server but temporarily not available, then two scenarios are possible. First, if the license wait mode is not turned on, then Quantus will look for the license right away and error out because the license is not available. Second, if the license wait mode is turned on, then IQuantus will wait and check for the license periodically until timeout. If the license is available before the timeout, turbo reduction will be performed but if the license is not available before timeout, IQuantus will error out. When set to `true`, the turbo reduction engine is `on`. However, if the required Quantus license is not installed in the license server, then Standalone Quantus and IQuantus will error out with a message and the run will stop. It is because setting the option to true means the user really wants to perform turbo reduction. When set to `false`, the turbo reduction engine is switched `off`. For details, see the table titled, Behavior of Turbo Reduction, below. However, note that the licensing rules given in this table are not applicable to tQuantus because tQuantus does not require any Quantus license. *Default:* `auto`
`-useQrcOAInterface {true | false}`	
	When set to `true`, specifies that OpenAccess (OA) interface be used for invoking Quantus extraction instead of using the DEF-based flow. *Default*: `false`
`-useShieldingInDetailMode {true | false}`	

	Assumes shielding for any wire segment of a clock net that does not have any shielding yet, and the space between the wire segment and its neighbor is greater than or equal to the following: `2s+w` where, *s* = minimum spacing or non-default spacing *w* = minimum width or non-default width This parameter is available in `postRoute -effortLevel low` mode only. *Default:* `false`
`-viaCap {true | false}`	Extracts capacitance values considering part of the via geometries that do not overlap with the wire geometries. Via geometries that do not overlap the wire geometries are often found if you are designing using newer design technologies such as 90nm or when using multiple cut via. This parameter is only available in `postRoute -effortLevel low` mode. *Default:* `true`
`-writeDefOptionsForSignoffExtract` *list_of_def_options*	Specifies the list of `defOut` options for signoff extraction. For signoff extraction, `setExtractRCMode -engine postRoute -effortLevel signoff`, the software internally calls the `defOut` command. However, in some specific scenarios, you need to provide additional options for the `defOut` command. Use this parameter to provide the list of `defOut` options to be included. When this parameter is specified, `extractRC` will include these options while calling the `defOut` command. *Default:* `""`

Behavior of Turbo Reduction

	Availability of Quantus QRC AA License		
Option Selected (setExtractRCMode –turboReduce true|false|auto)	Quantus QRC AA Installed and Available (IQRC gets the license right away even in the wait mode because sufficient licenses are available in the license server)	Quantus QRC AA Installed but not Available (If license wait mode is not turned on, then Quantus looks for the license . If the wait mode is turned on and if the license is temporarily not available, then IQRC waits and checks for the license periodically until timeout.)	Quantus QRC AA Not Installed on License Server
auto	perform turbo reduction	1. error out if wait mode is not on or if the specified wait time is exceeded 2. perform turbo reduction if wait mode is on and the license is available within the specified time.	print warning and do not perform turbo reduction
true	perform turbo reduction	error out	error out because the user explicitly wants to use turbo reduction
false	do not perform turbo reduction	do not perform turbo reduction	do not perform turbo reduction

Examples

- The following command selects the fastest postRoute extraction engine:

```
setExtractRCMode -engine postRoute -effortLevel low
extractRC
rcOut -rc_corner corner1 -spef fe_extended.spef
```

- The following is a typical command sequence for the metal fill parameter:

```
setExtractRCMode -engine postRoute -effortLevel low
-assumeMetFill 1
extractRC
```

- The following command resets the `-relative_c_th` parameter to its default value:

```
setExtractRCMode -reset -relative_c_th
```

- The following command selects the Standalone Quantus for signoff grade extraction and uses a user supplied command file:

```
setExtractRCMode -engine postRoute -effortLevel signoff -qrcCmdFile
custom_qrc.cmd -qrcCmdType custom
extractRC
rcout -rc_corner corner1 -spef signoff.spef
```

Related Information

- `extractRC`
- `setDesignMode`
- `getExtractRCMode`
- The following topic in the *Innovus User Guide*
  - Performing Extraction in Innovus

setShrinkFactor

```
setShrinkFactor
[-help]
shrinkFactor
```

Sets the value by which the software shrinks the design before extraction. The shrink factor is used only for extraction calculations. It does not change the actual design.

Note: You do not need to specify the shrink factor if the capacitance table file in use contains the shrink factor specification in its header.

Parameters

`-help`	Outputs a brief description that includes type and default information for the `setShrinkFactor` parameter. For a detailed description of the command and its parameter, use the `man` command: `man setShrinkFactor`
`shrinkFactor`	Specifies the value by which the software shrinks a design. *Default:* `1.0`

Example

The following command sets the shrink factor to 0.9:

```
setShrinkFactor 0.9
```

Setting the shrink factor to 0.9 reduces the wire lengths, widths, and spacings in the design by 0.9 times the original values.

spefIn

```
spefIn
[-help]
fileNameList
[-extended]
[-idx]
[-scaleNets netFileName]
[-scaleRC]
[-starN | -noStarN]
[{-rc_corner list_of_rc_corners [-spef_field {1 2 3 … N}]}]
[-via_variation_file viaVariationFileName]
```

Loads resistors and capacitors for the interconnects in SPEF into the Innovus database to calculate delays or build a timing graph. Use this command to read in a SPEF file generated by a third-party extraction tool.

Note: You can use this command to load a SPEF file, which is compressed (`.gzip`) format.

Note: This command supports multi-threaded SPEF reading. The number of CPUs can be specified using the standard use model of Innovus.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `spefIn` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man spefIn`
`-extended`	Enables the reading of "`$llx=<value1> $lly=<value2> $urx=<value3> $ury=<value4> $LAYER=<number>`" to set the layer number for nodes of a resistance from Quantus extended SPEF file. It also reads in extended `*LAYER_MAP section`, if it is present. This parameter can also read in "`$l=<length> $w=<width> $si_w=<swidth> $lvl=<number>`" to set the width, silicon width, or layer for nodes of a resistance from `StarRC` extended SPEF file.
`-idx`	Enables Inter-Die Extraction (IDX) SPEF reading. IDX SPEF models the Inter-Die capacitive impact in the form of coupling and ground capacitances. Individual die and IDX SPEFs need to be extracted by Quantus and in the extended SPEF (xSPEF) format. The `-extended` parameter is also required to be specified to read the xSPEF format. The software also supports multiple IDX SPEF reading. Flat die-level SPEFs need to be specified along with IDX SPEFs. With the `-idx` parameter, die-level and IDX SPEFs can be specified in any order.
fileNameList	Specifies a SPEF file or list of SPEF files as input for flat chip or hierarchical SPEF stitching, respectively.
`-rc_corner` *list_of_rc_corners*	Annotates the parasitics to the predefined RC corners for multi-corner analysis. You can specify a list of RC corners to be annotated. If you want to use SPEF information when calculating delays in multi-mode multi-corner analysis (MMMC) mode, you must annotate the parasitics for all RC corners in the design.

A few examples are provided below to explain different scenarios of specifying rc corners are their corresponding corner indices and SPEF files.

- `spefIn -rc_corner {rcCorner1 rcCorner2 rcCorner3 rcCorner4 rcCorner5} -spef_field {1 2 3 4 5} rc-spef.gz`

  This means that SPEF file can contain parasitics from N RC corners and names of RC corners in the RC corner list map to the index fields specified using the `-spef_field` option as shown above. Assuming that the SPEF file, `rc-spef.gz` has RC fields from the specified five RC corners, the above command would be interpreted as follows:
  1st field in SPEF maps to RC corner, `rcCorner1`
  2nd field in SPEF maps to RC corner, `rcCorner2`
  3rd field in SPEF maps to RC corner, `rcCorner3`
  4th field in SPEF maps to RC corner, `rcCorner4`, and
  5th field in SPEF maps to RC corner, `rcCorner5`

- `spefIn -rc_corner {rc_max rc_min} -spef_field {2 5} rc-spef.gz`

  Assuming `rc-spef.gz` in above example has RC fields from "N" RC corners, the above command would read SPEF data for two RC corners only and would be interpreted as follows:
  2nd field in SPEF maps to RC corner, rc_max
  5th field in SPEF maps to RC corner, `rc_min`

- `spefIn -rc_corner {rcCorner1 rcCorner2 rcCorner3} -spef_field {1 1 3} rc-spef.gz`

  Assuming `rc-spef.gz` in the above example has RC fields from N RC corners, the above command would read SPEF data for 3 RC corners only and would be interpreted as follows:

  1st field in SPEF maps to RC corner, `rcCorner1`
  1st field in SPEF also maps to RC corner, `rcCorner2`
  3rd field in SPEF maps to RC corner, `rcCorner3`

- `spefIn -rc_corner {rcCorner1 rcCorner2 rcCorner3 rcCorner4 rcCorner5} -spef_field {1 2 3 4 5}`
  `{top.spef.gz block1.spef.gz block2.spef.gz}`

  In the above example, hierarchical design SPEF files are read in. It reads top level multi-field SPEF file followed by the multi-field SPEF files from `block1` and `block2`.

Note: SPEF reading will not be triggered until SPEF files for all active RC corners are specified.

`-scaleNets` *`netFileName`*

	Enables the scaling of resistances and capacitances for user-specified nets as per the specified scale factors. The list of nets is specified in a file. The scale factors are specified using the `create_rc_corner` and `update_rc_corner` commands. **Note**: This parameter can only be used if the `-scaleRC` parameter is specified. Otherwise, it will be ignored. For example: `spefIn -scaleRC -scaleNets netFileName -rc_corner r1 detail.spef`
`-scaleRC`	Scales the SPEF read in for the specified corner as per the `postRoute_cap`, `postRoute_xcap`, and `postRoute_res` scale factors defined using the `create_rc_corner` and `update_rc_corner` commands. When this parameter is specified, the scale factors for extraction effort-level `high` are used for RC scaling. However, if they are not available, the priority shifts to the scale factors for effort-level `medium` and `low`, in that order, if specified. **Note**: Scale factors of `postRoute_clkcap, postRoute_clkxcap,` and `postRoute_clkres` are not applied even when the net is a clock attribute.
`-spef_field {1 2 3 … N}`	Specifies the list of RC corner indices in SPEF to be loaded. This parameter provides the flexibility to perform order-independent and field-independent mapping to RC corners. For example, SPEF may contain data for 10 corner fields but you can choose to read data only for 6 corners. You can also choose to use data from one particular field to map to one or more RC corners. A few examples to illustrate different scenarios are provided in the description of the `-rc_corner` parameter above. **Note:** This parameter is relevant only when the `-rc_corner` parameter is specified. The `-spef_field` is an optional parameter, and if not specified, the software assumes the default fields of {1 2 3 … N} where N is equal to the number of RC corners provided in the `-rc_corner` list.
`-starN |-noStarN`	Specifies whether or not to read the *N statements in the SPEF file. The *N statements define the location of the RC nodes. The `-starN` parameter reads the *N statements and the `-noStarN` parameter ignores the *N statements. *Default:* `-StarN` (By default, the software reads the *N statements in the SPEF file.)
`-via_variation_file viaVariationFileName`	

	Specifies the name of the file for modeling via variation. The contents of the file include all the via layer names with corresponding MEAN_SHIFT and STDDEV so that all the VIA resistance in SPEF can be mapped to their own variation multiplier. This option is used to specify the via_variation file only when the design has a single corner.
	
	For example,
	
	`spefIn`
	
	`-rc_corner rcCornerName \`
	
	`-via_variation_file viaVariationFileName`

A sample via_variation file is provided below:

```
// corner_name  : rcMax

// wildcard to cover default
object_type     : design
delay_type      : via

layer_name      : *

area            : 0.20 0.40 0.80

// no nominal for wildcard default
table_min_sigma : 0.80 0.90 0.95

table_max_sigma : 1.60 1.30 1.15

table_meanshift : 0.05 0.03 0.02

table_stdev     : 0.10 0.05 0.02

// per via layer data
object_type     : design
delay_type      : via
layer_name      : VIA1

Area            : 0.0004 0.0008 0.0016

table_min_sigma : 0.80 0.90 0.95

table_max_sigma : 1.60 1.30 1.15

table_meanshift : 0.015 0.015 0.012

table_stdev     : 0.214 0.150 0.117

object_type     : design

delay_type      : via

layer_name      : VIA2

area            : 0.0004 0.0008 0.0016

table_min_sigma : 0.80 0.90 0.95

table_max_sigma : 1.60 1.30 1.15

table_meanshift : 0.015 0.012 0.014

…..

……

table_stdev : 0.223 0.183 0.140
```

Note: Each line in the file lists the basic components of the statistical variation approach.

The values in the "area" line list all possible areas. In the above example, the area line lists three cases that can happen in the design. It can list different number of cases, for example one or four. The subsequent lines list the corresponding values matching to the areas defined in the area line.

Examples

- The following command loads the SPEF file `TOPCHIP_SP.spef` for a flat chip methodology for RC corner, `corner1`:

  ```
  spefIn -rc_corner corner1 TOPCHIP_SP.spef
  ```

- The following command loads multiple SPEF files for hierarchical SPEF stitching:

  ```
  spefIn -rc_corner corner1 { PTN/results_conv/results_conv.spef tdsp_core/tdsp_core/tdsp_core.spef
  PTN/TOPCHIP_SP/TOPCHIP_SP.spef}
  ```

- The following commands first setup the appropriate scale factors for the corners `RCmax` and `RCmin` and then scale the SPEF read for the defined corners `RCmax` and `RCmin`:

  ```
  === MMMC setup ====

  create_rc_corner -name RCmax -postRoute_cap 1.4 -postRoute_xcap 1.4 -postRoute_res 1.4
  create_rc_corner -name RCmin -postRoute_cap 0.8 -postRoute_xcap 0.8 -postRoute_res 0.8
  ...

  === run script===
  ...

  spefIn -rc_corner RCmax typSPEF.spef -scaleRC
  spefIn -rc_corner RCmin typSPEF.spef -scaleRC
  ```

Related Commands

- rcOut

wireload

```
wireload
[-help]
[-outfile fileNamePrefix]
[-scale factor]
[-percent samplingRate]
[-cell cellName | -inst instanceName [-name modelName]]
[-instanceBased]
[-cellLimit moduleSize]
[-custom]
[-noSmooth]
[-netCoverRatio]
[-logarithmic]
[-peakCap]
[-view viewName]
```

Generates the wireload models and outputs the models in hierarchical and flat formats. Use this command after extracting the RC data in your design.

The wireload models in the hierarchical format are generated for cells and instances based on external nets (hierarchical view). The hierarchical format considers only nets that crosses the boundaries of child modules within the module, while the flat format considers all nets within the module and its child modules.The wireload models in the flat format are generated for cells and instances based on internal nets (flat view).

Two wireload model formats are available: standard and custom.

Parameters

`-help`	Outputs a brief description of the `wireload` command. For a detailed description of the command, use the `man` command: `man wireload`
`-cell` *`cellName`*	Specifies the cell name for generating a wireload model.
`-cellLimit` *`moduleSize`*	Specifies the module size limit of cells or instances for generating a wireload model. Cells or instances that contain fewer than the *`moduleSize`* cells or instances will not have wireload models generated. *Default:* `100`
`-custom`	Generates the custom wireload model format, which is also known as the long format. The default is the standard wireload model format, which is also known as the short format.
`-inst` *`instanceName`*	Specifies the name of the hierarchical instance in a path for which to generate a wireload model. The hierarchical instance can be at any point in the path or at the beginning or end of the path.
`-instanceBased`	Generates wireload models for each instance in the design. The default is to generate wireload models for each cell type used in the design.
`-logarithmic`	Uses logarithmic average of the fanout value to calculate the wireload model.
`-name` *`modelName`*	Renames the cell name or instance name in the wireload model file.
`-netCoverRatio`	Specifies the percentage of nets to be considered for generating wireload model.
`-noSmooth`	Suppresses the smoothing of the wireload models.
`-outfile` *`fileNamePrefix`*	Specifies the filenames for the generated wireload models. The software generates four files for the hierarchical and flat models, and one command file each to load the model files back into the synthesis tool.
`-peakCap`	Uses peak fanout value to calculate the wireload model.
`-percent` *`samplingRate`*	Specifies the sample rate of the number of nets for calculation of wireload models. The values are between `0.0` and `1.0` (all sampled). *Default:* `1.0`
`-scale` *`factor`*	Specifies the scaling value used to multiply the results. *Default:* `1.0`.
`-view` *`viewName`*	Generates the wireload models for the specified analysis view. *Default*: Uses the default analysis view.

Examples

- The following command generates instance-based wireload models and outputs two model files, `design_name.wl.flat` and `design_name.wl.hier` and two command files for loading:

  ```
  wireload -instanceBased
  ```

- The following command uses logarithmic average of the fanout value to calculate the wireload model and outputs two model files, `design_name.wl.flat` and `design_name.wl.hier`:

  ```
  wireload -celldtmf_chip -logarithmic-outfile dtmf.wl
  wireLoad Option : -cell dtmf_chip -logarithmic -outfile dtmf.wl design/module characterization
  flags:
  ...
  ...
  Generation hierarchical Wireload Model File dtmf.wl.hier ...
  Generation flat Wireload Model File dtmf.wl.flat ...
  ```

Related Commands

- `extractRC`
- `setExtractRCMode`

write_extraction_spec

```
 write_extraction_spec
[-help]
[-no_design_data]
[-out_dir {dir_name}]
[-rc_corners {list_of_rc_corners}]
```

Creates the Quantus command file or the Common Command Language (CCL) file in the current working directory and saves the design data for running standalone Quantus. The command may be specified with a directory path where technology library file, LEF list file (for DEF-based flow), and DEF or OA design will be stored. However, if no directory path is specified, then a directory will be created in the current directory. The name of the directory will be in the format: `tmp_qrc_pid_time`. You can also specify whether you want to save the design data or not by using the `-no_design_data` parameter. If it is specified, then no design data, such as DEF or OA design will be saved.

In addition, to generate a command file for the OA-based flow, ensure that the `setExtractRCMode -useQrcOAInterface` parameter is set to `true`.

Note: Run this command after loading the design, setting up the MMMC environment, and specifying the CCL layer map file, if required.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `write_extraction_spec` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_extraction_spec`
`-no_design_data`	When this parameter is specified, no design data, such as DEF or OA design will be saved. By default, the design data will be saved. If this option is specified, then follow the steps listed below to run Quantus. 1. For DEF-based flow, provide the DEF file while invoking standalone Quantus. 2. For OA-based flow, the command file that is generated will assume an OA design in the following directory: `<lib name>/<top level cell name>/for_qrc` The value of `<lib name>` and `<top level cell name>` will be written into the command file that is generated. If you want to specify a different OA design path, modify the command file. **Note**: It is recommended that you use this parameter if you already have the DEF or OA design saved.
`-out_dir {dir_name}`	Specifies the location of the output directory in which the technology library file and associated data, and design data will be saved. If no path is specified, then a directory, `tmp_qrc_pid_time` will be created in the current directory by default.
`-rc_corners {list_of_rc_corners}`	Specifies the list of RC corners for which the Quantus command file is created. By default, the command outputs all active RC corners. If this parameter is specified, then only the specified corners are included in the Quantus command file. For example, Consider two RC corners, `RC1` and `RC2`, of which only `RC1` is active. • If this parameter is not specified, then the command will generate a CCL file with one active corner, `RC1`. • If this parameter is specified with a non-active corner, `RC2`, then the command will create a CCL file for the specified corner. `write_extraction_spec -rc_corners RC2` *Default*: `all active corners`

Related Information

- `extractRC`
- `setExtractRCMode`
- The following topic in the *Innovus User Guide*
  - Standalone Quantus for Signoff Extraction

RC Extraction Global Variable

- extract_shrink_factor

extract_shrink_factor

`extract_shrink_factor` *`shrink_factor_value`*

Type: Double

Default: `1.0`

Specifies the shrink factor by which to shrink the design before extraction. The shrink factor is used only for extraction calculations. It does not change the actual design.

This global variable must only be used when restoring design.

Note: This global is not recommended for newer technologies where shrink factor is defined in the Quantus techfiles or capacitance tables.

To set this global, use the `set` command.

Example

- The following global variable sets the shrink factor to `0.9`:

  ```
  set extract_shrink_factor 0.9
  ```

  Setting the shrink factor to `0.9` means the value of wire lengths, widths, and spacings in the design will shrink to 90% of their original values.

add_tracks

```
add_tracks
[-help]
[-honor_pitch]
[-keep_default_width]
[-mask_pattern {{layer1  mask [mask …]} [layer2 ...] }]
[-mode {replace append}]
[-offsets {layer1 horiz|vert [die_box] offset} [{layer2 …}] ...}]
[-pitch_pattern {layer1 offset offset pitch pitch [pitch pitch …]} [{layer2 …}]...}]
[-pitches {layer1 horiz|vert pitch} [{layer2 horiz|vert pitch}] ...}]
[-rect_only_pattern {{layer1 [pattern ...]} {layer2 [pattern ...]} .. }]
[-route_rule route_rule_name]
[-snap_ml_track_to_cell_pins]
[-width_pitch_pattern {{layer1 offset offset width width pitch pitch [width width pitch pitch]...} [{layer2 …}]...}]
```

Deletes existing routing tracks and generates new routing tracks based on the technology data or user specific values. If no parameters are given to the command, it examines the LEF layer offset and pitch values, but may adjust them based on the LEF width and spacing rules, via-rules, or the width and height of the standard cells to create tracks optimized for routing. If you want to override the automatically generated pitch and offset values, you should use the parameters below:

- Use `-offsets` and `-pitches` to create uniform track patterns.
- Use `-pitch_pattern` or `-width_pitch_pattern` for non-uniform track patterns.

The Innovus software generates tracks automatically. You do not have to run this command unless you want to override the defaults or if you have imported a DEF file using the `defIn` command and you wanted to overwrite the track definitions in the DEF file. To overwrite the track definitions, run this command after running the `defIn` command. Various warning messages are generated if any values given will likely give poor routing results (For example, A pitch less than minimum wire-to-via spacing, or a bottom routing layer tracks that do not align to the standard-cell heights.)

- Non-preferred routing tracks of each layer are aligned with the preferred routing tracks of the next lower layer.
- Non-preferred routing tracks of the first layer are aligned with the tracks of the next upper layer.

If the LEF FIRSTLASTPITCH property (or OA equivalent) is defined for a layer, then non-uniform tracks will be created with the first and last pitch of the tracks set to align to the standard cell rows. This makes the tracks aligned with the standard-cell power rails having a wider-pitch on both sides to allow a wider power-route with min-spacing to the next routing track.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `add_tracks` parameter. For a detailed description of the command and all of its parameters, use the man command: `man add_tracks`.
`-honor_pitch`	Honors the pitch specified in the LEF file. By default, the `add_tracks` command adjust the pitch to what it considers best. The `-honor_pitch` parameter forces `add_tracks` to use the layer pitch value specified in the LEF or OA technology file. If the layer pitch specified in the LEF file is smaller than the minimum line-to-via pitch, the pitch is reset to the minimum line-to-via pitch and a warning message is displayed in the log file. **Note:** The `-honor_pitch` parameter cannot be used with any of the options setting pitch values directly (`-pitches, -pitch_pattern, -width_pitch_pattern`). *Data_type*: bool, optional
`-keep_default_width`	Keeps user specified default width between routing tracks. **Note:** This enables the interoperability of width spacing patterns with Virtuoso. *Data_type*: bool, optional
`-mask_pattern {{layer1 [mask ...]} {layer2 [mask ...]} .. }`	

	Specifies the mask pattern for the specified layers that have multiple masks. The mask values are applied to the preferred direction tracks, and then repeat. There is no color for non-preferred direction tracks. If `-pitch_pattern`, or `-width_pitch_pattern` is given, the number of elements in `-mask_pattern` must match for each layer or an error occurs. • *layer*: You can use LEF layer names or built-in routing-layer names (Metal1 for the first routing layer, Metal2 for the second layer) for the *layer* name. • *mask*: Specify 1, 2, or 3. The layer must be defined to use the specified number of masks. For example, `-mask_pattern {metal1 1 2 3 1 2 metal2 1 2 1 2 1}` *Data_type*: string, optional
`-mode {replace append}`	Enables incremental replace/append operations for tracks and regenerates tracks for specified layers only. In the incremental mode, you can replace or append any specific tracks one-by-one. You do not need to specify a long list of track definitions anymore. • `replace`: Enables the `add_tracks` command to remove all the tracks in the specified layers and then only generate/add specified tracks from the command line. • `append`: When specified, the `add_tracks` command does not remove any tracks. It will append specified tracks into existing tracks. *Data_type*: enum, optional
`-offsets {`*layer1* `horiz|vert [die_box]` *offset*`} [{`*layer2* `…}] ...}`	
	Specifies the horizontal offset or vertical offset for the specified layers. • *layer*: You can use LEF layer names or built-in routing-layer names (Metal1 for the first routing layer, Metal2 for the second layer) for the *layer* name. • *offset*: Specifies the offsets (in microns) for the specified layer. **Note:** The value of *offset* is relative to the lower-left corner of the core_box that is aligned to the standard cell rows, and can be a negative number. If die_box is given, the *offset* is relative to the lower-left corner of the die_box rather than the core_box. **Note:** die_box should not be used for the first two routing layers that need to align with the standard cells pins, but it can be used to align some of the upper routing layer tracks with a power-route grid structure. For example, `-offsets {metal1 horiz 0.1 metal2 vert 0.0 metal4 vert die_box 0.3}` *Data_type*: string, optional
`-pitch_pattern {`*layer1* `offset` *offset* `pitch` *pitch* `[pitch` *pitch* `…]} [{`*layer2* `…}] ...}`	
	Specifies an offset, and pitch pattern for the tracks in the preferred routing direction when non-uniform spacing is needed. These values override any `-pitches` or `-offsets` values for this layer in the preferred direction. • *layer*: You can use LEF layer names or built-in routing-layer names (Metal1 for the first routing layer, Metal2 for the second layer) for the *layer* name. • *offset*: Specifies the offsets (in microns) for the specified layer. • *pitch*: Specifies the pitch value. You can repeat the last pitch value using `repeat num`. It is best to add {} to make it clear which pitch value is repeated. For example, `-pitch_pattern {metal1 offset 0.2 pitch 0.2 {pitch 0.1 repeat 9} pitch 0.2 metal2 offset 0.1 pitch 0.2 {pitch 0.1 repeat 8}` } **Note**: {} are ignored but allowed to make it easier to read the command. For example, in the following command the first track is placed at 44.00, the next 0.55 away and then 66.00 away and then repeat 0.55.and 0.66. `add_tracks -pitch_pattern { metal15 offset 44.00 pitch 0.55 pitch 66.00}` *Data_type*: string, optional
`-pitches {`*layer1* `horiz|vert` *pitch*`} [{`*layer2* `horiz|vert` *pitch*`}] ...}`	

	Specifies the horizontal pitch or vertical pitch for the specified layers. This is only used for layers that have uniform track spacing. • *layer*: You can use LEF layer names or built-in routing-layer names (Metal1 for the first routing layer, Metal2 for the second layer) for the *layer* name. • *pitch*: Specifies the pitch value (in microns). **Note**: {} are ignored but allowed to make it easier to read the command. For example, `-pitches {metal1 vert 0.1 metal2 horiz 0.1 metal4 horiz 0.3}` *Data_type*: string, optional
`-rect_only_pattern {{layer1 [pattern ...]} {layer2 [pattern ...]} .. }`	
	Enables you to specify which subset of tracks would only allow rectangular shapes (rect_only). **Note:** In the GUI, 'rect_only' is added behind the width to indicate that the track has the “RECTONLY PARTIALTRACKS” LEF property assigned to it. The presence of the *rect_only* tag indicates that the track has the 'rectangular shape only' restriction and should be honored in routing. • *layer*: The layer must be defined to use the rect_only routing pattern. • *pattern*: Use 0 or 1 to specify the rect_only routing pattern. ◦ 0: Indicates no rect_only in generated tracks. ◦ 1: Indicates rect_only in generated tracks. For example, `add_tracks -rect_only_pattern {m2 0 0 1 1 1}` *Data_type*: string, optional

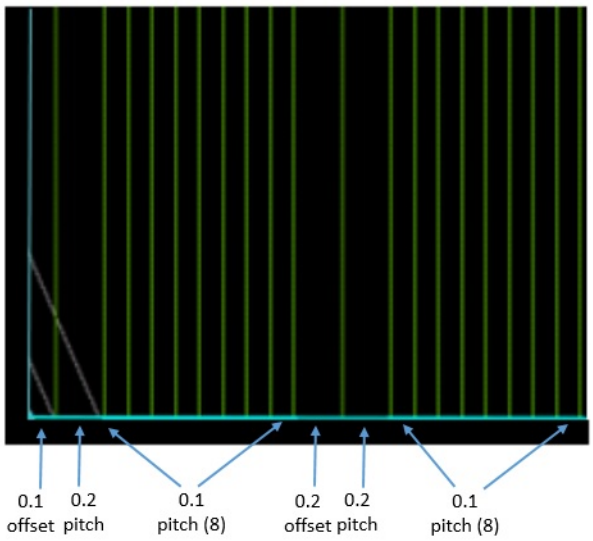
`-route_rule route_rule_name`	Specifies the name of a non-default route rule. When specified, the existing tracks are not deleted. Instead, an additional set of tracks are created for use by this *route_rule_name* on top of the existing tracks.
	Note: When the `-route_rule` parameter is used, you must specify everything for this specific *route_rule_name* in one command, irrespective of what `-mode` option you specify.
	Example:
	In the following command, M6 and M8 NDR tracks are added in one command. These should ***NOT*** be done in the two commands.
	`set addTrack_pitch_pattern_2w "{\`
	`{m6 offset 0.490 width 0.076 pitch 0.076 width 0.076 pitch 0.076 width 0.076 pitch 0.076 width 0.076 pitch 0.076 width 0.076 pitch 0.304} \`
	`{m8 offset 0.490 width 0.076 pitch 0.076 width 0.076 pitch 0.076 width 0.076 pitch 0.076 width 0.076 pitch 0.076 width 0.076 pitch 0.304}}"`
	`add_tracks -width_pitch_pattern $addTrack_pitch_pattern_2w -mode append -route_rule {TrunkNDR_2W}`
	Note: To later modify/append NDR tracks, you must delete all tracks (including default and NDR tracks) using the `deleteTrack` command and then regenerate all of them.
	Data_type: string, optional

`-snap_m1_track_to_cell_pins`	Extracts pins to generate tracks for the first routing layer. When specified, it scans all standard cells in the library and tries to extract all possible rectangle pins shapes and mask numbers. Tracks are created to hit the center of these pins. All tracks are assigned a mask based on the pin mask value, if specified. This is currently only intended for some 10nm technologies. *Data_type*: bool, optional
`-width_pitch_pattern { {layer1 offset offset width width pitch pitch [width width pitch pitch]...} [{layer2 …}] ...}`	

	Specifies track width patterns for the preferred direction. Use { } to specify track width pattern for more than one layer.
	Specifies the width and pitch pattern for the tracks in the preferred routing direction, for technologies that need a width value attached to each track. These values override any `-pitches` or `-offsets` values for this layer in the preferred direction. If `-pitch_pattern` is given for any of the layers, `-width_pitch_pattern` will override the `-pitch_pattern` values.
	• *`layer`*: You can use LEF layer names or built-in routing-layer names (Metal1 for the first routing layer, Metal2 for the second layer) for the *`layer`* name.
	• *`width`*: Specifies the width value.
	• *`pitch`*: Specifies the pitch value (in microns).
	Note: You can repeat the last width and pitch value using `repeat num`. It is best to add {} to make it clear which value are repeated.
	For example,
	`-width_pitch_pattern`
	`{metal1 offset 0.2 width 0.2 pitch 0.2 {width 0.1 pitch 0.1 repeat 8} width 0.1 pitch 0.2`
	`metal2 offset 0.1 width 0.2 pitch 0.2 {width 0.1 pitch 0.1 repeat 8} width 0.1 pitch 0.2 }`
	Data_type: string, optional

Examples

- The following command deletes any existing tracks, and generates new routing tracks based on the LEF or OA layer offset and pitch settings, and the standard-cell pins.
  ```
  add_tracks
  ```
- The following command generates uniform vertical tracks on metal1 with a horizontal offset of 0.1 from the core_box, a horizontal pitch of 0.2, and horizontal tracks on metal2 with a vertical offset of 0.2 from the core_box, and a vertical pitch of 0.3. Other layers will use the LEF or OA layer settings.
  ```
  add_tracks -offsets {metal1 horiz 0.1 Metal2 vert 0.2} -pitches {metal1 horiz 0.2 Metal2 vert 0.3}
  ```
- The following command generates a non-uniform pattern of tracks for the preferred routing direction, using the values given. Extra {} are added to make it more readable.
  ```
  add_tracks -pitch_pattern {metal1 offset 0.1 pitch 0.2 {pitch 0.1 repeat 8} metal2 offset 0.2 pitch 0.2 {pitch 0.1 repeat 8} }
  ```



- The following command generates a non-uniform pattern of tracks with width values for the preferred routing direction, using the values given settings.
  ```
  add_tracks -width_pitch_pattern \
  {{metal1 offset 0.1 width 0.2 pitch 0.2 {width 0.1 pitch 0.1 repeat 8} width 0.1 pitch 0.2} \
  {metal2 offset 0.2 width pitch 0.2 {pitch 0.1 repeat 8}} }
  ```

Pitch Rule Examples

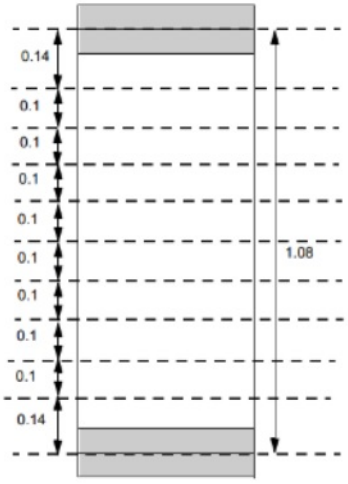
Example 1

The following example shows how routing_tracks are created for a layer with FIRSTLASTPITCH.
Suppose the LEF has this statement for the Metal1 layer.

```
PROPERTY LEF58_PITCH STRING "
    PITCH 0.1 FIRSTLASTPITCH 0.14 ; ";
```

Then the horizontal metal1 tracks will be created as shown below by default, with no extra parameters passed to add_tracks.

Example 2



In this example, the cell height is 1.08. The dotted line represents the routing tracks. The first and last tracks are 0.14 from the cell row boundary while the intermediate tracks are 0.1 apart making 2 * 0.14 + 8 * 0.1 = 1.08. The routing track definition would be repeated based on the cell rows.

addChannelDensityControl

```
addChannelDensityControl
[-help]
llx lly urx ury layer ratio
```

Controls the routing density for a specified area on a layer by setting a maximum density percentage that early Global Route cannot exceed. Use the `addChannelDensityControl` command after performing placement.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `addChannelDensityControl` parameter. For a detailed description of the command and all of its parameters, use the man command `man addChannelDensityControl`.
`layer`	Specifies the layer on which to specify the routing density control. **Note:** Layers can be specified using the layer names or layer ID numbers. *Data_type*: string, required
`llx`	Specifies the lower left x coordinate of the density area. *Data_type*: float, required
`lly`	Specifies the lower left y coordinate of the density area. *Data_type*: float, required
`ratio`	Specifies the maximum routing density allowed for the area, as a percentage. *Min*: 0 *Max:* 100 *Value:* `0` (zero percent) to `1` (100 percent) *Data_type*: float, required
`urx`	Specifies the upper right x coordinate of the density area. *Data_type*: float, required
`ury`	Specifies the upper right y coordinate of the density area. *Data_type*: float, required

Examples

The following command creates a routing density control area on layer Metal3 with a maximum density of 50 percent:

```
addChannelDensityControl 10 10 500 30 Metal3 0.50
```

check_tracks

```
check_tracks
[-help]
[-direction {horiz | vert | H | V}]
[-grid spacing]
[-layer layer_name]
[-mask mask_name]
[-offset string]
[-origin {design | core | D | C}]
```

Checks a predefined set of tracks to verify their routing track offset, direction, and grid. It reports the following conditions in the Innovus log file:

1. Tracks whose `STEP` is smaller than the minimum pitch for the designated layer.
2. The percentage of on-track pins and pins that are not accessible (for regular routing).
3. Fully blocked pins and potential off-grid track pins (for special routing).

Before running this command, complete the following steps:

- Load a LEF file with the library and technology information.
- Place the design.

Parameters

`-direction {horiz | vert | H | V}`	Specifies the direction of the tracks to check. *Data_type*: string, optional
`-grid spacing`	Specifies the track spacing. *Data_type*: string, optional
`-help`	Outputs a brief description that includes type and default information for each `check_tracks` parameter. For a detailed description of the command and all of its parameters, use the man command: `man check_tracks`
`-layer layer_name`	Specifies the track layer. *Data_type*: string, optional
`-mask mask_name`	Specifies the mask name. *Data_type*: string, optional
`-offset string`	Specifies the track offset from the starting point. *Data_type*: string, optional
`-origin {design | core | D | C}`	Specifies the track starting point. *Data_type*: string, optional

Examples

- The following command checks the tracks in the horizontal direction on layer M3 with a grid spacing of 3.
  ```
  check_tracks -direction H -layer M3 -grid 3
  ```

  The following output displays on screen:

  ```
  Total 35 tracks meet specification: layer=Metal3 dir=horiz offset=0 grid=3
  Total 2622 tracks not hit under specified command line options
  ```

Related Information

checkTQuantusModelFile

```
checkTQuantusModelFile
[-help]
```

Checks the TQuantus model file created using the `createTQuantusModelFile` command. It ensures that the TQuantus model file is consistent with the following input files inside the Innovus database:

- QRC techfiles
- Pitch information from the technology LEF file
- RC corners

The following commands invoke this command automatically to check the consistency of the TQuantus model file if TQuantus is chosen as the extraction engine.

- `routeDesign -trackOpt`
- `optDesign -postRoute`
- `timeDesign`
- `extractRC`

Note: The software issues warnings if inconsistencies are detected between the TQuantus file and the RC corner information, QRC techfile, or pitch information in the LEF technology file. If such warnings are issued, the TQuantus model file will have to be re-generated manually.

Parameter

`-help`	Outputs a brief description of the `checkTQuantusModelFile` parameter. For a detailed description of the command, use the man command: `man checkTQuantusModelFile`.

Example

- The following commands create the RC model data and store it in the `tQuantus_model.bin` file and then check the TQuantus model file:

  ```
  createTQuantusModelFile -file tQuantus_model.bin
  checkTQuantusModelFile
  ```

Related Topic

colorize_cell_library

```
colorize_cell_library
[-help]
[-cell cell_name]
[ [-reset ] | [-enforce ] ]
```

Colors each standard cell in the library, using the pre-color method.

Parameters

`-cell` *cell_name*	Specifies the name of the cell to colorize. The `colorize_cell_library` command only targets the specified cell, irrespective of the cell type. *Data_type*: (libCell/ptnCell)+, optional
`-help`	Outputs a brief description that includes the type and default information for each `colorize_cell_library` parameter. For a detailed description of the command and all of its parameters, use the man command `man colorize_cell_library`.
`-enforce`	Specifies that re-colorization will be enforced. It colors the cell even if it is already colored. *Data_type*: string, optional
`-reset`	Resets the library cell color data. It cleans the color of every standard cell, except the LEF-color. *Data_type*: bool, optional

Example

- The following command resets the library cell color data.
  ```
  colorize_cell_library -reset
  ```

Related Information

- `setNanoRouteMode`
- Using the NanoRoute Router chapter in the *Innovus User Guide*

createShield

```
createShield
[-help]
[-selected]
[-crosstie_only]
[-include_fixed]
```

Creates shield wires for the NanoRoute router. After creating the shields, the router generates a report that includes shielding coverage statistics.

Parameters

`-crosstie_only`	Adds crosstie for coaxial shielding only. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `createShield` parameter. For a detailed description of the command and all of its parameters, use the man command `man createShield`
`-include_fixed`	Includes fixed wires for shielding. The wire will not be changed but the electrical characteristics can be altered by adding shielding so that this option is required to include the fixed wire for shielding. *Data_type*: bool, optional
`-selected`	Creates shield wires for the selected nets. If you do not specify this option, all the clock nets will be shielding. *Data_type*: bool, optional

Example

- The following command creates shield wires for selected nets:
  ```
  createShield -selected
  ```

Related Information

- `deleteShield`
- `reportShield`
- Using the NanoRoute Router chapter in the *Innovus User Guide*
  - Performing Shielded Routing

createTQuantusModelFile

```
createTQuantusModelFile
[-help]
-file rc_model_file_name
[-reset]
```

Creates the RC model data and stores it in a TQuantus model file. This data is used by the RC extractor. This command eliminates the need for the RC extractor to rebuild the RC models every time it runs. It can just use the model data created using this command. Before creating the TQuantus model file, ensure the following:

- QRC techfiles are available
- Pitch information from the technology LEF file is available
- All RC corners are set up

The consistency of the created TQuantus model file is checked using the `checkTQuantusModelFile` command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `createTQuantusModelFile` parameter. For a detailed description of the command and all of its parameters, use the man command `man createTQuantusModelFile`.
`-file rc_model_file_name`	Writes the created RC model data into a file with the specified file name. *Data_type*: string, optional
`-reset`	Resets the RC model file. *Data_type*: bool, optional

Example

- The following command creates the RC model data and stores it in the `tQuantus_model.bin` file:
  ```
  createTQuantusModelFile -file tQuantus_model.bin
  ```

Related Topic

deleteShield

```
deleteShield
[-help]
{-nets list_of_signal_nets | -selected}
[-routes_only {0 | 1}]
```

Deletes physical shielding wires from the specified or selected signal nets and removes `SHIELDNET` attributes from the nets. Use the `deleteShield` command after setting the `SHIELDNET` attribute on a net. To set the `SHIELDNET` attribute, use the setAttribute command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `deleteShield` parameter. For a detailed description of the command and all of its parameters, use the man command `man deleteShield`
`-nets list_of_signal_nets`	Specifies a list of signal nets with one or more `SHIELDNET` attributes. You can use the asterisk (`*`) wildcard in the net names. *Data_type*: string, optional
`-routes_only {0 | 1}`	Specifies that only shield wires and vias will be deleted. *Data_type*: enum, optional
`-selected`	Lets you select nets. *Data_type*: bool, optional

Examples

- The following command deletes `SHIELDNET` attributes and physical shielding wires from net `clk1`:
  ```
  deleteShield -nets clk1
  ```
- The following command deletes `SHIELDNET` attributes and physical shielding wires from nets `c*`:
  ```
  deleteShield -nets c*
  ```
- The following command deletes `SHIELDNET` attributes and physical shielding wires from selected nets:
  ```
  deleteShield -selected
  ```

Related Information

- `reportShield`
- Using the NanoRoute Router chapter in the *Innovus User Guide*
  - Performing Shielded Routing

detailRoute

```
detailRoute
[-help]
[-select]
[area]
```

Uses the NanoRoute router to perform detailed routing on the entire design, an area of the design specified by the bounding box, or on selected nets. If you do not specify parameters, the router routes the entire design. If you specify both the bounding box and selected nets, the router routes only selected nets within the bounding box. You can perform detailed routing on specified area only if you are rerouting the design. If you have not already run detailed routing on the entire design, you cannot run detailed routing on a specified area.

Note: This command supports multiple-CPU processing.

Use this command after completing the following steps:

1. Placing the design.
2. Routing special nets.
3. Setting net attributes with `setAttribute` and NanoRoute run-time options with `setNanoRouteMode`.
   Note: This step is optional. Complete this step only if you do not want to use the current values for attributes or default values for options.
4. Running global routing with `globalRoute`.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `detailRoute` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man detailRoute`
area	Specifies the x and y coordinates of the bounding box area. *Data_type*: rect, optional
`-select`	Routes selected nets. To select a net, use the `selectNet` command or click the net in the design display window. **Tip**: You can also specify `setNanoRouteMode -route_selected_net_only true` to route the selected nets. *Data_type*: bool, optional

Example

The following command selects `net1` and runs detailed routing on it:

```
selectNet net1
detailRoute -select
```

  - Detailed Routing

dumpCongestArea

```
dumpCongestArea
[-help]
file_name
[-all]
```

Writes the routing congestion information to an ASCII output file. The output file reports the coordinates of overflow cells, vertical tracks, and horizontal tracks. You can use the `dumpCongestArea` command after running Early Global Route.

Parameters

`-all`	Writes the congestion information for all gcells in the design to the specified output file, regardless of the congestion level. If the `-all` parameter is not specified, this command writes the congestion information for only the most congested gcells in the design to the specified output file. *Data_type*: bool, optional
file_name	Specifies the name of the output file to which the congestion information is written. *Data_type*: string, required
`-help`	Outputs a brief description that includes the type and default information for each `dumpCongestArea` parameter. For a detailed description of the command and all of its parameters, use the man command `man dumpCongestArea`.

Example

- The following command writes the routing congestion information for all gcells to the `congest.txt` file:

  ```
  dumpCongestArea -all congest.txt
  ```

Related Information

- `dumpNanoCongestArea`
- `dumpNetsInCongestedArea`
- `reportCongestArea`
- Using Early Global Route for Congestion and Timing Analysis chapter in the *Innovus User Guide*

dumpNanoCongestArea

```
dumpNanoCongestArea
[-help]
file_name
[-all]
```

Writes the NanoRoute routing congestion information to an ASCII output file. The output file reports the total number of overflowed tracks, and the coordinates of overflow cells, vertical tracks, and horizontal tracks. The following example shows the information for a gcell in the ASCII output file:

```
(1192900, 974400) (1209700, 991200) V: -1/9/24 H: 0/16/39
```

The gcell has one vertical (`V`) track overflow (`-1`) from a layer. However, if all tracks are counted, it has nine remaining vertical tracks among 24 total tracks.

For horizontal (`H`) tracks, there was no overflow from any layer (`0`), and it has 16 remaining tracks among 39.

You can use the `dumpNanoCongestArea` command after running the NanoRoute `globalRoute` command.

Parameters

`-all`	Writes the congestion information for all gcells in the design to the specified output file.
`file_name`	Writes the congestion information for only the most congested gcells in the design to the specified output file.
`-help`	Outputs a brief description that includes the type and default information for each `dumpNanoCongestArea` parameter. For a detailed description of the command and all of its parameters, use the man command `man dumpNanoCongestArea`.

Related Information

- `dumpCongestArea`
- `dumpNetsInCongestedArea`
- `earlyGlobalRoute`
- Using the NanoRoute Router chapter in the *Innovus User Guide*

dumpNetsInCongestedArea

```
dumpNetsInCongestedArea
[-help]
file_name
```

Outputs the names of nets in the congested area of the design into the specified file, based on `earlyGlobalRoute` results. You can use the `dumpNetsInCongestedArea` command after running Early Global Route.

Parameters

file_name	Specifies the name of the file in which to output the net names. *Data_type*: string, required
-help	Outputs a brief description that includes the type and default information for each `dumpNetsInCongestedArea` parameter. For a detailed description of the command and all of its parameters, use the man command `man dumpNetsInCongestedArea`.

Related Information

- `dumpCongestArea`
- `dumpNanoCongestArea`
- `earlyGlobalRoute`
- Using Early Global Route for Congestion and Timing Analysis chapter in the *Innovus User Guide*

earlyGlobalRoute

```
earlyGlobalRoute
[-help]
```

Early Global Route (`earlyGlobalRoute`) is a quick global routing for estimating routing-related congestion and parasitic (resistance and capacitance) values. The Early Global Route results are also used for pin assignment when you commit partitions in hierarchical designs. Early Global Route does not guarantee DRC-clean routing results. Do not perform signal integrity analysis on a design that has been routed using Early Global Route, because these routes are only used to estimate parasitic values for timing analysis. Route designs with the NanoRoute router if you want to perform signal integrity analysis.

Wire overlap can occur if a gcell is only partially covered by a routing blockage or pre-routed wires. Overlapping of non-default rule wires can also occur during track assignment; however, this information is modeled when the router estimates congestion. You can use the `earlyGlobalRoute` command after running placement. If the design uses additional placement features, such as clock tree synthesis and scan groups, use the command after running these placement features. If you have run IPO commands on your design, you must run the `earlyGlobalRoute` command to update interconnections for the design.

Notes:

- You can set the global parameters for the Early Global Route program by using the `setRouteMode` command. Parameters that you specify with `setRouteMode` are then used automatically whenever you run Early Global Route, either explicitly through the `earlyGlobalRoute` command or internally during in-place optimization, partitioning, or placement.
- The `assignPtnPin` command reports the number of guide pins from route guides and fixed pins. Since `earlyGlobalRoute` chooses guide points provided by `assignPtnPin` to lay wires on partition boundary, the `earlyGlobalRoute` report clearly differentiates between fixed pins and the pins which are in the pin guide.
- The Early Global Router supports nested partitions. The partitions specified with the `setRouteMode -earlyGlobalRoutePartitionHonorFence` and the `setRouteMode -earlyGlobalRoutePartitionHonorPin` parameters are routed in the style that honors fence and pin constraints. All other partitions are still routed flat.
- The Early Global Router supports get_metric APIs and enables you to query existing routing metrics at command line. To enable this capability, `routeDesign` just calls the 'get_metrics' API after generating the routing metrics.
- If bus guides have been created in the GUI, the `earlyGlobalRoute` command honors the bus guides automatically.
- The `earlyGlobalRoute` command honors multiple-CPU setting for track assignment inside `earlyGlobalRoute` by default.
- The Early Global Router supports blackboxes by default. It internally calls the `assignPtnPin` command and places and routes all unplaced blackbox pins.
- The Early Global Router supports uses two-row-height gcells with congestion modelling improvement for the technology nodes whose row-height is smaller than 7 track. It uses 2x2 gcell size as default for small default gcell size (<=7). By default, it checks for the number of tracks rather than checking the technology of the design to grow gcell size.
  Note: This enhancement is designed only for N7 designs as these designs have less than 7 tracks. If an N7 design has more than 7 tracks then these setting will not be applied in order to ensure a better congestion accuracy.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `earlyGlobalRoute` parameter. For a detailed description of the command and all of its parameters, use the man command: `man earlyGlobalRoute`.

Example

- The following command honors partition fences with single entry and does not allow crossing other partitions, when `earlyGlobalRoute` is run:

```
setRouteMode -earlyGlobalRoutePartitionHonorFence {.}
earlyGlobalRoute
```

- The following command does quick global routing for estimating routing-related congestion and parasitic values.

```
earlyGlobalRoute
```

```

ecoRoute

```
ecoRoute
[-help]
[-ignore_route string]
[-handlePartition ]
[-fix_drc [-cut_color_flip {0 1}]
[-trim_layer_patch ] [-layer_range bottomLayer:topLayer] [area]]
[-fix_filler_drc_with_patch_only [-passive_fill ] [-layer_range bottomLayer:topLayer] [area]]
[-fix_filler_drc_with_patch_only | -fix_drc ]
[-target | -fix_drc | -prototype ]
[-modifyOnlyLayers bottomLayer:topLayer | -fix_drc ]
```

This command is part of an ECO flow process and is based on the NanoRoute® router. Based on information from the `ecoDefIn` command, this command preprocesses the design for the NanoRoute router and launches ECO routing within the router. This command retrieves the router's mode settings and returns them to their original state at the end of the ECO routing operation.

- When you specify two layers to modify, the first number representing the bottom layer should be smaller than the second number representing top layer (for example, `-modifyOnlyLayers 2:3`), `ecoRoute` checks for pin accessibility for new or modified nets and drops `VIA12,` as necessary.

  Note: The `via12` and `via34` will be used, but tool will not change the metal shapes on M1 and M4.
- When a net is modified, some parts of the wire must be reassigned to the new nets. Initially, a whole wire between two cells is assigned to `netA`. When a buffer is inserted on `netA`, `ecoRoute` cuts the wire segment and assigns the left side of the wire to `netA` and the remaining segment on the right to `netB`.
- You must first run `ecoDefIn` and `ecoPlace` before you use this command.
- You can run ECO routing in multiple-CPU processing mode.

Parameters

area	Fixes DRC violations is the specified route area. You can specify the area using the *x1 y1 x2 y2* coordinate values. **Note**: The parameter must be used with the `-fix_drc` parameter. *Data_type*: rect, optional
`-cut_color_flip {0 1}`	
	Fixes cut color DRC violations by flipping. When enabled (1), the ecoRoute command fixes the cut same-mask spacing violations by flipping the color of the cut. **Note**: The parameter must be used with the `-fix_drc` parameter.
`-fix_drc`	Fixes violations on existing DRC markers in the design. When enabled, it allows NanoRoute to fix only the DRC's on existing DRC markers in the design. If violations increase then the ecoRoute command reverts to the original snap shot of the design. **Note:** If open nets are found in the design, NanoRoute will error out. **Note:** This parameter does not support the `-modifyOnlyLayers` arguments. *Data_type*: bool, optional
`-fix_filler_drc_with_patch_only`	Fixes filler related drc with metal patch only. • If only the filler-related metal patch drc exists after filler insertion, it can be fixed with the `-fix_filler_drc_with_patch_only` parameter. • The recommendation flow for chip-finish is: 1. `ecoRoute`. For changed cell eco 2. `addFiller`. Inserts full fillers, even if decap and filler insertion is performed in single or multiple steps. 3. `ecoRoute -fix_filler_drc_with_patch_only` **Note:** Some decap cells might be replaced with normal filler cells due to handling of the vertical stack rule during `addFiller`. As a result DRC violations relating to patch metal may still be left after full filler insertion if router is called after only decap cells are inserted. Hence, Cadence recommends you to follow the above mentioned chip-finish flow. *Data_type*: bool, optional

`-help`	Outputs a brief description that includes the type and default information for each `ecoRoute` parameter. For a detailed description of the command and all of its parameters, use the man command: `man ecoRoute`
`-handlePartition`	Turns on handling partition flag. For the nets in hierarchical partition design, the ECO routing performed is partition aware with this option. • Pure top level nets should be routed only in top area. • Inter-partition nets should be routed based on partition pin locations, and there are no multiple entries to a connected partition, the specific partition pin is the only entry for the partition connection. • Intra-partition nets should be routed inside corresponding partition fence. *Data_type*: bool, optional

`-ignore_route` *string*	When specified, the selected net will be routed with highest priority by ignoring existing routes in post-route mode.
	• `all`: Ignores all other nets in the design that are not selected, including clock, secondary PG, and signal nets.
	• `signal`: Ignores only other signal nets that are not selected, but honors clock and secondary PG nets.
	For example, the following commands select and route a list of nets by ignoring only other signal nets, and considers secondary PG and clock nets during routing. After that, a second `ecoRoute` is run to fix DRC violations:
	`selectNet {net1 net2 net3}`
	`setNanoRouteMode -route_selected_net_only true`
	`ecoRoute -ignore_route signal`
	`setNanoRouteMode -reset -route_selected_net_only`
	`verify_drc -limit 0`
	`ecoRoute`
	Default: " "
	Type: string, optional

`-layer_range` *bottomLayer:topLayer*	Enables the NanoRoute router to fix violations on existing DRC markers in the specified layer range (*bottomLayer:topLayer*). *Type:* string, optional
`-modifyOnlyLayers` *bottomLayer:topLayer*	
	Enables the NanoRoute router to remove segments of net routing in the specified layer range, from `bottomLayer` to topLayer, inclusively. You must include a colon (`:`) between the `bottomLayer` and `topLayer` values. This option also restricts eco routing to carry out only on eco nets. *Default:* ECO routing can occur on any layer and any nets. **Note:** You might want to use `-modifyOnlyLayers` to specify all layers in order for `ecoRoute` to avoid touching non-eco nets. In some cases, approach could be faster and result in fewer DRCs. This command is similar to `-bottomRoutingLayer` and `-topRoutingLayer` parameters of the `setDesignMode` command and the `-route_with_eco` parameter of the `setNanoRouteMode` command. For more information on the `ecoRoute` command, see the ECO Flows chapter of the *Innovus User Guide*. **Note:** The NanoRoute router does not support the `-modifyOnlyLayer` option for 10nm and below nodes and displays an error when used. **Note:** The `-modifyOnlyLayers` parameter cannot be specified with the `-fix_drc` parameter. **Note:** The recommended methods to know the layers and vias that were touched in the freeze metal routing with `-modifyOnlyLayers` *bottomLayer:topLayer* are: • Use the `defComp -metalShapeDiff` command to compare the def file before and after using the `ecoRoute` command. • Use `Pegasus` to compare the gds file. *Data_type*: string, optional
`-passive_fill`	When specified, it does passive fill after filler fixing. This helps to save extra import/export time. *Data_type*: bool, optional

`-prototype`	Enables prototyping while doing ECO routing. When specified, it enables NanoRoute to work on the nets selected to route and stop early before DRC cleanup to provide a quick snapshot for the designer. This mode is intended to help the designer know if the routing is possible and if the ECO can improve timing. **Note:** In this mode the routes are not DRC clean
`-target`	Enables NanoRoute to work on only eco nets identified by NanoRoute to route. In this mode, the router ignores the already existing DRC violation markers that are not on the ECO nets or are on nets selected to route. *Data_type*: bool, optional
`-trim_layer_patch`	Enables the ecoRoute command to only add trim and patch metals in a given area. Using the `-trim_layer_patch` parameter, you can fix drc violations flagged in sign-off/verify_drc and only add trim and patch metals where minimum spacing criteria is not met. *Data_type*: bool, optional

Examples

The following example allows the NanoRoute router to perform ECO routing only on or between layers 2 and 3, VIA12 will be dropped if necessary :

```
ecoRoute -modifyOnlyLayers 2:3
```

If DRCs exist after you run the `ecoRoute` command, this could be because `ecoRoute` cannot touch non-eco nets. You can reroute the DRC area as shown below:

```
setNanoRouteMode -quiet -route_with_eco true
ecoRoute -modifyOnlyLayers 1:3
setNanoRouteMode -quiet -route_selected_net_only false
globalDetailRoute 100.0 1200.0 350.0 600.0
```

fix_drc_with_patch

```
fix_drc_with_patch
[-help]
[area]
[-layer_range bottomLayer:topLayer]
```

Fixes violations by adding trim/patch in the whole design which includes fixed cell objects, preRouted nets, and special nets on a preRoute db. You can use this command after floorplanning the design or after PG routing or on preRouted routing database, however, you must use it before running `routeDesign`.

Note: Cadence recommends you to use the `fix_drc_with_patch` command to check the sign-off on preRoute db. It should not be used for flow continuation.

Parameters

area	Enables the tool to trim/add patches and fix DRC violations in the specified route area. You can specify the area using the *x1 y1 x2 y2* coordinate values. *Data_type*: box, optional
-help	Outputs a brief description that includes the type and default information for each `fix_drc_with_patch` parameter. For a detailed description of the command and all of its parameters, use the man command: `man fix_drc_with_patch`
-layer_range *bottomLayer:topLayer*	Enables the tool to trim/add patches and fix DRC violations within the specified layer range (*bottomLayer:topLayer*). *Type:* string, optional

Examples

The following command adds patches and fixes DRC violations within the 2:4 layer range:

```
fix_drc_with_patch -layer_range 2:4
```

Related Topic

getAttribute

```
getAttribute
[-help]
-net netName
[-quiet]
```

Displays the current net attribute settings in the Innovus console and in the Innovus log file. At the end of the display, the NanoRoute router lists each attribute, enclosing it in braces (`{}`) so you can use it in a Tcl script with variables. See `setAttribute` for descriptions of NanoRoute attributes.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `getAttribute` parameter. For a detailed description of the command and all of its parameters, use the man command `man getAttribute`.
`-net netName`	Specifies the net for which to display attributes. *Data_type*: string, required
`-quiet`	Displays the current settings for the specified parameters in Tcl list format only. If you specify `-quiet` without any parameters, the software displays the current settings of all `setAttribute` parameters in Tcl list format. *Data_type*: bool, optional

Example

The following command displays the attributes for `net1`:

```
getAttribute -net net1
```

The Innovus software returns the following:

```
#NET net1 attributes:
# weight = 2 (default)
# non_default_rule = default (default)
# shield_net = none (default)
# pattern = steiner (default)
# top_preferred_routing_layer = 15 (default)
# bottom_preferred_routing_layer = 0 (default)
# preferred_extra_space = 0 (default)
# avoid_detour = false (default)
# skip_routing = false (default)
# skip_antenna_fix = false (default)
# si_post_route_fix = false (default)
{weight 2} {non_default_rule default} {shield_net none} {pattern steiner} {top_preferred_routing_layer 15} {bottom_preferred_routing_layer
0} {preferred_extra_space 0} {avoid_detour false} {skip_routing false} {skip_antenna_fix false} {si_post_route_fix false}
```

Returns information about the specified `setNanoRouteMode` parameter in the Innovus log file and the console. The following information is returned:

- Option name
- Current value
- Type (Boolean, string, and so on)
- Whether the current value was set by user

If you do not specify a parameter, the software displays information for all of the `setNanoRouteMode` mode parameters.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `getNanoRouteMode` parameter. For a detailed description of the command and all of its parameters, use the man command: `man getNanoRouteMode`.
`parameter_names`	Displays information for the specified parameters. You can specify one or more parameters. See `setNanoRouteMode` for descriptions of the parameters you can specify.
`-nonDefault`	Displays the current settings which are not default settings.
`-quiet`	Displays the current settings for the specified parameters in TCL list format only. If you specify `-quiet` without any parameters, the software displays the current settings of all `setNanoRouteMode` parameters in TCL list format.

Examples

- The following command displays the current setting of the `-route_detail_fix_antenna` parameter:

  ```
  getNanoRouteMode -route_detail_fix_antenna
  ```

  The software displays the following information:

  ```
  -route_detail_fix_antenna true # bool, default=true
  true
  ```

- The following command displays the current setting for the `-route_detail_fix_antenna` parameter in Tcl list format only:

```
getNanoRouteMode -quiet -route_detail_fix_antenna
```

The software displays the following information:

```
true
```

- The following command displays the current settings for all `setNanoRouteMode` parameters:

  ```
  getNanoRouteMode
  ```

- The following command displays the current settings for all `setNanoRouteMode` parameters in Tcl list format only:

  ```
  getNanoRouteMode -quiet
  ```

```

Returns information about the specified Early Global Route mode parameter in the Innovus log file and the console. The following information is returned:

- Parameter name
- Current value
- Type (Boolean, string, and so on)
- Whether the current value was set by user

If you do not specify a parameter, the software displays information for all of the Early Global Route mode parameters.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `getRouteMode` parameter. For a detailed description of the command and all of its parameters, use the man command: `man getRouteMode`
`-nonDefault`	Displays the current settings that are not default settings.
`parameter_names`	Displays information for the specified parameters. You can specify one or more parameters. See `setRouteMode` for descriptions of the Early Global Route parameters you can specify.
`-quiet`	Displays the current settings for the specified parameters in Tcl list format only. If you specify `-quiet` without any parameters, the software displays the current settings of all `setRouteMode` parameters in Tcl list format.

Examples

- The following command displays the current setting for the `-earlyGlobalNumTracksPerClockWire` parameter:

  ```
  getRouteMode -earlyGlobalNumTracksPerClockWire
  ```

  The software displays the following information:

  ```
  -earlyGlobalNumTracksPerClockWire 0 # int, default=0, min=0, max=8
  0
  ```

- The following command displays the current setting for the `-earlyGlobalRoutePartitionPinGuide` parameter:

  ```
  getRouteMode -earlyGlobalRoutePartitionPinGuide
  ```

  The software displays the following information:

  ```
  -earlyGlobalHoutePartitionPinGuide true # bool, default=true
   {earlyGlobalRoutePartitionPinGuide true}
  ```

globalDetailRoute

```
globalDetailRoute
[-help]
[-select]
[area]
```

Uses the NanoRoute router to perform both global and detailed routing with one command. When you load a partially routed database, the router completes the routes.

- To perform global routing only, use `globalRoute`.
- To perform detailed routing only, use `detailRoute`.

This command supports multiple-CPU processing.

Use this command after completing the following steps:

1. Placing the design.
2. Routing special nets.
3. Setting net attributes with `setAttribute` command, and NanoRoute run-time options with `setNanoRouteMode` command.

Note: To use NanoRoute current values for attributes, and default values for options, this step is optional.

Parameters

area	Specifies the coordinates (*x1 y1 x2 y2*) of the bounding box area for detailed routing. The entire design is globally routed. *Data_type*: rect, optional
-help	Outputs a brief description that includes the type and default information for each `globalDetailRoute` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man globalDetailRoute`
-select	Routes selected nets. To select a net, use the `selectNet` command or click the net in the design display window. **Tip**: You can also specify `setNanoRouteMode -route_selected_net_only true` to route the selected nets. *Data_type*: bool, optional

Note: If you have not already run detailed routing on the entire design, you cannot run detailed routing on a specified area.

Example

The following commands run global and detailed routing, save the design as `droute`, and generate a routed DEF file named `droute.def`.

```
globalDetailRoute
saveDesign droute
defOut -floorplan -placement -routing droute.def
```

  - Routing Phases

globalRoute

```
globalRoute
[-help]
```

Plans the interconnect by breaking the routing portion of the design into rectangles called global routing cells (gcells) and assigning the signal nets to the gcells.

Note: If you are running ECO routing, use `globalDetailRoute`. Your results are not predictable with other routing commands.

Use this command after completing the following steps:

1. Placing the design.
2. Setting net attributes with `setAttribute`, and NanoRoute run-time options with `setNanoRouteMode`. To use current values for attributes and default values for options, this step is optional.

Parameters

`-help`	Outputs a brief description of the `globalRoute` command. For a detailed description of the command, use the man command: `man globalRoute`

Example

The following command globally routes the design and saves the design as `droute`.

```
globalRoute
saveDesign droute
```

report_route

```
report_route
[-help]
[-clock]
[-em]
[-fanout integer]
[-fill]
[-inst string]
[-multi_cut]
[-ndr]
[-net net_name]
[-net_length length]
[-patch]
[-pg_net string]
[-secondary_pg_nets {cellName1:pinName1}]
[-selected]
[-shield]
[-summary]
[-via_pillar]
[-track_utilization [-area {{lx1 ly1 ux1 uy1} {lx2 ly2 ux2 uy2}...} | -view_window ]
  [-layer string] [-include_regular_routes ]]
```

Report all the routing related information of the design. The `report_route` command is used for reporting:

- Congestion
- Single-cut or multi-cut table for each layer.
- Via Usage summary
- DFM via reporting
- Shield coverage
- EM coverage
- Wire length
- Wire density
- DRC violations
- Statistics for selected nets
- Track utilization

Parameter

`-area {{lx1 ly1 ux1 uy1} {lx2 ly2 ux2 uy2}...}`	
	Specifies the coordinates of one or more area regions for reporting track utilization. For example, `report_route -track_utilization -area {299.9015 301.332 371.8345 372.4}` *Data_type*: box_list, optional
`-clock`	Reports statistics of clock nets. *Data_type*: bool, optional
`-em`	Reports EM statistics of nets. *Data_type*: bool, optional
`-fanout integer`	Specifies the minimum fanout for limit. *Data_type*: int, optional
`-fill`	Specifies the patch wire and active fill information. *Data_type*: bool, optional

`-help`	Outputs a brief description that includes type and default information for each `report_route` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_route`
`-include_regular_routes`	Reports track utilization for tracks blocked by regular wiring. **Note:** By default, the `report_route` command does not include regular wiring when computing track utilization. *Data_type*: bool, optional
`-inst` *string*	Specifies the instance name. *Data_type*: string, optional
`-layer` *layer* | *layer:layer*	Specifies the layer or layer range for which track utilization report is generated. For example: `report_route -track_utilization -layer 1:4` *Data_type*: string, optional
`-multi_cut`	Prints single-cut and multi-cut table for each layers. If you specify the DFM via list with `setNanoRouteMode -dbViaWeight` then this *Data_type*: bool, optional
`-ndr`	Reports NDR statistics of nets. *Data_type*: bool, optional
`-net` *net_name*	Specifies the name of the net for which the report is generated. *Data_type*: string, optional
`-net_length length`	Specifies the minimum wire length of the net for reporting the net statistics. All nets whose length is more than the specified value *Data_type*: float, optional
`-patch`	Adds the patch length information to the report. *Data_type*: bool, optional
`-pg_net` *string*	Specifies the PG net name. *Data_type*: string, optional
`-secondary_pg_nets {`*cellName1*`:`*pinName1*`}`	
	Specifies the secondary pg pin information. It reports the routing length of the secondary pg pin from the grid tap point to pin. You report all the secondary pg pins and sort the results in descending order. Use model: `report_route -secondary_pg_nets {ENDCAP:BIASNW}` *Data_type*: string, optional
`-selected`	Reports statistics for selected nets only. *Data_type*: bool, optional
`-shield`	Reports shield coverage for nets routed by the NanoRoute router. *Data_type*: bool, optional
`-summary`	Specifies that just the summary table should be displayed in the report. The summary report contains: • Number of objects, such as cells, nets, and pins • Number and percentage of nets with one, two, three, four, or more terminals. • Names and numbers of primitives used. • Net length and connection length statistics • Total wire length and number of vias, per layer. *Data_type*: bool, optional
`-track_utilization`	Reports the track utilization. *Data_type*: bool, optional

`-via_pillar`	Reports stacking via statistics. *Data_type*: bool, optional
`-view_window`	Report area in ui_view_box. *Data_type*: bool, optional

Example Report

- The following command reports the track utilization in the specified area for layers Metal1-Metal4 and include regular routes.

```
report_route -track_utilization -area {299.9015 301.332 371.8345 372.4} -layer 1:4 -include_regular_routes

#Calculating Track Utilization in region ( 299.90150 301.33200 371.83450 372.40000 ) for layer range: 1-4 [Metal1-Metal4] ...

Related Information

- Using the NanoRoute Router chapter in the *Innovus User Guide*

report_tracks

```
report_tracks
[-help]
[-prefer_only]
```

Reports track definitions for each layer. The output is in the DEF TRACKS format. This command can be used after the floorplan is created or after using the `add_tracks` command to see exactly which tracks were created.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `report_tracks` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_tracks`.
`-prefer_only`	Reports track definitions only for the preferred direction of each layer. *Data_type*: bool, optional

Example

- The following command reports the track definitions for each layer:
  report_tracks

```
TRACKS Y 560 DO 2657 STEP 1120 LAYER Metal6 ;
TRACKS X 660 DO 1503 STEP 1980 LAYER Metal6 ;
TRACKS X 660 DO 2255 STEP 1320 LAYER Metal5 ;
TRACKS Y 560 DO 2657 STEP 1120 LAYER Metal5 ;
TRACKS Y 560 DO 2657 STEP 1120 LAYER Metal4 ;
TRACKS X 660 DO 2255 STEP 1320 LAYER Metal4 ;
TRACKS X 660 DO 2255 STEP 1320 LAYER Metal3 ;
TRACKS Y 560 DO 2657 STEP 1120 LAYER Metal3 ;
TRACKS Y 560 DO 2657 STEP 1120 LAYER Metal2 ;
TRACKS X 660 DO 2255 STEP 1320 LAYER Metal2 ;
TRACKS X 660 DO 2255 STEP 1320 LAYER Metal1 ;
TRACKS Y 560 DO 2657 STEP 1120 LAYER Metal1 ;
```

- The following command reports the track definitions only for the preferred direction of each layer:
  `report_tracks -prefer_only`

```
TRACKS X 660 DO 1503 STEP 1980 LAYER Metal6 ;
TRACKS Y 560 DO 2657 STEP 1120 LAYER Metal5 ;
TRACKS X 660 DO 2255 STEP 1320 LAYER Metal4 ;
TRACKS Y 560 DO 2657 STEP 1120 LAYER Metal3 ;
TRACKS X 660 DO 2255 STEP 1320 LAYER Metal2 ;
TRACKS Y 560 DO 2657 STEP 1120 LAYER Metal1 ;
```

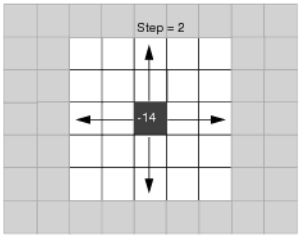
reportCongestArea

```
reportCongestArea
[-help]
[-num [all | numOfHotSpot ]]
[-cutOffRatio cutOffRatioOfPeakHotSpot ]
[-cutOffValue cutOffCongestNum ]
[-mode modeName]
[-step num ]
[-cutoffArea cutOffGcellNum ]
[-outfile fileName ]
```

Reports the congestion hot spots in the design.

The Innovus software uses the following algorithm to define the boundaries of hot spots:

1. Finds the most over-congested gcell (that is, the gcell with the largest overflow value) in the design. A gcell has overflow if its demand exceeds its supply. Typically, the supply is the number of unobstructed tracks crossing the gcell, and the demand is the number of wires assigned to it.
2. Starting from the over-congested gcell, checks a specified number of gcells (using -step) in one direction for congestion. If the gcells have an overflow value that is less than the specified congestion threshold (using `-cutOffRatio` or `-cutOffValue`), the software determines this to be the boundary for that side of the hot spot, and begins checking in a new direction.



3. After the software establishes the boundaries for the first hot spot, it finds the next most over-congested gcell that is not part of the already defined hot spot and begins defining the boundaries for it. You can use the `reportCongestArea` command after running Early Global Route.

Parameters

`-cutoffArea` *`cutOffGcellNum`*	Filters out any hot spots that have an area (specified in gcells) that is less than *`cutOffGcellNum`*. *Default:* `0` (Reports all hot spots in the design) *Data_type*: int, optional
`-cutOffRatio` *`cutOffRatioOfPeakHotSpot`*	Specifies the minimum congestion threshold value a gcell must have to be considered part of the hot spot, as a ratio of the peak overflow value. The software checks the congestion for the gcell by dividing the overflow value of the most over-congested gcell (that is, the peak overflow value) by the overflow value of the gcell. If the resulting congestion value is less than the specified *`cutOffRatioOfPeakHotSpot`*, the software determines this to be the boundary for that side of the hot spot, and begins checking in a new direction. *Min*: `0` *Max*: `1` *Default:* `0.01` *Data_type*: float, optional
`-cutOffValue` *`cutOffCongestNum`*	Specifies the minimum overflow value a gcell must have to be considered part of the hot spot. *Default:* `-2` *Data_type*: int, optional
`-mode` *`modeName`*	Specifies the mode, average or max, on which congestion hot spots in the design are reported. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `reportCongestArea` parameter. For a detailed description of the command and all of its parameters, use the man command `man reportCongestArea`.
`-num [all | numOfHotSpot]`	
	Specifies how many hot spots to report. *Default:* `10` • all: Reports all hot spots in the design. • *`numOfHotSpot`*: Reports up to the specified number of hot spots in the design. *Data_type*: string, optional
`-outfile` *`fileName`*	Outputs the hot spot report to the specified file. *Data_type*: string, optional
`-step` *`num`*	Specifies the number of gcells to check for congestion. *Default:* `3` *Data_type*: string, optional

Examples

- The following command outputs a report describing up to10 hot spots in the design that are found by checking three gcells at a time, using an absolute congestion threshold of `-2` and a relative threshold value of `0.01`:

  ```
  reportCongestArea -step 3 -cutoffRatio 0.010000 -cutoffValue -2 -num 10 -mode average
  ```

  The resulting report contains the following hot spot information for vertical and horizontal congestion:

  - The largest overflow value for the hot spot (`#Peak`)
  - The location of the gcell that contains the largest overflow value (`Location`)
  - The boundary coordinates for the hot spot (`Boundary Box`)
  - The area of the hot spot, in gcells (`Area`)
  - The following example shows the congestion hot spot report generated by the previous command:

    ```
    # Vertical Congestion Area Report
    #Peak   Location(X,Y)      Boundary Box                Area(#Gcell)
    -36      (1791.7,  376.4)    (1778,  332) (1792,  786)    (6x123)
    -23      ( 607.2,  284.1)    ( 580,  251) ( 607,  306)    (12x15)
    -20      (1791.7, 2236.1)    (1778, 2214) (1792, 2247)    (6x9)
    -18      ( 607.2,  125.5)    ( 593,   92) ( 607,  148)    (6x15)
    -15      ( 637.1,  380.1)    ( 630,  347) ( 720,  435)    (39x24)
    -14      (1791.7,  859.8)    (1778,  860) (1792,  982)    (6x33)

    # Horizontal Congestion Area Report
    #Peak   Location(X,Y)      Boundary Box                Area(#Gcell)
    -92      (1777.9, 114.4)    (1750, 4) (1854, 114)         (45x30)
    -60      ( 623.3, 114.4)    ( 472, 4) ( 816, 125)         (150x33)
    ```

- The following line from the example shows that the largest overflow value for one hot spot is `-36`, the gcell that contains the overflow value is located at `1791.7 376.4`, the coordinates for the hot spot boundary are (`1778, 332`) (`1792, 786`), and the hot spot is 6 gcells by 123 gcells in size:

  ```
  -36      (1791.7,  376.4)    (1778,  332) (1792,  786)    (6x123)
  ```

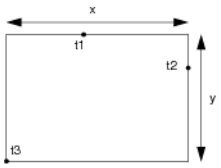
reportRoute

```
reportRoute
[-help]
[-clock]
[-em]
[-ndr]
[-selected_net_only]
[-via_pillar]
```

Reports routing statistics for signal nets, including the following information:

- Number of objects, such as cells, nets, and pins
- Number and percentage of nets with one, two, three, four, or more terminals
- Names and numbers of primitives used
- EM statistics of nets.
- NDR statistics of nets.
- Net length and connection length statistics
  These values are computed using the net bounding box half-perimeter.
  The following figure shows a net bounding box for a net that must be connected to three terminals, t1, t2, and t3. The net bounding box is the perimeter of the smallest rectangle that can be formed that has sides passing through the three terminals. The half-perimeter is the length of `x` plus the length of y.



- Total wire length and number of vias, per layer
  These are the actual wire length and number of vias on each layer. The actual wire length might be different from the net bounding box half-perimeter if the net detours.
  The layer statistics are in the last paragraph of the report.

Note: Use the `reportWire` command to generate a more detailed wire statistics report. Use the `reportSpecialRoute` command to generate a report for special nets.

You can use the `reportRoute` command after routing with any of the routing commands in the Innovus System software.

Parameter

`-clock`	Reports statistics of clock nets. *Data_type*: bool, optional
`-em`	Reports EM statistics of nets. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes type and default information for each `reportRoute` parameter. For a detailed description of the command and all of its parameters, use the man command: `man reportRoute`
`-ndr`	Reports NDR statistics of nets. *Data_type*: bool, optional
`-selected_net_only`	Reports statistics for selected nets only. *Data_type*: bool, optional
`-via_pillar`	Reports stacking via statistics. *Data_type*: bool, optional

Example Report

In the example report the terms `long connection`, `nrCon`, `and total length` are used.

- `long net` is a net that is longer than the last net listed in the report. In the report that follows, it is any net longer than `1.82e+06`.
- `nrCon` is the total number of I/O connections in the nets with long connections.
- `total length` is the total wire length.

reportShield

```
reportShield
[-help]
[-crosstie]
[-include_layer]
[-out_file fileName]
[-selected]
[-verbose]
```

Reports shield coverage for nets routed by the NanoRoute router.

Parameters

`-crosstie`	Reports the shield coverage of all shielded nets with crosstie attributes. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes type and default information for each `reportShield` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man reportShield`.
`-include_layer`	Reports the shielding ratio per layer per net in addition to the ratio for the whole net. *Data_type*: bool, optional
`-out_file fileName`	Specifies the report file name. *Default:* `designName_shield.rpt` *Data_type*: string, optional
`-selected`	Reports statistics for selected nets only. *Data_type*: bool, optional
`-verbose`	Includes a list of nets that are skipped, which includes the following nets: • `FIXED` nets • `SPECIAL` nets • Nets with the `skip_routing` attribute • Nets with opens *Data_type*: bool, optional

Examples

The following command reports for selected nets only but breaks them down by segment. The summary report will be printed in log, and detailed report will be in *myDesign_shield.rpt* file.

```
reportShield -crosstie -selected -verbose -out_file myDesign_shield.rpt
In myDesign_shield.rpt file:
NET in:

reportWire

```
reportWire
[-help]
[fileName]
[threshold]
[-detail]
[-maxFanout integer]
[-minWireLength float]
[-sort {ratio wire_length half_perimeter}]
[-summary]
```

Creates a report file that contains wire statistics for signal nets with a real wire length or minimum wire length that is greater than the specified threshold ratio. The wire statistics for signal nets can also be based on the fanout or wire length of the net.

Ratio (*r*) is calculated as *r* = (*total net routing length*) / (*half-perimeter of net bounding box*).

The wire information reported includes the net name, the wire ratio, the real and minimum wire lengths, the number of vias, and the number of fanins and fanouts on the net. Use the `reportWire` command after routing with any of the routing commands in the Innovus software.

Note: Use the `reportRoute` command to generate a layer-by-layer wire statistics report. Use the `reportSpecialRoute` command to generate a report for special nets.

Parameters

`-detail`	Includes detailed information in the report. This includes the wire length and number of vias for each layer, and a summary of the total wire length and via number for the design. *Data_type*: bool, optional
fileName	Creates a report file using the specified name. *Default:* Creates a report file named <`topcell`>`.wirerpt` *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `reportWire` parameter. For a detailed description of the command and all of its parameters, use the man command `man reportWire`.
`-maxFanout` *fanout*	Specifies the maximum number of net's fanout. *Data_type*: int, optional
`-minWireLength` *length*	Specifies the minimum wire length of the net. *Data_type*: float, optional
`-sort {ratio wire_length half_perimeter}`	Specifies the order in which the nets are sorted in the output report. The nets can be sorted as per the ratio, wire length, or half perimeter length. *Data_type*: enum, optional
`-summary`	Specifies that just the summary table should be displayed in the report. *Data_type*: bool, optional
threshold	Reports wire statistics for wires with lengths greater than the specified threshold ratio. If you do not specify a threshold ratio, the `reportWire` command calculates wire information for wires with a ratio greater than `1.0`. *Default:* `1.0` **Note:** There are many situations in which the threshold ratio can be less than `1.0`. To ensure that the software creates a report on all nets, specify a ratio value of `0`. *Data_type*: float, optional

Examples

- The following command writes the wire statistics for all nets with wire lengths greater than the 1.0 threshold ratio:
  ```
  reportWire 1.0
  ```

The following example shows a section of the wire information reported:

```
ratio      wire_length  half_perimeter  vias fan_in fan_out net_name
                            length
------------------------------------------------------------------------
1.08 Total   177.090     164.16 Total     4     1       1     dOut2[1]

1.09 Total   456.740     155.76 Total    10     1       4     s2[0]
...
```

- The following command writes the detailed wire statistics for all nets with wire lengths greater than the 1.0 ratio to the `detail.wirerpt` file. This report includes the wire length and number of vias for each layer, and a summary of the total wire length and via number for the design:

  ```
  reportWire -detail detail.wirerpt 1.0
  ```

  The following example shows a section of the wire information and the summary from the end of the report:

  ```
  ratio      wire_length      half_perimeter  vias fan_in fan_out net_name
                                length

route_fix_signoff_drc

```
route_fix_signoff_drc
[-help]
[-fix_rule ruleName | -exclude_rule ruleName]
```

Fixes sign-off DRC. It fixes third party DRC violations which cannot be detect by the Innovus verification tool (like verify_drc). The third party markers need to be converted with the `loadViolationReport` command. The supported drc types include, spacing, mincut, colorLoop, area, minhole, maxstackedvia, enclosure, width, and minstep.

Parameters

`-exclude_rule` *ruleName*	Specifies the sign_off tool rule type to exclude. *Data_type*: string, optional
`-fix_rule` *ruleName*	Specifies the sign_off tool rule type to fix. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `route_fix_signoff_drc` parameter. For a detailed description of the command and all of its parameters, use the man command `man route_fix_signoff_drc .`

routeDesign

```
routeDesign
[-help]
[-backside]
[-bump]
[-highFrequency]
[-selected]
[-viaPillarOpt]
[[[-clockEco ] [-globalDetail ]
  [-placementCheck | -noPlacementCheck ]
  [[ -trackOpt ] [-idealClock ]]
  [-viaOpt ] [-wireOpt ]] | [-passiveFill ]]
```

Runs routing or postroute via or wire optimization using the NanoRoute router. If you specify this command without any arguments, it runs global and detailed routing.

The `routeDesign` command has the following characteristics:

- It supports multiple-CPU processing.
- It checks for conflicts in option settings and issues warning messages when it finds problems. For example, trying to fix postroute lithography problems and optimize vias concurrently can cause conflicts.
  If `routeDesign` detects requests for both types of operation, it issues a warning, turns off via optimization, and proceeds with fixing lithography problems.
- It honors all `setNanoRouteMode` settings that do not have conflicts
- `routeDesign` is a super command that handles the setting of NanoRoute variables so that it is run in timing-driven mode then sets them back postRoute. It runs SMART routing by default; that is, it runs in both timing- and signal integrity-driven mode by default.
  Note: The other routing commands are not timing- or signal-integrity driven by default, but you can use the following `setNanoRouteMode` parameters to turn on timing- and signal-integrity-driven routing for those commands:
  To turn on timing-driven routing, run the following command before running `routeDesign`:
  ```
  setNanoRouteMode -routeWithTimingDriven true
  ```
  To turn on SI-driven routing, run the following command before running `routeDesign`:
  ```
  setNanoRouteMode -routeWithSIDriven true
  ```
  If you run either (or both) of these commands, the software stores the mode settings in the .mode file. If you restore the design and run `routeDesign` again, it honors the these settings. For example, if you type the following commands, the next time you restore the design and run `routeDesign`, it routes the design in timing-driven mode:
  ```
  setNanoRouteMode -routeWithTimingDriven true
  routeDesign -globalDetail
  saveDesign
  ```
- It updates the timing file automatically after all the nets are detail routed in timing-driven mode. Updating the file ensures that critical nets are not touched during postroute multiple-cut via swap, wire spreading and wire widening. When determining whether all the nets are detail routed, the router skips pins without physical ports.
- It runs a placement check prior to routing and displays a warning message if the placement is not clean.
- To turn off the placement check, specify the following parameter: `-noPlacementCheck`
- It changes the status of clock nets from FIXED to ROUTED so it can modify them during routing and routes them before routing other nets. Once the status of the clock nets is set to ROUTED, it does not change it back to FIXED.
  To keep clock nets' status FIXED, run the following command before running `routeDesign`:
  ```
  setNanoRouteMode -routeDesignFixClockNets true
  ```
  To stop the router from routing clock nets first, run the following command before running `routeDesign`:
  ```
  SetNanoRouteMode -routeDesignRouteClockNetsFirst false
  ```

Note: You can use the `check_design -type route` command to detect the potential problems and correct the design before running the `routeDesign` command

- For issues related to unplaced instances that clearly affect routing, the `check_design` command displays error messages and returns a status to discontinue the flow. You must resolve the issue before continuing to the route phase.
- For issues related to adherence to the track rules, the `check_design` command checks the design. It currently makes a basic check that the structures needed for routing adhere to the tracking rules before routing begins.
- For issues related to unplaced top level pins that clearly affect routing, the `check_design` command displays error messages and returns a status to

discontinue the flow. You must resolve the issue before continuing to the route phase.

- For issues related to adherence to the third party routing rules, the check_design command checks the design for metal violations. If the design is taped out or known to be clean, the presence of violations represents a discrepancy between the design and the tech.lef. It normally indicates that the tech may be of the wrong version or may need to be updated to the technology that the design was taped out using. These issues must be understood in detail and waved individually and on purpose by changing the tech.lef before continuing to the route phase.
- For issues related to overlapping cells that clearly affect routing, the `check_design` command displays error messages and returns a status to discontinue the flow. You must resolve the issue before continuing to the route phase.
- For issues related pin spacing violations, the `check_design` command checks if the pin has a spacing violation with the same cell or a different metal cell. It checks macro pin related spacing violations and runs the `verify_drc` command to catch spacing issues that may block the pin access.You must resolve the issue before continuing to the route phase.
- For issues related to routing congestion, the `check_design` command checks the NanoRoute congestion table and reports the congestion in the NanoRoute log format (with the information that the source is NanoRoute Global). Alternatively, it reports the Early Global Route congestion in the NanoRoute format. By default, the `check_design` command stops if the Worst Over Congested Gcell is above 0.75%. Even though these issues can be ignored, it is recommended that you understand them in detail and wave them individually before continuing to the route phase.
- For issues related to a blockage between the pin and the attribute constraint layer at the pin location, the `check_design` command displays error messages and returns a status to discontinue the flow. You must resolve the issue before continuing to the route phase.
- For issues related to pre-existing violations in ECO routing, the `check_design` command runs the `verify_drc` command and then checks the results for routing wire DRC and ignores non-routing wire DRC. If any metal violation is found, the `check_design` command displays error messages and returns a status to discontinue the flow. You must resolve the issue before continuing with ECO routing.
- For issues related to adherence to the third party routing rules, the check_design command checks the design for metal violations. If the design is taped out or known to be clean, the presence of violations represents a discrepancy between the design and the tech.lef. It normally indicates that the tech may be of the wrong version or may need to be updated to the technology that the design was taped out using. These issues must be understood in detail and waved individually and on purpose by changing the tech.lef before continuing to the route phase.
- For issues related to unplaced top level pins that clearly affect routing, the `check_design` command displays error messages and returns a status to discontinue the flow. You must resolve the issue before continuing to the route phase.
- For issues related to pin access for non-default rules, the `check_design` command checks each NDR nets output pin for two-cut APA accessibility. For macros, it checks if the pin width is less than or equal to the NDR. The `check_design` command displays error messages if the NDR is hard or if the no taper property is set to true. You must resolve the issue before continuing to the route phase.

Parameters

`-backside`	Routes back side layers only. The NanoRoute router supports back side routing for the layers defined as "BACKSIDE" in LEF and cell library pins. When the `-backside` parameter is enabled, the router connects the pins in the back side layers only. **Note:** Back side routing layer has the “BACKSIDE” LEF property assigned to it. The back side rule is used to specify that the routing layer is used on the underside of the die. *Data_type*: bool, optional
`-bump`	Enables interposer routing to connect the macro bumps with bus routing patterns. **Note:** Before enabling this functionality, you must specify the routing settings using the `-route_interposer*` parameters of the `setNanoRouteMode` command. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes type and default information for each `routeDesign` parameter. For a detailed description of the command and all of its parameters, use the man command: `man routeDesign`.
`-highFrequency`	Runs high frequency routing. It routes high frequency digital signals to achieve critical performance. *Data_type*: bool, optional
`-clockEco`	Runs eco routing only on clock nets. *Data_type*: bool, optional

`-globalDetail`	Runs timing-driven and SI-driven global and detailed routing. `-globalDetail` is the default value for this command. When specified, it unfixes the clock nets and then routes all nets, including clocks that still need to be routed. It does not ECO route the clock nets prior to other signals so clock nets are not given priority as they are with `routeDesign`. **Note**: Running the `routeDesign` command without the `-globalDetail` parameter, unfixes the clock nets and will ECO route the clock nets first before routing the remaining signal nets. *Data_type*: bool, optional
`-idealClock`	Performs timing optimization using ideal clocks instead of propagated clocks. Using ideal clocks enables you to either optimize timing without building a clock tree first, or to ignore the existing clock tree, to close ideal timing. If this parameter is not specified, the software assumes that the clock tree has been built, and optimizes timing based on propagated clocks. **Note**: The `-trackOpt` parameter must be specified while using this parameter. **Note**: When this parameter is specified, all propagated clock mode settings are reset; the `setAnalysisMode -clockPropagation` parameter is set to `forcedIdeal`. *Data_type*: bool, optional
`-noPlacementCheck`	Turns off placement checking. By default, `routeDesign` runs a placement check before routing and displays a warning message if the placement is not clean. For information on the types of checks and the violation report, see `checkPlace`. *Data_type*: bool, optional
`-passiveFill`	Performs passive fill. *Data_type*: bool, optional
`-placementCheck`	Checks for placement violations before routing. If the placement is not clean, `routeDesign` display a warning message. To bypass this check use `routeDesign -noPlacementCheck`. *Data_type*: bool, optional
`-selected`	Routes selected nets only. *Data_type*: bool, optional
`-trackOpt`	Performs timing optimization after track assignment. Specify this option to ensure that TQuantus model file is used during `timeDesign` and `optDesign -postRoute` stages. **Note**: If this parameter is specified and the TQuantus model file is missing, the TQuantus model file will be generated and set automatically. If the timing library does not exist, timing optimization will be skipped and continue routing. For details of the TQuantus model file usage, see the "Creating RC Model Data in TQuantus Model File" section in the *Innovus User Guide*. *Data_type*: bool, optional
`-viaOpt`	Optimizes vias after routing. **Warning**: Exercise caution with the use of this parameter, as the router might create violations during postroute via optimization. It runs a search and repair step after optimization if violations occur. *Data_type*: bool, optional
`-viaPillarOpt`	Performs opportunistic via pillar insertion. **Note**: After the design is routed or post-route optimized, the NanoRoute router looks for available tracks around the instance pin to either add a new via pillar or upgrade the original smaller via pillar to the one with more fingers. You can perform opportunistic via pillar insertion by using the `routeDesign -viaPillarOpt` command. After opportunistic via pillar insertion, there is no need for `ecoRoute`; opportunistic via pillar insertion is DRC clean by construction. *Data_type*: bool, optional
`-wireOpt`	Optimizes wires after routing. This parameter, when specified, widens and shrinks wires after detail routing has been performed. The settings specified using the following `setNanoRouteMode` options impact the behavior of this parameter: • `-droutePostRouteWidenWire` • `-droutePostRouteSpreadWire` • `-droutePostRouteWidenWireRule` *Data_type*: bool, optional

Examples

Routing

- To run timing- and SI-driven global and detailed routing, type the following command:
  ```
  routeDesign
  ```
- To run timing- and SI-driven global and detailed routing, type the following commands:
  ```
  routeDesign -globalDetail
  ```
- To run non-timing-driven global and detailed routing, type the following commands:
  ```
  setNanoRouteMode -routeWithTimingDriven false
  routeDesign -globalDetail
  ```

Postroute Yield Optimization

- To run postroute via reduction, type the following commands:
  ```
  setNanoRouteMode -drouteMinSlackForWireOptimization slack
  setNanoRouteMode -droutePostRouteMinimizeViaCount true
  routeDesign -viaOpt
  ```
  Note : When you run these commands, the software optimize and reduce the via count. Use these commands only if no concurrent via optimization was done.
- To run postroute single-cut via to multiple-cut via swap, type the following commands:
  ```
  setNanoRouteMode -drouteMinSlackForWireOptimization slack
  setNanoRouteMode -droutePostRouteSwapVia multiCut
  routeDesign -viaOpt
  ```
- To run non-timing-driven postroute single-cut via to multiple-cut via swap, type the following commands:
  ```
  setNanoRouteMode -routeWithTimingDriven false
  setNanoRouteMode -droutePostRouteSwapVia multiCut
  routeDesign -viaOpt
  ```
- To run postroute multiple-cut via to single-cut via swap, type the following commands:
  ```
  setNanoRouteMode -drouteMinSlackForWireOptimization slack
  setNanoRouteMode -droutePostRouteSwapVia singleCut
  routeDesign -viaOpt
  ```
- To run non-timing driven postroute multiple-cut via to single-cut via swap, type the following commands:
  ```
  setNanoRouteMode -routeWithTimingDriven false
  setNanoRouteMode -droutePostRouteSwapVia singleCut
  routeDesign -viaOpt
  ```
- To run postroute wire widening, type the following commands:
  ```
  setNanoRouteMode -drouteMinSlackForWireOptimization slack
  setNanoRouteMode -droutePostRouteWidenWireRule ruleName
  setNanoRouteMode -droutePostRouteWidenWire widen
  routeDesign -wireOpt
  ```
- To run non-timing driven postroute wire widening, type the following commands:
  ```
  setNanoRouteMode -droutePostRouteWidenWireRule ruleName
  setNanoRouteMode -routeWithTimingDriven false
  setNanoRouteMode -droutePostRouteWidenWire widen
  routeDesign -wireOpt
  ```
- To run postroute wire unwidening, type the following commands:
  ```
  setNanoRouteMode -drouteMinSlackForWireOptimization slack
  setNanoRouteMode -droutePostRouteWidenWireRule ruleName
  setNanoRouteMode -droutePostRouteWidenWire shrink
  routeDesign -wireOpt
  ```
- To run non-timing-driven postroute wire unwidening, type the following commands:

```
setNanoRouteMode -droutePostRouteWidenWireRule ruleName
setNanoRouteMode -routeWithTimingDriven false
setNanoRouteMode -droutePostRouteWidenWire shrink
routeDesign -wireOpt
```

- To run postroute wire spreading, type the following commands:
  ```
  setNanoRouteMode -drouteMinSlackForWireOptimization slack
  setNanoRouteMode -droutePostRouteSpreadWire true
  routeDesign -wireOpt
  ```
- To run non-timing-driven postroute wire spreading, type the following commands:
  ```
  setNanoRouteMode -routeWithTimingDriven false
  setNanoRouteMode -droutePostRouteSpreadWire true
  routeDesign -wireOpt
  ```

saveRouteGuide

```
saveRouteGuide
[-help]
[-rguide routeGuideFileName]
[-selNetFile selNetFileName]
```

Saves the routing information to a route guide format file. Routing guide files help control the routing topology by creating regions in which Early Global Route can create wires. You can use the `saveRouteGuide` command after running Early Global Route or after restoring routing data.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `saveRouteGuide` parameter. For a detailed description of the command and all of its parameters, use the man command `man saveRouteGuide`.
`-rguide` *routeGuideFileName*	Specifies the route guide file to which to save the routing information. *Data_type*: string, optional
`-selNetFile` *selNetFileName*	Specifies a file of hierarchical net names for which to save route information. Routing information is saved only for these nets. *Data_type*: string, optional

Examples

- The following command writes the route information in route guide format to the `cts_3.guide` file:
  ```
  saveRouteGuide -rguide cts_3.guide
  ```

[-min_stack_layer layer_number]
[-stack_distance distance]
[-mask mask_number]
[-layer_mask bottomLayerNum:topLayerNum]
[-one_side_spacing bottomLayerNum:topLayerNum]
```

Attaches attributes to nets and subnets. Attaching the attributes allows the NanoRoute routing commands (`globalRoute`, `detailRoute`, `globalDetailRoute`, `routeDesign`, and `setNanoRouteMode`), and the `earlyGlobalRoute` command to route the nets following specific requirements. Attributes are persistent; that is, throughout the routing process, from global routing to optimization, the routers honor the attributes. The attributes are saved in the Innovus System database. If you save the database and exit, the attributes remain attached to the nets when you re import the database.

Note: Attributes are not saved in the DEF file.

To see the current attribute settings, use the `getAttribute` command. If you attempt to run the `setAttribute` command on any net that is part of a diffPair, matchLength, or complex shield constraint group, or a simple or complex netClass, the command reports an error stating that the command cannot be run on nets with integration constraints.
Tip: To revert to the default value of an attribute, specify default for the attribute.

Parameters

`-avoid_detour {true | false}`	Avoids detours of roughly more than a few gcell grids on the specified nets. This attribute affects global routing only. **Note:** Cadence recommends that you use caution with this attribute, as it adds congestion to the design. *Data_type*: string, optional
`-bottom_preferred_routing_layer layer_number`	

	Specifies the preferred lowest routing layer. This attribute is a soft limit; that is, NanoRoute might use a layer below the specified layer if necessary to complete routing. *Range:* 0-15 **Note:** Layers can only be specified using their layer ID numbers. Use of LEF layer names is not supported by this parameter. **Note:** If the top routing layer is equal to or greater than 4 and no bottom preferred routing layer is specified for clock nets, the router automatically sets the bottom preferred routing layer for clock nets to 3, to prevent the clock nets from blocking other nets. *Data_type*: string, optional
`-bottom_preferred_shielding_layer` *layer_number*	
	Specifies the preferred lowest shielding layer. **Note:** Layers can only be specified using their layer ID numbers. Use of LEF layer names is not supported by this parameter. *Data_type*: string, optional
`-cell_pin` *cell_name*:*pin_name*	Specifies attributes for all the nets connected to pins of instances having the same master cells. You can use : or / as a delimiter when you specify the cell name and the corresponding pin name. **Note:** If the specified `setAttribute` commands conflict, then the last setting takes precedence over all the previous `setAttribute` settings. *Data_type*: string, optional
`-coaxial_shield_interval` *tracks_number* | *metal_layer_name*:*tracks_number …*	
	Specifies the interval of crossties by routing track. *Range:* 0-63 *Default*: 0. Every track could be used by crosstie. For example, when `-coaxial_shield_interval 2` is specified, two tracks between two crossties will be empty. *Data_type*: string, optional
`-coaxial_shield_limit` *layer_number:layer_number*	
	Specifies the bottom and top routing layer limits for coaxial shields. *Data_type*: string, optional
`-coaxial_shielded_layers` *layer_number*:*layer_number*	
	Specifies the bottom and top routing layer for coaxial shields. *Data_type*: string, optional
`-comp_pin` *comp*:*pin_name list*	Specifies attributes for all nets and sub-nets connected to pins of instances having the same component. You can specify a list of pins. You can use **:** or / as a delimiter when you specify the component names and the corresponding pin names. *Data_type*: string, optional
`-em_ndr_dist` *double*	Specifies the distance from source to sink where it is needed to be applied with the EM ndr rule *Default*: 0 *Data_type*: string, optional
`-em_ndr_rule` *ruleName*	Specifies the non-default rule name which is used for EM issue fixing. *Default*: " " empty *Data_type*: string, optional

`-em_width_rule` *`layer width:dist pairs`*	Specifies the table of layer width:distance pairs. The layer width pair denotes the width for any layer to be changed from default width for EM fixing in distance X from driver. For example, `Metal1 1.0:0.5, Metal2 2.0:1.0` **Note**: The `-em_width_rule` parameter must be used with the `-em_ndr_dist` parameter. It can not be used with the `-em_ndr_rule` parameter as only one parameter can specify the non default width to apply. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `setAttribute` parameter.For a detailed description of the command and all of its parameters, use the man command: `man setAttribute`.
`-inst_pin` *`instance:pin_name list`*	Specifies attributes for all nets and sub-nets connected to pins of the same instance. You can specify a list of pins. You can use **:** or / as a delimiter when you specify the pin names and the corresponding instance names. *Data_type*: string, optional
`-layer_mask` *`bottomLayerNum:topLayerNum`*	
	Specifies the layer range to which the mask constraint should be applied. For example, if you specify 3:4, it means that the constraint should be applied on layers, Metal3 and Metal4. *Data_type*: string, optional
`-mask` *`mask_number`*	Masks constraint setting for the net. Legal values are from 0 to the mask number for the layers. A value of 0 indicates that there is no mask constraint on the net. A non-zero value indicates that all wiring on the net should be created on the specified mask. Layers that do not support the specified value will be treated as unconstrained. *Data_type*: string, optional
`-max_fanout` *`integer`*	Specifies the maximum fanout value for nets and subnets. Specifying `setAttribute -net` *`netname`* `-max_fanout` *`value`* provides per net based max_fanout constraint/control for a net. ◦ If `-max_fanout value` of a net is 0, and the `-pattern` of the net is `trunk`, the NanoRoute router honors the value of `getNanoRouteMode -routeTrunkWithClusterTargetSize` as the max fanout. ◦ If `-max_fanout value` of a net is larger than 0, and the `-pattern` of the net is `trunk`, the `-max_fanuout` value overrides the value of `getNanoRouteMode -routeTrunkWithClusterTargetSize` for the net. *Default*: 0 *Data_type*: string, optional
`-min_stack_layer` *`layer_number`*	Specifies the minimum stacking layer. It indicates that stacked vias should be added to the specified layer on output pin only. If a pin already has pre-defined custom stacked vias, and the uppermost layer of the vias is still below the specified layer, additional stack vias should be added to the specified layer. Then, regular routing would start from the specified layer of the stacked vias. *Data_type*: string, optional
`-multi_cut_via_effort {low|medium|high}`	
	Specifies the multi-cut via effort. The effort level can be low, medium, or high. *Data_type*: string, optional
`-ndr_si_length_limit {`*`layer:distance`* `list}`	

	Specifies the table of parallel run length on each layer. For example, Metal1 1.0, Metal2 2.0. It relaxes a hard NDR into a soft NDR whenever the parallel run length between the NDR wire and an other wire is smaller than the specified value
	For example,
	`setNanoRouteMode -route_strict_honor_route_rule true`
	`setAttribute -net {xgxs_tx_rdy_lane[1]} -ndr_si_length_limit {metal3:0.054}`
	Where, xgxs_tx_rdy_lane[1] is the net name, metal3:0.054 is the prl limit 0.054 in Metal3 layer.
	This setting is for, if parallel run length is less than distance(0.054) in the layer(Metal3) for the specified net, no NDR spacing is needed for this net (wire segment).
	Data_type: string, optional

`-net` *netName*	Specifies the net for which to set attributes. Do not enter more than one net name. • To specify more than one net, use `*` and `?` wildcard characters. • To specify nondefault rule nets, use `@RULE`. • To specify clock nets, use `@CLOCK`. (To select clock nets use `selectNet -allDefClock`.) • To specify prerouted nets, use `@PREROUTED`. **Note**: Remove an attribute from a net by specifying none. For example, to remove the - shield_net attribute from net_1, specify the following command: `setAttribute -net net_1 -shield_net none` *Data_type*: string, optional
`-non_default_rule` *rule_name*	Identifies the nondefault routing rule to use with the specified net. Use this attribute for critical nets, such as clock nets, that might need to have wider wires or wider spacing than other nets. The NanoRoute router treats nondefault rule spacing as a soft attribute; that is, when routing resources are available, it honors the nondefault rule. If the area is too congested, and resources are not available, the router might not honor nondefault spacing rules. You can override this behavior by specifying `setNanoRouteMode -route_strict_honor_route_rule true`. When you specify this parameter, the router uses the nondefault spacing rules. You define nondefault routing rules in the NONDEFAULTRULE statement of the LEF file. *Data_type*: string, optional
`-non_default_rule_effort {auto|soft|hard|no_taper}`	
	Specifies the non-default rule effort to use with the specified net. You can set any one of the options: • `auto`: follows the HARDSPACING for the NDR in the LEF file. • `hard`: makes the NDR hard even if HARDSPACING is not set in the LEF file. • `soft`: makes the NDR soft even if HARDSPACING is set in the LEF file. • `no_taper`: follows the HARDSPACING for the NDR in the LEF file and does not allow tapering at all pins. *Default*: `auto` *Data_type*: string, optional
`-one_side_spacing` *bottomLayerNum:topLayerNum*	
	Specifies the layer range that the `one_side_spacing` constraint should be applied on. This constraint means that spacing is reserved on any one side. For example, 3:4 means that the constraint should be applied on layers, Metal3 and Metal4. *Data_type*: string, optional
`-pattern {steiner | trunk}`	Specifies the routing pattern. Select one of the following: • `steiner`: Routes all pins with a single steiner tree. • `trunk`: Routes pins to the nearest special net of the same name. Creates multiple steiner trees and connects them to the trunk. • *Data_type*: string, optional

`-preferred_extra_space` *integer*	Specifies the preferred extra spacing for nets. Gives additional pitch spacing to the specified net. Use this attribute to give critical nets extra space to reduce coupling. Specify `-preferred_extra_space 1` to give a net 1 extra pitch spacing, compared to other nets. This parameter creates a soft rule and, if the design is congested, might not give the extra space to the net. *Range:* 0-3 **Note:** If you specify this attribute, Early Global Route also gives additional space to the specified nets. *Data_type*: string, optional
`-preferred_routing_layer_effort {low | medium | high | hard}`	
	Determines how flexible the NanoRoute router is when setting layer limits for routing specified nets. Use this attribute with the `-top_preferred_routing_layer` and `-bottom_preferred_routing_layer` attributes. Specify medium, high, or hard to make NanoRoute less flexible (that is, to make NanoRoute obey the preferred routing layer range more strictly). When set to hard, NanoRoute prevents the nets from going to the non-preferred routing layers by setting large costs. *Default:* low (more flexible) *Data_type*: string, optional

`-reset`	Currently you cannot reset all the attributes of a net. You can reset each attribute of a net by using the `-reset` parameter with the attribute or you can use the “default” keyword for the value of each attribute.
	For example:
	• The following command sets the weight attribute of the net (scan_in_1) to 3 and the mask attribute to 2:
	`setAttribute -net scan_in_1 -weight 3 -mask 2`
	• The following command resets the weight attribute of the net:
	`setAttribute -net scan_in_1 -reset -weight -mask 2`
	• The following command resets the mask attribute of the net:
	`setAttribute -net scan_in_1 -weight 3 -mask default`
	Data_type: string, optional

`-shield_net` *special_net_name*	Specifies a special net to use as a shield for a critical or high-speed net. Typically, you route shielded nets before routing other nets. You can specify one or two shield nets, however, you cannot control which side is used by the special net that is routed on the same layer as the signal routing. The shield terminates near the pin. Shielding information is saved in the DEF file. **Note:** The router does not support shielding nets that are defined in the SPECIALNET section of the DEF file. This limitation extends to nets that are defined partly in the SPECIALNET section and partly in the regular NET section of the file, such as some clock nets. If you set the shielding attribute on these nets, the router automatically sets the - skip_routing attribute on them as well. As a result, the nets are not modified by the router and, if they are not completely routed already, the router does not try to finish the connections. The router does not delete the shielding wires. *Data_type*: string, optional
`-shield_side {one_side | two_sides}`	
	Specifies the number of sides to route shield. *Default*: `two_sides` *Data_type*: string, optional
`-si_post_route_fix {true | false}`	
	Repairs crosstalk violations on specified nets. *Data_type*: string, optional
`-skip_antenna_fix {true | false}`	Prevents the router from repairing violations on specified nets with process antenna violations. This attribute is useful on nets that will have antenna violations repaired at the next level of hierarchy. *Data_type*: string, optional

`-skip_routing {true | false}`	Prevents the NanoRoute router from routing or rerouting unrouted or partially routed nets. When you specify `-skip_routing` for a net, the router treats the net as if you had marked it + FIXED in the DEF file and it becomes an obstruction for other nets. If the net is partially routed, the router does not complete the routing. **Note**: The value you specify for this attribute also applies to Early Global Route. **Note:** To skip routing on prerouted nets, specify `setAttribute` *Data_type*: string, optional
`-stack_distance` *distance*	Specifies the stacking distance in microns. *Default*: `0` *Data_type*: string, optional
`-stripe_layer_range` *minLayer*`:`*maxLayer*	Specifies the layer range that accommodates different StripeLayerRanges for different nets and subnets. You need to specify the following values with this parameter: • *maxLayer*: Specifies the top-most floating stripe layer allowed for connection. • *minLayer*: Specifies the bottom-most floating stripe layer allowed for connection For example, 3:4 means that the constraint should be applied on M3 and M4. *Data_type*: string, optional

`-sub_net` *sub_net_name*	Specifies the subnet for which to set attributes. This parameter is used with the `-net` parameter.
	For example:
	`setAttribute -net` *netName* `-sub_net` *sub_net_name*
	Note: Cadence recommends you to use the `dbSet` command for changing the specified attribute value for a database object. The `dbSet` command takes an object or object list as a starting point, then uses a period to traverse to other related objects, or access attributes. Additional periods can be used to continue traversing the database schema.
	For example, to specify the top preferred routing layer and bottom preferred routing layers attributes for a subnet, you can use the following `dbSet` commands:
	`dbSet [dbGet [dbGet head.libcells.name $cell_name -p].pgTerms.name $pg_pin_name -p].topPreferredLayer [dbGet head.layers.num 3 -p]`
	`dbSet [dbGet [dbGet head.libcells.name $cell_name -p].pgTerms.name $pg_pin_name -p].bottomPreferredLayer [dbGet head.layers.num 2 -p]`
	instead of using the `setAttribute -sub_net` command.
	`setAttribute -net VDD1 -sub_net VDD1_2 -inst_pin iA/FEAOB*:TVDD -top_preferred_routing_layer 3 -bottom_preferred_routing_layer 2`
	Data_type: string, optional

`-top_preferred_routing_layer` *layer_number*	
	Specifies the preferred highest layer for routing specified signal nets. This attribute is a soft limit; that is, NanoRoute might use a layer above the specified layer if necessary to complete routing. Use this attribute to improve timing by restricting the routing layers available for critical nets, while simultaneously routing other nets on all routing layers. *Range:* 0-15 **Note:** Layers can only be specified using their layer ID numbers. Use of LEF layer names is not supported by this parameter. *Data_type*: string, optional
`-top_preferred_shielding_layer` *layer_number*	
	Specifies the preferred highest shielding layer. **Note:** Layers can only be specified using their layer ID numbers. Use of LEF layer names is not supported by this parameter. *Data_type*: string, optional

`-weight integer`	Specifies a relative weight for the nets. This value is honored by placement and not by the router. *Default:* 2 *Data_type*: string, optional

Examples

- The following command sets the net weight for `net1` to `4`:
  ```
  setAttribute -net net1 -weight 4
  ```
  Setting the weight to `4` forces the router to route `net1` before it routes nets whose net weight is less than 4.
- The following command sets the net weight for all nets whose net name starts with `net1` to `4`:
  ```
  setAttribute -net net1* -weight 4
  ```
- The following command limits routing for `net1` to layers Metal4 and Metal5 if possible:
  ```
  setAttribute -net net1 -top_preferred_routing_layer Metal5\
  -bottom_preferred_routing_layer Metal4
  ```
- The following command adds two additional grid units around `net1`. The additional grid units do not have any routing.
  ```
  setAttribute -net net1 -preferred_extra_space 2
  ```
- The following command uses the nondefault rule `wide_wire1` for routing `net1`:
  ```
  setAttribute -net net1 -non_default_rule wide_wire1
  ```
- The following command uses the default rule for routing `net1`.
  ```
  setAttribute -net net1 -non_default_rule default
  ```
- The following commands shield `net1` with both power and ground wires, and shield `net2` with a ground wire:
  ```
  setAttribute -net net1 -shield_net {vdd vss}
  setAttribute -net net2 -shield_net vss
  globalDetailRoute
  ```
- The following commands show how to shield two nets (do not shield more than one net with the same command):
  ```
  setAttribute -net net1 -shield_net abc_gnd
  setAttribute -net net2 -shield_net abc_gnd
  ```

Controls certain aspects of how the NanoRoute router routes the design. Use the `getNanoRouteMode` command to return the current settings for the `setNanoRouteMode` command. The `setNanoRouteMode` parameters affect the behavior of the following commands:

- `detailRoute`
- `globalRoute`
- `globalDetailRoute`
- `routeDesign`

Notes:

- The Nanoroute Router honors litho routing halos (`addRoutingHalo -lithoHalo`). It only allows planar connections to macro pins inside the litho routing halos. It does not allow any other wire or via insertion above and below the litho halo.
- The NanoRoute Router enables off grid shielding when the default track is not available in order to optimize the routing resources.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `setNanoRouteMode` parameter. For a detailed description of the command and all of its parameters, use the man command: `man setNanoRouteMode`.
`-extract_keep_fill_wires {true|false}`	When enabled, the NanoRoute Router imports metal fill wires so that RC extraction can calculate them. *Default:* `false` *Data_type:* bool

`-reset`	Restores all parameters modified using `setNanoRouteMode` to their default settings. The `-reset` parameter must be the first parameter specified. If you specify -reset by itself, the software resets all `setNanoRouteMode` parameters to their default values. If you specify parameters after `-reset`, the software resets only those parameters to their default values. Any values that do not already match the default value and are reset will be reported.
`-route_add_antenna_inst_prefix` *value*	Specifies the prefix that is added in the diode inst names. These diodes are added to fix antennas during routing. *Default*: " " *Data_type*: string
`-route_adjust_auto_via_weight {true|false}`	Allows auto tuning of internal via weight. It adjusts auto via weight for via swapping. • When set to `true`, it enables NanoRoute to auto tune internal via weight for double cut via ratio improvement. • When set to `false`, it disables NanoRoute to auto tune internal via weight and the via weight specified using the `-route_via_weight` parameter is honored for via swapping. **Note**: NanoRoute does not swap the existing dcut via's to DFM via's. *Default:* `true` *Data_type:* bool
`-route_allow_inst_overlaps {true|false}`	Specifies that instance overlap check will be skipped when this parameter is set to true. *Default:* `true` *Data_type:* bool
`-route_allow_pin_as_feedthru {true|TRUE|false|FALSE|none|NONE|output|input|inout,` *bottomLayerNum*`:`*topLayerNum*`}`	
	Specifies that pins are allowed as feedthrough within the specified layer range. • `true`: Specifies that input/output/inout pins can be used as feedthrough. • `false`: Specifies that output/inout pins can be used as feedthrough. • `none`: Specifies that no pin is allowed as feedthrough. • `output`: Specifies that output pins can be used as feedthrough. • `input`: Specifies that input pins can be used as feedthrough. • `inout`: Specifies that all inout pins can be used as feedthrough. • `bottomLayerNum:topLayerNum`: Specifies the layer range that allows pins as feedthroughs. For example, the following command allows feedthrough for M1 and M2 pins only. `setNanoRouteMode -route_allow_pin_as_feedthrough "true, 1:2"` *Default:* `true` *Data_type*: enum
`-route_antenna_cell_name {"`*cell_name*`" | "`*list_of_cell_names*`"}`	Specifies antenna diode cells to use during postroute optimization. The cells must have the same LEF `SITE` definition as the standard cells. Use this parameter with `-route_antenna_diode_insertion`. *Default:* `""` (empty string) If you do not specify a cell, the router uses a core macro of type ANTENNACELL specified in the LEF MACRO statement. *Data_type*: string

`-route_antenna_diode_insertion {true|false}`	Inserts and places antenna diode cells if there are available placement locations. By default, the NanoRoute router repairs antenna violations by changing layers (also called antenna stapling or layer hopping), but it can also repair antenna violations by inserting diode cells as close as possible to input gates to discharge current. The router inserts antenna diode cells even if filler cells are already placed. It can swap filler cells with antenna diode cells and fill the gap automatically if an antenna diode cell is not the same size as the filler cell it replaced. To specify the diode cells, use `-route_antenna_cell_name`. *Default:* `false` *Data_type*: bool
`-route_concurrent_minimize_via_count_effort value`	Specifies the effort level for reducing the total number of vias during routing. Use this parameter together with the `-route_detail_use_multi_cut_via_effort` parameter to control the effort toward reducing the total number of vias and the effort toward increasing the ratio of double-cut vias to single-cut vias concurrently with routing. If you specify `-route_detail_use_multi_cut_via_effort medium` or `high`, the software sets the value of `-route_concurrent_minimize_via_count_effort` to medium unless you specify `-route_concurrent_minimize_via_count_effort` yourself. To realize further savings, set `-route_concurrent_minimize_via_count_effort` to high. This could further reduce the total via count up to 10 percent. **Note:** If you specify `setDesignMode -flowEffort express`, the software sets the value of `-route_concurrent_minimize_via_count_effort` to `high`. **Note:** Results might vary with your design. Specify one of the following parameters: • `low`: Reduces the total via count using low effort. • `medium`: Reduces total via count by 15 percent, with negligible runtime overhead. This is the default setting. • `high`: Reduces the total via count by 20 percent to 25 percent, with marginal runtime overhead. *Default:* `medium` *Data_type*: string
`-route_connect_to_bumps {true | false}`	Enables bump to bump routing. *Default*: false *Data_type*: bool
`-route_detail_add_passive_fill_only_on_layers layers`	Specifies the layers where passive fill will be added. *Default:* `""`(empty string) *Data_type:* string
`-route_detail_allow_passive_fill_only_in_layers layers`	When specified, allows passive fill only in layers. *Default:* false *Data_type:* string

`-route_detail_antenna_eco_list_file` *file_name*	Specifies the file generated during process antenna repair that contains the list of diodes that were inserted. If you insert diodes during more than one detailed routing pass, the NanoRoute router creates a separate file for each pass and gives it a unique name. For example, if you use the default filename, the router creates the following files: • After the first detailed routing pass: `nano_ant_diode.list` • After the second detailed routing pass: `nano_ant_diode.list1` • After the third detailed routing pass: `nano_ant_diode.list2` *Default:* `""`(empty string) *Data_type:* string
`-route_detail_auto_stop {true | false}`	Controls whether NanoRoute continues routing if there are many violations. In highly congested designs, NanoRoute stops if the number of violations is too high. Specify false to continue routing until there is no improvement. **Note:** `-route_detail_auto_stop` is `false` by default for 20nm designs and below. **Note:** You should only override this setting when you are sure that NanoRoute will be able to resolve the violations. There are several reasons due to which NanoRoute may find the design unrouteable and stop: • Congestion: Review the congestion map to identify hot spots. If the majority of the violations are centered on these hot spots then reduce the congestion in this area by reducing the placement density using partial placement blockages or by modifying the floorplan. • Pin Access Issue: If majority of violations are on Metal1 and Metal2, it can indicate pin access problems on standard cell pins. Review the violations at these pins and determine why they are occurring. For example, check if the blockage is too close to the pin, pin is off the routing grid, or a proper via is not defined which can be dropped to the pin. • Pins under Stripes: If the violations are occurring when trying to route to standard cells placed under stripes, then use the `setPlaceMode -place_detail_preroute_as_obs` command to treat these stripes as placement blockages. *Default:* `true` *Data_type:* bool
`-route_detail_check_mar_on_cell_pin {true|false}`	Enables mar checking on used cell pins. *Default:* `false` *Data_type:* bool
`-route_detail_end_iteration` *pass_number*	Specifies the last pass in a detailed routing step. To run postroute optimization and repair remaining violations, including process antenna violations, set this parameter to its default value using the following command: `setNanoRouteMode -reset -route_detail_end_iteration` When set to its default value, the router dynamically decides when to stop. However, when you specify `-route_detail_end_iteration 0`, the end iteration will be at 0. **Note:** Specifying a higher value than 20 for `-route_detail_end_iteration` generally does not improve results. *Default:* `0` *Data_type:* int

`-route_detail_fix_antenna {true|false}`	Repairs process antenna violations by jumping layers (antennastapling). The router repairs process antenna violations if it can do so without creating DRC violations. The router might need to make several passes before repairing all antenna violations. Specify `-route_detail_fix_antenna true` to fix antenna violation on clock net during ccopt and routeDesign (clock eco). **Note**: You must set this option to true explicitly. The default value is true if you have antenna information defined in the LEF, but the router fixes antenna violations only on data nets during `routeDesign`, `globalDetailRoute`, or `detailRoute`. *Default:* `true` *Data_type:* bool
`-route_detail_fix_antenna_on_secondary_pg_nets {true|false}`	Fixes the antenna violation on secondary pg nets. *Default*: `false` *Data_type*: bool
`-route_detail_fix_antenna_with_gate_array_filler_mode {true|false}`	When enabled, the NanoRoute routers detects the GA filler flow and uses the GA filler diode cells for antenna violation fixing. *Default*: `false` *Data_type*: bool
`-route_detail_merge_abutting_cut {true|false}`	Allows you to enable or disable the capability to merge cell cut shapes. When enabled, it merges two abutting cell cut shapes into a new one. *Default:* `true` *Data_type:* bool
`-route_detail_min_length_for_spread_wire {`*`layer_1 length_1 ... layer_n length_n`*`}`	

	Specifies the minimum length in microns for a wire segment of a net before the necessity or a jog to avoid OPC issues. Spreading wires further apart (creating jogs in the wires) helps avoid design rule violations, signal integrity problems, and yield loss caused by shorts in the wires.
	This parameter supports the following values:
	• `layer`: Specifies the metal layer. The supported metal layer name is Mx, they are Metal1, Metal2, Metal3, etc.
	• `length`: Specifies the minimum length, in microns. The length value can be a floating number, default, or *skip*.
	  ◦ The default value is 0, it means wire spreading will determine the threshold automatically.
	  ◦ The *skip* value means there is no wire spreading on this layer.
	Note: You should specify the value for each metal layer. To get the number of metal layers used in the design, use db command (dbGet head.layers.name).
	Note: Turn wire spreading on or off with `-route_detail_post_route_spread_wire`
	For example, when you specify the following command, no wire spreading is done on layer Metal1. For layer Metal2, the wire spreading value is set to 0 signifying that wire spreading will determine the threshold automatically. Similarly, for layers Metal3, Metal4, Metal5, and Metal6 the wire spreading length is set to 2.0.
	`setNanoRouteMode -route_detail_min_length_for_spread_wire {Metal1 skip Metal2 0 Metal3 2.0 Metal4 2.0 Metal5 2.0 Metal6 2.0 }`
	Default: 0
	Data_type: string

`-route_detail_min_length_for_widen_wire` *value*	Specifies the minimum length in microns for a wire segment of a net before the segment is a candidate for widening. Wires are widened by an amount defined by a nondefault rule. They are not widened unless they meeting the following criteria: • Timing is not adversely affected • Routing resources are available • No overflow is created • No design rule or process antenna violations are created Widening wires helps avoid design rule violations, signal integrity problems, and yield loss. **Note**: To enable this parameter, you must also include a wide wire nondefault rule in the LEF file and specify the `-route_detail_post_route_wire_widen_rule true` parameter. *Default*: `1` *Data_type:* float
`-route_detail_min_slack_for_opt_wire` *value*	Specifies the minimum slack on pins associated with nets that are candidates for wire spreading or wire widening. Using this parameter reduces the timing impact of wire spreading, wire widening, and via swapping, and helps reduce congestion and the yield loss due to shorts and opens. **Note**: To enable this parameter, you must also specify `-route_with_timing_driven true`. Wire spreading and wire widening use the minimum slack value differently. While wire spreading only works for timing critical nets where the worst setup slack is less than the minimum slack value, wire widening only works for non-timing critical nets where the worst setup slack is greater than the minimum slack value. You can use the `-route_detail_min_slack_for_opt_wire` parameter to reduce the timing closure effort during post-route ECO. NanoRoute will replace via to multi-cut via on non-critical nets, if a violation does not occur. *Default*: `1` *Data_type:* float
`-route_detail_no_taper_in_layers` "*bottom_layer_number*`:`*top_layer_number*"	Prohibits the detailed router from tapering in the specified layer range, creating non-default-width wires in that range. *bottom_layer_number*`:`*top_layer_number* signifies the layer range format. *Default:* "" (empty string) *Data_type:* string
`-route_detail_no_taper_on_output_pin {true|false|auto}`	Prohibits the detailed router from tapering at standard cells, macro cells, and block output pins. **Note**: The default value of `-route_detail_no_taper_on_output_pin` is `auto` for 32nm and below nodes. *Default:* `false` *Data_type:* ternary
`-route_detail_on_grid_only none | false | true | all | {[wire [m1:mh]] | [via [m1:mh]]}`	

	Controls the routing of the objects, wires, and vias in relation to the user-defined routing tracks. • On grid wire means that the center of the wire is on the preferred routing track. • On grid via means that the center of the via is on the intersection of preferred routing tracks. **Note**: A preferred routing track is the track which has the same direction as that of the metal routing direction defined in the LAYER section in LEF. • When there are off-grid objects on fully-routed data, NanoRoute skips those nets and issues a warning message. • When there are fixed off-grid objects, NanoRoute skips those nets and issues a warning message. • When there are non-fixed off-grid objects, NanoRoute deletes those nets and issues a warning message. Specify one of the following arguments: • `all`: Specifies that all routing objects (vias and wires) have to be on the preferred and non-preferred routing tracks. It forces all routing objects to be on grid. • `none`: Specifies that the routing objects (vias and wires) can be off-grid. It does not force routing objects to be on grid . They can go off-grid depending on other restrictions. • `via [ml:mh]`: Specifies that the center of the vias must be at the intersection of preferred routing tracks. If `ml` and `mh` are specified, all the vias between `ml` and `mh` must be at the intersection of preferred routing tracks. For example, via [1:3] means all via12 must be at the intersection of preferred routing tracks of layer Metal1 and Metal2 and all via23 must be at the intersection of preferred routing tracks of layer Metal2 and Metal3. • `wire [ml:mh]`: Specifies that the center of the wire must be on preferred routing tracks. When a wire makes a turn on the non-preferred direction, the center of the wire might not fall on any routing tracks. If `ml` and `mh` are specified, all the center of the wires in between those metal layers `ml` and `mh` must be on the preferred routing tracks. For example, wire [1:3] means the center of the Metal1, Metal2, and Metal3 wires must be on the preferred routing tracks of Metal1, Metal2, and Metal3. • `false`: For backward compatibility purpose, the `-route_detail_on_grid_only` parameter also takes the value of `false`. This is equivalent to `'none'`. • `true`: Specifies that all wires have to be on the preferred and non-preferred routing tracks, but vias can be off the preferred and non-preferred routing tracks. **Note**: Block pins can be accessed by planar off-track wires. *Default:* `none` *Data_type:* string
`-route_detail_post_route_litho_repair {true|false}`	Corrects bridging, necking, and line-end shortening problems caused by lithography. Takes the severity of the problems into account and fixes the high-severity problems first. Prior to running the router with this parameter, import a hotspot interface format (HIF) file with `loadViolationReport`. *Default:* `false` *Data_type:* bool
`-route_detail_post_route_spread_wire {auto| true | false | 0 | 0.25 | 0.5 | 1 }`	

	Spreads routing, post route, by the percentage of the track. The router moves the wires without moving the vias. Specifying false for this parameter signifies no spreading, while specifying true signifies 0.5 / 1 track spreading by default for all nodes. The use of `true` and `false` is not needed as a value greater than `0` and less than equal to `1` (0<x=<1) activates the spreading. Specifying this parameter will not increase the overall routing run-time much but helps avoid yield loss caused by shorts and improve the timing as well. Specify one of the following: • `auto`: Spreading is on if the timing effort is set to high (`setDesignMode -flowEffort express`). Otherwise it is off. • `true`: 0.5 / 1 track spreading. Set `-route_detail_post_route_spread_wire` to `true` if you want to spread. • `false`: no spreading • `0.25`: 0.25 / 0.5 / 1 track spreading • `0.5`: 0.5 / 1 track spreading • `1`: 1 track spreading **Note:** To turn off this feature, set `setNanoRouteMode -route_detail_post_route_spread_wire` to `false` explicitly. To call wire spreading explicitly, set `-route_detail_post_route_spread_wire` to true and call `routeDesign -wireOpt`. Post route wire spreading automatically avoids fractional spreading for DPT designs. If `-route_detail_post_route_spread_wire` is enabled in 20nm designs and below, only 1 track wire spreading is done on DPT layers. *Default:* `auto` *Data_type:* string
`-route_detail_post_route_swap_via {true | multicut | false | none}`	Swaps single-cut vias for multiple-cut vias or reverses swapping on critical nets in a fully routed design, so that multiple-cut vias are swapped for single-cut vias on those nets. It swaps single-cut vias to multi-cut vias including vias of non-default nets. However, while swapping multi-cut vias to single cut vias, NanoRoute does not swap the vias of non-default rule nets. In timing-driven routing, does not swap vias if doing so would negatively impact timing. A net with a pin on a critical path is considered a critical net if the pin slack, plus the margin defined by the `-route_detail_min_slack_for_opt_wire` parameter, is less than or equal to 0. Use this parameter with the `routeDesign` command. You do not have to specify a value for this parameter when you run the following command, because the software does so automatically: `routeDesign -viaOpt` **Note:** This parameter is not enabled concurrently with postroute wire widening or wire spreading. In addition, the software does not perform via swapping if `-route_detail_post_route_litho_repair true` is specified. Specify one of the following: • `true`: Swaps all nets. The nets with attributes will get double cut and DFM precedence for others. Its weight can be specified with `-route_via_weight`. • `multicut`: All nets will be swapped with dcut precedence. • `none`: Does not swap vias. • `false`: Only nets with attributes are swapped. *Default:* `false` *Data_type:* string
`-route_detail_postroute_via_priority {auto | allNets | criticalNetsfirst | nonCriticalNetOnly}`	

	Sets the net priority for postRoute via swapping based on timing. • `auto`: Specifies the current behavior of the software, which is to detect the node and timing files to determine whether to do `criticalNetsFirst` or `nonCriticalNetOnly`. This is the default behavior. • `allNets`: Swaps single-cut vias for multiple-cut vias on all nets. • `criticalNetsFirst`: Specifies that swapping should be performed first on timing critical nets and then on other nets. This option is recommended for process nodes below 32nm. • `nonCriticalNetOnly`: Specifies that swapping should not be performed on timing critical nets. This option is recommended for 32 nm and above process nodes. *Default*: `auto` *Data_type:* string
`-route_detail_post_route_via_pillar_effort {none | low | medium | high}`	Specifies the effort levels for adding via pillars. Specify one of the following: • `none`: Adds via pillars only during routing that are required for EM constraints. • `low`: Adds via pillars during timing-driven global routing where they help in timing and do no impact congestion • `medium`: Adds via pillars more aggressively during routing. • `high`: Adds via pillars throughout routing to maximize via pillar impact on timing and area. *Default*: `low` *Data_type:* string
`-route_detail_post_route_wire_widen {widen | shrink | none}`	Applies the rule specified by the `-route_detail_post_route_wire_widen_rule` parameter to widen or shrink wires. Use this parameter with the `routeDesign` command. **Note:** This parameter is not enabled concurrently with postroute via swapping. **Note:** Wire widening is not performed on layer Metal1. Specify one of the following: • `widen`: During timing-driven routing, widens only non-critical nets; otherwise widens as many nets as possible that are covered by the non-default rule for widening wires. • `shrink`: During timing-driven routing, shrinks only critical nets; otherwise shrinks as many nets as possible that are covered by the non-default rule for widening wires. • `none`: Turns off this parameter, so the router does not widen or shrink wires. *Default:* `none` *Data_type:* string
`-route_detail_post_route_wire_widen_rule` *rule_name*	Specifies the non-default rule for widening wires. The rule is specified in the LEF file. Use this parameter with the `routeDesign` command. *Default:* "" (empty string) *Data_type:* string
`-route_detail_search_and_repair {true|false}`	Runs a search-and-repair step after the initial detailed routing (end iteration 20). **Tip:** Specify `false` for this parameter and run detailed routing to determine quickly if the design is routable. *Default:* `true` *Data_type:* bool

`-route_detail_signoff_effort {high | medium | low | auto | n}`	Specifies when to skip fixing violations related to fixed objects. The default value is `high`. In this mode, the software will ignore violations related to fixed objects after 20 detail route iterations and will continue with post-route operations. • When set to `medium`, the software will ignore any violations related to fixed objects after detail route iteration number 15. • When set to `low`, the software will ignore any violations related to fixed objects after detail route iteration number 5 and it will also skip post-route operations. • When set to `auto`, the software will automatically detect when to ignore violations related to fixed objects and it will also skip post-route operations. You can also specify the number of iterations or "n". When the iteration number is specified, the software will ignore violations related to fixed objects after the specified number of detail route iteration and will also skip post-route operations. **Note**: n must be between 3 and 20. *Default*: `high` *Data_type:* string
`-route_detail_stub_routing_in_first_layer {true|false}`	Specifies that minimum routing should be done on the first routing layer defined in the LEF. *Default:* false *Data_type:* bool
`-route_detail_use_multi_cut_via_effort {low | medium | high}`	Specifies the effort level toward increasing the ratio of double-cut vias to single-cut vias concurrently with routing. Increasing the effort level increases the double-cut via ratio and decreases the total number of vias in the design, which means that it also decreases the number of single-cut vias. The lower the number of single-cut vias, the better the yield will be. After routing with this parameter specified, you can add more double-cut vias or larger overhang vias by using the `routeDesign` command. Specify one of the following: • `low`: Specifies normal routing, so the router uses single-cut vias only. • `medium`: Balances the need for a high double-cut viaration with run time and congestion. Specifying this parameter increases the run time somewhat compared with the low parameter. The router inserts some double-cut vias, although not as many as if the high parameter were specified. • `high`: Specifies the highest yield possible for vias, as the router puts its best effort toward achieving the highest possible double-cut via ratio at the expense of run time and congestion. *Default:* `low` *Data_type:* string
`-route_diode_insertion_for_clock_nets {true|false}`	Inserts diodes to repair process antenna violations on clock nets that are in the regular net section of the DEF file. *Default:* `false` *Data_type*: bool

`-route_eco_ignore_existing_route` *value*	When specified, the selected net will be routed with highest priority by ignoring existing routes in post-route mode.
	• `all`: Ignores all other nets in the design that are not selected, including clock, secondary PG, and signal nets.
	• `signal`: Ignores only other signal nets that are not selected, but honors clock and secondary PG nets.
	For example, the following commands select and route a list of nets by ignoring only other signal nets, and considers secondary PG and clock nets during routing. After that, a second `ecoRoute` is run to fix DRC violations:
	`selectNet {net1 net2 net3}`
	`setNanoRouteMode -route_selected_net_only true`
	`setNanoRouteMode -route_eco_ignore_existing_route signal`
	`ecoRoute`
	`setNanoRouteMode -reset -route_selected_net_only`
	`setNanoRouteMode -reset -route_eco_ignore_existing_route`
	`verify_drc -limit 0`
	`ecoRoute`
	Default: " "
	Type: string

`-route_enable_route_rule_si_limit_length` *value*	Use MAR wire length as NDR PRL requirement for metal spacing check. *Default:* `false` *Data_type*: string
`-route_enforce_route_rule_on_special_net_wire {false | true |` *special_net_name_list*`}`	
	Specifies that non-default rule will be enforced on all special wire segments of specified nets. Specify one of the following parameters: • *`false`*: When specified, the non-default rule is not enforced on any wire segment of any special net. It is the default value. • *`true`*: When specified, the non-default rule is enforced on all wire segments of all special nets (with non default rules attached). • *`specified_special_net_list`*: When specified, the non-default rule is enforced on all wire segments of those specified special nets. *Default:* `false` *Data_type*: string
`-route_extra_via_enclosure` *distance*	Specifies an extra via enclosure to use when connecting to block pins and special wires. To center vias for via access, specify a value that is equal to one-half the width of the largest pin or wire. An extra enclosure of this size forces NanoRoute to connect tie-high and tie-low nets to the center of power routes. *Default:* `0` (microns) *Data_type*: float

`-route_fix_clock_nets {true|false}`	Specifies whether to maintain the current status of clock nets when the `routeDesign` command runs or change the status to ROUTED. • If you specify true for this parameter, the `routeDesign` command does not change the status of clock nets. • If you do not specify this parameter (or you specify false for this parameter), the `routeDesign` command changes the status of clock nets changes to ROUTED. **Note**: The settings of this parameter apply to the `routeDesign` command only. They do not impact the `globalRoute`, `detailRoute`, or `globalDetailRoute` commands. *Default:* false *Data_type*: bool
`-route_high_freq_constraint_groups {order net match bus pair shield}`	
	Routes only the specified constraint groups. The constraint groups can be - `net match bus pair shield`. **Note:** You can add "order" in front to control the route order. If order is present, the NanoRoute high frequency router will honor the order, if not, the router will determine the order. *Default: " "* *Data_type*: string
`-route_high_freq_match_report_file` *file_name*	Specifies the name of the match report file. *Default*: " " *Data_type*: string
`-route_high_freq_num_reserved_layers` *value*	Specifies the number of metal layers to reserve for high frequency routing above the standard cell area so that routing has more resources to access standard cell pins. *Default*: 1 *Data_type*: int
`-route_high_freq_remove_floating_shield {true|false}`	Removes floating shield segments for high frequency nets. *Default*: `false` *Data_type*: bool
`-route_high_freq_search_repair {auto | false | true | only}`	Runs search and repair to remove violations. *Default*: `auto` *Data_type*: string
`-route_high_freq_shield_trim_length` *value*	Specifies the shielding wire length. All shielding wires longer than the specified value are preserved by NanoRoute for high frequency nets. *Default*: 0 *Data_type*: float
`-route_honor_exclusive_region {true|false}`	When set to true, it enables the NanoRoute router to honor exclusive region routing. *Default:* `true`

`-route_honor_power_domain {true|false}`	Routes nets without crossing power domains. • If a net connects pins that all belong to one power domain, the software tries to route the net within that power domain. If completing the routing is not possible without breaking the rules, due to congestion for example, completes the routing and issues a warning message. • If a net connects pins that belong to different power domains, the software tries to route the net within the involved power domains, without crossing over into other power domains that do not include any of the pins in the net. If completing the routing is not possible without breaking this rule, completes the routing and issues a warning message. **Note:** You must specify a power domain before using this parameter. *Default:* `false` *Data_type*: bool
`-route_ignore_antenna_top_cell_pin {true|false}`	If true, ignores any process antenna data from external I/O pins (e.g. DEF PIN ANTENNA* data), so only the routing and antenna data from cells inside the design are used to find and repair local antenna violations. This is most commonly used with methodologies that insert diodes at the boundary pins (either inside the block or at the next level up), or in bottom-up flows where the block is routed, updated antenna data is created with the `verify_antenna` command, and then passed up to the top-level in an updated block abstract for the top-level to resolve any violations with added diodes or layer-hops. If false, the external IO antenna data is used to find and repair violations. This option will add protection diodes if needed to any external output/inout IOs that have antenna data that requires protection (e.g. have gate area), and will include the effects of external antenna data when finding and fixing local antenna violations. This is used when the user has “antenna budgets” added to the external IOs that estimate the worst-case top-level routing and gate-areas that needs protection inside this block. Currently these types of antenna budgets can only be added with defIn or oaIn. *Default:* `true` *Data_type*: bool
`-route_ignore_follow_pin_shapes {true|false}`	Ignores follow pin via shapes. *Default:* `false` *Data_type:* bool
`-route_interposer_allow_diagonal_trunk {auto | true | false}`	Allows you to control the trunk patterns in interposer routing. • `auto`: Allows the routing to decide the diagonal or straight trunk patterns based on the routing resources. • `true`: Enables diagonal trunk in interposer routing. • `false`: Disables diagonal trunk in interposer routing. *Default*: " " *Data_type*: string
`-route_interposer_interlayer_shielding_layers "`*`layer_name direction layer_name1:layer_name2 direction …`*`"`	

	Specifies the signal layers that require shielding along with the direction - top, bottom, both. By default, all routing layers (used by current routing command) are shielded from bottom. For example, the following command specifies that the M2/M3/M4 signal layers will be shielded from the top, M7 from the bottom, and M9 will be shielded from both sides: `setNanoRouteMode -route_interposer_interlayer_shielding_layers "M2:M4 top M7 bottom M9 both"` *Default*: " " *Data_type*: string
`-route_interposer_interlayer_shielding_nets "layer_name1:layer_nameN net_name …"`	
	Specifies the inter-layer shielding nets. For example, the following command specifies that the M3/M4/M5/M6 shielding net name is VSS and the M8/M9/M10 shielding net name is VDD: `setNanoRouteMode -route_interposer_interlayer_shielding_nets "M3:M6 VSS M8:M10 VDD"` *Default*: " " *Data_type*: string
`-route_interposer_interlayer_shielding_offsets "layer_name offset layer_name1:layer_name2 offset …"`	
	Specifies the center-to-center offset values between the shielding and signal wires. By default, all routing layers (used by current routing command) have an offset value of 0. For example, the following command specifies that the offset value is 1.1 um between the M1 shielding wire and signal wire and the offset value is 2.2 um between M2:M3 shielding wire and signal wire: `setNanoRouteMode -route_interposer_interlayer_shielding_offsets "M1 1.1 M2:M3 2.2"` *Default*: " " *Data_type*: string
`-route_interposer_interlayer_shielding_widths "layer_name width layer_name1:layer_name2 width …"`	
	Specifies the inter-layer shielding widths. By default, all routing layers (used by current routing command) are shielded by the default width wires. For example, the following command specifies that the shielding M1 wires width is 1.1 um, shielding M2/M3 wires width is 2.2 um: `setNanoRouteMode -route_interposer_interlayer_shielding_widths "M1 1.1 M2:M3 2.2"` *Default*: " " *Data_type*: string

`-route_interposer_same_layer_shielding_net net_name`	Specifies the same-layer shielding nets.
	For example, the following commands specifies that the M1/M3/M5 shielding net name is VSS:
	`setNanoRouteMode -route_interposer_trunk_routing_layers {M1 M3 M5}`
	`setNanoRouteMode -route_interposer_same_layer_shielding_net {VSS}`
	Default: " "
	Data_type: string

`-route_interposer_same_layer_shielding_width_spacing {width width}`	

	Specifies the same-layer shielding widths. For example, the following commands specify that the shielding width space between M1/M3/M5 is 0.6 and 1.2: `setNanoRouteMode -route_interposer_same_layer_shielding_width_spacing {0.6 1.2}` *Default*: " " *Data_type*: string
`-route_interposer_trunk_routing_layers` *value*	Specifies the trunk routing layers. For examples, the following command sets layers M1, M3, and M5 as the interposer trunk routing layers. `setNanoRouteMode -route_interposer_trunk_routing_layers {M1 M3 M5}` *Default*: " " *Data_type*: string
`-route_interposer_trunk_routing_width_spacing {`*width width*`}`	Specifies the trunk routing width spacing. For example, `setNanoRouteMode -route_interposer_trunk_routing_width_spacing {1.0 1.0}` *Default*: " " *Data_type*: string
`-route_number_fail_limit` *integer*	Specifies the maximum number of command fails allowed. In interactive mode, if a command fails you can continue with the next command. But in batch mode, if one command fails, the script stops at the failed command, however you can increase the fail limit to let it continue. *Default:* 1 *Data_type:* int
`-route_number_thread` *number_processors*	**Note:** This parameter is included for backward compatibility. Cadence recommends that you use the `setMultiCpuUsage` command to specify the number of threads in multiple-CPU processing. Specifies the maximum number of threads to use in multi-threading. Generally, using more threads decreases the run time. Specify this parameter before running any routing commands. There is no absolute limit to the number of threads the router can use, however, Cadence recommends that you do not specify more threads than the number of CPUs available. The router does not necessarily use the number of threads you specify – it determines the optimal number up to the value you specify. A small design generally uses fewer threads than a large design. *Default:* `1` *Data_type:* int **Note:** To enable a value greater than `1` for this parameter, you must have licenses available for the additional threads.
`-route_number_warning_limit` *integer*	Specifies the maximum number of warning messages for any one command reported to the log file. After reaching this number, the router continues processing, but does not report warnings for this command. *Default:* `20` *Data_type:* int

`-route_process_node` *value*	Specifies the process node. This parameter is an umbrella option to set the process related settings for routing. It supports the following values: • `S2`: Sets the Samsung 2nm process related settings. • `N2`: Sets the TSMC 2nm process related settings. • `N2X`: Sets the TSMC N2X process related settings. • `S3`: Sets the Samsung 3nm process related settings. • `N3`: Sets the TSMC 3nm process related settings. • `N3E`: Sets the TSMC N3E process related settings. • `S4` : Sets the Samsung 4nm process related settings. • `I5` : Sets the INTEL 5nm process related settings. • `N6`: Sets the TSMC 6nm process related settings • `C7`: Sets the SMIC 7nm process related settings. • `G7`: Sets the GlobalFoundries 7nm process related settings. • `I7` : Sets the INTEL 7nm process related settings. • `N7`: Sets the TSMC 7nm process related settings. • `S7`: Sets the Samsung 7nm process related settings. • `I10`: Sets the ICF 10nm process related settings. • `N10`: Sets the TSMC 10nm process related settings. • `SU10`: Sets the Samsung 10LPU process related settings. • `S11`: Sets the Samsung 11nm process related settings. • `G12`: Sets the GlobalFoundries 12nm process related settings. • `N12`: Sets the TSMC 12nm process related settings. • `G14`: Sets the GlobalFoundries 14nm process related settings. • `N22`: Sets the TSMC 22nm process related settings. **Note**: Some advance process nodes may have minimum width pins smaller than the default width defined in the LEF. For such cases, the NanoRoute Router automatically tapers from the default width to the min width pin. *Default:* " " *Data_type:* string
`-route_rc_extraction_corner` *value*	Specifies the RC extraction corner to use in routing. This helps in better resistance calculation. *Default:* " " *Data_type:* string
`-route_relaxed_route_rule_spacing_to_power_ground_nets {`*layer*`:`*spacing layer*`:`*spacing*`}`	

	Relaxes the spacing requirement from NDR spacing for the layers. *Layer_spacing* signifies a distance in microns (per layer) of how close any net with NDR can get to to the power/ground stripes.
	For example,
	`setNanoRouteMode -route_strict_honor_route_rule true`
	`setNanoRouteMode -route_relaxed_route_rule_spacing_to_power_ground_nets {metal1:0.04 metal2:0.04 metal3:0.04 metal4:0.04 metal5:0.04}`
	It only works for PG usage net and relaxes the NDR requirement to the specified spacing. The specified spacing should be greater than the `min_spacing` and less than the `hard_ndr_spacing`.
	Default: `none`
	Data_type: string

`-route_reserve_space_for_multi_cut {true|false}`	Reserves space to insert multicut vias in postroute stage. This option has to be set before routing. After routing with this parameter specified, you can add double-cut vias or larger overhang vias by using the `routeDesign -viaOpt` command. **Note:** `-route_reserve_space_for_multi_cut` is `true` by default for 32nm designs and below. *Default*: `false` *Data_type*: bool
`-route_reverse_direction {(lx ly ux uy bottom_layer:top_layer)}`	Reverses the preferred routing direction in the specified area or layer. You can specify one or more areas. **Note**: *bottom_layer* and *top_layer* can be either layer names or layer routing IDs. **Note**: Changing the routing direction can conflict with the power planning and pin access for macros and standard cells. It can also add congestion that may impact the runtime and result in violations. Cadence recommends that you use caution when using this parameter. *Default*: `" "` *Data_type*: string
`-route_route_clock_nets_first {true|false}`	Detects whether clock nets require ECO routing after the `routeDesign` super command checks whether the existing clock nets were fully or partially routed with the NanoRoute router and reroutes them before routing the remaining nets. If the existing clock nets were not routed with NanoRoute, `routeDesign` skips routing on those nets. *Default:* `true` *Data_type*: bool
`-route_selected_net_only {true|false}`	Specifies whether NanoRoute routes all nets at once or routes selected nets only. To route critical nets as short as possible, select the critical nets and set this parameter to `true`. NanoRoute does the following: • Removes incomplete nets unless they are marked `+ FIXED` or have a `-skip_routing` net attribute. • Routes the remaining selected nets. **Note:** To select a net, use the selectNet command or click the net in the design display window. *Default*: `false` *Data_type*: bool

`-route_shield_crosstie_offset {`*`layerName`*`:`*`numTrack1 layerName2`*`:`*`numTrack2`*`...}`	Specifies the offset in terms of number of tracks for adding crossties. It enables you to control the starting track for adding crossties. Default is 0 offset for all layers. *Default:* " " *Data_type*: string
`-route_shield_length_threshold` *value*	Specifies the minimum route segment length below which shielding is not required. *Default*: `-1` *Data_type*: float
`-route_shield_report_skip_status {true|false}`	Generates a report file containing a list of nets that have been skipped for shielding. *Default*: `false` *Data_type*: bool
`-route_shield_tap_cell_insertion {true|false}`	Specifies the tap cell names for shielding. *Default:* " " *Data_type*: string
`-route_shield_tap_cell_name` *string*	Specifies the tap cell names for shielding. *Default:* " " *Data_type*: string
`-route_skip_analog {true|false}`	Skips routing nets or pins marked `+ USE ANALOG` in the DEF file or where `signalType` modified to `analog` in the OA DB. Specify this parameter for NanoRoute to skip the routing of nets with Analog Signal Type. *Default:* `false` *Data_type:* bool
`-route_strictly_honor_1d_routing {true | false |` *bottomLayerNum*`:`*topLayerNum*`}`	When specified, the NanoRoute router strictly honors 1d routing. This enables you to turn off jog routing on a per layer basis. *Default*: `false` *Data_type*: string

`-route_strict_honor_route_rule {true | false | bottomLayerNum:topLayerNum | wire bottomLayerNum:topLayerNum}`	Uses nondefault spacing rules for nondefault wires. Note: The router tapers wires and uses default vias even when this parameter is set to `true`. You define nondefault routing rules in the `NONDEFAULTRULE` statement of the LEF file. Specify one of the following arguments: • `false`: Specifies that the nondefault rule (NDR) spacing is a soft rule. In congested areas NanoRoute may need to use the extra NDR spacing to meet the minimum foundry rule set. • `true`: Specifies that the nondefault rule spacing is a hard rule. NanoRoute will attempt to honor the requested NDR spacing irrespective of resource availability. • *bottomLayerNum*:*topLayerNum*: Specifies that the nondefault rule spacing is a hard rule for all the layers specified in the layer range. • `wire` *bottomLayerNum*:*topLayerNum*: Specifies that the nondefault rule spacing is a hard rule for the wire but not the via metal to enable better DFM via optimization. For example, • `setNanoRouteMode -route_strict_honor_route_rulee 3:6` Specifies that the NDR spacing will be used in layers Metal3, Metal4, Metal5, and Metal6 for wire and via metal. • `setNanoRouteMode -route_strict_honor_route_rule "wire 3:6"` Specifies that the NDR spacing will be used in Metal3, Metal4, Metal5, and Metal6 for wire and not via metal. **Note:** Setting the rule to `false` will attempt to honor the NDR rule and allow short hot spots without detouring. If you set the rule to `true` (hard rule) we recommend you work more on minimizing the congested areas to preserve the NDR topology. *Default:* `false` *Data_type*: string
`-route_stripe_layer_range "bottomLayerNum:topLayerNum"`	Specifies the range of routing layers for stripes. *Default:* `""` (empty string) *Data_type*: string
`-route_third_party_data {true|false}`	When enabled, NanoRoute supports third-party data as input. It accepts non-DEF connectivity models, multiple NDRs per net, and other third-party structures in order to enable ECO routing on non-native data. **Note:** Since the third-party data uses DEF data types for different purposes and is formed for a completely different use model, it is important to translate it into Cadence types. With proper setup Innovus accepts third-party data for ECO Routing. *Default:* `false` *Data_type:* bool

`-route_tieoff_to_shapes "auto | stripe | ring | followpin | powergroundpin"`	Specifies the target to special wire shapes or target instance pin for tie net connection. Specify one of the following arguments:
	• `auto`: Specify `auto` to target special wire shapes, including stripe, ring, and standard cell followpin.
	• `stripe`: Specify `stripe` to target stripes only. Stripes are the special wiring used for creating the power mesh.
	• `ring`: Specify `ring` to target only rings. The power mesh along the macro boundary forms a ring. If it is in a macro placed in the design, only exposes power ring-pin shapes. When power stripes are added across the macro, they connect to each side of the ring-pin but do not go inside the ring.
	• `followpin`: Specify `followpin` to target standard cell followpin only. Followpin is the special wiring used for connecting standard cells to power mesh.
	• `powergroundpin`: Specify `powergroundpin` to target the power and ground pin of the instances only.
	• `auto powergroundpin`: Specifies the target to special wire shapes or target instance pin for tie net.
	Note: The target shapes can be specified together. The value `auto` can only be specified with `powergroundpin`, since the other values stripe, ring, and followpin are included in auto.
	For example:
	• The following command signifies that it can tie to followpin or stripe.
	`-route_tieoff_to_shapes "followpin stripe"`
	• The following command signifies that it can tie to followpin or power ground pin
	`-route_tieoff_to_shapes "followpin powergroundpin"`
	• The following command signifies that it can tie to stripe or power ground pin
	`-route_tieoff_to_shapes "stripe powergroundpin"`
	Note: Using "`auto stripe`" is not recommended as `stripe` is included by auto.
	Default: `auto`
	Data_type: string

`-route_trim_pull_back_distance_from_boundary {layer:value ...}`	Specifies the boundary pullback value per layer for trim metal layers. The pullback value signifies how far the trim metal router brings signals and fill metal to a boundary (for example, block edge) in the absence of any obstructions. *Default*: " " *Data_type*: string
`-route_trunk_with_cluster_target_size integer`	Controls the routing pattern of nets with the trunk pattern attribute. By default, the router connects each pin in nets on which you have applied `setAttribute -pattern trunk` directly to the trunk of the special net; use this parameter to change the routing pattern for those nets: • Specify 0 to route nets with the trunk pattern specified with a `Steiner` tree pattern instead of a trunk pattern. • Specify an integer greater than 1 to route the nets with a fishbone pattern. In a fishbone pattern, several pins in a column are clustered together before connecting to the special net. The value of this parameter represents the approximate number of pins in each cluster. *Default*: 1 *Data_type*: int

`-route_use_auto_via` *value*	When specified, it allows the use of internal generated vias. In new advance nodes, it enables you to specify some custom via's names from the LEF for the router to use. This helps to provide better pin access.
	The following is the syntax of the supported values:
	`{true | false| auto | {-rule ruleName1 viaName viaName} {-rule ruleName2 viaName viaName} {-prefix_name viaPrefix }}`
	Specify one of the following arguments:
	• `true`: Specify true to turn on auto via generation.
	• `false`: Specify false to turn off auto via generation.
	• `auto`: Specify auto to enable via generation based on process nodes and allow Innovus to decide to turn on or off.
	• `-rule` *`ruleName1 viaName viaName`*: Specify -rule to enable Innovus to use the provided via list for the specified rule.
	• `-prefix_name`: Specify -prefix_name to add a prefix to the auto generated via names. By default, NR_ prefix is used by the tool.
	For example,
	• The following command signifies that M0 pins use VIA0_1 and VIA0_2 for default routing.
	`setNanoRouteMode -route_use_auto_via "-rule default VIA0_1 VIA0_2"`
	• The following command signifies that for nets with HV_NDR rule, use the specified list via's only for those layers. For other layers Innovus can choose other via's defined in the NDR rule section or it can auto generate. Only 5 via's per layer per rule can be defined:
	`setNanoRouteMode -route_use_auto_via {-rule HV_NDR HV_NDR_VIA4_2x1 HV_NDR_VIA5_2x1 HV_NDR_VIA6_2x1HV_NDR_VIA7_2x1}`
	Note: If you have two NDR rules for which you want to specify a list of via's then it should be specified as one string.
	`setNanoRouteMode -route_use_auto_via { {-rule ruleName viaName viaName} {-rule ruleName2 viaName2 } }`
	`routeDesign/globalDetailRoute`
	Note: The NanoRoute router treats VIA and USEVIA definitions as soft constraints when the `-routeUseAutoVia` parameter is enabled (default is enabled). The vias specified with VIA or USEVIA LEF rules are considered as target vias along with other auto-generated vias. To specify a hard constraint for the vias to use, use the USEVIACUTCLASS rule. Alternatively, specify the following:
	`setNanoRouteMode -route_use_auto_via -rule ndr_rule_name viaName`
	• The following command signifies that the NanoRoute router will use blockA as the prefix for auto generated vias names instead of NR_.
	`setNanoRouteMode -route_use_auto_via "-prefix_name blockA"`
	Default: `auto`
	Data_type: string

`-route_via_weight{`*`via_name via_weight ...`*`}`	Specifies the priority or the order of vias for post route via swap to use. It sets the via weight for the specified via. The bigger the number, the higher priority the via is given. A negative value means the via will not be used.
	You can use wildcards for the *via_name*. For example:
	`setNanoRouteMode -route_via_weight {*FBD* 8, *FBS* 7, *PBD* 6, *PBS* 5, *2cut_p1* 4, *2cut_p2* 3, *2cut_p3* 2, *FAT* 1}`
	Note: Via name can be a predefined class of vias such as @1cut and @2cut. Here, @1cut stands for single cut vias, @2cut stands for double cut vias.
	In case of duplicated value setting of via, the latest value will be used. For example:
	`setNanoRouteMode -route_via_weight {@1cut 2 @2cut 4 VIA12_1cut 1}`
	Here, VIA12_1cut was first set weight to 2, and then set to 1, the final weight of VIA12_1cut is 1.
	When you specify this option to do post route via swap, it's important to set the related options to improve the DFM and double cut via ratio.
	• Specify `-route_reserve_space_for_multi_cut true` before detail route to reserve space for inserting multicut vias in postroute via swap stage.
	• Specify `-route_with_timing_driven false` and `-route_detail_post_route_swap_via multiCut` to swap the single cut via to DFM and double cut via as much as possible.
	Note: If you have two NDR rules for which you want to specify a list of via's then it should be specified as one string.
	`setNanoRouteMode -route_use_auto_via { {-rule rule_name via_name via_name} {-ruleruleName2 viaName2 } }`
	`routeDesign/globalDetailRoute`
	Note: The NanoRoute router treats VIA and USEVIA definitions as soft constraints when the `-routeUseAutoVia` parameter is enabled (default is enabled). The vias specified with VIA or USEVIA LEF rules are considered as target vias along with other auto-generated vias. To specify a hard constraint for the vias to use, use the USEVIACUTCLASS rule. Alternatively, specify the following:
	`setNanoRouteMode -route_use_auto_via -rule ndr_rule_name viaName`
	The following command signifies that the NanoRoute router will use blockA as the prefix for auto generated vias names instead of NR_.
	`setNanoRouteMode -route_use_auto_via "-prefix_name blockA"`
	Default: `auto`
	Data_type: string
	Range: `-1 to 256`
	Default: `""`(empty string)
	Data_type: string

`-route_with_eco {true|false}`	Routes in engineering change order (ECO) mode if `globalDetailRoute` is specified. During ECO mode, NanoRoute completes partial routes with added logic, while maintaining the existing wire segments as much as possible. **Note:** The Innovus software also has an `ecoRoute` command. *Default*: false *Data_type*: bool
`-route_with_litho_driven {true|false}`	Avoids lithography problems during routing by avoiding certain routing patterns that might lead to the creation of lithography hotspots. *Default*: false *Data_type*: bool

`-route_with_si_driven {true|false}`	Prevents or reduces crosstalk. Works in conjunction with timing-driven routing. When timing-driven routing is specified, uses SMART routing to identify victim nets and minimize crosstalk by wire spacing, layer hopping, net ordering, and minimizing the use of long parallel wires. When timing-driven routing is not specified, uses an older signal integrity engine to minimize crosstalk by preventing or reducing the use of long parallel wires. Specify `-route_with_timing_driven` and `-route_with_si_driven` to run SMART routing. *Default*: false *Data_type*: bool
`-route_with_timing_driven {true|false}`	Minimizes timing violations by analyzing the timing slack for each path, the drive strengths of each cell in the library, and the maximum capacitance and maximum transition limits. During timing-driven routing, NanoRoute routes multi-pin nets to the most critical sink first, performs wire optimization by reducing resistance and coupling, and continually adjusts detouring. When this parameter is set to true, the router automatically generates a timing information file named .timingfile.tif in the working directory. It uses this file when it runs timing driven routing. **Note**: Specify the following commands and to skip the CTE call and timing file generation step and use the specified file: `writeDesignTiming` *file_name* `setNanoRouteMode -route_with_timing_driven true` Specify `-route_with_timing_driven` and `-route_with_si_driven` to run SMART routing. You can use the `-route_with_timing_driven` parameter to reduce the timing closure effort during post-route ECO. NanoRoute will replace via to multi-cut via on non-critical nets, if a violation does not occur. *Default*: false *Data_type*: bool

`-route_with_trim_metal` *value*	Specifies the preferred trim metal grid for NanoRoute Router to use. You can specify the value in the following format:
	
	`{-layer layerNumber -mask1 {-pitch value -core_offset value} -mask1 { -pitch value ... } -mask2 { -pitch value ... } -mask2 {-pitch value ... }}`
	
	For example, the following command specifies the preferred trim metal grid on layer 2.
	
	`SetNanoRouteMode -route_with_trim_metal {-layer 2 -mask1 {-pitch 0.300 -core_offset 0.025 } \`
	`-mask1 {-pitch 0.300 -core_offset 0.195 } \`
	`-mask2 {-pitch 0.300 -core_offset 0.065 } \`
	`-mask2 {-pitch 0.300 -core_offset 0.235 }}`
	
	Note: The width value is taken from the LEF.
	
	Default: " "
	
	Data_type: string

`-route_with_via_in_pin {true| false | bottomLayerNum:topLayerNum}`	Encloses via geometries completely inside standard cell pins. Specify true for this parameter to avoid MINSTEP violations for standard cell pin access. Default: false
	Note: To avoid violations, specify the same value for this parameter throughout the entire design flow.
	• `true`: Enclose vias inside standard cell pins on all layers.
	• `false`: The router is not required to enclose vias inside standard cell pins.
	• `bottomLayerNum:topLayerNum`: Enclose vias inside standard cell pins on layers in the specified layer range.
	  ◦ `1:1`: Specifies that Metal1 pins must enclose vias.
	  ◦ `2:5`: Specifies that pins on Metal2, Metal3, Metal4, and Metal5 must enclose vias. Pins on other layers are not required to enclose vias.
	Default: false
	Data_type: string

`-route_with_via_only_for_block_cell_pin value`	Encloses via in pin shape for macro cell pins. *Default*: false *Data_type*: string

`-route_with_via_only_for_stdcell_pin {true| false | bottomLayerNum:topLayerNum}`	Allows standard cell pins to be accessed by vias only. Prohibits planar access. Default: false
	• `true`: Always use vias for standard cell pin access on all layers.
	• `false`: Use vias or planar access for standard cell pins on all layers.
	• *`bottomLayerNum:topLayerNum`*: Always use vias for pin access in the specified layer range.
	  ◦ `1:1`: Always use vias for access to Metal1 standard cell pins. Metal2 and above can use vias or planar access.
	  ◦ `2:5`: Always use vias for access to standard cell pins on Metal2, Metal3, Metal4, and Metal5. Metal1 and Metal6 (and above) can use vias or planar access.
	Note: Set this option before any routing or verification because it affects the pin access preparation steps. In addition, after you set this option, the access remains for same the entire Innovus session. Do not change the setting, even for future routing sessions that load saved data from the database or a saved DEF file.
	For example, if a design with pins on Metal1 and Metal2 is routed with this option set to 1:1, the router uses vias for access to all standard cell pins on Metal1, and vias or planar access to standard cell pins on Metal2. If you save the design after routing, then import the design in a different Innovus session and route it again with this option set to true (that is, forcing the router to use vias to access all standard cell pins on all layers), you might have planar connections (from the previous routing session) to pins on Metal2. All the planar connections to those pins become violations, because they are not allowed when this option is set to true.
	Default: false
	Data_type: string

Examples

- The following commands show the steps in basic routing strategy with the NanoRoute router.
  The router globally routes the design:
  ```
  globalRoute
  ```
- The router does the initial detailed routing (iteration 0 does not include a search-and-repair step), and saves the design as `droute0`:
  ```
  setNanoRouteMode -route_detail_end_iteration 0
  detailRoute
  saveDesign droute0
  ```
- The router does the first search-and-repair iteration, and saves the design for analysis:
  ```
  setNanoRouteMode -route_detail_end_iteration 1
  detailRoute
  saveDesign droute1
  ```
- The router does the second to nineteenth search-and-repair iterations, and saves the design for analysis. The switch box grows larger as the iteration number increases.
  ```
  setNanoRouteMode -route_detail_end_iteration 19
  detailRoute
  saveDesign droute19
  ```
- The router runs postroute optimization (-`route_detail_end_iteration default`) and additional search-and-repair operations, and saves the design as `droute`:
  ```
  setNanoRouteMode -route_detail_end_iteration default
  detailRoute
  saveDesign droute
  ```
- The following commands route selected nets, then route the remaining nets in the design:
  ```
  setNanoRouteMode -route_selected_net_only true
  globalDetailRoute
  setNanoRouteMode -route_selected_net_only false
  globalDetailRoute
  ```
- The following commands route a placed design in timing-driven mode and output a routed DEF file:
  ```
  restoreDesign
  setNanoRouteMode -route_with_timing_driven true
  saveDesign init
  globalDetailRoute
  saveDesign droute
  defOut -floorplan -routing droute.def
  ```
- The following command resets the `-route_selected_net_only` parameter to its default value:
  ```
  setNanoRouteMode -reset -route_selected_net_only
  ```
- The following command resets all `setNanoRouteMode` parameters to their default values:
  ```
  setNanoRouteMode -reset
  ```
- The following command sets the weight of via12 o 1 and via23 to 2:
  ```
  setNanoRouteMode -route_via_weight {via12 1 via23 2}
  ```
- The following command resets the weight of via12 to 3:
  ```
  setNanoRouteMode -route_via_weight {via12 3 via34 2}
  ```

[-earlyGlobalRouteSecondPG {true|false}]
[-earlyGlobalRouteSelectedNetsOnly {true|false}]
[-earlyGlobalRouteStripeLayerRange {layerIdx1:layerIdx2}]
[-earlyGlobalSecondPGMaxFanout integer]
```

Sets global parameters for the Early Global Route or `earlyGlobalRoute`. The parameters that you specify with `setRouteMode` are then used automatically whenever you run the Early Global Router through the `earlyGlobalRoute` command or internally during in-place optimization, partitioning, or placement.

The `setRouteMode` command parameter settings affect the results of the Early Global Router, which is run in all the steps during the preRoute flow. Consequently, with changes in these settings, the results of `place_opt_design`, `ccopt_design`, and postCTS will change.

Note: If not required, it is best not to change the tool technology settings.

Use the `getRouteMode` command to return the current settings for the `setRouteMode` command.

Early Global Route supports nested partitions. The partitions specified with the `-earlyGlobalRoutePartitionHonorFence` and the `-earlyGlobalRoutePartitionHonorPin` parameters are routed in the style that honors fence and pin constraints. All other partitions are routed

Parameters

`-earlyGlobalEffortLevel {standard| medium | low }`	
	Specifies the congestion effort level. **Note:** The `low` effort level value will reduce the runtime while `standard` effort level will increase the congestion accuracy • `standard`: Congestion is more accurate and runtime is larger. • `medium`: Runtime will be much smaller and congestion report will have less accuracy. • low: Runtime is faster than `medium` but less accurate. *Default*: `standard` **Note:** While the `setRouteMode -earlyGlobalEffortLevel` parameter is mainly used for speed (low and medium will make it faster but less accurate), the `setDesignMode -congEffort` parameter is used to increase optimization effort to resolve congestion. Even though these parameters are not related directly, changing the Early Global Route effort level (decreasing it) will change the results for the required congestion effort. Hence, if you set the `setDesignMode -congEffort` as high, it is recommended that you keep the `setRouteMode -earlyGlobalEffortLevel` parameter at standard (default) level. *Data_type*: enum, optional
`-help`	Outputs a brief description that includes type and default information for each `setRouteMode` parameter. For a detailed description of the command and all of its parameters, use the man command: `man setRouteMode`.
`-earlyGlobalHonorMsvRouteConstraint {true | false}`	

	Honors MSV domain constraints. This option is used to decide whether Early Global Route should honor power domain settings. By default, Early Global Route ignores the power domain settings and routes as flat design. When enabled, Early Global Route honors power domain settings and route wires inside preferred power domain as much as possible. *Default* : false *Data_type*: bool, optional
`-earlyGlobalNumTracksPerClockWire value`	Specifies the special number of tracks per clock wires. *Max*: `8` *Min*: 0 *Default*: `0` *Data_type*: int, optional
`-reset`	Restores all parameters modified using `setRouteMode` to their default settings. The `-reset` parameter must be the first parameter specified. If you specify -reset by itself, the software resets all `setRouteMode` parameters to their default values. If you specify parameters after `-reset`, the software resets only those parameters to their default values. Any values that do not already match the default value and are reset will be reported.
`-earlyGlobalReverseDirection "( x1 y1 x2 y2 ) Metal2:Metal2 ( x3 y3 x4 y4 ) Metal3:Metal3 ... "`	

	Reverses the routing direction in the given region on the specified layer-range. It specifies an area in which the Early Global Router routes wires in the non-preferred direction.
	Note: You can define the reverse direction routing area by *"(x1 y1 x2 y2)"* and routing layer by *"Metal2:Metal2"*. In release 16.1, the Early Global Router only supports a single layer with this option. Consequently, *"Metal2:Metal3"* is not supported.
	The `-earlyGlobalReverseDirection` parameter only has impact on the congestion value calculation. By routing on reverse direction, you can reduce the routing capacity on the specified layer and add extract resource on the above and below layers. Innovus does not display the routing wires in reverse direction routing region.
	For example, the following command reverses the routing direction in the specified region on layer *Metal3*.
	`setRouteMode -earlyGlobalReverseDirection "(757.996 542.697 995.323 772.5685) Metal3:Metal3"`
	 	The congestion value without reverse direction routing:
	`Overflow after earlyGlobalRoute 0.02% H + 0.00% V`
	The congestion value with reverse direction routing:
	`earlyGlobalRoute overflow: 0.93% H + 0.10% V`
	Default: ""
	Data_type: string, optional

`-earlyGlobalRouteBumpNets {true|false}`	
	Specifies that the Early Global Router will honor a net with a connecting bump and enable bump net routing. By default, Early Global Route ignores bump nets as they are marked as special in the database. When enabled, the Early Global Route honors bump nets and routes them. *Default*: false *Data_type*: bool, optional
`-earlyGlobalRoutePartitionAllowFeedthru` *list_of_ptn_cell_names*	
	Specifies the partition cell names for which the Early Global Router honors partition fences. *Default* : "" *Data_type*: string, optional
`-earlyGlobalRoutePartitionHonorFence` *list_of_ptn_cell_names*	

	Honors partition fences with a single-entry constraint and also honors fixed pins. Under the single-entry constraint once a hierarchical route enters a partition fence it does not cross the boundary again. The `-earlyGlobalRoutePartitionHonorFence` parameter routes a net belonging to more than one partition so that the routing does not violate partition boundaries, in addition to routing intra-partition and global nets using the specifications of the partitions. For example, if a net belongs to partitions P1 and P3, but not P2, the net is routed without going over the P2 partition boundary. **Notes:** • For flat partitioned designs, you can specify `-earlyGlobalRoutePartitionHonorFence` to simulate channel-based routing. For channelless designs, you must perform feedthrough insertion before using this parameter. • Supports designs with up to 180 partitions. • Early Global Route supports nested partitions. The partitions specified with the `-earlyGlobalRoutePartitionHonorFence` and the `-earlyGlobalRoutePartitionHonorPin` parameters are routed in the style that honors fence and pin constraints. All other partitions are routed flat. *Default* : "" *Data_type*: string, optional
`-earlyGlobalRoutePartitionHonorPin` *list_of_ptn_cell_names*	
	Honors partition fences with single-entry constraint and pre-assigned pins (pins marked `FIXED`) and assigned pins (pins marked `PLACED`). *Default*: "" *Data_type*: string, optional
`-earlyGlobalRoutePartitionPinGuide {true | false}`	
	Honors partition pin guides. It uses the pin guide statements in the floorplan file to guide the routing through partition pin points. **Note:** Fixed pins and pin guides are only honored when `-earlyGlobalRoutePartitionPinGuide` is `true`. *Default*: true *Data_type*: bool, optional
`-earlyGlobalRouteSecondPG {true | false}`	
	Specifies whether the secondary PG pin should be routed or not. When enabled, it routes the pin specified by the `setPGPinUseSignalRoute` command. *Default*: `false` *Data_type*: bool, optional
`-earlyGlobalRouteSelectedNetsOnly {true | false}`	
	Specifies that only the nets that are selected in the database are to be routed. *Default*: `false` *Data_type*: bool, optional
`-earlyGlobalRouteStripeLayerRange` { *layerIdx1*:*layerIdx2* }	
	Specifies the stripe layer range that is routed to the secondary PG pin. *Default*: `" "` *Data_type*: string, optional
`-earlyGlobalSecondPGMaxFanout` *integer*	

	Specifies the maximum fanout value during secondary PG pin routing. *Max*: `INT_MAX` *Min*: `1` *Default*: `2147483647` *Data_type*: int, optional

Example

- The following command honors partition fences with single entry and does not allow crossing other partitions, when `earlyGlobalRoute` is run:
  ```
  setRouteMode -earlyGlobalRoutePartitionHonorFence {.}
  earlyGlobalRoute
  ```
- The following command honors partition fences with single entry and also honors placed pins, when `earlyGlobalRoute` is run:
  ```
  setRouteMode -earlyGlobalRoutePartitionHonorPin {.}
  earlyGlobalRoute
  ```
- The following command resets all `setRouteMode` parameters to their default values:
  ```
  setRouteMode -reset
  ```

writeHif

```
writeHif
[-help]
-file filename
```

Writes out a HIF file after the NanoRoute router fixes lithography problems. The file reports the areas where the router made changes. Use this command with `loadViolationReport` for incremental lithography checking and fixing.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `writeHif` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man writeHif`.
`-file filename`	Specifies the HIF file to write out. *Data_type*: string, required

Example

The following example writes the HIF file `result.hif` marking the areas in which the NanoRoute router has made changes to fix lithography problems:

```
writeHif -file result.hif
```

Related Information

- `loadViolationReport`

route_fix_ir

```
route_fix_ir
[-help]
[-concurrent_pg_and_signal {0 1}]
-ground_net string
[-hotspot_boxes {{lx1 ly1 ux1 uy1} {lx2 ly2 ux2 uy2}...}]
[-irdrop_threshold float]
-power_net string
[-rail_path string]
-top_layer string
```

Fixes IR Drop (voltage drop) violations with the NanoRoute engine. It creates additional PG connection paths from top layer PG stripes down to low layer PG rail shapes based on rail analysis results. This method also makes it possible to concurrently route signal nets and IR drop fixing PG nets. It has congestion driven and timing aware capabilities.

You can use the `route_fix_ir` command after postroute.

Parameters

`-concurrent_pg_and_signal {0 1}`	When set to 1, the NanoRoute router routes the signal nets and pg nets for IR drop fixing together. When set to 0, the NanoRoute router routes the PG net wires only and does not touch the signal nets. *Default:* 0 *Data_type*: enum, optional
`-ground_net string`	Specifies the ground net name for IR drop fixing. *Data_type*: string, required
`-help`	Outputs a brief description that includes the type and default information for each `route_fix_ir` parameter. For a detailed description of the command and all of its parameters, use the man command `man route_fix_ir`.
`-hotspot_boxes {{lx1 ly1 ux1 uy1} {lx2 ly2 ux2 uy2}...}`	
	Specifies coordinates of the hotspot boxes. **Note**: When this option is specified, the `-rail_path` option is ignored. *Data_type*: box_list, optional
`-irdrop_threshold float`	Specifies the minimum allowed voltage IR drop for the domain being analyzed. **Note**: This option works with the `-rail_path` option. *Data_type*: float, optional
`-power_net string`	Specifies the power net name for IR drop fixing. *Data_type*: string, required
`-rail_path string`	Specifies the path of the rail analysis results. The NanoRoute router then calls the debug IR drop functionality to create hotspot files. **Note**: If the rail analysis path directory is not specified, the NanoRoute router automatically calls the power analysis, rail analysis, and debug IR drop functionalities to create hotspot files. **Note**: This option works with the `-irdrop_threshold` option. *Data_type*: string, optional
`-top_layer string`	Specifies the top stripe layer to connect the PG nets for IR drop fixing. *Data_type*: string, required

Examples

- The following command uses the rail analysis results for IR drop fixing.
  ```
  route_fix_ir  -rail_path rail_static/ALL_85C_avg_1 -top_layer M15 -irdrop_threshold 0.08 -power_net VDD -ground_net VSS
  ```
- The following command specifies the hotspot boxes.
  ```
  route_fix_ir -hotspot_boxes {{box1} {box2} …} -top_layer M15 -power_net VDD -ground_net VSS
  ```

Route Global Variables

- trPrintIgnoredPadNets

trPrintIgnoredPadNets

```
trPrintIgnoredPadNets value
```

Type: Integer

Default: 0

Sets a limit to the number of nets to be printed during earlyGlobalRoute. This limit is used to warn about the nets that have connectivity from a pad term to a `fterm` without geometry. Without a geometry on the terminal these nets can not be routed. A pad term is a pin of a pad logically connected to a top level module port (fterm).

Type 'set trPrintIgnoredPadNets ' prior to earlyGlobalRoute to have it report each net up to limit value.

The default value of this integer variable is 0

```

Displays the following information about a `set_signal_em_analysis_mode` parameter in the system log file and in the system console:

- Parameter name
- Current value
- Type (Boolean, string, and so on)
- Whether the current value was set by user

If you do not specify a parameter, the software displays information for all of the `set_signal_em_analysis_mode` parameters.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `get_signal_em_analysis_mode` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_signal_em_analysis_mode`.
`parameter_names`	Displays information for the specified parameters. You can specify one or more parameters. See `set_signal_em_analysis_mode` for description of the parameters you can specify.
`-quiet`	Displays the current settings for the specified parameters in Tcl list format only. If you specify `-quiet` without any parameters, the software displays the current settings of all `set_signal_em_analysis_mode` parameters in the Tcl list format.

Examples

The following command displays the current setting of the `-use_db_freq` parameter:

```
get_signal_em_analysis_mode -use_db_freq
```

The software displays the following information:

```
[DEV]innovus 8> get_signal_em_analysis_mode -use_db_freq
-use_db_freq false                      # bool, default=false
false
```

```

Sets global parameters for signal electromigration. Use this command to specify the required `verify_AC_limit` mode settings before running any commands that perform signal electromigration. The parameters specified with the `set_signal_em_analysis_mode` command are then used automatically whenever signal electromigration takes place.

Use the `get_signal_em_analysis_mode` command to return the current settings for the `set_signal_em_analysis_mode` command.

Note: Use the `-method` parameter to specify the waveform calculation method to be used (`rms`, `peak`, or `avg`).

Parameters

`-help`

Outputs a brief description that includes type and default information for each `set_signal_em_analysis_mode` parameter.

For a detailed description of the command and all of its parameters, use the `man` command:
`man set_signal_em_analysis_mode`

`-additional_individual_violation_report`

Specifies to generate separate violation reports for each current waveform calculation method (`rms`, `peak`, or `avg`). If this parameter is not speci violation report file is generated using the `-method {RMS AVG peak}` parameter. This parameter gives you the flexibility of generating either a s report or individual reports for each analysis method.

Example:

```
set_signal_em_analysis_mode \
-method {rms peak avg} \
-report context1.rpt \
...
-additional_individual_violation_report
```

This command will generate 3 different reports, namely `context1.rpt_avg`, `context1.rpt_peak`, and `context1.rpt_rms`. If there are no EM viol method, the tool will not generate the corresponding separate report. In this example, if there are violations for `avg` and `rms` but none for `peak`, t only two reports, `context1.rpt_avg` and `context1.rpt_rms`.

`-avgRecovery` *`em_recover`*

Specifies the recovery factor used for calculating I_{avg} current density with recovery. By default, the recovery factor (per layer) is read from the C you specify `-avgRecovery em_recover`, it overrides the Quantus tech `em_recover` factor for all layers used in I_{avg} limits. The minimum `-avgRec` and the maximum is `1`.

Note: If you do not specify `-avgRecovery` and the `em_recover` factor is not specified in the Quantus techfile as well, the tool gives an error that computed.

`-check_thermal_aware_em {true | false}`

Specifies to use the thermal map for EM checks. The thermal map file is specified using the `-read_thermal_map` parameter. The Rail Analysis temperature specified in the thermal map file for EM analysis. EM limit has a strong temperature dependency. For a chip that has substantial t variation across the chip, the Rail Analysis engine can use the temperature specified in the thermal map file to perform accurate EM analysis.

Default : `false`

`-current_scale_factor {{avg` *`value`*`} {rms` *`value`*`} {peak` *`value`*`}}`

Scales the signal EM current by the respective factor for avg, rms, or peak current specified by `{avg` *`value`*`} {rms` *`value`*`} {peak` *`value`*`}`.

The value specified for this parameter must be > 0 and <= 10.

`-current_scale_table` *`current_scale_table_file`*

Specifies the name of the scale table file used for layer-based scaling of the signal EM current. The scale table contains the scale factor for av current for each layer.

This parameter is mutually exclusive with `-current_scale_factor`. The `-current_scale_table` parameter takes precedence over `-current_sc`

The format of the table is given below:

```
layer         avg             rms           peak

layer1    scalefactor1    scalefactor2    scalefactor3
layer2    scalefactor1    scalefactor2    scalefactor3
```

Here,

- layer name is the LEF layer name that could be a metal/via layer.
- avg, rms, peak correspond to the respective scale factor for avg, rms, or peak current. The scale factor value must be > 0 and <= 10.

`-default_freq_for_unconstrained_nets` *`freq_in_Hz`*

Specifies the frequency for EM calculation when a net has no defined frequency or has a defined frequency of 0 Hz in the design.

Default: `1MHz`

`-delta_T` *`temp`*

	Specifies the maximum temperature rise permitted in units of Celsius. This value is normally used in the Quantus tech file for the RMS current example: `em_jmax_ac_rms EQU sqrt(12.66 * delta_T * (w - 0.003)^2 * (w - 0.003 + 0.264) / (w - 0.003 + 0.0443))` *Default*: `5`
`-delta_T_layer_list {{<LEF_layer_name> <delta_T_in_C>}+}`	
	Specifies the delta temperature for specific LEF layers during signal EM RMS current limit analysis.
`-detailed`	Generates a detailed report containing information for all signal nets, including those without violations.
`-effort_level {low | medium | high}`	

	Specifies the method used for current calculation of nets in the Signal ElectroMigration analysis flow. The two methods are:
	• **non-simulation mode** - use the capacitance ratio to distribute the current down the stream from the driver to the receiver.
	• **simulation mode** - simulates resistance and capacitance to get the true current on each segment. This mode is more accurate but requires
	This parameter has the following three arguments:
	• `low`: enables the non-simulation mode for all nets where the current distribution is based on the capacitance ratio.
	• `medium`: enables the simulation mode for the nets with physical loops, and the non-simulation mode for the non-loop nets.
	• `high`: enables the simulation mode for all nets.
	The detailed report (`set_signal_em_analysis_mode -report <filename> -detailed`) shows "`N/A`" in the `Cap` column for nets in the simulation
	The default value for `-effort_level` is `low`. The `medium` and `high` levels require a VTS-AA license.
	Note: For the simulation mode with effort level `medium` or `high`:
	• If you use `extract_rc`, run `set_extract_rc_mode -qrcCmdType partial -qrcCmdFile qrc.user.cmd`, where `qrc.user.cmd` must include the commands:
	`extraction_setup -analysis em -cluster_vias_in_em true`
	`output_db -type spef -subtype "EXTENDED"`
	Refer to the example below:
	`output_db \`
	` -type spef -busbit_delimiter "[]" -escape_special_character false \`
	` -hierarchy_delimiter "/" -output_incomplete_nets true \`
	` -output_unrouted_nets true -pin_delimiter ":" -subtype "EXTENDED" \`
	` -disable_subnodes false -add_explicit_vias true \`
	` -include_parasitic_res_width true -include_parasitic_res_width_drawn true`
	• If you run standalone Quantus to generate the required SPEF file in the extended format separately, then instead of `extract_rc`, use the fo for signal EM analysis:
	`read_spef -starN -extended spef_file`

`-em_cdf_percentage value`	
	Specify the Cumulative Distribution Factor (CDF) derating factor for the EM rules specified in the ICT file or the technology file. This paramete calculate the fail rate and reliability of a design. The value of the CDF percentage should be between 0 and 100. If the `-em_cdf_percentage` parameter is not specified, and the CDF related rule exists in the technology file, the software will error out.
`-em_limit_scale_factor {{avg value} {rms value} {peak value}}`	
	Scales the calculated signal EM limits by the respective factor for avg, rms or peak current limit specified by `{avg value} {rms value} {peak` software compares the current through the net against the scaled EM limit to report violations in signal EM. The value specified for this parameter must be > 0 and <= 10.
`-em_limit_scale_table em_limit_scale_table_file`	

	Specifies the name of the scale table file used for layer-based scaling of the signal EM limit. The scale table contains the scale factor for avg, current for each layer.
	This parameter is mutually exclusive with `-em_limit_scale_factor`. The `-em_limit_scale_table` parameter takes precedence over `-em_limit`
	The format of the table is given below:
	`layer avg rms peak`
	`layer1 scalefactor1 scalefactor2 scalefactor3`
	`layer2 scalefactor1 scalefactor2 scalefactor3`
	Here,
	• layer name is the LEF layer name that could be a metal/via layer.
	• avg, rms, peak correspond to the respective scale factor for avg, rms, or peak current. The scale factor value must be > 0 and <= 10.

`-em_res_width {drawn silicon}`	
	Specifies width used to get EM limit. The legal values are: • `drawn` • `silicon` *Default*: `drawn`
`-em_temperature value`	
	Specifies the temperature expected for the device and is used to look up the temperature scaling factor. By default, no scaling is done. The `va` units of degrees Celsius.
`-em_temperature_layer_list {{<LEF_layer_name> <em_temperature_in_C>}+}`	
	Sets a different temperature for specific LEF layers during signal EM AVG current limit analysis.
`-em_threshold value`	
	Specifies to report violations in signal EM above the threshold value. The value is the ratio of signal current (avg/peak/rms) to the respective E `1.0`.
`-enable_seb {true | false}`	
	Specifies to enable the Statistical ElectroMigration Budgeting (SEB) analysis. *Default* : `false`
`-env_temperature <temperature in °C>`	
	Specifies the ambient temperature used to calculate S_{DC} for SEB analysis. *Default* : `25`
`-error value`	
	Controls the number of errors to be included in the signal EM violation report file. If you do not specify this parameter, the top 10000 signal net be included in the violation report. This parameter can be used to control the size of the violation report file. *Default:* `10000`
`-extraction_tech_file filename`	
	Specifies an extraction technology file for the Signal ElectroMigration analysis flow. If this parameter is not specified, then by default the extra file will be taken from the analysis view (current RC corner). This parameter must be used when the technology file is not specified through the analysis view (`create_rc_corner -qx_tech_file`). If you s `create_rc_corner -qx_tech_file` and `set_signal_em_analysis_mode -extraction_tech_file`, then the technology file specified with the `-extraction_tech_file` parameter will take precedence. In addition, if a technology file is not specified using either of these two command par software displays a warning message for the missing technology file, and will not read the EM models specified through the `-ict_em_models` p
`-forceHoldView`	
	Forces `set_signal_em_analysis_mode` to use the hold view for current calculation even during setup fixing.

`-handle_pin_obs_via`

Specifies to consider the vias defined in the `OBS` (obstructions/blockages) section of LEF in the Signal ElectroMigration flow. By default, the sc consider via in obstruction.

This parameter does not honor the via obstructions with "`SPACING 0`".

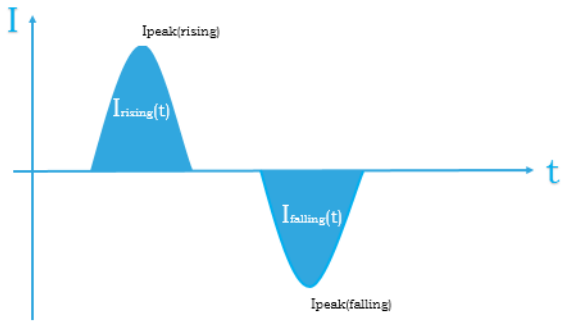
`-ict_em_models` *`file`*

Specifies the ICT-EM file which only contains the EM rules and excludes the RC extraction data in ICT. The software will use the EM rules in EM file to calculate EM limits for signal net EM analysis even if there are embedded EM rules in the Quantus tech file.

`-Ipeak_Td_method {effective_width_from_integration effective_half_peak_width max_equivalent_dc_peak sum_half_peak_width}`

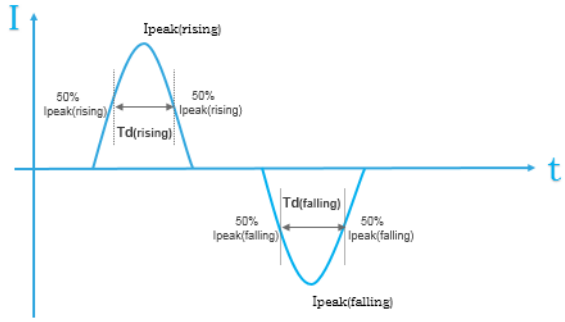
Specifies the Td calculation method for Ipeak check. The legal values are depicted below.

`effective_width_from_integration`



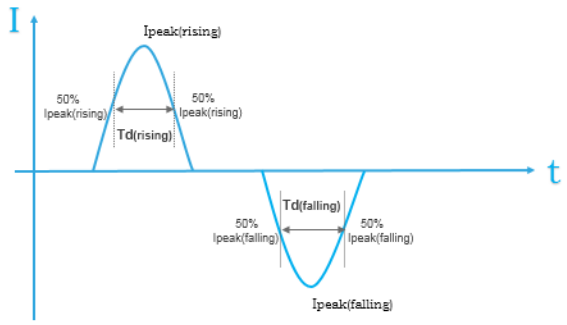
- $Td = \frac{\int_0^{Tsw} |I(t)|dt}{Ipeak_measured}$
  - Tsw = Period of one switching cycle (rising + falling)
  - Ipeak_measured = abs.max(Ipeak(rising), Ipeak(ralling))

`effective_half_peak_width`



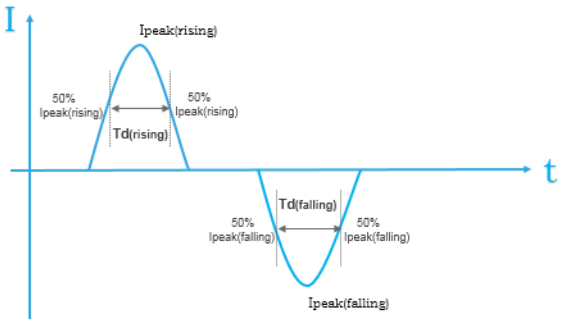
- When Ipeak(rising) >= Ipeak(falling)
  $Td = Td(rising) + (\frac{Ipeak(falling)}{Ipeak(rising)})^2 * Td(falling)$
- When Ipeak(rising) < Ipeak(falling)
  $Td = Td(falling) + (\frac{Ipeak(rising)}{Ipeak(falling)})^2 * Td(rising)$

max_equivalent_dc_peak



- $R(rising) = Td(rising)/(T/2)$
- $R(falling) = Td(falling)/(T/2)$
- Choose $max(Ipeak_{(rising)}*sqrt(R_{(rising)}), Ipeak_{(falling)}*sqrt(R_{(falling)}))$ to compare against Ipeak_dc_limit
- $Ipeak_ac_limit = Ipeak_dc_limit/sqrt(R)$
- When $Ipeak_{(rising)}*sqrt(R_{(rising)}) >= Ipeak_{(falling)}*sqrt(R_{(falling)})$
  $Td = 2*Td(rising)$
- When $Ipeak_{(rising)}*sqrt(R_{(rising)}) < Ipeak_{(falling)}*sqrt(R_{(falling)})$
  $Td = 2*Td(falling)$

sum_half_peak_width



- $Td = Td_{(rising)} + Td_{(falling)}$

Default: `effective_width_from_integration`

`-ircx_models {RC.ircx EMIR.ircx}|{RC.ircx}`	
	Specifies an encrypted or unencrypted RC/EM technology (.ircx) file. The foundry-specific IRCX file, which contains the process information f modeling, can be used when the ICT-EM file is not available for electromigration analysis. You can either specify two IRCX files, one file containing the RC process data (`RC.ircx`) and the other file containing EM rules (`EM.ircx`), or a includes both the RC and EM sections (`RC.ircx`). A single IRCX file is used for the mature nodes, and separate RC and EM IRCX files are us process nodes.
`-lifetime` *value*	
	Specifies the total hours of operation expected for the device, and is used to look up the lifetime scaling factor. *value* is used to find the scalin interpolating from a piece-wise-linear table in the LEF (see `ACCURRENTDENSITY HOURSPWL` table) or the Quantus tech file (`em_jmax_ac model` wit table). If there is no scaling factor table, no scaling is done. *value* is a float, in units of hours.
`-method {rms peak avg}`	
	Specifies the current waveform calculation method. You can specify one or more of the following options: • `avg`: Checks I_{avg} limits and reports any average current limit violations in the design. • `peak`: Checks I_{peak} limits and reports any peak current limit violations in the design. • `rms`: Checks I_{rms} limits and reports any RMS current limit violations in the design. *Default*: `rms` **Notes** • If you specify `peak` or `avg` but AAE is not enabled, the tool displays an error message. • When you run set_signal_em_analysis_mode -method `rms`, the command uses AC limit rules in LEF even if the EM qrcTechfile is provide `set_signal_em_analysis_mode -method rms -useQrcTech` to check rms EM limits from qrcTechfile.
`-minPeakDutyRatio` *duty_ratio*	
	Sets the minimum duty ratio value for I_{peak} calculation. If the calculated duty ratio of a net is lower than the specified value, the specified valu calculate I_{peak}. The minimum value for *duty_ratio* is `0.0` and the maximum is `1.0`. Default: `0.05` The following determines the priority and precedence of the `-minPeakDutyRatio` parameter: • When there are explicit duty ratio (r) dependencies on EM rules, the user-specified `minPeakDutyRatio` value will overwrite the software-cal (r), if the calculated duty ratio is smaller than the user-specified `minPeakDutyRatio` value. The `minPeakDutyRatio` value will then be applied selection to find the corresponding EM rule with duty ratio (r) dependency for EM limit calculation. • When there are no explicit duty ratio (r) dependencies on EM rules, the user-specified `minPeakDutyRatio` value will overwrite the tool-calcu if the calculated duty ratio is smaller than the user-specified `minPeakDutyRatio` value, and the software will calculate the EM limit based on `minPeakDutyRatio`. If you do not specify a value to `minPeakDutyRatio`, the default value of 0.05 will be applied.
`-minPeakFreq` *freq_in_Hz*	
	Ignores I_{peak} current limit calculation for signal nets that have an effective frequency below the specified value (in Hertz). *Default*: `1e+06 Hz (1 MHz)`
`-net {`*netNames*`}| -selected`	

	Specifies whether to check named or selected nets. If you name only one net, you do not need the braces around the net name. If you specify you must separate the net names with a space. For example, `set_signal_em_analysis_mode -nets {clk0 clk1}`.
	The `-selected` parameter analyzes the net specified with the `selectNet {netName} | [command]` command, and/or by selecting a net in the ma The following are examples of this parameter:
	Example 1:
	`selectNet {netA}`
	`set_signal_em_analysis_mode -selected`
	Example 2:
	`selectNet [get_ccopt_clock_tree_nets]`
	`set_signal_em_analysis_mode -selected`
	Default: If you do not specify `-nets` or `-selected`, `set_signal_em_analysis_mode` verifies all nets.

`-net_file list_file`	

	Specifies the net from file to check the signalEM analysis. The format is one net name per line, with comments using # as the first character. F
	`#list of nets to skip`
	`net_a`
	`net_b`
	`net_c`

`-net_freq_file filename`	

	Specifies a file containing the user-specified frequency for a list of nets. This parameter allows you to overwrite the frequency for specific nets set by `-toggle` needs to be modified.
	The format of the file is:
	`<net name>  <freq in Hz>`
	Example:
	`IN_1    1000000000`
	`n_I2_1  2700000000`
	`OUT_1   1200000000`

`-read_detail_delta_temperature_file filename`	
	Specifies to read the detailed delta temperature file generated by the `analyze_self_heat` command (self-heat analysis).
`-report filename`	
	Specifies the report file for the violation data. The report file includes name of the net, I_{rms}, interpolated `ACCURRENTDENSITY` limit (I_{limit}), layer, wi location, rise and fall time, effective frequency for the net (F_{eff}), Cnet and Vdd for each net.
`-reset`	Resets all the specified parameters back to the default values.
`-report_db`	
	Specifies to write the signal EM data into a database file (*`filename.db`*) after performing signal EM analysis. This file contains the information loading and displaying signal EM data in GUI. *`filename`* is the name specified using the `-report` parameter.
`-seb_lifetime value`	
	Specifies the life time of product in hours. *Default* : `43800` hours (that is, 5 years)
`-seb_table table_filename`	
	Specifies the file name of the Failures in Time (FIT) table. This file is provided by the foundry. The file has the following columns: • Layer • MTF • Sigma • Activate energy • Current density exponent

`-seb_temperature` *temperature*	

	Specifies the temperature used to update the median time to failure (MTF) with respect to the ambient temperature.
	• If this temperature is specified, it would be used globally for all the resistors.
	• If this temperature is not specified, the seb_temperature may take the following possible values depending on the specific circumstances:
	  ◦ If detailed delta temperature file is not used for SEB, the `seb_temperature` always takes the same value as that used for EM analysis.
	  ◦ If detailed delta temperature file is used for SEB, the seb_temperature is calculated by the following equation:
	  `seb_temperature = env_temperature + delta_T`
	  Where delta_T is the maximum temperature rise, including joule heat and coupling heat from FEOL, in the resistor's bounding box with

`-set_current_file` *filename*	

	Specifies the current of a macro's output pins for EM calculation, in case the macro does not have the respective timing library. When the mac current is set by the current file, the value calculated (if any) from AAE is overwritten.
	The format of the current file is:
	`{CELL` *cell_name*`|INSTANCE` *instance_name*`} PIN` *pin_name* `RMS` *rms_current* `PEAK` *peak_current* `AVG` *avg_current* `Td <`*value*`> NetFreq <v`
	The unit of `Td` is Nanosecond and `NetFreq` is GHz.
	Following are few examples of the current file format:
	`CELL cell_macro_A PIN Q1 RMS 0.01 PEAK 0.1 AVG 0.01`
	`CELL cell_macro_B PIN Q1 RMS 0.01 PEAK 0.1 AVG 0.01`
	`INSTANCE inst_macro_1 PIN Q2 RMS 0.01 PEAK 0.1 AVG 0.01`
	`INSTANCE inst_macro_2 PIN Q2 RMS 0.01 PEAK 0.1 AVG 0.01`

`-simulation_net` *list_of_nets*	
	Forces the specified nets to use the simulation mode.
`-simulation_net_file` *filename*	
	Forces the nets in the specified file to use the simulation mode.
`-skip_category_mode {0 | 1 | 2}`	

Specifies to skip nets that belong to categories mapping to the specified mode. This parameter allows you to specify three modes, namely 0, 1

The following table lists the common categories for all modes, and the categories specific to each mode:

Common Categories	0 Skip Category Mode	1 Skip Category Mode	2 Skip Category Mode
• Non top scope nets • Internal nets on boundary path • P/G nets • Constant nets • User-defined skipped nets • Nets below effective frequency threshold • Physically broken nets • Nets without loading capacitance annotation • Nets with SPEF back-annotation failures during simulation • Nets failed in analysis	• Slave nets by Verilog Assign • Nets (non-constant) without frequency annotation • Nets without physical shape for output pin • Nets without wire shape connection to output pin • Nets with zero pin current	• Equivalent nets by Verilog Assign • Nets without driver • Nets without receiver	• Nets without pins • Equivalent nets by Verilog Assign • Nets without driver • Nets without receiver

For example, if you set `set_signal_em_analysis_mode -skip_category_mode to 1`, the report file lists all categories listed in the *Common Ca* *Skip Category Mode* columns.

Following is a snippet of the report file for mode **1**:

```
Total Nets in Design:               33451
Total Selected Nets in Design:          4
Total Analyzed Nets:                    0
Total Skipped Nets:                     4
  Non top scope nets:                                          0
  Internal nets on boundary path:                              0
  Equivalent nets by Verilog Assign:                           0
  P/G nets:                                                    0
  Constant nets:                                               2
  User-defined skipped nets:                                   0
  Nets below effective frequency threshold:                    0
  Nets without driver:                                         1
  Nets without receiver:                                       1
  Physically broken nets:                                      0
  Nets without loading capacitance annotation:                 0
  Nets with SPEF back-annotation failures during simulation:   0
  Nets failed in analysis:                                     0
```

`-skip_net` *`net_name_list`*

Specifies the net to be skipped in the signalEM analysis.

Refer to the example below:

```
{net_a net_b net_c}
```

`-skip_net_file` *`list_file`*

Specifies the net file to be skipped in the signalEM analysis.

The format is one net name per line, with comments using # as the first char. For example:

```
#list of nets to skip
net_a
net_b
net_c
```

`-toggle` *`value`*

Specifies the switching factor for signal nets. A value of `1.0` means that if a flip-flop is clocked by a 20 Mhz clock, it changes state on 100% of Therefore, the signal has 20 million transitions, which is half the number of transitions of the input clock. As a result, the final switching freque net is 10 Mhz.

Default: `1.0`
Value Range: `0.0` to `1.0`

`-useQrcTech`	Forces I_{rms} checks to use the Quantus tech file instead of the technology LEF file. If either I_{peak} or I_{avg} is also checked, all checks will use th including I_{rms}. This parameter is enabled by default. **Note:** The `-method avg` and `-method peak` analysis will only support AC current density rules from Quantus tech file. If either `avg` or `peak` is als all checks will use the Quantus tech file equations, including RMS.
`-use_rms_delta_t {true | false}`	
	When this parameter is set to `true`, the `delta_T` used to calculate `seb_temperature` would be based on the RMS delta T (joule heat only). If this parameter is set to `false`, the `delta_T` used to calculate `seb_temperature` would be based on the sum of self-heat delta T and RMS delta *Default* : `false`
`-view viewName`	
	Specifies the name of the view.

Example

- The following command specifies to calculate current waveform using the rms, avg, and peak methods, and save violations in a report named `sigem.rpt`

```
set_signal_em_analysis_mode \

    -method {rms avg peak} \
    -detailed true \
    -report sigem.rpt \
    -avgRecovery 0  \
    -useQrcTech true \
    -ict_em_models /../ictfile.ict \
    -em_threshold 0 \

verify_AC_limit
```

- The following is an example of the `-extraction_tech_file` parameter:

```
set_signal_em_analysis_mode -method {avg rms peak} -detailed \
-ict_em_models ../../EMdata.ict \
-extraction_tech_file qrc_file-em_temperature 105 \
-avgRecovery 0.5 -report AC_signalEM.tcf.rpt -error 100000000
```

- The following command specifies different temperature values to the layers M1, M2, M3, VIA1, VIA2, and VIA3 for average current limit analysis:

```
set_signal_em_analysis_mode
...
   -em_temperature 110 \ #temperature for the remaining layers
   -em_temperature_layer_list {M1 125 M2 115 M3 105 VIA1 115 VIA2 105 VIA3 120} #layer-based temperature
```

  The log file will display the following info message:

```
Layer specific EM temperature will be used for AVG check for layer M1(125C), M2(115C), M3(105C), VIA1(115C), VIA2(105C), VIA3(120C).
```

check_noise

```
check_noise
[-help]
[-all]
[-check_only {receiver_no_propagation_model | receiver_no_dc_tolerence |
driver_no_current_source_model | driver_no_model}]
[-instance_list string]
[-instance_only {true | false}]
[-pin_list string]
[-type {receiver_model | driver_model}]
[-unique {true | false}]
[-verbose]
[-view string]
[ [ > | >> ] filename ]
```

Performs several consistency and completeness checks on noise models specified for a design. These checks help to ensure that the right set of models are available for the SI analysis engine to perform crosstalk noise analysis.

Note: You need to set `setDelayCalMode -siAware` to `true` before running the `check_noise` command.

Parameters

`-help`	Prints out the command usage.
`-all`	Displays all the debug information.
`-check_only {receiver_no_propagation_model | receiver_no_dc_tolerence | driver_no_current_source_model | driver_no_model}`	Checks the warning name. The following warnings are checked: • `receiver_no_propagation_model`: Shows how many design pins are missing the receiver model for propagation. • `receiver_no_dc_tolerence`: Shows how many pins have no DC VH/VL tolerance specified. • `driver_no_current_source_model`: Shows how many design pins are missing the current source model. • `driver_no_model`: Specifies how many design pins are missing the driver model.
`-instance_list string`	Specifies the instance name.
`-instance_only {true | false}`	Prints each instance only once.
`-pin_list string`	Specifies the instance pin names.
`-type {receiver_model | driver_model}`	Checks the presence of a valid model type - `receiver_model` or `driver_model`. If the specified model is missing, a warning will be issued. The valid receiver models are the models having vivo tables, such as, CDB, CCSN, ECSMN. The valid driver models are CDB, CCS, ECSM, NLDM, and UDN.
`-unique {true | false}`	Reports unique cells or pins for each power domain.
`-verbose`	Generates verbose details.
`-view string`	Specifies the view name.
`>filename`	Redirects output to a file.
`>>filename`	Appends to an output file.

Examples

- The following command generates the output as shown below:

```
check_noise -type receiver_model

   **WARN: (IMPESI-3125): AAE_WARN: The analysis view specified to check_noise is not found or specified. Checking view
   default_emulate_view_setup.
   --------------------------------------------------------------------------------
```

```
CHECK NOISE SUMMARY
------------------------------------------------------------------------------
Warning Number of Warning
------------------------------------------------------------------------------
receiver_no_propagation_model 17931
receiver_no_dc_tolerence 17931

------------------------------------------------------------------------------
# CHECK NOISE WARNING DESCRIPTIONS:

# receiver_no_propagation_model: The receiver model for glitch
# propagation or ROP is not available, only RIP analysis will be performed.

# receiver_no_dc_tolerence: The input pin do not have vh/vl dc
# tolerence specified in the noise file. Default tolerences will be used.

------------------------------------------------------------------------------
```

```

Generates the SPICE trace for a path.

While generating a Spice Deck, the `create_spice_deck` command looks for library cells required to run Spice and adds all cells as ".include" in the generated Spice netlist.

The output SPICE deck includes:

- Active and passive devices such as field-effect transistors (FETs), capacitors, and resistors.
- Initial conditions and voltage sources
- Actual names of the gates, nets, and cell instances, which helps the simulator interpret this information effectively. For example, consider the following excerpt, which shows an entry for a gate named `U0` in the SPICE deck:

```
*Gate U0
*--------------------
*Cell ports in order : x a VSS VDD
*--------------------
XU0 U0/x U0/a 0 U0/VDD inv_ahvt_64
*--------------------
```

Note: In order to output a Spice deck that generates the same report output as the `report_timing` command, you must run the `create_spice_deck` command with the `-report_timing`, `-segment_start`, and `-segment_end` parameters.

Parameters

`-help`	Prints out the command usage.
`-add_side_load_measurement {true | false}`	Adds the side load measurement in clock mesh Spice deck. By default, Innovus only measures the latencies, delays, and slews of arcs that are part of clock mesh specified using the `-from`/`-to` parameters. When set to `true`, the software additionally measures the latencies and slews of the side recievers at each stage. *Default*: `false`
`-add_voltage_for_missing_sensitization`	Adds the voltage for missing sensitization.
`-bbox_cells string`	Specifies the list of cells to be considered as black boxes for SPICE simulations. This parameter enables you to continue with the simulations even if subckts are missing for one or more cells. All the instantiations of these cells will be replaced by pin caps to replace the input pins connectivity of black-boxes, and the software computed PWL waveforms applied at the output pins of black boxes. The SPICE delays/slews reported for these blackboxes will be the software computed values.
`-depth integer`	Creates a clock mesh Spice deck of the specified stage depth. Innovus only traces the clock mesh up to the user-specified depth, starting from the specified `-from` pin. If both the `-depth` and `-to` parameters are specified, then Innovus generates the deck till the depth which is minimum of the `-to` pin depth and the user-specified depth.
`-enable_arrival_measurements {true | false}`	Allows adding arrival measurements.
`-enable_fast_simulation {true | false}`	When set to `true`, the software enables the fast simulation mode. In this mode, additional clock cycles are not required to initialize sequential cells in the Spice deck - this speeds up Spice simulations. All the sequential cells are initialized using the initial conditions and only a single clock edge is applied as input. By default, this parameter is set to `false`. In this mode, two clock cycles are applied as input to the clock network, where the first triggering edge is used for initialization of sequential cells, and the second edge is used for delay measurement.
`-enable_spectre_x {true | false}`	Enables the spectreX license checkout when launching Spectre.
`-exclude_side_load_cells string`	Specifies a list of cells for which the pin capacitance will be used for side loads instead of instantiating them.
`-exclude_side_load_cells_for_missing_subckt {true | false}`	When set to `true`, the software will add side load pin capacitance for missing Spice subckt cell instead of instantiating it.

`-file_prefix` *string*	Adds the specified prefix to the generated Spice deck files. If this parameter is not used, one of the following default names of the generated Spice decks will be used: • `path_<index>_setup.sp: for setup paths` • `path_<index>_hold.sp: for hold paths` • `path_<index>_vl_glitch.sp: for VL glitch` • `path_<index>_vh_glitch.sp: for VH glitch` The `<index>` in the above file names is controlled based on the number of decks that are generated using the `create_spice_deck` command. A user-specified string (specified using this parameter) is used as a prefix to the above mentioned file names.
`-force_delete_output_dir`	Removes the directory specified by the user using the `-outdir` parameter.
`-format` *string*	Allows you to make changes to the run path simulation internal reporting format. The format columns should be compatible with the `report_timing_format` settings.
`-from` *string*	Creates the Spice deck with mesh net starting from the specified pin.
`-from_fall` *string*	Creates the Spice deck with mesh net starting from the falling transition of the specified from pin.
`-from_rise` *string*	Creates the Spice deck with mesh net starting from the rising transition of the specified from pin.
`-generate_output_only {true | false}`	Generates the report output only, without triggering any simulations. *Default*: `false`
`-glitch_simulation_mode {input_output | output}`	Specifies the glitch simulation mode. When set to `input_output`, the software uses both the RIP and ROP for Spice calculations. When `output` is specified, the Spice ROP will be computed using the RIP.
`-ground` *string*	Specifies a list of ground nodes.
`-include_cell_variation {true | false}`	Writes out the Spice deck required to run simulations. When set to `true`, the software runs Monte-Carlo simulations from within the Tempus software. *Default*: `false`
`-lsf_job_string` *string*	Specifies a handle to the farm job for launching the simulation.
`-mc_simulation_init_args` *string*	Passes necessary Monte Carlo parameters that are required to run MC simulations. The Monte Carlo analysis refers to “statistics blocks”, where statistical distributions and correlations of netlist parameters are specified. This parameter initializes these parameters under the statistics block. **Note**: This parameter can be used when `-include_cell_variation` is set to `true`.
`-mc_simulation_tran_args` *string*	Initializes full transient time of simulation and transient time step.
`-measure_point {all | path | stage}`	Specifies whether to add all, path, or stage measurements. *Default*: `all`
`-merge_spice_deck {true | false}`	Allows you to enable merged Spice deck.
`-model_file` *string*	Specifies the path of SPICE model files, which contains spice model information. This information is necessary to get accurate Spice information. If sub-circuit and model files are not provided and cdBs are available, spice information is dumped using cdB.

`-no_hard_stop_at_to_pins {true | false}`	When set to `false` (default mode), the Spice deck is generated only for traced paths starting from the `-from` pin and ending at the `-to` pin. It does not traverse through the fanout branches that do not lead to the `-to` specified pin. When set to `true`, traversal occurs through the whole fanout cone of the `-from` pin till it hits a clock pin of a flop, or any stop point specified with the `-to` parameter, or passes through a depth specified with the `-depth` parameter.
`-outdir` *string*	Specifies the name of the output directory that will contain the generated delay and/or glitch spice decks. If simulation is also performed using the `-run_simulation` parameter, the Spice simulations output will also be saved in this directory.
`-power` *string*	Specifies the list of global names for the power nets. If the `-power` and `-ground` parameters are not specified, the software obtains this information from the power/ground supplies set via other ways in the design, such as, from the libraries/cdb, and so on. If the information is not available, the software uses the default list of power node names (VDD and VCC) and ground node names (GND and VSS).
`-receiver_pin` *string*	Specifies the list of receiver pins for which glitch Spice decks need to be generated. When used with the `-run_simulation` parameter, the software writes out a comparison report comparing various glitch parameters between Innovus and Spice, such as RIP, input glitch area, and ROP (only if ROP node name is available in the noise models) for the given receiver pins.
`-report_noise` *string*	Specifies the `report_noise` command parameters as a list of arguments within brackets. When specified, the Spice deck will be generated for all the receiver pins that are reported by the `report_noise` command for the specified options. When specified with the `-run_simulation` parameter, the software writes out a comparison report comparing various glitch parameters between Innovus and Spice, such as, RIP, input glitch area, and ROP (only if ROP node name is available in the noise models).
`-report_timing` *string*	Specifies the `report_timing` command options as a list of arguments within curly brackets. You can use this option to define the paths for which to generate a Spice trace. To select the paths for generating the Spice trace, specify the `report_timing` command options, as shown: `create_spice_deck -report_timing {-clock_from CLK -clock_to CPU_CLK -nworst 2}` When the `-report_timing` option is not used, the software generates a Spice trace for the worst path identified by the `report_timing` command. If the `-path_type {full_clock}` is used, then the clock path will also be processed. See the `report_timing` command for a complete list of options that can be used as arguments with the `-report_timing` option. **Note:** The `end` and `summary` values of the `-path_type` option of `report_timing` are not supported.
`-run_simulation`	Enables path simulation in addition to generating Spice Deck.
`-segment {data_path | launch_path launch_clock_path | capture_path all}`	Creates the Spice deck of a segment out of the path spice deck. The following command/global variable settings have the following impact on the `-segment` parameter options: • `-path_type full_clock` is defined under the create_spice_deck-report_timing parameter, then the -segment default value is `launch_path`. • `-path_type full_clock` is not specified, then default value is `data_path`. • `timing_disable_retime_clock_path_slew_propagation` global variable is set to `false`, the default value is `launch_path` (irrespective of `-path_type` settings). • `timing_disable_retime_clock_path_slew_propagation` global variable is set to `true` (default), then `launch_clock_path` and `capture_path` options are supported only when the `-path_type full_clock` option of the `create_spice_deck -report_timing` parameter is used.
`-segment_end` *string*	Specifies the name of the segment end term.

`-segment_start` *string*	Specifies the name of the segment start term.
`-side_path_level` *integer*	Specifies the number of levels of side path stages to be included in the Spice trace. The maximum number of levels that can be specified is 4. *Default*: `1`
`-spectre` *string*	Specifies the location of the Spectre version that should be used for simulation. If the path is not specified with this option, the software will check if you have the Spectre location defined in your path.
`-spectre_analysis_options <string>`	Adds Spectre analysis options to the run. When specified, the software provides instructions to Spectre, e.g., run a session with extra accuracy.
`-spectre_cmd_options` *string*	Specifies the command line options for Spectre.
`-spectre_lang_escape_chars` *string*	Specifies a list of escape characters in Spectre.
`-spice_include` *string*	Specifies the user-defined lines that should be written to the Spice deck. For example, `create_spice_deck -spice_include {.include extra_cmds.sp}` where `extra_cmds.sp` includes additional SPICE commands that are required for the run and are not included in the SPICE model file loaded with the `-models` parameter.

`-stimuli_file` *string*	Allows you to specify the file path containing stimuli to be used for the specified library cells. The cells' sensitization coming from the user-specified stimuli file takes precedence over the software inferred sensitization.
	Syntax for delay Spice decks is given below:
	`lib_cell` *string* `<from | from_rise | from_fall>` *string* `<to | to_rise | to_fall>` *string* `input_vector` *string* `num_clk_pulse` *integer*
	Syntax for glitch Spice decks is given below:
	`lib_cell` *string* `glitch_type <VL | VH> output_pin` *string* `input_vector` *string* `num_clk_pulse` *integer* `# For victim driver sensitization`
	`lib_cell` *cell_name* `glitch_type <VL | VH> input_pin` *string* `input_vector` *string* `num_clk_pulse` *integer* `# For victim receiver sensitization`
	The `num_clock_pulse` *integer* holds significance in case of sequential arcs, and specifies where to align the data pin transition with respect to the clock transition.
	For example, a value of '1' (default setting) specifies that the data pin transition needs to be aligned before the last clock transition where delay measurement is intended. This value can be used in case of regular flip-flops.
	The value '2' specifies that data pin transition needs to be aligned with respect to the second-last triggering clock edge. This value can be used for cascaded 2-bit flip flops.
	Additionally for sequential arcs, the first pin in the user-specified input vector needs to be the data pin, the signal of which will be latched in the sequential cell.
	Here are some examples of stimuli file:
	• The following example shows the stimuli file containing sensitizations for CP(rise)->Q(fall) and CP(rise)->Q(rise) timing arcs of library cell FF1:
	`lib_cell FF1 from_rise CP to_fall Q input_vector !D&CDN&!SE&!SI num_clk_pulse 2`
	`lib_cell FF1 from_rise CP to_rise Q input_vector D&CDN&!SE&!SI num_clk_pulse 2`
	• The following example shows the stimuli file containing sensitizations for the victim driver cell AOI for both VL and VH glitches:
	`lib_cell AOI glitch_type VL output_pin Z input_vector !A&!B&!C`
	`lib_cell AOI glitch_type VH output_pin Z input_vector A&!B&C`

`-subckt_file` *string*	Specifies the path of Spice sub-circuit file which contains the Spice information. This information is necessary to get accurate Spice information. If subcircuit and model files are not provided and cdBs are available, then Spice information in dumped using cdB.
`-sweep_range` *float*	Specifies the range to sweep the victim.

`-sweep_steps` *integer*	Specifies the number of steps by which the victim is swept.
`-sweep_victim {true | false}`	Enables victim sweep.
`-supply_voltage_file` *string*	Specifies a user-defined power/ground voltage file.
`-temperature` *float*	Specifies a user-defined temperature to be used in SPICE simulations. *Unit*: Celsius
`-through` *string*	Creates the Spice deck with mesh net going by `-through` points.
`-to` *string*	Creates the Spice deck with mesh net ending at the specified to pins.
`-use_control_param {true | false}`	Allows you to control the power/ground voltage levels in the created Spice deck through user-specified parameters. When set to `true`, an additional file with the same name as the deck, and extension .control is created that contains the parameterized design voltage levels of the PG pins of all the cells instantiated in the deck. Your can modify the *.control file as per the requirement without modifying the original deck.
`-use_distributed_load_for_side_receivers {true | false}`	Allows you to control whether to use the receiver output load as distributed or lumped load. *Default*: `false`
`-user_defined_measure_statements {append | overwrite}`	Specifies whether to overwrite the default measurement statements in the Spice deck by user-defined measurements specified using the `-user_defined_measure_statements_file` parameter, or append it with default measure statements. *Default*: `append`
`-user_defined_measure_statements_file` *string*	Allows you to add the delay/slew measurement statements for any given segement of the path for which Spice deck is generated. The format of the file is given below: `<MEASURE_TAG_NAME TRIGGER_PIN_NAME TARGET_PIN_NAME>` Multiple such lines with unique tags can be specified in the file. The measure statement is written in the Spice deck for delay measurement between `TRIGGER_PIN` and `TARGET_PIN`, and slew measurement at `TARGET_PIN`.
`-view` *string*	Specifies the view name - if a glitch Spice deck is created for a view other than the default view.
`-waveform_aware_pulse_width_checks {true | false}`	Generates the Spice deck for waveform-aware pulse width checks.
`-xtalk {delay | vl_glitch | vh_glitch | vlu_glitch | vho_glitch}`	Generates the SI Spice deck for the stage specified using the `report_timing` parameter. • A stage can start with victim driver input to victim receiver input. • A stage can start with victim driver input to victim receiver output. The stage will be specified in the `report_timing` command using the `-point_to_point` parameter. You can specify one of the following options: • `delay`: Allows to dump the SI delay Spice deck. • `vl_glitch | vh_glitch`: Specifies the type of glitch (VL or VH) the Spice deck will be used for. This option must be used for glitch Spice deck generation. • `vlu_glitch` | `vho_glitch`: Supports simulation of vlu/vho glitches.

Examples

- The following set of commands generate a SPICE deck for a path and output it in the `path1_spice` directory:

```
set rpt_tim_opt [ list -clock_from CLK -clock_to CPU_CLK -nworst 2 ]
create_spice_deck -outdir path1_spice -report_timing $rpt_tim_opt
-subckt_file  /path/subckt.sp  -model_file /path/models.sp
```

- The following command creates a SPICE deck and simulates it using the Spectre simulator:

```
create_spice_deck -run_simulation -spectre /tools/spectre
-subckt_file  /path/subckt.sp  -model_file /path/models.sp
```

- The following command creates a SPICE deck in `mydir` and keeps the instances up to three levels for each side path attached with the main path:

```
create_spice_deck -side_path_level 3 -outdir mydir
-subckt_file  /path/subckt.sp  -model_file /path/models.sp
```

- The following command creates a SPICE deck for the best path:

```
create_spice_deck -report_timing { -early }
-subckt_file  /path/subckt.sp  -model_file /path/models.sp
```

- The following command creates a Crosstalk Spice Deck for the specified Stage:

```
create_spice_deck -xtalk delay -model_file /path/models.sp -subckt_file /path/subckt.sp -report_timing {-point_to_point -from
<victim_driver_input> -to <victim_receiver_driver_output>} -output spice_output
```

- The following command dumps the VL spice deck `report_timing` command options so that the transition at receiver pin is failing:

```
create_spice_deck -xtalk glitch -report_timing < -from driver/input -to_fall receiver/input -point_to_point > -outdir <output dir> -
model_file <model file> -subckt_file <subckt file>
```

- The following command dumps the VH spice deck `report_timing` command options so that the transition at receiver pin is rising:

```
create_spice_deck -xtalk glitch -report_timing < -from driver/input -to_rise receiver/input -point_to_point > -outdir <output dir> -
model_file <model file> -subckt_file <subckt file>
```

- The following command run simulations and then generates a report:

```
create_spice_deck -report_timing "-net -from clk -to ca53/as_12/ff/D -path_type full_clock" -run_simulation -include_cell_variation
true > spice.socv.rpt
```

- The following command generates a report (if simulations have already been run):

```
create_spice_deck -generate_output_only true -report_timing "-net -from clk -to ca53/as_12/ff/D -path_type full_clock" -run_simulation
-include_cell_variation_true -format {arrival spice_arrival spice_arrival_detail arrival_error_detail hpin} > spice.socv.rpt
```

- The following section in SPICE deck specifies global supplies and transient analysis window time.

```
*---------------------
*Command and Options
*---------------------
.GLOBAL vdd vbbnw

```

- The following section shows the measurement statements for delay and slew.

```
*---------------------
*Measurement statements
*---------------------
.MEASURE TRAN Stage_0001_module1/inst_1/clk_DELAY_
module1/inst_1/q                                  ---------clk to q delay
+ TRIG V(module1/inst_1/clk) VAL=0.5 TD=167.9p RISE=1       of module1/inst_1
+ TARG V(module1/inst_1/q) VAL=0.5 TD=167.9p RISE=1
.MEASURE TRAN Stage_0001_module1/inst_1/q_SLEW
+ TRIG V(module1/inst_1/q) VAL=0.30 TD=167.9p RISE=1
+ TARG V(module1/inst_1/q) VAL=0.70 TD=167.9p RISE=1  ---------Slew at
.MEASURE TRAN Stage_0002_module1/inst_1/q_DELAY_              module1/inst_1/q pin
module1/inst_2/a
+ TRIG V(module1/inst_1/q) VAL=0.5 TD=167.9p RISE=1   ---------Interconnect Delay
+ TARG V(module1/inst_2/a) VAL=0.5 TD=167.9p RISE=1          and Input Slew
.MEASURE TRAN Stage_0002_module1/inst_2/a_SLEW
+ TRIG V(module1/inst_2/a) VAL=0.30 TD=167.9p RISE=1  ---------Interconnect Delay
+ TARG V(module1/inst_2/a) VAL=0.70 TD=167.9p RISE=1         and Input Slew
```

Note: The `DELAY` and `SLEW` keywords in the `MEASURE` statements indicate that these are the measurement statements for delay and slew respectively.

Also, Stage numbers (Stage_0001 and Stage_0002) in the `MEASURE` statement indicate the respective stages; first and second stage, in the timing path, which makes it easier for correlation with the `report_timing` report.

- The following shows an example for generating a VL glitch SPICE deck:

```
create_spice_deck -xtalk vl_glitch -receiver_pin x1/x2/I -outdir SPICE/net1_vl -model_file ./all_cells.model -subckt_file
./all_cells.sp
```

- The following shows an example for generating a VH glitch SPICE deck:

```
create_spice_deck -xtalk vh_glitch -receiver_pin x1/x2/I -outdir SPICE/net1_vh -model_file ./all_cells.model -subckt_file
./all_cells.sp
```

- The following command sets the simulation time stop criteria to be 13.40 ns and step time to be 1ps:

```
create_spice_deck -mc_simulation_init_args "stop=1.34e-08 step=1p"
```

- The following command `writes` out statistics block in a deck to run Monte Carlo simulations:

```
create_spice_deck -mc_simulation_init_args "numruns=3000 seed=1234 distribute=fork numprocesses=8 variations=mismatch
scalarfile=MCDataSetLoad.txt dut=[%s]"
simulator lang = spectre

mc1 montecarlo numruns=3000 seed=1234 distribute=fork numprocesses=8 variations=mismatch scalarfile=MCDataSetLoad.txt dut=[

define_bundled_bus

```
define_bundled_bus
[-help]
[-add_members string]
[-delete_members string]
[-name string]
```

Allows you to control user-defined bus groups.

The software automatically identifies bus nets. However, in some cases the software may not be able to mark bus bits properly (or treat marked bits as bus). For improved bus identification, the `define_bundled_bus` command allows you to control the nets that you want to add (or remove) from the list of recognized bus bits.

Parameters

`-help`	Prints out the command usage.
`-add_members string`	Specifies the name of nets to be added to the group.
`-delete_members string`	Specifies the name of nets to be deleted from the group.
`-name string`	Specifies the name of the group.

Examples

- The following example command will create a bus named bus1 with 3 net members x[1] and x[2]:

```
define_bundled_bus -name bus1 -add_members {x[1] x[2]}
report_bundled_bus -type user_defined
############################################################

Summary:
Total number of user defined bus groups reported = 1
Total number of tool inferred bus groups reported = 0

------------------------------------------------------------

Group Name (user_defined) : bus1

Constituents:
- x[1]
- x[2]
```

- The following example command will add one more member x[3] and delete member x[2] to the bus 'bus1':

```
define_bundled_bus -name bus1 -add_members x[3] -delete_members x[2]

Added [1] net(s) to group 'bus1'.

Deleted [1] net(s) from user-defined group 'bus1'.
```

Related Commands

- report_bundled_bus

fixACLimitViolation

```
fixACLimitViolation
[-help]
[-excludeIO {true | false}]
[-excludeNetFile filename]
[-fixNetCategory {dataOnly | clockOnly | clockAndData}]
[-fixingMethod {route_rule | down_size | buffer}]
[-postCTS]
[-selectNetFile filename]
[-useReportFile filename]
[-useSegmentBasedNDR {true | false}]
```

Repairs violations associated with AC current density, wire-self-heat, Joules heat, or electromigration, mostly in a postRoute stage. Fixing methods are applying routing rules, downsizing drivers or adding a buffer to split up the net load on the violated nets. Use this command in conjunction with the `verifyACLimit` command. The `verifyACLimit` command can mark the violating net for the `fixACLimitViolation` command to repair, and it can generate the report file that `fixACLimitViolation` can read.

The `fixACLimitViolation` command only applies a single fixing method to fix EM violations. You can select the fixing method by specifying the `-fixingMethod` parameter. If the method is not specified, the command will fix EM violations by setting route rules on violating routes. For example, the following usage will apply route rules for both clock and data nets while excluding nets with I/O pins:

```
fixACLimitViolation -fixNetCategory clockAndData -excludeIO true
```

Before running `fixACLimitViolation`, you can generate an incoming EM violation report using the `verifyACLimit` command. This operation will ensure that the appropriate data for `fixACLimitViolation` is included in the violation report. After that, this report should be provided as an input to `fixACLimitViolation` using the `-useReportFile` parameter. The following is an example of the sequence of operations:

```
verifyACLimit -report beforeFix.rpt -view hold_view

fixACLimitViolation -useReportFile beforeFix.rpt

verifyACLimit -report afterFix.rpt -view hold_view
```

By default, `verifyACLimit` will calculate EM currents using the hold view. This means that `verifyACLimit` will internally invoke a hold timing update. If it is desired to maintain the current setup timing graph in memory for use after EM fixing, the `-forceHoldView` parameter should be provided to `verifyACLimit` so that the hold timing update doesn't nullify the setup timing graph. Below is an example of this scenario:

```
timeDesign -postRoute
verifyACLimit -report beforeFix.rpt -forceHoldView
fixACLimitViolation -useReportFile beforeFix.rpt
verifyACLimit -report afterFix.rpt -forceHoldView
```

Note: It is important to set the right switching activity factor on the nets before using the `verifyACLimit` command. Refer to the `set_power_analysis_mode`, `set_default_switching_activity` and `set_switching_activity` commands for further details on the default behaviors of the software and how to modify them. The example below shows how to set the global switching activity for verifying and fixing AC limit violations.

```
set_default_switching_activity -global_activity 0.2
propagate_activity -set_net_freq true
verifyACLimit -use_db_freq -report em.report
fixACLimitViolation -useReportFile em.report
```

Alternatively, `verifyACLimit -toggle` parameter can be used for more pessimistic analysis. In this case, modifying `set_default_switching_activity` is not needed. The following is an example of forcing every signal net to toggle at 50% of the clock rate:

```
verifyACLimit -toggle 0.5 -report em.report
fixACLimitViolation -useReportFile em.report
```

See `verifyACLimit` for further command parameters and usage.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `fixACLimitViolation` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man fixACLimitViolation`
`-excludeIO {true | false}`	If set to `true`, excludes nets connected to I/O pins during violation fixing. *Default:* `false`
`-excludeNetFile` *filename*	Specifies a file that contains the names of nets to exclude from AC limit violation repair.
`-fixNetCategory { dataOnly | clockOnly | clockAndData}`	Specifies fixing net types. For `dataOnly`, fixes data nets only. If `clockOnly` is specified, fixes clock nets. If `clockAndData` is specified, fixes clock and data nets. **Note**: For clock nets, only route rules will be used for fixing. Downsizing or buffering will not be used. *Default:* `dataOnly`
`-fixingMethod {route_rule | down_size | buffer}`	Specifies the fixing method for correcting EM violations. You can specify any of the following: • `route_rule`: routing rules will be applied for fixing violations • `down_size`: driver cell downsizing will be applied for the violating nets • `buffer`: buffering will be applied to the violating nets. *Default*: `route_rule`
`-postCTS`	If specified, enables fix for the clock nets, for postCTS DBs. This parameter should be used only with `-fixNetCategory clockOnly`. *Default*: `omitted`
`-selectNetFile` *fileName*	Specifies a file that contains the names of nets for which to perform AC limit violation repair.
`-useReportFile` *filename*	Reads the `verifyACLimit` report, and uses the violation information from the report file to set up a proper routing rules. This is recommended for the best fixing performance.
`-useSegmentBasedNDR {true | false}`	Enables/disables segment-based route rules. If set to `true`, generates and applies segment-based route rules for fixing violations. This approach enables you to specify the desired width and distance for each layer of the violated net. *Default*: `true`

Examples

- The following command performs buffering only, for the nets specified in the `netFile.txt` only:
  ```
  fixACLimitViolation -fixingMethod buffer -selectNetFile "netFile.txt"
  ```
- To use downsizing, excluding nets with I/O pins:
  ```
  fixACLimitViolation -fixingMethod down_size -excludeIO true
  ```
- To fix both clock and data nets with route rules:
  ```
  fixACLimitViolation -fixNetCategory clockAndData
  ```
- The following example shows how to feed `verifyACLimit` report through the `-useReportFile` parameter.
  ```
  fixACLimitViolation -useReportFile em.report
  ```

get_glitch_threshold

```
get_glitch_threshold
[parameter_names]
```

Displays information for the specified `set_glitch_threshold` parameters for the current Tempus session. If you do not specify a parameter, the software displays information for all `set_glitch_threshold` parameters.

Parameters

parameter_names	Displays information for the specified parameter. You can specify one or more parameters. See `set_glitch_threshold` for descriptions of the timing analysis mode parameters you can specify.

Examples

- The following command shows the failure threshold for ROP for single stage cells:
  ```
  get_glitch_threshold -failure_point last
  ```
  Here's the command output:
  ```
  value=0.4 -threshold_type reporting -glitch_type both -pin_type all -failure_point last -failure_dependency none
  ```
- The following command shows the failure threshold for the ROP for the internal net of multi-stage cells:
  ```
  get_glitch_threshold -failure_point internal
  ```
  Here's the command output:
  ```
  value=0.2 -threshold_type reporting -glitch_type both -pin_type all -failure_point internal -failure_dependency none
  ```
- The following command shows the failure threshold for the RIP for the input net of cells without CCSN/ECSMN/cdB
  ```
  get_glitch_threshold -failure_point input
  ```
  Here's the command output:
  ```
  value=0.5 -threshold_type reporting -glitch_type both -pin_type all -failure_point input -failure_dependency none
  ```

[-switch_prob]
[-unconstrained_net_use_inf_tw]
[-use_infinite_TW]
[-quiet]
```

Displays the following information about the specified `setSIMode` parameters in the Innovus log file and the Innovus console:

- Parameter name
- Current value
- Type (Boolean, string, and so on)
- Whether the current value was set by user

If you do not specify any parameters, the software displays information for all of the parameters.

Parameters

parameter_names	Displays information for the specified parameters. You can specify one or more parameters. See `setSIMode` for descriptions of the parameters you can specify.

`-quiet`	Displays the current settings for the specified parameters in Tcl list format only. If you specify `-quiet` without any parameters, the software displays the current settings of all the `setSIMode` parameters in Tcl list format.

Examples

- The following command displays the current setting of the `-analyzeNoiseThreshold`, and `-deltaDelayThreshold` parameters:

  ```
  getSIMode -analyzeNoiseThreshold -deltaDelayThreshold
  ```

  The software displays the following information:

  ```
  -analyzeNoiseThreshold 20 # int, default=20
  -deltaDelayThreshold -1 # float, default=-1
  {analyzeNoiseThreshold 20} {deltaDelayThreshold -1}
  ```

- The following command displays the current settings for all `setSIMode` parameters in Tcl list format only:

  ```
  getSIMode -quiet
  ```

  The software displays the following information:

  ```
  {acceptableWNS same} {analyzeNoiseThreshold 20} {deltaDelayThreshold -1} {insCeltICPostTcl {}} {insCeltICPreTcl {}} {maxNrIter 2}
  {noiseTwfMode {}} {targetPathGroups {reg2reg in2out in2reg reg2out}} {usePrevCeltICRunDir {}{vaDecoupleThreshold 10} {vaThreshold 15}
  {vaMode cap}}
  ```

readTransitionFile

```
readTransitionFile
-file fileName
[-view viewName]
```

Reads external transition files that are used to perform maximum transition violation reporting and fixing.

The contents of a transition file must be in the following format:

```
setTranTime [-add] [-maxR slewValue | -maxF slewValue] {pinName}
```

or

```
setTranTime [-add] [-minR slewValue | -minF slewValue] {pinName}
```

Where:

- `-add`: Specifies that the transition value is incremental.
- `-maxR | -maxF`: Specifies the maximum rise or fall transition.
- `-minR | -minF`: Specifies the minimum rise or fall transition.

  Note: The minimum transition values will be ignored while performing transition violation fixing.
- *`pinName`*: Specifies the pin name for which the transition value is specified. To specify multiple pin names, you need to use separate `setTranTime` statements as given below:

  ```
  setTranTime -add -maxR 3.5 inst/A
  setTranTime -add -maxR 3.5 pinB
  ```

Note: The `readTransitionFile` command uses the time unit that is written in the slew file. If time unit is specified as 1e-12, it reads the values in picoseconds. For time unit specified as 1e-09, the command reads the values in nanoseconds. For example,

```
# Time Unit : 1e-09 seconds
setTranTime -minR 0.80050 {AAA/BBB/CCC/A}
setTranTime -minF 0.580300 {AAA/BBB/DDD/A}
```

When a transition file is read and third-party slew values are annotated, Innovus uses the following command to report transition violations with the annotated slews:

```
timeDesign {-postRoute | -signoff | -reportOnly} -useTransitionFiles
```

Parameters

`-file` *`fileName`*	Specifies the name of the file that contains information about the transition time.
`-view` *`viewName`*	Specifies the view name for which the transition file will be read in case of MMMC designs. You need to ensure that you specify the transition files for all setup views to perform transition violation fixing. **Note**: This parameter is required for MMMC designs only.

Example

- The following command reads an external transition file called `sampleFile` for non-MMMC designs:

  ```
  readTransitionFile -file sampleFile
  ```
- The following commands read view specific external transition files for a MMMC design:

  ```
  readTransitionFile -view view1 -file sampleFile1
  readTransitionFile -view view2 -file sampleFile2
  ```

report_bundled_bus

```
report_bundled_bus
[-help]
[-name string]
[-nets string]
[-type {user_defined | tool_inferred}]
[[ > | >> ]]
```

Generates a report for bundled buses.

Parameters

-help	Prints out the command usage.
-name *string*	Specifies the name of the user-defined bus group(s) to be reported.
-nets *string*	Specifies the name of the net(s) to be reported.
-type {user_defined | tool_inferred}	Reports the type of bundled bus(es) - user-defined or tool-inferred - to include in the report. By default, the `report_bundled_bus` command generates reports for both user-defined and software-inferred type of buses.
> *filename*	Redirects the output to the specified file.
>> *filename*	Appends to the specified output file.

Examples

- The following command shows the user-defined bus groups:

```
report_bundled_bus

Summary:
Total number of user defined bus groups reported = 3
Total number of tool inferred bus groups reported = 41

-----------------------------------------------------
Group Name (user_defined) : grp1

Constituents:

report_double_clocking

```
report_double_clocking
[-help]
[-file string]
[-max_delta_delay float]
[-nworst integer]
[-reverse_slope_limit float]
[-reverse_voltage_change_threshold float]
[-view string]
```

Reports noise impact on clock nets by generating information on the double clocking, transition type, and reverse slope.

The report output displays violations in sorted order - based on the absolute value of the slope, a negative value indicates a reverse slope.

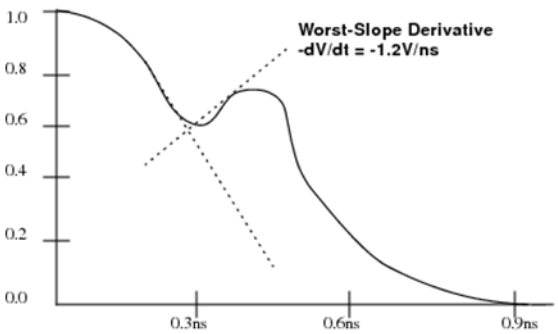
Note: The `report_double_clocking` command requires that clocks have been defined and applied prior to timing analysis with SI (`update_timing` or `report_timing`). The `report_double_clocking` command does not work with the glitch-only flow (`update_glitch`).

Double clocking occurs when the noise glitch attacks a transitioning signal. The multiple transition or double clocking check supplements the transition time check performed in static timing analysis. Transition time is defined as the duration of time that a signal takes to make the transition between two threshold points. However, transition time does not account for the waveform shape between the voltage thresholds.

For special signals such as clocks it is important to analyze the waveform shape between the voltage threshold in case the signal transitions slowly or in the opposite direction (even for a short duration of time) causing multiple clock edges. This command enables you to report the worst-case slope (dV/dtfor rising signal and -dV/dt for falling signal) of a signal transitioning between the voltage thresholds. The slope derivative is measured in units of volts per nanosecond (V/ns). This value can be positive if the signal does not change direction, 0 if the signal is flat, and negative if the signal changes direction even for a short duration of time.

The following figure shows two falling signal transitions:

Figure: Negative Worst-Slope Derivative



In the above figure, the falling signal transitions have identical transition times. However, the worst-case slope derivatives for the two falling waveforms are different. If a clock signal exhibits a negative slope derivative, there is a possibility of a double clocking functional failure. A higher reverse slope results in a higher possibility of a double clocking functional failure.

The double clocking report contains the following sections and their corresponding fields:

- **Double Clocking**
  - Rise Slope (V/ns): Specifies the worst reverse slope of the rising clock signal as a measure of volt per nano-second.
  - Fall Slope (V/ns): Specifies the worst reverse slope for the falling clock signal as a measure of volt per nano-second.
  - VictimNet: Specifies the name of the victim net.
- **Instance Pin**: Displays the name of the instance pin.
- **Transition Type:** Indicates the type of transition the net is undergoing – R for rising, F for falling.
- **Reverse Slope:** Indicates the slope that is opposite to the transition type and the value reported is the worst reverse slope.

Parameters

`-help`	Prints out the command usage.
`-file <string>`	Specifies the output filename. *Default*: {$parm_filename_prefix}_clock.text
`-max_delta_delay float`	Reports clock nets, for which the delay change caused due to noise, exceeds the specified number. *Default*: 0
`-max_slew float`	Reports clock nets for which the transition time, including SI, exceeds the specified number. *Default*: 0
`-nworst integer`	Specifies the number of clock nets to report in each category. *Default*: 1
`-reverse_slope_limit float`	Reports the clock nets for which the slope is below the specified number. *Default*: 0
`-reverse_voltage_change_threshold float`	Controls the reverse slope failure criteria by allowing you to supply a minimum voltage change as a percentage of VDD. The reverse slope must be sustained in order for it to be considered as failing. *Default*:0.1
`-view string`	Specifies the view name for which the report to be generated.

Examples

- The following command reports clock nets that have a reverse slope less than -1:
  ```
  report_double_clocking -reverse_slope_limit -1
  ```
- The following command reports 100 clock net violations of each category:
  ```
  report_double_clocking -nworst 100
  ```
- The following command shows the double clocking report for `default_emulate_view` view:

  ```
  report_double_clocking -view default_emulate_view

  ********************************************************************************

report_instance_cdb

```
report_instance_cdb
[-help]
[-analysis_type {early | late}]
[{instance_list or collection}]
[-output_file filename]
[-quiet]
[-view viewname]
```

Allows you to report the cdB associated with all the instances or a subset of instances in a design.

Note: This command must be issued after `report_timing`, `update_timing`, or `update_glitch` commands.

Parameters

`-help`	Outputs a brief description that includes type and default information for each`report_instance_cdb` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_insance_cdb`
`-analysis_type { early | late }`	Specify the analysis type for the query. *Default*: `late`
instance_list or collection	
	Specify the instance for which the cdB association is desired. By default, the cdB association for all the instances is reported.
`-output_file` *filename*	Specify the output filename for the instance report to go to. By default, the report output is displayed on the screen.
`-quiet`	Suppresses warning messages for cells missing in CDB files.
`-view {`*viewnames*`}`	
	Specifies the view names. By default, values for all the views are reported.

Examples

- The following command reports the cdB instance connection for all the instances in the design and write it to the inst_cdb.rpt file:

```
> report_instance_cdb -output_file inst_cdb.rpt
```

- The following command reports the cdB instance connection for the u5 instance to the screen:

```
> report_instance_cdb u5

VIEW: default_emulate_view -- ANALYSIS TYPE: late
u5 : inv_t1 : test1.cdb.txt
```

- The following command reports the cdB instance connection for the early analysis type for the u5 and u6 instances

```
> report_instance_cdb -analysis_type early {u5 u6}

VIEW: default_emulate_view -- ANALYSIS TYPE: early
u5 : inv_t1 : test1.cdb.txt
u6 : inv_t2 : test2.cdb.txt
```

Related Commands

- `report_timing`

[-output_format string]
[-output_file string]
[-overshoot_undershoot]
[-pins string]
[-precision integer]
[-quiet_nets]
[-remove_status_row <string>]
[-report_virtual_attacker_constituents]
[-reverse_voltage_change_threshold float]
[-slack float]
[-skip_nets_or_pins_in_header]
[-sort_by string]
[-style {default | extended}]
[-threshold float]
[-txtfile filename[.gz]]
[-view]
```

Generates text-based noise reports.

Note: You need to ensure that the `setSIMode -enable_glitch_report` (to generate glitch report) or `-enable_delay_report` (to generate detailed delay report) parameters are set to `true`, before the `report_timing`, `update_timing`, or `update_glitch` commands are run.

Parameters

`-help`	Prints out the command usage.
`-bumpy_waveform`	Flags nets with bumpy waveforms at the receiver. **Note**: This parameter will always show maximum delay bumpy report (even if the `-delay min` option is specified).
`-cell_type {bbox | clock | data | latch}`	Generates a glitch report for the user-specified cell-type. You can specify one of the following options: • `bbox`: Generates a report for only the black-box receivers • `clock`: Generates a report for only the clock pin receivers • `data`: Generates a report for only the data pin receivers • `latch`: Generates a report for only the latch pin receivers
`-delay {min | max}`	Reports delay uncertainty instead of noise values. The only legal values are `min` or `max` for minimum or maximum path delay analysis.
`-double_clocking`	Enables double clocking reporting.
`-exclude_failures`	Excludes all failing nets from the glitch report.
`-expand_virtual_attacker_bus`	Reports virtual attacker components and expands bus bits in the noise reports. This parameter works only when the bus virtual attacker feature is enabled using the `setSIMode -enable_virtual_attacker_constituent_report true` setting.

`-failure`	Reports receiver peak failures and DC tolerance failure nets. Use this option only for glitch noise failure reports.
	The `report_noise`, without the `-failure` option, will use 0.10 of vdd as default.
	When you specify `-failure` option you need to use `-threshold` to lowest order of noise that is saved, if not specified which is 0.05 of Vdd.
	Option: Directory Name:
	`-sort_by noise glitch`
	`-sort_by rcvr_peak glitch`

`-format` *string*	Specifies the output glitch report format fields. The valid fields are: arc, attacker_edge, attacker_logical_correlation_phase, attacker_net, attacker_offset, attacker_peak, attacker_slew, attacker_source, attacker_status, attacker_vdd, attacker_xcap, cell_type, delay, glitch_slack, incr_delay, level, peak, receiver_cell, receiver_input_failure_threshold, receiver_input_pin, receiver_output_failure_threshold, receiver_output_peak, slack, slack_status, stage_info, thresh_source, verbose_logical_correlation_report, victim_edge, victim_library, victim_logical_correlation_phase, victim_net, victim_slew, victim_total_area, victim_total_cap, victim_total_cross_cap, victim_vdd, victim_width Each field corresponds to the following columns of the glitch report: • arc: Arc • attacker_edge: Edge • attacker_net: Net • attacker_offset: Offset (ps) • attacker_peak: Peak (mV) • attacker_slew: Slew (ps) • attacker_source: Constituents: Source • attacker_status: Statue • attacker_vdd Vdd (V) • attacker_xcap: Xcap (fF) • glitch_slack: Slack • level: Level • peak: Peak (mV) • receiver_cell: Receiver cell • receiver_input_failure_threshold: Receiver Input Threshold • receiver_input_pin: ReceiverNet • receiver_output_failure_threshold: Failure threshold • receiver_output_peak: Receiver output peak Value • stage_info • thresh_source: ReceiverThresholdType (Global | User | Library) • victim_library: Library • victim_net: VictimNet • victim_total_area: TotalArea • victim_total_cap: TotalCap (fF) • victim_vdd: Vdd (V) • victim_width: Width (ps) The following options are not available with the single line format: • delay • incr_delay • slack • thresh_source • victim_edge • victim_slew • victim_total_cross_cap To choose whether the report format should be on a single line or multiple lines, you can use the `-output_format` parameter.

`-gui_victim_nets_file`	Generates the GUI format glitch reports (`aae or aae_<viewname>` files under the reporting directory) and incremental delay reports (`aae_<max/min>_incDelay or aae_<viewname>_<max/min>_incDelay` files under the reporting directory) to be used in the Display Noise Net form.
`-histogram`	Generates the noise histogram.
`-level {vl | vh | vlu | vho}`	Specifies the level for which a report needs to be generated when single-level report is desired. You can specify one of these options - `vl`, `vh`, `vlu`, and `vho`.
`-max_threshold` *float*	Specifies the maximum peak noise or receiver peak thresholds to report on.
`-merge_dir` *string*	Takes a directory name and generates a software compatible database.
`-nets` *string*	Reports the specified nets in the noise report.
`-output_file` *string*	Specifies the name of the output file name prefix. The name of the output file is generated by combining the prefix and the specified view name. If you do not specify this option: • The software automatically names the text report as 'glitch' for noise glitch reports and 'delay' for noise delay reports. • The software dumps the generated report to the console window for better usability. **Note**: If the text report file with the `.gz` extension is used, the output file is gzipped to generate a compressed report.
`-pins` *string*	Specifies the name of the pins to be reported.
`-precision` *integer*	Specifies the precision value up to which the glitch data is to be printed. The allowed values are 0, 1, 2 and 3.
`-output_format` *string*	Specifies if the output format should be on a single line or on multiple lines. You can specify one of the following options: • `single_line` • `multiple_line` If the `single_line` option is specified and the attacker info is chosen as a field, then all the attacker related format options will be printed together. The `-output_format` parameter only works with the `-format` option and does not affect the default reporting output format. *Default*: `multiple_line`
`-overshoot_undershoot`	Reports the overshoot (VHO) and undershoot (VLU) glitches. The `setSIMode -enable_overshoot_undershoot_glitch` must be set to `true` before the analysis is performed, in order to generate the overshoot-undershoot glitch report. *Default*: If this option is not used during glitch reporting, then VL and VH type of glitches will be reported.
`-quiet_nets`	Generates a report of all the quiet attackers.
`-remove_status_row <string>`	Shows only the active attackers and filters out Sb, UF, and LC from the glitch report.
`-report_virtual_attacker_constituents`	Specifies the maximum slack value for a bumpy net.
`-reverse_voltage_change_threshold <float>`	Reports the clock nets with reverse swing greater than the user-specified threshold value (ratio of VDD). By default, the threshold value is set to 0.1.
`-slack` *float*	Generates a report for bumpy nets based on slack.
`-skip_nets_or_pins_in_header`	Generates the glitch report without a list of nets or pins in the report header.

`-sort_by` *string*	Requests the sorting of entries. You can sort by: • `noise` • `receiver_peak` • `slack` • `cell_type` The software determines the default HTML output directories based on the options you choose. Depending on the sorting option you select, the software sorts the report fields in the following order: **-sort_by Option Level 1 Level 2 Level 3 Level 4** rcvr_peak receiver peak noise netname level noise noise - netname level
	For example, if you use the `-sort_by noise` option, the first level of sorting will be based on noise, followed by receiver peak, netname, and level. **Note**: The report displays the `vl` noise level before the `vh` noise level. *Default*: `receiver_peak`
`-style {default | extended}`	Generates reports in one of the styles - `extended` or `default`. • `extended`: Generates extended reports with victim and aggressor timing windows, dropped aggressor slews, and reasons for dropped aggressors. Additionally, the report also shows driver pins and driver library pins. • `default`: Generates the default report, which is similar to the text report generated using the `-text` parameter.
`-threshold` *float*	Specifies the minimum peak noise, absolute delay uncertainty, relative delay uncertainty, and receiver peak thresholds to report on. *Default*: • 0.10 of vdd for nets - when the glitch report is generated using the `report_noise -sort_by noise` option. • 10 (ps) for nets - when a detailed delay report is generated using the `report_noise -delay` parameter). **Note**: • The `-threshold` parameter accepts percentage values. • All `-sort_by` values that represent voltages will be in mV.
`-txtfile` *filename[.gz]*	Specifies the name of the text report file. If the specified file name is compressed, with the .gz extension, the file is gzipped. If you do not specify the `-txtfile` option: • The software automatically names the text report as ‘glitch’ for noise glitch reports and ‘delay’ for noise delay reports. • The software dumps the generated report to the console window for better usability. If the `-txtfile` parameter is not used, then Innovus will output the SI report to the screen. When the `-txtfile` parameter is specified, then Innovus uses the user-specified name. In case of MMMC, Innovus uses the <txtfile Name>_<view Name> naming convention.
`-view`	Specifies the view name.

Examples

- The following command reports noise for the view named `default_emulate_view`:

```
report_noise -delay max -threshold 1600 -txtfile delay_max_format.rpt -format {attacker_slew  attacker_xcap  attacker_status
attacker_edge   attacker_net stage_info slack  victim_slew  victim_total_cross_cap victim_net }

# Command: report_noise -threshold 0.20
# View: default_emulate_view
############################################################

Report Options:
--------------------------------------------------------------------------------
-type glitch
-threshold 20% (of vdd)
```

- To generate a glitch report, you can use the following command:
  ```
  report_noise -txtfile glitch.txt
  ```
- To generate a glitch report sorted by input noise, you can use the following command:
  ```
  report_noise -txtfile sort_by_glitch_input.txt -sort_by noise
  ```
- To generate a glitch failure report, you can use the following command:
  ```
  report_noise -txtfile glitch_failure.txt -failure
  ```
- To generate a glitch report for VL noises sorted by input noise, you can use the following command:
  ```
  report_noise -sort_by noise -level vl
  ```
- To generate a glitch report for only latch receiver pin cell types, you can use the following command:
  ```
  report_noise -txtfile latch_glitch.txt -cell_type latch
  ```

Related Commands

- report_timing
- report_timing_format
- check_noise

report_noise_lib_pin

```
report_noise_lib_pin
[-help]
[> filename]
```

Generates a report providing information on all the user-specified noise mappings in the design.

Parameters

`-help`	Prints out the command usage.
`> filename`	Writes the report to the specified file name. If the file already exists, the software will overwrite it.

Examples

- The following command generates the output report 'noise_mapping.rpt' which contains all the noise mappings present in the design:
  ```
  report_noise_lib_pin > noise_mapping.rpt
  ```

  noise_mapping.rpt

  ```
  ---------------------------------------------------
  from_pin                    to_pin
  ---------------------------------------------------
  library1/inverter/I         library2/macro/A
  library1/buffer/I           library3/memory/ADD[0]
  ---------------------------------------------------
  ```

Related Commands

- set_noise_lib_pin
- reset_noise_lib_pin

report_noise_propagation

```
report_noise_propagation
[-help]
[-level {VL | VH | worst | all}]
[-max_paths integer]
[-max_slack float]
[-nets string]
[-nworst integer]
[-pins string]
[-source_depth integer]
[-views string]
[ [ > | >> ] ]
```

Prints text-based noise propagation reports that show glitch-source tracing for all the user-specified or all-violating receiver pins. The report allows you to view full paths showing the glitch propagating from the source to the violating receiver pin. This helps to easily identify and fix glitch violations.

Note: You need to set `setSIMode -enable_glitch_report` parameter to `true` to enable glitch reporting.

Parameters

`-help`	Prints out the command usage. For a detailed description of the command and all of its parameters, use the `man` command: `man report_noise_propagation`
`-level {VL | VH | worst | all}`	Reports paths for specified glitch level. You can specify one of these options - VL, VH, worst, or all.
`-max_paths integer`	Reports the specified number of paths.
`-max_slack float`	Reports paths with glitch slack equal to or lesser than the specified value.
`-nets string`	Reports paths with endpoint being all the input pins connected to the specified net.
`-nworst integer`	Specifies the maximum number of sources per endpoint for which paths need to be reported.
`-pins string`	Reports the paths for the specified endpoint pins.
`-source_depth integer`	Specifies the maximum number of sources to be traced in any given branch in the fanin cone of violation.
`-views string`	Reports the paths for the specified view.
`> filename`	Redirects output to the specified file.
`>> filename`	Appends output to the specified output file.

report_voltage_scaling

```
report_voltage_scaling
[-help]
[objectListOrCollection]
[-analysis_type {early | late}]
[-view string]
[-output_file string]
```

Reports instances whose timing data is interpolated due to voltage mismatch. When a cell is operating in the design at a voltage different from voltages at which it is characterized in the timing libraries, delay calculation (DC) interpolates/derives the timing data at the operating voltage.

Parameters

`-analysis_type {early | late}`	Specifies whether early or late views have to be checked for voltage scaling. If unspecified, only 'late' views are checked.
`-output_file string`	Specifies the name of the output file to which the report will be written. When the specified file name contains a directory path, the directory hierarchy is automatically created, if not present. If this option is not specified, the report is written to standard output (screen).
objectListOrCollection	Specifies the name(s) or a collection of leaf-level instance(s) for which voltage scaling needs to be checked and reported. If not specified, all instances of the design are checked.
`-view string`	Specify the name(s) of view(s) to be checked for voltage scaling. If unspecified, all active analysis views are checked.

Examples

The following example shows a sample `report_voltage_scaling` report:

```
tempus 2 > report_voltage_scaling i_6 -analysis_type late -view func_worst_cmax

VIEW: func_worst_cmax -- ANALYSIS TYPE: late
<pin-name> : <cell-name> : <actual-voltage> : <low-lib-name> : <high-lib-name>
i_6/Y      : BUFX5MTH    : 0.820            : elc_08v        : elc_09v
```

The report is generated with the `func_worst_cmax` view. You can use the `-view` parameter to report for other views.

You can run the `report_analysis_views` command to list views.

report_voltage_swing

```
report_voltage_swing
[-help]
-high_threshold float
-low_threshold float
[-output_file string]
[-required_width {all | clock}]
[-view string]
```

Reports the voltage swings that are shorter than the user-specified thresholds for both clock and data signals.

Parameters

`-help`	Outputs a brief description of the `report_voltage_swing` command. For a detailed description of the command, use the man command: `man report_voltage_swing`
`-high_threshold float`	Specifies the high threshold percentage of the pin supply voltage.
`-low_threshold float`	Specifies the low threshold percentage of the pin supply voltage.
`-output_file string`	Specifies the name of the output file.
`-required_width {all | clock}`	Reports the required high and low pulse widths corresponding to the user-specified high and low thresholds. You can specify one of the following options: • `clock`: Reports the required widths for all clock pins in the design. • `all`: Reports the required pulse widths for all input pins in the design. *Default*: `all`
`-view string`	Specifies the name of the view being defined. **Note**: If this option is not specified, it will dump report for all views.

Examples

An output file in the text format containing violating pin information is presented below:

```
View Name: default_setup_view1
Hpin     Type_of_Voilation   Vdd    Vss    Slews(Rise/fall)  Margin (threshold)
X/buf/A (upper/lower)       0.9v   0.0V   210ps/240ps       745mv (810mv)
```

reset_glitch_derate

```
reset_glitch_derate
[-help]
[-derate_height]
[-derate_width]
[-glitch_type string]
[-instance_pin string]
[-offset]
[-pin string]
[-view string]
```

Removes the derating factors for glitch waveforms that were previously set using the `set_glitch_derate` command.

Parameters

`-help`	Prints out the command usage.
`-derate_height`	Resets the derate height.
`-derate_width`	Resets the derate width.
`-glitch_type string`	Specifies the glitch type vl, vh, or both.
`-instance_pin string`	Specifies the instance pin names on which derate factors are to be reset.
`-offset`	Resets the derate offset.
`-pin string`	Specifies the library pin names on which derate factors are to be reset.
`-view string`	Specifies the view name.

Related Commands

- `set_glitch_derate`

reset_noise_lib_pin

```
reset_noise_lib_pin
[-help]
[-all]
[-to string]
```

Allows you to reset any noise property mapping, specified previously using the `set_noise_lib_pin` command.

Parameters

`-help`	Prints out the command usage.
`-all`	Resets all the noise mappings in the design.
`-to string`	Specifies the library pin name for which the user-specified noise mapping (if any) needs to be reset. **Note**: The `-to` parameter accepts library cell pin names (that can be obtained using the `get_lib_pins` command). This parameters does not honour collections or instance pin names.

Examples

- The following command resets any noise mapping previously applied to the library pin library1/macro_cell/A :
  ```
  reset_noise_lib_pin -to library1/macro_cell/A
  ```
- The following command resets all the existing noise mappings in the design:
  ```
  reset_noise_lib_pin -all
  ```

Related Commands

- `set_noise_lib_pin`
- `report_noise_lib_pin`

set_annotated_glitch

```
set_annotated_glitch
[-help]
[-port string]
[-vh_glitch string]
[-vho_glitch string]
[-view string]
[-vl_glitch string]
[-vlu_glitch string]
```

Allows the ability to annotate glitches at any specified pin/port. This command setting will override the VH/VL glitch with the specified value on the given point and use that glitch value to propagate downstream.

If the defined annotated glitch waveforms do not start and end at 0, then the software will not consider those waveforms and a warning will be issued. In the following example both VL and VH waves should start and end with 0.0 values. Since the VH wave is not ending at 0, this waveform will be ignored.
`set_annotated_glitch -vl_glitch {0 0 100e-12 0.01 200e-12 0.04 300e-12 0.03 600e-12 0} -port dff1/CK -vh_glitch {0 0 100e-12 0.1 200e-12 0.4 300e-12 0.3 600e-12 0.1} .`

The software does not save (and report) waveforms below 5% of VDD. Consider for example, the annotated glitch defined on a pin as:
`set_annotated_glitch -port dff1/CK -vh_glitch {0 0 100e-12 0.01 200e-12 0.04 300e-12 0.03 600e-12 0}`

In this case, the glitch peak is 0.04 (40mV), which is below 5% of VDD (1080mV) - equal to 54mV. Since this annotated glitch waveform peak is very low, the `report_noise` command will not report it. However, if the failure criteria is lower than 5%, then the software will save and report small glitch violations.

Parameters

`-help`	Prints out the command usage.
`-port string`	Specifies port or pin names on which you need to apply glitches. This parameter works only when `setSIMode -enable_glitch_propagation true` is set in the `report_timing` flow. In the `update_glitch` flow, the `-enable_glitch_propagation` parameter is already set to `true`.
`-vh_glitch string`	Specifies a list of VH glitch wave points. You must specify at least 3 time value pairs.
`-vho_glitch string`	Specifies a list of VHO glitch wave points.
`-view string`	Specifies a list of view names.
`-vl_glitch string`	Specifies a list of VL glitch wave points. You must specify at least 3 time value pairs.
`-vlu_glitch string`	Specifies a list of VLU glitch wave points.

Examples

- The following example annotates the specified VL glitch wave points:
  ```
  set_annotated_glitch -vl_glitch {0 0.0  0.2e-9 0.540 0.405e-9 0} -vh_glitch {0.1e-9  0  0.205e-9 0.50 0.405e-9 0.200  0.6e-9 0.0} -port {A}
  ```
- The following command overrides the glitch value at RIP with the annotated glitch, because glitch is annotated at the receiver input:
  ```
  set_annotated_glitch -vl_glitch {0 0 100e-12 0.1 200e-12 0.4 300e-12 0.3 600e-12 0} -port seg2/u9/D
  update_glitch
  report_noise -nets seg2/n8

  ------------------------------------------------------------------------
  Peak(mV) Level TotalCap(fF) TotalArea Width(ps) Vdd(mV) Library VictimNet
  399.924  VL    144.11       110.00    550.104   1080    cell_w  seg2/u9/D {seg2/n8}

  Receiver Input Threshold:
  Value    (Threshold)  ReceiverNet Receiver failure_type
  399.924  (431.244)    seg2/u9/D   (DFF)    [bbox]

  Constituents:

  ```

```
-------------------------------------------------------------------------
```

- In the following example, the impact of aggressors coupled with the victim stage (along with the annotated glitch) is also considered because annotation is done at the driver output:

```
set_annotated_glitch -vl_glitch {0 0 100e-12 0.1 200e-12 0.4 300e-12 0.3 600e-12 0} -port seg2/u8/Y
update_glitch
report_noise -nets seg2/n8

```

Related Commands

- report_noise
- update_glitch

set_cdb_binding

```
set_cdb_binding
[-help]
-from <string>
-to <string>
```

Provides an overriding mechanism that allows overriding a UDN to Liberty mapping at the Tempus command file level.

This command helps to correct any mismapped cases by enabling the software to select a user-specified cdB to Liberty mapping.

Parameters

`-help`	Prints out the command usage.
`-from <string>`	Specifies the CDB file name and cell name.
`-to <string>`	Specifies the library file name.

Examples

When loading multiple cdB's with the same PVT, but different secondary voltages, you can use the `set_cdb_binding` command to ensure that they get bound correctly, as shown below:

```
set_cdb_binding -from pvt1_1.cdb -to pvt1_1.lib
set_cdb_binding -from pvt1_2.cdb -to pvt1_2.lib
```

set_glitch_derate

```
set_glitch_derate
[-help]
[-derate_height float]
[-derate_width float]
[-glitch_type string]
[-instance_pin string]
[-offset float]
[-pin string]
[-view string]
```

Sets the derating factors for glitch waveforms and determines the effect of on-chip variation on noise.

Parameters

`-help`	Prints out the command usage.
`-derate_height float`	Specifies the derate height value. This parameter scales all the glitch waveforms on the specified pins. A value of 1.0 indicates that no glitch waveform derating will take place. A value greater than 1.0, such as 1.1, indicates a 10 percent increase in the magnitude of the complete glitch waveform, which results in an increase in propagated noise and noise failure. A value less than 1.0 reduces the magnitude of the complete glitch waveform.
`-derate_width float`	Specifies the derate width value.
`-glitch_type string`	Specifies the glitch type - vl, vh, or all.
`-instance_pin string`	Specifies the instance pin names on which derate is to be applied.
`-offset float`	Specifies the derate offset value.
`-pin string`	Specifies the library pin names on which derate value is to be applied.
`-view string`	Specifies the name of the view.

Related Commands

set_glitch_threshold

```
set_glitch_threshold
[-help]
[-cell <string>]
[-failure_point {none | input | internal | last}]
[-glitch_type {both | vl | vh | vlu | vho | vl_vh | vlu_vho}]
[-library_pins <string>]
[-nets string]
[-pins string]
[-pin_type {clock | data | latch | all}]
[-threshold_type {failure | reporting | propagation}]
-value float
[-views string]
```

Allows for additional control of failure criteria for SI glitch analysis.

Parameters

`-help`	Prints out the command usage. For a detailed description of the command and all of its parameters, use the `man` command: `man set_glitch_threshold`.
`-cell <string>`	Specifies list of library cell names.
`-failure_point {none | input | internal | last}`	Specifies where the failure or reporting criteria applies. ◦ `none`: Criteria does not apply. ◦ `input`: Threshold applies when the failure point is at the input pin of the receiver cell. ◦ `internal`: Threshold is applied when the failure point is internal to the cell. This occurs for multi-stage cells. The failure point will be the output of the first stage inside the cell. ◦ `last`: Threshold is applied when the failure point is the output of the cell. This occurs for single-stage cells, such as, inverters. *Default*: `internal` and `last`
`-glitch_type {both | vl | vh | vlu | vho | vl_vh | vlu_vho}`	Specifies the glitch type the command applies to. • `both`: Refers to `vl` and `vh` type of glitches. • `vl_vh`: Includes VL and VH noise. • `vlu_vho`: Includes VLU and VHO noise. *Default*: `both`
`-library_pins string`	Specifies a list of library pin names.
`-nets string`	Specifies the list of nets the command applies to. Default is not net-specific.
`-pins string`	Specifies the list of pins or primary ports. Default is not pin-specific.
`-pin_type {clock |data | latch |all}`	Specifies the pin type the command applies to. *Default*: all

`-threshold_type {failure | reporting | propagation}`	Specifies whether the command options apply to failure, reporting, or propagation criteria. In case of VL/VH glitch analysis, it is mandatory to specify the `-threshold_type` parameter. This is because when the computed glitch (ROP) at any given stage exceeds the failure threshold (when glitch propagation is enabled), then it is not propagated and is flagged as failure in the noise report. With the `-threshold_type failure` setting, the propagation will stop as per the new threshold, and the failure flagging will change accordingly. However, with the `-threshold_type reporting` setting, the propagation threshold remains unchanged, but the failure reporting is updated. When `-threshold_type propagation` is used, the software allows for failing nets with ROP values less than the propagation threshold to propagate through single stage cells. In case of VLU/VHO glitch analysis, it is optional to use the `-threshold_type` parameter because the above flow is not applicable. *Default*: `failure`
`-value float`	Specifies the value for the threshold as a ratio of the local VDD. *Default*: 0.1
`-views string`	Specifies a list of view names.

Examples

Here are some examples.

- The following command moves the failure point from ROP to RIP for `inst1/a1` and uses a RIP failure of *0.2*ReceiverVDD*:
  ```
  set_glitch_threshold -failure_point input -pin inst1/a1 -threshold_type failure -value 0.2
  ```
- The following command sets clock failure criteria to 0.1*VDD, latch failure criteria to 0.2*VDD and all other nets to 0.3*VDD (set before update_glitch):
  ```
  set_glitch_threshold -threshold_type failure -pin_type all -failure_point last -value 0.3
  set_glitch_threshold -threshold_type failure -pin_type clock -failure_point last -value 0.2
  set_glitch_threshold -threshold_type failure -pin_type latch -failure_point last -value 0.1
  ```
- The following command sets the failure threshold at the output of the 1st channel connect inside all the instances of macro1 to be 0.2 (set before update_glitch):
  ```
  set_glitch_threshold -threshold_type failure -cell {macro1} -failure_point internal -value 0.2
  ```
- The following command changes the reporting criteria for latches to be 0.15*VDD (set after `update_glitch`):
  ```
  set_glitch_threshold -threshold_type reporting -pin_type latch -value 0.15
  ```

  If you need to set all the data failure criteria to be 0.3, then you need to make the following settings:
  ```
  set_glitch_threshold -failure_point internal \
  -threshold_type failure -value 0.3 \
  -pin_type data

  set_glitch_threshold -failure_point last \
  -threshold_type failure -value 0.3 \
  -pin_type data
  ```

Related Commands

- `get_glitch_threshold`
- `update_glitch`

set_model_priority

```
set_model_priority
[-help]
[-objects string]
[-priority_list string]
```

Allows you to define the priority order of models.

Parameters

`-help`	Prints out the command usage
`-objects string`	Specifies a list of library cells or library pins for which priority is specified.
`-priority_list string`	Specifies a list of pin model priority. Default: `{ecsm ccs nldm cdb udn}`

Examples

To force CCSN to be used, you can set `timing_library_read_ccs_noise_data` global variable to `true` before reading the timing libraries and then use the following command before using the `update_glitch` command:

```
set_model_priority -priority_list ccs
```

Related Commands

- `update_glitch`

set_mutex_condition

```
set_mutex_condition
[-help]
[netNames]
```

Allows the software to use one of the specified attackers - each attacker is then evaluated and the worst one (for each victim net) is selected.

This command applies a mutex group to a set of attackers (for a victim) to reduce pessimism. A mutex group is a group of nets of which only one can transition in a given cycle.

Parameters

`-help`	Prints out the command usage.
netNames	Specifies the net names of the mutex group.

Examples

- The following example shows that only one of the specified nets, between abc[0-3], can switch at any given point of time:
  ```
  set_mutex_condition {abc[0] abc[1] abc[2] abc[3]}
  ```

  Each of the specified attackers will be evaluated and the worst one will be used.

set_noise_lib_pin

```
set_noise_lib_pin
[-help]
-from string
-to string
```

Allows you to map noise properties of an instance pin to that of different library cell pin.

Parameters

`-help`	Prints out the command usage.
`-from string`	Specifies the library pin name whose definition will be mapped from the given pin name.
`-to string`	Specifies the library pin name whose definition will be mapped to the given pin name. When multiple `set_noise_lib_pin` commands are run on the same `-to` pin, the software will honor the first command only. **Note**: The `-from` and `-to` parameters also accept library cell pin names (that can be retrieved using the `get_lib_pins` command). These parameters do not honor collections or instance pin names.

Examples

- The input pin A of the `macro_cell` cell inherits the noise characteristics of the input pin I of the library cell, `ccs_noise_lib/inv`. This information is used to calculate the noise immunity of the pin, `library1/macro_cell/A`.
  ```
  > set_noise_lib_pin -to library1/macro_cell/A -from ccs_noise_lib/inv/I
  ```
- The following syntax specifies the library pin name whose definition will be mapped from the given pin name to the given pin name:
  ```
  > set_noise_lib_pin -from [from_lib/from_cell/from_pin] -to [to_lib/to_cell/to_pin]
  ```
- The following syntax specifies that a bidi pin is mapped to two from pins; that is, – 1 input pin and 1 output pin.
  ```
  > set_noise_lib_pin -to library1/macro_cell/PAD -from "ccs_noise_lib/inv/I ccs_noise_lib/inv/Z"
  ```

Related Commands

- `report_noise_lib_pin`
- `reset_noise_lib_pin`
- `report_noise`

set_quiet_attacker

```
set_quiet_attacker
[-help]
[-analysis_type {early | late}]
[-attacker string]
[-transition {rise | fall}]
[-victim string]
[-view string]
```

Specifies one or more coupled nets as non-attackers (silent) for the delay and glitch analysis of a given victim net.

You can run the `update_glitch` or `update_timing` command and view the results in the `report_noise` or `report_timing` command output.

Parameters

`-help`	Prints out the command usage.
`-analysis_type {early | late}`	Specifies the analysis type for which the attackers will be assumed quiet. If no value is specified, attackers are skipped for both `early/late` analysis.
`-attacker string`	Specifies the attackers which should be made quiet for given victim net(s). If no attacker is specified, all the aggressors of given victim(s) will be ignored. **Note**: If no victim is specified, the specified attackers are made quiet for all victim nets in the design.
`-transition {rise | fall}`	Specifies the victim transition for which attackers will be assumed quiet. If no value is specified, attackers are skipped for both `rise` and `fall` transitions of the victim net.
`-victim string`	Specifies a list of victim nets for which attackers should be made quiet. Specific attackers can be skipped using the `-attacker` option of this command. If the `-attacker` option is not specified, all the attackers of the given nets are made silent and SI analysis will not be performed on these nets. **Note**: If this option is not specified, the attackers specified in the `-attacker` option are made quiet for all the nets in the design.
`-view string`	Specifies the view for which attackers should be made quiet. If no view is specified, attackers are assumed quiet in all views

Examples

Consider a design having an attacker `agg` to victim nets `vic1` and `vic2`. The following command sets the attacker `agg` as quiet for both the victim nets `vic1` and `vic2`.

```
set_quiet_attacker -attacker {agg}
```

- The following command sets the attackers A1 and A2 as quiet when V1 is rising during late analysis.

  ```
  set_quiet_attacker -victim V1 -attacker A1 A2 -transition rise -analysis_type late
  ```

- The following command sets the attacker A1 quiet for victim V1 in the analysis view VIEW1. In this case, A1 may be a valid attacker during SI analysis for victim V1 in views other than VIEW1.

  ```
  set_quiet_attacker -victim V1 -attacker A1 -view {VIEW1}
  ```

Consider a design having victim `vic` with attackers `agg1` and `agg2`:

- The following command sets both the attackers `agg1` and `agg2` as quiet for the victim net `vic`.

  ```
  set_quiet_attacker -victim {vic}
  ```

- The following command sets the attacker `agg1` as quiet for the given victim net `vic`

  ```
  set_quiet_attacker -attacker {agg1} -victim {vic}
  ```

Related Commands

setOutboundReport

```
setOutboundReport
[-help]
-delay {early | late | both}
[-filename_prefix string]
[-report_constant_nets {true | false}]
[-type {lower | upper | both}]
```

Controls what extrapolation information is to be saved in the log file(s). The slew extrapolation information can be stored into separate files.

When this command is not specified, slew extrapolation will be reported for both minimum and maximum analysis, if outbound reporting has been enabled by specifying the `setDelayCalMode -reportOutBound true` command.

Parameters

`-help`	Prints out the command usage
`-delay {early | late | both}`	Control whether extrapolation information is to be shown for min or max (or both) analyses. *Default*: `both`
`-filename_prefix string`	Specify the prefix to be used in the name(s) of the report file(s). *Default*: `design-name`
`-report_constant_nets {true | false}`	Controls whether extrapolation information is to be shown for constant nets or not.
`-type {lower | upper | both}`	Controls whether extrapolation information is to be shown for lower or upper (or both) outbound slews.

Examples

The following command will will dump slew extrapolation information for maximum analysis into the myreport.dc.outbound.slew.late.<view-name>.txt file:

```
setOutboundReport -delay late -filename_prefix myreport
```

```

Sets signal integrity configuration parameters used for crosstalk analysis and repair.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `setSI` parameters, use the man command: `man setSIMode`
`-reset`	Resets all or specified options to their default value. **Note**: Any values that do not already match the default value and are reset will be re

`-accumulated_small_attacker_factor` *double*	Specifies the multiplication factor that controls the effect of the cap mode accumulat attacker that represents the sum of all the weak attackers on a specified net. To redu value to anything between 0 and 1. A value of 0 means that the cap mode accumula *Default*: `1` **Note**: This option does not work with the current mode accumulated small attacker,
`-accumulated_small_attacker_mode {cap | current | zero_mean}`	Specifies whether to use the current-matching based method for accumulated small `cap`: Uses the accumulated small attacker method, which matches the total coupling virtualized. This is the default mode for all process nodes above 45nm. `current`: Uses the current-matching based method for accumulated small attackers. Piece Wise Linear (PWL) waveforms. The PWL waveforms are generated in a way induced by all accumulated small attacker components. `zero_mean`: A new accumulation method where series of small attackers, that is, atta transition in opposing directions and thus cancel one another in aggregate. *Default*: `current` - for 45nm and below process nodes.
`-accumulated_small_attacker_threshold` *double*	Changes the accumulated small attacker glitch threshold. If the virtual attacker prod coupling capacitors of the accumulated small attacker are split into two ground capa value is specified as a ratio of VDD. To disable the accumulated small attacker, set the value greater than or equal to 1. *Default*: `10.01` By default, this option is disabled.
`-attacker_alignment {path | path_overlap | timing_aware_edge}`	Specifies the attacker alignment. `path`: The victim worst arrival edge is used while determining the attackers. Crosstal victim for max/min analysis. `path_overlap`: The full timing window of victim is considered while determining the a anywhere in timing window, which may experience maximum impact. `timing_aware_edge`: Realistic analysis similar to path-based analysis is performed. I timing window edge aligns with the victim. However, to ensure GBA bounds PBA a timing properties in GBA analysis. *Default*: `path`
`-clock_delta_delay_threshold` *double*	Specifies the value above which the clock delta delay should be calculated. *Default*: `-1` The `-clock_delta_delay_threshold` parameter provides a way to specify different d
`-clocks {asynchronous | synchronous}`	Treats the clocks either synchronous or asynchronous to each other. *Default*: `synchronous`
`-constrained_input_threshold_failure_point {input | both}`	Allows you to control the glitch failure criteria when a user specifies an object-speci When set to `input`, the software skips ROP analysis and performs RIP-based failure threshold is set using the `set_glitch_threshold -failure_point input -net` (or `-pi` When set to `both`, the software performs both RIP and ROP failure checks, whereve flagged as a RIP violation. If RIP criteria passes and receiver noise models exist, th for failure determination. For the following cases where the object-specific RIP thresholds are not specified, t • For receiver pins with noise models present, ROP-based failure check is perform • For receiver pins with noise models missing, the RIP-based failure criteria is che *Default*: `input`

`-delta_delay_annotation_mode {lumpedOnNet | arc}]`	Calculates the delay for each arc (cell arc and net arc) in a path. By default, AAE ca view the SI delay separately, it would show annotated to each arc. Alternatively, you can choose to annotate the SI delay solely to the net. In this case, solely to the net. `lumpedOnNet`: Lumps the delta delay all onto the net if it is broken out. `arc`: Separates the delta delay onto each cell arc and net arc as calculated *Default*: `arc`
`-delta_delay_threshold <double>`	Specifies a threshold value for a design below which the crosstalk impact will be re impact on a stage if the impact is less than the specified threshold. The threshold va *Default*: -1 By default, the software uses the `-delta_delay_threshold` settings. If you set the `-c` nets. When a threshold value using the -`delta_delay_threshold` parameter is specified (a used), then Tempus will use the `-delta_delay_threshold` value for both data and cl If you define values for both `-delta_delay_threshold` and `-clock_delta_delay_thr` data and clock, respectively.
`-enable_bus_attacker_correlation {true | false}`	Enables the software to treat bits of bus as correlated attackers. When set to `true`, the bits of bus type nets are grouped together based on their cum The bus bits that act as attackers to a specific victim are treated as a group. All the a attackers form one group and bits of the same bus form multiple other groups. In cas combined effect of a full bus can be used to decide whether an attacker is significan *Default*: `false`
`-enable_double_clocking_check {true | false}`	Enables double clocking check in AAE. This option enables double clocking analysis and `report_double_clocking` comma *Default*: `false`

`-enable_delay_report {true | false}`	Enables SI delay reports.
	For generating SI delay report, use the following:
	`setSIMode -enable_delay_report true;`
	`report_noise -delay max -txtfile max_delay.txt;`
	`report_noise -delay min -txtfile min_delay.txt`
	To run `report_noise -delay`, you need to set this parameter prior to `update_timing`.
	Default: `false`

`-enable_drv_with_delta_slew {true | false}`	When set to `true`, the `max_transition` violations are reported based on the SI slews the `signoffOptDesign` command and should be applied prior running the `signoffTi` *Default*: `false`
`-enable_dynamic_receiver_peak_limits {true | false}`	Enables automatic computation of ROP threshold value of two-stage cells, using the When set to `true`, the software computes the noise threshold of the last stage from tl *Default*: `false`
`-enable_logical_correlation {true | false}`	Enables the AAE-SI logical correlation. Logical correlation refers to correlation of lo simple case would be input and output nets of an invertor never switch in the same *Default*: `false` **Note**: You can use this parameter for Glitch Analysis also.

`-enable_two_stage_driver_weakening {true | false}`	Enables the two-stage driver weakening mode. A non-failing significant glitch at the input of a two-stage driver can propagate throug crosstalk-induced glitch to amplify at the next stage receiver (though it may not be si enabled, the software considers weakened holding resistance for the two-stage driv The following diagram illustrates two-stage driver weakening:  The dual stage driver weakening honors the glitch propagation threshold criteria. **Note**: This feature is supported with CCS-N models only. *Default*: `true`
`-enable_virtual_attacker_constituent_report {true | false}`	Enables virtual attacker constituent reporting. The virtual attacker constituent reporting feature is useful for identifying significant b This feature is enabled when the `setSIMode -enable_bus_attacker_correlation` pa Default: false
`-enable_glitch_propagation {true | false}`	Enables glitch propagation through single stage cells and driver weakening through software does not delete the glitch waveform saved on instance input pins. The wav receiver pin. *Default*: `false`
`-enable_glitch_propagation_spice_deck {true | false}`	
	Enables the driver input glitch waveform to be printed in the SPICE deck such that S is set to `true`, the software does not delete the glitch waveform saved on instance in the next stage receiver pin. *Default*: `false`

`-enable_glitch_report {true | false}`	Enables the storage of glitch information for further debug using the `report_noise` c
	When set to `false`, the `timeDesign`/`optDesign` command will still report glitches in th will not be available for use.
	When set to `true`, the `report_noise` command may be used and glitch information w
	For generating a `report_noise` glitch report, you can use the following commands:
	`setSIMode -enable_glitch_report true;`
	`report_noise -txtfile glitch.txt`
	Default: `false`
	Note: For SI glitch fixing, you must set the `-enable_glitch_report` parameter to `tru` fixing.

`-enable_overshoot_undershoot_glitch {true | false}`	Enables overshoot/undershoot analysis and reporting. The life span of transistors can be described by the overshoot and undershoot value overshoot/undershoot, then it may suffer a reduced life span. *Default*: `false`
`-glitch_accuracy_level <int>`	Specifies the accuracy levels for glitch analysis. *Default*: 0

`-glitch_analysis_type {source | full_propagation}`	Specifies the glitch analysis type - `source` or `full_propagation`. *Default*: `source`
`-hold_slack` *double*	Specifies the slack reselection threshold for hold. *Default*:`-1e-12` seconds
`-individual_attacker_clock_threshold` *float*	Sets the glitch tolerance for individual attacker nets on victim clock nets. The softwa victim. If the peak of this noise exceeds the value of `individual_attacker_clock_th` constituents section of the report. Otherwise, this aggressor becomes eligible for the `accumulated_small_attacker_threshold`, the aggressor nets in the virtual attacker a `individual_attacker_clock_threshold` is not specified, then clock nets will use the **Note**: The minimum allowed individual attacker for clock nets to be kept is 0.1% of v 0.001. *Default*: `1.5%` or `0.015`
`-individual_attacker_threshold` *double*	Sets the glitch tolerance for individual attacker nets on the victim net. The software e the peak of this noise exceeds the value of `individual_attacker_threshold`, the att of the report. Otherwise, this aggressor becomes eligible for the virtual attacker. If th `accumulated_small_attacker_threshold`, the aggressor nets in the virtual attacker a **Note**: Minimum allowed individual attacker to be kept is `0.1%` of vdd, which is equiva *Default*: 1.5% or 0.015
`-input_glitch_full_propagation_threshold` *double*	Specifies the receiver input glitch threshold beyond which Tempus will not propaga flagged.
`-input_glitch_full_propagation_vh_threshold` *double*	Specifies the receiver VH input glitch threshold beyond which Tempus will not prop flagged. This parameter takes precedence over `-input_glitch_full_propagation_threshol`
`-input_glitch_full_propagation_vl_threshold` *double*	Specifies the receiver VL input glitch threshold beyond which Tempus will not propa flagged. This option takes precedence over `-input_glitch_full_propagation_threshold`.
	Note: These parameters can be used only when full propagation mode is enabled u
`-individual_attacker_simulation_filtering {true | false}`	Uses electrical filtering to reduce pessimism due to small attackers being preserved value. *Default*: `true` **Note**: This option can only be used when the accumulated small attacker is turned o
`-input_glitch_threshold` *double*	Specifies the input glitch failure threshold value during AAE analysis. *Default*: `0.4`
`-input_glitch_vh_threshold` *double*	Specifies the input glitch `vh` failure threshold value during AAE analysis. *Default*: `0.4`
`-input_glitch_vl_threshold` *double*	Specifies the input glitch `vl` failure threshold value during AAE analysis. *Default*: `0.4`
`-nonlinear_attacker_slew {true | false}`	Uses a non-linear attacker. If set to `false`, it uses a linear attacker. *Default*: `true`
`-num_si_iteration` *value*	Specifies the maximum number of timing window iterations that should be performe to the timing windows, which can potentially change the victim/attacker net combina where the delay changes are negligible. *Default*: `2` **Note**: The minimum allowed timing window iterations is `2` for performing SI analysis

`-pessimistic_mode {advanced | advanced_node | reduced_pessimism | increased_pessimism | high_pessimism}`	Specifies the pessimistic mode setting for adjusting delay calculation results. You c • `advanced`: This is the default mode. This option may give good results at 28nm, b • `advanced_node`: This option works for newer technology nodes, such as 7nm onw tool by adjusting pin capacitances, which may help with slew alignment, whilst m • `reduced_pessimism`: In cases where Innovus is too pessimistic when correlating t a better match. This mode may be useful at technology nodes, such as 16nm. • `high_pessimism`: In cases where Innovus is too optimistic when correlating to ext better match. This mode is similar to `advanced_node`, but without the pin capacita • `increased_pessimism`: In cases where Innovus is too optimistic when correlating for a better match. This is an older option, `high_pessimism` or `advanced_node` opti **Note**: This parameter impacts delay calculation only when the `setDesignMode -pes` `high_pessimism`, and `increased_pessimism` options should give results that are on th nodes.
`-receiver_clk_peak_limit double`	Defines the glitch check limit for clock inputs in receiver peak mode. This parameter *Default* : `0.05` (5 percent of VDD)
`-receiver_latch_peak_limit double`	Defines the glitch check limit for latch inputs in receiver peak mode. This parameter *Default* : `0.1` (`10` percent of VDD)
`-receiver_peak_limit double`	Defines the receiver peak/glitch peak limit at all nodes. The value specified for this p *Default*: `0.15`
`-report_max_virtual_attacker_constituents int`	Specifies the maximum number of virtual attacker constituents to report. This feature works only when bus virtual attacker constituent reporting is enabled us setting. *Default*: 5
`-report_si_slew_max_transition {true | false}`	Enables reporting of SI slews for DRV maximum transition reporting only. The delay commands, such as `reportTranViolation`, `report_constraint`, `reportDelayCalcul` `timeDesign` under the ./timingReports/<design name>.tran file only and the number `timeDesign` summary report. **Note**: The `setSIMode -report_si_slew_max_transition true` does not enable fixin `timeDesign` DRV reporting. To enable SI slew fixing, use `setOptMode -opt_post_ro` *Default*: `false`
`-secondary_attacker_decoupling_factor <double>`	Specifies decoupling factor for secondary aggressors. *Default*: 1
`-separate_delta_delay_on_data {true | false}`	Separates the delta delay on data (delta delay is always separated for clock). Works with `-delta_delay_annotation_mode` to determine where the separated delay shows in th Using this parameter, you can increase runtime/memory. *Default*: `false`
`-setup_slack <double>`	Specifies the slack reselection threshold for setup. *Default*:`-1e-12` seconds
`-si_reselection {delta_delay | slack}`	Specifies the SI reselection criteria during timing window iterations. `delta_delay`: Reselects a net for calculation if the delta delay on the net is greater th `slack`: Re-selects nets that have failing slacks during timing window iterations. *Default*: `slack`

`-si_reselection_delay_threshold` *double*	Allows you to change the delay reselection criteria. You can specify `-si_reselection_delay_threshold` with the `-delta_delay` parameter only. *Default*: `1e-11` Units in seconds
`-skip_noise_model_check` *pins*	Specifies a list of pins for which noise model check will not take place. Default= " "
`-skip_tw <nets>`	Specifies the list of nets for which timing window is to be skipped. The timing windo When specified, only the last setting is retained. The `setSiMode -skip_tw` command *Default*: `" "`
`-switch_prob <double>`	Sets the attacker switching probability. If you specify a value less than `0.0` or more t of `0.3`. *Default*: `0.3`
`-use_infinite_TW {true | false}`	Uses infinite timing windows in a single SI run. *Default*: `false`
`-unconstrained_net_use_inf_tw {true | false}`	Specifies that unconstrained nets will have an infinite timing window. To turn this of *Default*: `true`

Examples

- The following command runs AAE keeping all individual attackers larger than `0.01*`VDD and not using any accumulated small attackers:
  ```
  setSIMode -individual_attacker_threshold 0.01 -accumulated_small_attacker_threshold 10.01
  ```
- The following command sets the glitch peak limit at `0.5*vdd` at data nodes, `0.1*vdd` at clock nodes, and `0.2*vdd` at latch nodes.
  ```
  setSIMode -receiver_peak_limit  0.5 -receiver_latch_peak_limit 0.2 -receiver_clk_peak_limit 0.1
  ```
- To keep all attackers less than the `setSIMode -individual_attacker_threshold` whose accumulated glitch bump exceeds 1% of VDD, you can use the following command
  ```
  setSIMode -accumulated_small_attacker_threshold 0.01
  ```

Related Information

- getSIMode
- report_timing
- report_noise
- update_glitch
- reportDelayCalculation

update_glitch

```
update_glitch
[-help]
[-effort {medium | high}]
```

Allows you to run glitch analysis without running SI delay analysis. This command provides the ability to run glitch analysis on all the nets in a design or on a subset of nets.

Using the `update_glitch` command without `report_timing` or `update_timing` will only run glitch analysis.

Note: It is not recommended to run the `update_glitch` command after the `report_timing` or `update_timing` command.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `update_glitch` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man update_glitch`.
`-effort {medium | high}`	Specifies the effort level for update glitch. When set to `high`, glitch analysis uses more accurate modeling of glitch for small attackers, thereby reducing pessimism. **Note**: The run time in `high` mode may be slightly higher, and is largely dependent on the distribution of coupling. *Default*: `medium`

Examples

- The following command will run glitch analysis without SI delay:
  ```
  > update_glitch
  ```

Related Commands

- `report_noise`
- `report_timing`
- `setSIMode`
- `getSIMode`

analyze_ir_paths

```
analyze_ir_paths
[-help]
-clock_period <float>
[-hierarchical_activity_file <string>]
[-max_slack <float>]
[-pre_simulation_period <float>]
-seq_activity <float>
-simulation_period <float>
[-user_defined_critical_paths <string>]
```

Generates a physical-aware multi-cycle switching activity file containing toggle information of voltage sensitive paths as well as timing critical paths in the design for Tempus Power Integrity analysis. This command generates ‘swsrc.txt’ file in the run directory, which then is fed back to the software using the `read_activity_file` command.

Parameters

`-help`	Prints out the command usage.
`-clock_period <float>`	Specifies the period of dominant clock of the design in library time units. Tempus PI refers to this specified period for multi-cycle activity generation.

`-hierarchical_activity_file <string>`	Provides a mechanism for different sequential activity for several partitions in the design. The following is the required format:
	`<hierarchical instance 1> <activity>`
	`<hierarchical instance 2> <activity>`
	…

`-max_slack <float>`	Specifies the maximum slack limit in library time units, above which the timing paths are not considered for activity generation.
`-pre_simulation_period <float>`	Specifies the pre-simulation duration that will be used by Tempus PI for activity generation. This parameter is useful when package model information is read-in using `set_package` command, as it allows the package oscillations to settle down. **Note**: The value specified must match to value specified under `set_rail_analysis_mode -record_results_start_time` setting.
`-seq_activity <float>`	Specifies the activity of sequential endpoints in the design. This value will be used to control the number of IR sensitive paths, along with their fanout cone, to toggle in each cycle.
`-simulation_period <float>`	Specifies the simulation period in library time units that Tempus PI dynamic power analysis will use. The larger the simulation period, the more will be the number of paths covered in the analysis. The following formula can be used to set the simulation period: *sim_cycles = (2/seq_act)*N* Where, • *seq_act* is the input sequential activity (e.g., 0.05, 0.1 etc.) • *N* is the number of nworst paths to be covered per endpoint • *sim_period* is equal to the sim_cycles*<time period of dominant clock> It is recommended to have N>=1, that is, at least one path per endpoint should be scheduled in the analysis.
`-user_defined_critical_paths <string>`	Specifies a collection of timing paths that are to be prioritized for toggling while generating Tempus PI activity. This feature is useful when designers have prior information on certain timing paths that may switch together and can potentially cause IR-induced STA violations.

Examples

- The following command generates the activity file for design with dominant clock of 2GHz, with input sequential activity being 0.1 and simulation duration being 20ns:

```
analyze_ir_paths -seq_activity 0.1 -simulation_period 20 -clock_period 0.5
```

- The following example specifies different sequential activity for different hierarchical partitions, with 0.2 sequential activity for unspecified partitions and top:

```
analyze_ir_paths -seq_activity 0.2 -simulation_period 30 -clock_period 0.5 -hierarchical_activity_file hact.txt
Contents of 'hact.txt':
hierA/inst1 0.25
hierB/inst2 0.15
```

- The following command specifies the pre-simulation duration, particularly useful for package oscillations to settle when package models have been read-in:

```
analyze_ir_paths -seq_activity 0.1 -simulation_period 30 -clock_period 0.5 -pre_simulation_period 10
```

define_glitch_holding_resistance

```
define_glitch_holding_resistance
[-help]
[-glitch_type {both | vl | vh | vlu | vho | vl_vh | vlu_vho}]
[-instance_pin string]
[-lib_pin string]
-value double
[-views string]
```

Allows you to specify the holding resistance.

You can use this command to define a net-specific holding resistance instead of using the default holding resistance of 1000 ohms.

This command can be specified more than once per net. If there is a duplicate specification, then the last setting is used.

Parameters

`-help`	Prints out the command usage.
`-glitch_type {both | vl | vh | vlu | vho | vl_vh | vlu_vho}`	Specifies the glitch type for resistance Hold application. The option `both` applies the value to VL and VH.
`-instance_pin string`	Specifies a list of instance pin names.
`-lib_pin string`	Specifies the instance/pin name of the driver that the holding resistance should be applied to.
`-value double`	Specifies the value in ohms of the holding resistance to be used by glitch analysis.
`-views string`	Specifies a list of view names. If this parameter is not specified, then by default all the views are applied.

Examples

- The following command sets the holding resistance on the Y pin of inst1 to 233ohms for VL:
  ```
  define_glitch_holding_resitance -glitch_type vl -pins {inst1/Y} 233
  ```
- The following command sets the holding resistance on the Y pin of inst2 to 380ohms for both VL & VH:
  ```
  define_glitch_holding_resitance -glitch_type both -pins {inst1/Y} 233
  ```

Structured Data Path Commands

- addSdpGroupMember
- addSdpObject
- checkSdpGroup
- createSdpGroup
- deleteSdpObject
- detachSdpGroup
- flipSdpObject
- getSdpGroupAttribute
- getSdpMode
- moveSdpObject
- placeSdpGroup
- readSdpFile
- setSdpGroupAttribute
- setSdpMode
- setSdpObjectStatus
- setSdpTopGroup
- writeSdpFile

addSdpGroupMember

```
addSdpGroupMember
[-help]
-group group_name
-object object_name_list
[-orientation orientStr]
[-before refObject | -after refObject]
```

Adds an object or member to an existing structured data path (SDP) group. The added object can be an instance or another SDP group.

The `addSdpGroupMember` command enables you to create a structured data path using TCL commands. You do not need to learn SDP relative placement format for creating a data path.

Before adding a member to an SDP group, you should have:

- Imported the design
- Created an SDP group. For more information, see `createSdpGroup`.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `addSdpGroupMember` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man addSdpGroupMember`.
`-after` *`refObject`*	Adds the SDP group or object after the specified reference object.
`-before` *`refObject`*	Adds the SDP group or object before the specified reference object.
`-group` *`group_name`*	Specifies the name of the SDP group to which you are adding the member.
`-object` *`object_name_list`*	Specifies the name of the object(s) to be added to the SDP group.
`-orientation` *`orientStr`*	Specifies the orientation to be set for the object. You can specify orientation as one of the following: `R0`, `R90`, `R180`, `R270`, `MX`, `MY`, `MX90`, `MY90` **Note:** If you do not specify this parameter, the object has `R0` orientation (no rotation) by default.

Examples

- The following example adds the `DTMF_INST/PLLCLK_INST` instance to the SDP group `sdpGrp1`. The instance is rotated 90 degrees counter-clockwise.
  ```
  addSdpGroupMember -group sdpGrp1 -object DTMF_INST/PLLCLK_INST -orientation R90
  ```
- The following examples adds two objects, `DTMF_INST/tdsp_core_inst/inst1` and `DTMF_INST/tdsp_core_inst/inst2`, to the `sdpGrp1` group.
  ```
  addSdpGroupMember -group sdpGrp1 -object {DTMF_INST/tdsp_core_inst/inst1
  DTMF_INST/tdsp_core_inst/inst2}
  ```

addSdpObject

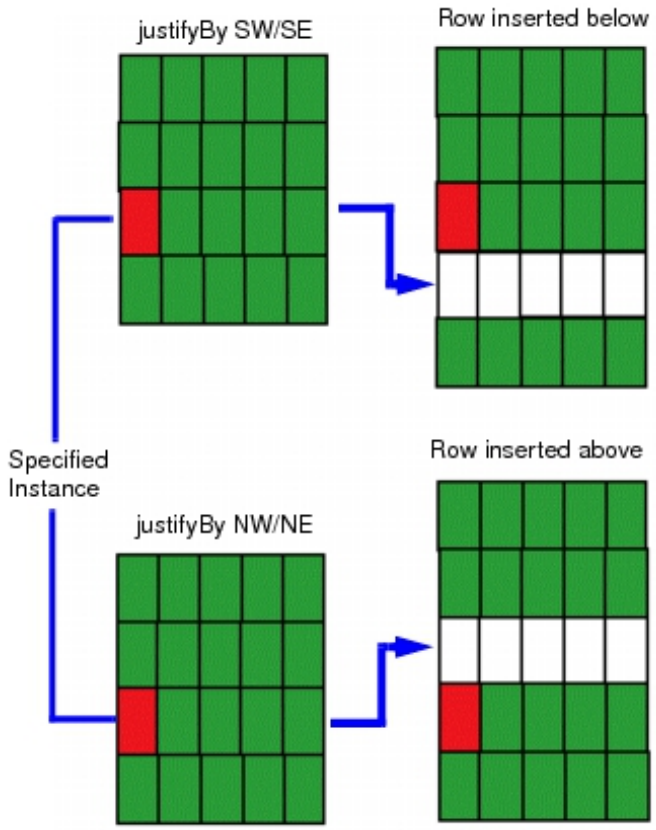
```
addSdpObject
[-help]
{-obstruct group_name_list | {-emptyRow instance_name -numRow value}}
```

Creates a placement blockage on top of the specified SDP group OR inserts one or more empty rows across the whole die above/below the specified instance.

Use the `addSdpObject` command to prevent cells from being placed inside the SDP group area. You can also use this command to create empty rows for clock or IPO buffers that will be inserted later on in the flow.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `addSdpObject` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man addSdpObject`.
`-emptyRow` *`instance_name`*	Inserts empty row(s) above/below the specified instance based on the `justifyBy` constraint of the group to which the instance belongs. The empty row(s) are inserted across all SDP groups. The number of rows to be inserted is specified by the `-numRow` parameter. If `-numRow` is not specified, one empty row is inserted by default. **Note:** The core boundary will be extended to accommodate the newly added rows if the current core box is not big enough.



`-numRow` *value*	Indicates the number of empty rows to be inserted.
`-obstruct` *group_name_list*	Creates a placement blockage over the specified SDP group(s). SDP Placement Blockage (`_SDP_OBSTRUCT_`*group_name*)

Examples

- The following example creates a placement blockage over the SDP group `sdpGrp1`.

  ```
  addSdpObject -obstruct sdpGrp1
  ```

- The following example inserts two empty rows below the `DTMF_INST/ROM_512x16_0_INST` instance.

  ```
  addSdpObject -emptyRow DTMF_INST/ROM_512x16_0_INST -numRow 2
  ```

checkSdpGroup

```
checkSdpGroup
[-help]
[-file fileName]
[-sdpGroups {sdp_name...}]
```

Checks current SDP placement against the SDP constraints, such as order, alignment, and orientation, which may have been originally specified via an SDP relative placement file or a set of TCL commands and reports violations. The `checkSdpGroup` command also creates markers in the GUI for any SDP violation it detects. The violation markers can be viewed in the Violation Browser.

Whenever you perform any manual editing and/or optimization step, you can use `checkSdpGroup` to check for any resulting SDP violations. This ensures that current placement is still valid as per the

SDP constraints you had originally specified.

Before checking SDP placement, you should have:

- Imported the design
- Created and placed SDP groups

Parameters

`-help`	Prints a brief description that includes type and default information for each `checkSdpGroup` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man checkSdpGroup`.
`-file` *`fileName`*	Generates a detailed report for the following checking categories: • SDP group/instance orientation • SDP group/instance justifyBy constraint • Alignment by pin name constraint • SDP group/instance flip constraint • Skip space constraint • SDP group/instance overlapping • Inside parent box violation For each of the above checking category, the report includes the following information: • Total number of violations • List of SDP group/instance names that have that violation *Default*: *`designName`*`.checkSdp.rpt`
`-sdpGroups {`*`sdp_name...`*`}`	Checks only the specified sdps. *Data_type*: string, optional

Example

- The following example checks SDP placement and generates the default report:

  ```
  checkSdpGroup
  ```

  Sample output:

  ```
  ############################################################
  # Generated By: Cadence Innovus 18.10-d183_1
  # Generated on: Fri Dec 15 08:53:35 2017
  # HostName: noi-leenap
  # Design: DTMF_CHIP
  # Command: checkSdpGroup
  ############################################################

  ############################################################
  Orientation and flip checking are only done for the object
  which constaint 'orient/flip' is specified in the sdp file.
  Due to the instance placement needs to match the row orientation,
  the instance actual orientation might not be same as the value
  that specified in the file. The orientation/flip checking will
  report this kind of mismatch
  ############################################################

createSdpGroup

```
createSdpGroup
[-help]
[-justifyBy {SW|SE|NW|NE|N|W|S|E|MID}]
-name sdpGroupName
[-type {row|col|space}]
{{-skip_space value} | -skip_space_by_site_width value siteName | -skip_space_by_micron
value}
| {{{-inst  WCardName... [-keepOrder ]} | -selected }
  [[-spread_group value ] | [-spread_group_by_site_width value siteName] | [-
spread_group_by_micron value]
| [[-numRow value] [-numCol  value]]]}
```

Creates an SDP group. The added object can be an instance or another SDP group.

The `createSdpGroup` command enables you to create a structured data path using TCL commands. You do not need to learn SDP relative placement syntax for creating a data path.

Before creating an SDP group, you should have:

- Imported the design

Parameters

`-help`	Outputs a brief description that includes type and default information for each `createSdpGroup` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man createSdpGroup`.
`-inst WCardName...`	Specifies one or more instance names. Use this parameter if you want to create the SDP group from the specified instances. You can additionally specify `-keepOrder` if you want the tool to honor the order in which SDP instance are specified in the list. **Note:** Wildcards can be used to specify the instance names.
`-justifyBy {SW|SE|NW|NE|N|W|S|E|MID}`	
	Specifies the anchor point that will be used to align the SDP group you are creating. *Default*: `SW`

`-keepOrder`	Honors the order of instances in the SDP instance list that you specify as input with the `-inst` parameter.
`-name` *sdpGroupName*	Specifies the name of the SDP group you are creating.
`-numCol` *value*	Indicates the number of columns to be created.
`-numRow` *value*	Indicates the number of rows to be created. **Note:** If you specify both `-numRow` and `-numCol`, use the `-type` parameter to specify the parent structure type (`row` or `col`). If you do not specify type, the default parent structure will be column.
`-selected`	Indicates that you want to create the SDP group from the current set of selected instances. If the selected cells are already placed and you specify neither the `-numRow` or `-numCol` options nor the `-type` option, the command will automatically generate one column with rows where the SDP structure will be based on the physical location of the selected cells. The tool will print the following message to indicate that the SDP structure created will be derived from the physical location of the selected cells: `Command is running with physical mode extraction where SDP structure will be derived from the existing physical cell placement.` If the selected cells are not yet placed or if some of the selected cells are placed while others are not, the tool prints a message indicating that SDP physical mode extraction cannot be activated and SDP structure cannot be derived from the existing physical placement because the selected instance is not placed.

`-skip_space` *value*	Specifies a space value to be skipped. By default, if `-skip_space` is defined in a column, its value represents the number of skipped rows. If `-skip_space` is defined in a row, its value is for column skipping and represents the number of M2 tracks (pitch of first vertical layer). Skip space value can also be specified as number of widths of a specified row site by using the `-skip_space_by_site_width` *value siteName* parameter. However, row site width should be specified only for an SDP row, and not for an SDP column. Alternatively, you can specify the `-skip_space_by_micron` parameter to specify the distance to be skipped in microns (`um`). **Note:** Use the `-skip_space` parameter with the `-type space` option to add row/column spaces.
`-skip_space_by_micron` *value*	Specifies the space value to be skipped in microns (`um`). If the specified distance value is not equal to the exact number of first vertical metal pitches or number of rows, `createSdpGroup` rounds off the value. **Note**: This option cannot be used with either `-skip_space` or `-skip_space_by_site_width`.
`-skip_space_by_site_width` *value siteName*	Specifies the number of row/column space to be skipped and the name of the tech site. Uses the width of the specified site as the skip unit in the horizontal direction. **Note**: This option cannot be used with either `-skip_space` or `-skip_space_by_micron`.
`-spread_group` *value*	Inserts space between group of instances. If `-spread_group` is specified in a column, spacing will be the number of added rows. If `-spread_group` is specified in a row, spacing will be the number of placement grids added between the columns in that row.
`-spread_group_by_micron` *value*	Specifies the space to be inserted between groups of instances in microns (`um`). **Note**: This option cannot be used with either`-spread_group` or `-spread_group_by_site_width`.

`-spread_group_by_site_width` *value siteName*	Specifies the number of row/column space to be inserted and the name of the tech site. Uses the width of the specified site as the spread unit in the horizontal direction. **Note**: This option cannot be used with either `-spread_group` or `-spread_group_by_micron`.
`-type {row|col|space}`	Indicates whether the new group is a row, column, or an empty (skipped) space. *Default*: `col`

Examples

- The following example creates an SDP group named `TestGrp` of type `space` with two spaces:
  ```
  createSdpGroup -name TestGrp -type space -skip_space 2
  ```
- The following example creates an SDP group named `sdpGrp1` of type `row` with four columns from the selected instances. The group is aligned in the South East direction:
  ```
  createSdpGroup -name sdpGrp1 -type row -justifyBy SE -numCol 4 -selected
  ```
- The following example creates a row data path that has three columns, each with two rows, for all the instances that have name matched the pattern `DTMF_INST/TDSP_CORE_INST*`:
  ```
  createSdpGroup -name sdp_group1 -type row -inst DTMF_INST/TDSP_CORE_INST* -numRow 2
  -numCol 3
  ```
- The following command automatically generates one column with rows where the SDP structure will be based on the physical location of the selected cells, provided that the selected cells are already placed:
  ```
  createSdpGroup -selected -name group2
  ```

deleteSdpObject

```
deleteSdpObject
[-help]
{-object object_name_list [-keepCellPlacement ] | -obstruct group_name_list | -emptyRow
instance_name [-numRow value]}
```

Deletes one of the following:

- SDP group(s) or element(s)
- A placement blockage associated with the specified SDP group(s)
- Empty row(s) adjacent to the specified instance

Use the `deleteSdpObject` command to modify structure of existing data path(s) easily and to remove existing SDP groups or elements.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `deleteSdpObject` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man deleteSdpObject`.
`-emptyRow` *`instance_name`*	Deletes the empty row(s) adjacent to the specified instance based on the `justifyBy` constraint of the group to which the instance belongs. If the group is justified by `SW`/`SE`, the empty rows below the specified instance are deleted. If the group is justified by `NW`/`NE`, the empty rows above the specified instance are deleted. **Note:** If the rows adjacent to the specified instances are not empty, an error message is returned.
`-keepCellPlacement`	
	Preserves the cell placement of remaining SDP members when an SDP object is deleted. If this parameter is not specified, `deleteSdpObject` unplaces all SDP members while deleting the specified SDPs. This option can be used only with `-object`.
`-numRow` *`value`*	Indicates the number of empty rows to be deleted. **Note:** If this parameter is not specified, one empty row is deleted by default.
`-object` *`object_name_list`*	Deletes the specified SDP group or instance. If you want to delete more than one object, enclose the object names in {}.
`-obstruct` *`group_name_list`*	Deletes the placement blockage over the specified SDP group(s).

Examples

- The following command deletes the SDP group `TestGrp`.

  ```
  deleteSdpObject -object TestGrp
  ```

- The following command deletes a placement blockage over the SDP group `sdpGrp1`.

  ```
  deleteSdpObject -obstruct sdpGrp1
  ```

- The following command deletes two empty rows below the `DTMF_INST/ ROM_512x16_0_INST`

instance where the group to which `ROM_512x16_0_INST` belongs has `justifyBy` constraint set as `SW`.

```
deleteSdpObject -emptyRow DTMF_INST/ROM_512x16_0_INST -numRow 2
```

detachSdpGroup

```
detachSdpGroup
[-help]
-name {objNames}
```

Detaches the specified Structured Data Path (SDP) object from the parent group.

Parameters

`-help`	Prints a brief description that includes type and default information for each `detachSdpGroup` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man detachSdpGroup`
`-name {objNames}`	Specifies the name of the SDP object to be detached from the parent group.

flipSdpObject

```
flipSdpObject
[-help]
-object object_name_list
[-x | -y ]
```

Flips an SDP group on X or Y axis along with its elements. The alignment information (`justifyBy`) is adjusted accordingly.

Use the `flipSdpObject` command when flipping can reduce wire length. In the traditional SDP flow, this command can be used while defining SDP constraints or while analyzing SDP alignment.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `flipSdpObject` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man flipSdpObject`.
`-object` *`object_name_list`*	Specifies the names of the SDP groups to be flipped.
`-x | -y`	Specifies the axis on which the specified group (along with its elements) should be flipped. *Default*: `-y` 
Examples

- The following command flips the SDP group `sdpGrp1` on Y axis.

  ```
  flipSdpObject -object sdpGrp1
  ```

getSdpGroupAttribute

```
getSdpGroupAttribute
[-help]
[-flip]
[-justifyBy]
-name sdp_name
[-orient]
[-origin]
[-padding]
[-skipSpace]
[-type]
```

Displays the current values of various attributes of the SDP group specified with `-name`. If you do not specify any parameter except `-name`, `getSdpGroupAttribute` returns information on all of the `setSdpGroupAttribute` parameters for the SDP group specified with `-name`.

Parameters

`-help`	Prints a brief description that includes type and default information for each `getSdpGroupAttribute` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man getSdpGroupAttribute`.
`-flip`	Returns the flip information of the specified SDP group.
`-justifyBy`	Returns the anchor point used to align the specified SDP group.
`-name sdp_name`	Specifies the name of the SDP for you which you want to retrieve settings. This parameter is mandatory.
`-orient`	Returns the orientation of the specified SDP group.
`-origin`	Returns the location of the top SDP group.
`-padding`	Returns the padding of the top sdp object.
`-skipSpace`	Returns the spacing pattern of the specified SDP group.
`-type`	Returns the type of the specified SDP group.

Example

- The following command returns information on all of the `setSdpGroupAttribute` parameters for the SDP group `group2`:

```
innovus 16> getSdpGroupAttribute -name group2
{flip NONE} {justifyBy SW} {orient R0} {origin (700.26 649.04)} {skipSpace {0 0 0 0
0 0 }} {type column}
```

Related Information

getSdpMode

```
getSdpMode
[-help]
[-clock_location]
[-disable_extended_core]
[-honor_dont_use]
[-honor_orient]
[-legalization]
[-legalization_effort]
[-max_move_distance]
[-num_column]
[-place_report]
[-pre_fixed_cells_blockage_direction]
[-quiet]
[-nonDefault]
```

Displays the current values of various SDP-related sticky options. Use this command when you want to retrieve current values of all or specified `setSdpMode` settings. If you do not specify any parameter, `getSdpMode` returns information on all of the `setSdpMode` parameters.

Parameters

`-help`	Prints a brief description that includes type and default information for each `getSdpMode` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man getSdpMode`.
`parameter_names`	Displays information for the specified parameters. You can specify one or more parameters. See `setSdpMode` for descriptions of the parameters you can specify.
`-quiet`	Displays the current settings for the specified parameters in Tcl list format only. If you specify `-quiet` without any parameters, the software displays the current settings of all `setSdpMode` parameters in Tcl list format.
`-nonDefault`	Displays the current settings that are not default settings.

Example

- The following command displays the current setting of the `-clock_location` parameter:

  ```
  getSdpMode -clock_location
  ```

  The software displays the following information:

  ```
  -clock_location center # string, default=center
  center
  ```

- The following command displays the current settings for all `setSdpMode` parameters in Tcl list format only:

  ```
  getSdpMode -quiet
  ```

  The software returns the following information:

  ```
  {clock_location center} {disable_extended_core true} {honor_dont_use false}
  {honor_orient false} {legalization NONE} {legalization_effort low}
  {max_move_distance 0} {num_column 2} {place_report {}}
  {pre_fixed_cells_blockage_direction NONE}
  ```

moveSdpObject

```
moveSdpObject
[-help]
moveObject {objNames}
{-before refObject | -after refObject}
```

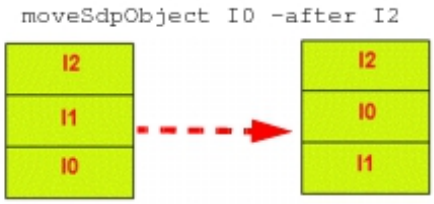
Moves specified SDP objects before or after the specified reference object. Use this command to:

- Move a subgroup or member to a different position within the current SDP group
- Move a subgroup or member to a different group to improve congestion and/or timing.
- Move multiple instances, SDP groups, or a mix of instances and SDP groups to the specified location.

In the traditional SDP flow, this command can be used while defining SDP constraints or while analyzing SDP alignment.

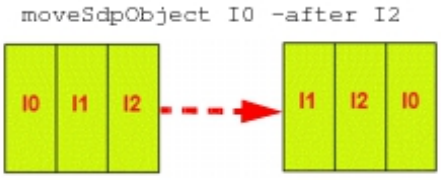
Parameters

`-help`	Prints a brief description that includes the type and default information for each `moveSdpObject` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man moveSdpObject`.
`-after` *`refObject`*	Indicates that the specified SDP objects should be moved after the reference object: • For column with `justifyBy SW/SE`, `after` means the specified SDP objects are placed above the reference object. Column with `justifyBy SW/SE` • For column with `justifyBy NW/NE`, `after` means the specified SDP objects are placed below the reference object.



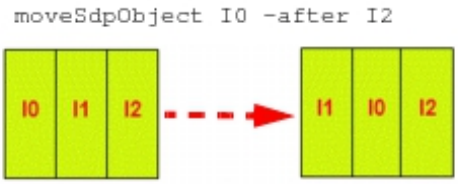
Column with `justifyBy NW/NE`

- For row with justifyBy SW/NW, `after` means that the specified SDP objects are placed on the right side of the reference object.



Row with `justifyBy SW/NW`

- For row with justifyBy SE/NE, `after` means that the specified SDP objects are placed on the left side of the reference object.

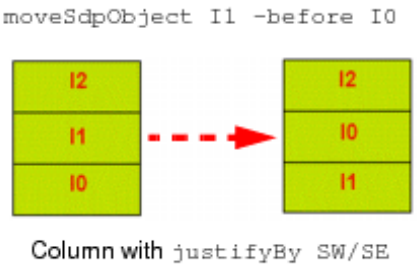


Row with `justifyBy SE/NE`

`-before` *`refObject`*

Indicates that the specified SDP objects should be moved before the reference object:

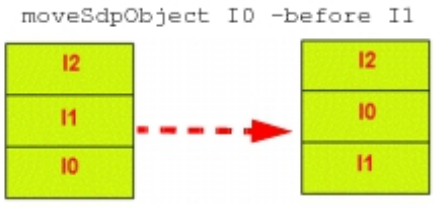
- For column with `justifyBy SW/SE`, `before` means the specified SDP objects are placed below the reference object.



Column with `justifyBy SW/SE`

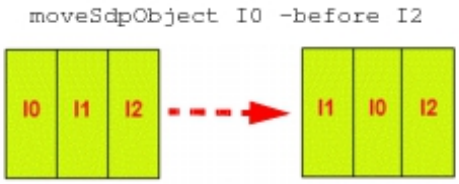
- For column with `justifyBy NW/NE`, `before` means the specified SDP objects are

placed above the reference object.



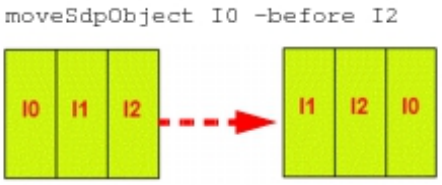
Column with `justifyBy NW/NE`

- For row with justifyBy SW/NW, `before` means that the specified SDP objects are placed on the left side of the reference object.



Row with `justifyBy SW/NW`

- For row with justifyBy SE/NE, `before` means that the specified SDP objects are placed on the right side of the reference object.



Row with `justifyBy SE/NE`

moveObject {objNames}	Specifies the names of the SDP objects to be moved. The objects can be SDP groups, instances, or a mix of both. If multiple SDP objects are specified, the option works as follows: • If both the objects being moved and the reference object are instances, the instances being moved will become members of the SDP group to which the reference instance belongs. • If both the objects being moved and the reference object are SDP groups, the SDP groups being moved will become members of the SDP group to which the reference SDP group belongs. • If the objects being moved are SDP groups and the reference object is an instance, the SDP groups being moved will become members of the SDP group to which the reference instance belongs. • If the objects being moved are instances and the reference object is an SDP group, the instances being moved will become members of the SDP group to which the reference SDP group belongs. • If the objects being moved are a mix of instances and SDP groups and the reference object is an instance, the instances and SDP groups being moved will become members of the SDP group to which the reference instance belongs and the result is based on the input sequence. • If the objects being moved are a mix of instances and SDP groups and the reference object is an SDP group, the instances and SDP groups being moved will become members of the SDP group to which the reference SDP group belongs and the result is based on the input sequence.

Examples

- The following command moves the SDP group `sdpGrp1`, which is an SDP group of type `row` with `justifyBy SE`, to the right side of the group `sdpGrp3`:

  ```
  moveSdpObject sdpGrp1 -before sdpGrp3
  ```

- The following command moves the SDP group `SDP_col145`, which is an SDP group of `type column` with `justifyBy NE`, to the position below `SDP_col170`.

  ```
  moveSdpObject SDP_col145 -after SDP_col170
  ```

- Consider the SDP group structure given below:

```
column group1 {
   justifyBy SW
   row selInstGrp_9 {
      justifyBy SW
      inst DTMF_INST/TDSP_CORE_INST/EXECUTE_INST/ar1_reg_1
      inst DTMF_INST/TDSP_CORE_INST/EXECUTE_INST/ar1_reg_13 orient MX
      inst DTMF_INST/TDSP_CORE_INST/EXECUTE_INST/ar1_reg_12
      inst DTMF_INST/TDSP_CORE_INST/EXECUTE_INST/ar1_reg_3
      inst DTMF_INST/TDSP_CORE_INST/EXECUTE_INST/ar0_reg_12 orient R0
      inst DTMF_INST/TDSP_CORE_INST/EXECUTE_INST/ar0_reg_13 orient MX
      inst DTMF_INST/TDSP_CORE_INST/PORT_BUS_MACH_INST/data_out_reg_8
      inst DTMF_INST/TDSP_CORE_INST/EXECUTE_INST/ar1_reg_14
   }
   .....
}
```

- The following command moves the specified instances before `selInstGrp_9`:

  ```
  moveSdpObject {DTMF_INST/TDSP_CORE_INST/EXECUTE_INST/acc_reg_30
  DTMF_INST/TDSP_CORE_INST/EXECUTE_INST/acc_reg_32} -before selInstGrp_9
  ```

  The resulting structure is as follows:

  ```
  column group1 {
     justifyBy SW
     inst DTMF_INST/TDSP_CORE_INST/EXECUTE_INST/acc_reg_30
     inst DTME_INST/TDSP_CORE_INST/EXECUTE_INST/acc_reg_32
     row selInstGrp_9 {
        justifyBy SW
        inst DTMF_INST/TDSP_CORE_INST/EXECUTE_INST/ar1_reg_1
        inst DTMF_INST/TDSP_CORE_INST/EXECUTE_INST/ar1_reg_13 orient MX
        inst DTMF_INST/TDSP_CORE_INST/EXECUTE_INST/ar1_reg_12
        inst DTMF_INST/TDSP_CORE_INST/EXECUTE_INST/ar1_reg_3
        inst DTMF_INST/TDSP_CORE_INST/EXECUTE_INST/ar0_reg_12 orient R0
        inst DTMF_INST/TDSP_CORE_INST/EXECUTE_INST/ar0_reg_13 orient MX
        inst DTMF_INST/TDSP_CORE_INST/PORT_BUS_MACH_INST/data_out_reg_8
        inst DTMF_INST/TDSP_CORE_INST/EXECUTE_INST/ar1_reg_14
     }
     .....
  }
  ```

- The following command moves the specified instances after `selInstGrp_9`:

  ```
  moveSdpObject {DTMF_INST/TDSP_CORE_INST/EXECUTE_INST/acc_reg_30
  DTMF_INST/TDSP_CORE_INST/EXECUTE_INST/acc_reg_32} -after selInstGrp_9
  ```

  The resulting structure is as follows:

  ```
  column group1 {
  ```

```
    justifyBy SW
    row selInstGrp_9 {
       justifyBy SW
       inst DTMF_INST/TDSP_CORE_INST/EXECUTE_INST/ar1_reg_1
       inst DTMF_INST/TDSP_CORE_INST/EXECUTE_INST/ar1_reg_13 orient MX
       inst DTMF_INST/TDSP_CORE_INST/EXECUTE_INST/ar1_reg_12
       inst DTMF_INST/TDSP_CORE_INST/EXECUTE_INST/ar1_reg_3
       inst DTMF_INST/TDSP_CORE_INST/EXECUTE_INST/ar0_reg_12 orient R0
       inst DTMF_INST/TDSP_CORE_INST/EXECUTE_INST/ar0_reg_13 orient MX
       inst DTMF_INST/TDSP_CORE_INST/PORT_BUS_MACH_INST/data_out_reg_8
       inst DTMF_INST/TDSP_CORE_INST/EXECUTE_INST/ar1_reg_14
    }
    inst DTMF_INST/TDSP_CORE_INST/EXECUTE_INST/acc_reg_30
    inst DTME_INST/TDSP_CORE_INST/EXECUTE_INST/acc_reg_32
    .....
}
```

placeSdpGroup

```
placeSdpGroup
[-help]
[-create_inst_group]
[-deleteOverlap {cell...} {sdp name...}]
[-sdpGroups {name...}]
[-noResolveOverlap | [-keepSdpArea]]
```

Places elements or instances of all defined SDP groups in row(s) and column(s) based on user-defined relative placement information. The `placeSdpGroup` command:

- Adjusts the core boundary automatically if the existing core is not big enough for placing all specified SDPs
- Resolves automatically the overlaps on the row/column cell list specified in `setSdpMode`.
- Honors the `alignByPinName` SDP constraint for column groups
- Marks all placed SDP instances to fixed status
- Places the SDP boundary outside the die area on the right hand side if origin information is not defined.

Before placing SDP groups, you should have:

- Imported the design
- Defined SDPs using TCL commands or modified SDPs, as required

Parameters

`-help`	Outputs a brief description of the `placeSdpGroup` command. For a detailed description of the command, use the `man` command: `man placeSdpGroup`.
`-create_inst_group`	Converts failed top sdp groups to instance groups. In the 2G flow, the tool supports the conversion of failed top SDP groups to instGroups by using this parameter. This option works only on top SDPs. This means the tool will convert the top SDPs to instGroups, irrespective of whether it was the top SDPs or child SDPs that failed. The instances in the instance groups are soft_fixed.
`-deleteOverlap {cell...} {sdp name...}`	Deletes specified physical cells that overlap with all or specified SDP groups. **Note:** If you do not specify *sdp name ...*, the specified physical cells are removed for all SDPs.
`-keepSdpArea`	Keeps the original SDP structure when resolving overlaps with other instances. Use this option if you want to resolve the cell overlap by moving the SDP structure instead of changing it.
`-noResolveOverlap`	Ignores overlaps with column/row cells that are specified in `setSdpMode`. Use this option to take a look at how the groups will be placed before resolving overlaps.
`-sdpGroups {name...}`	Places only the specified SDP groups.

Examples

- The following command places all defined SDP groups without removing overlaps:
  ```
  placeSdpGroup -noResolveOverlap
  ```

readSdpFile

```
readSdpFile
[-help]
-file file_name
[-hierPath path]
[-leftoverGroup]
[-origin llx lly]
[-skipPlacement]
```

Reads in a relative placement file (in .sdp format) and then calls `placeSdpGroup` to place all the structured data path (SDP) elements defined in the file. If `-skipPlacement` is specified, placement is skipped.

If the SDP file refers to an instance that is not present in the netlist or design, the software issues a warning but continues to load the rest of the SDP file.

Before using `readSdpFile`, you should have:

- Imported the design

Parameters

`-help`	Outputs a brief description that includes type and default information for each `readSdpFile` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man readSdpFile`.
`-file` *`file_name`*	Specifies the name of the input file containing SDP definitions. The SDP file format supports wildcards (`*` and `?`) for instance names. It also supports numeric bus bit range as part of an instance name.
`-hierPath` *`path`*	Specifies the hierarchical path name of the SDP elements specified in the SDP file. This path name is appended to all SDP instances defined in the file.
`-leftoverGroup`	
	Stores all remaining instances in the current hierarchical path that do not belong to any SDP group into a new SDP group called *`SDPname`*`_LEFTOVER_RPLGRP`. An error is issued if a logical hierarchy has more than one SDP group.
`-origin` *`llx lly`*	Defines the SDP location by specifying the SDP block origin. The origin information is applied to all SDPs specified in the SDP file.
`-skipPlacement`	
	Reads in the SDP group definition but does not place the group.

Examples

- The following command reads the `dtmf_chip.sdp` file and places all defined SDP elements. It also appends the specified hierarchical path to all elements.

  ```
  readSdpFile -file dtmf_chip.sdp -hierPath DTMF_CHIP/TDSP_CORE_INST
  ```

setSdpGroupAttribute

```
setSdpGroupAttribute
[-help]
[-flip {X Y XY NONE}]
[-justifyBy {SW SE NW NE MID}]
-name sdp_name
[-orient {R0 MX MY R180 NONE}]
[-origin {x y}]
[-padding {x y}]
[-skipSpace spacing_pattern]
```

Sets or modifies the specified attributes of an existing SDP group. This command can be used in anywhere in the flow after an SDP group is created.

Parameters

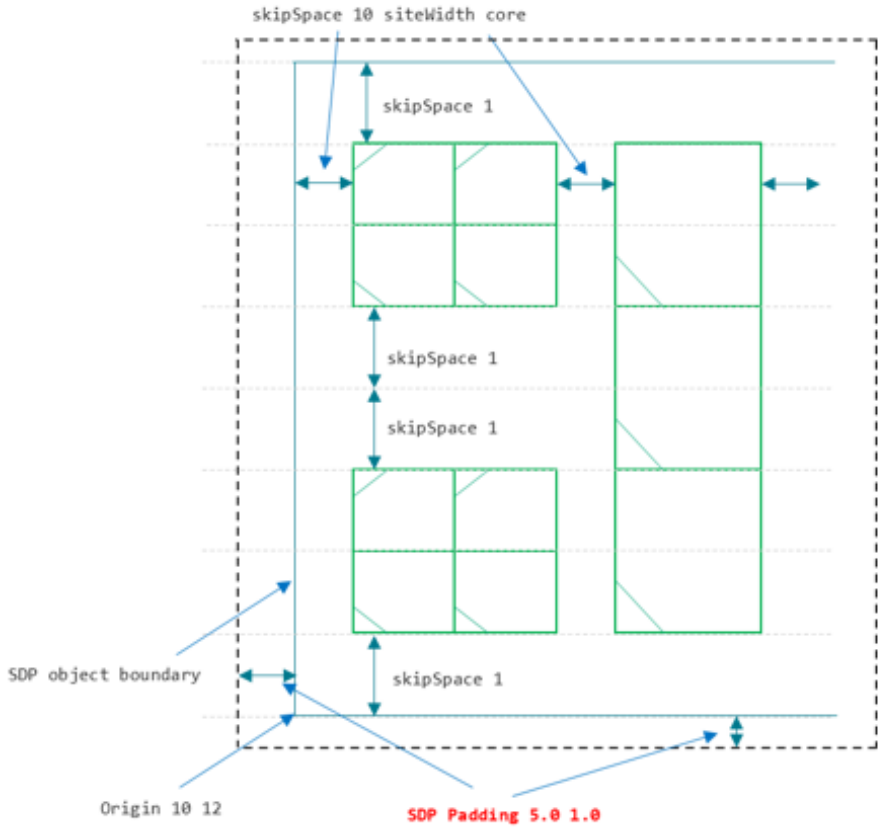
`-help`	Prints a brief description that includes type and default information for each `setSdpGroupAttribute` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setSdpGroupAttribute`.
`-flip {X Y XY NONE}`	Specifies that the SDP group should be flipped on the X or Y axis along with its elements. The alignment information is adjusted accordingly.
`-justifyBy {SW SE NW NE MID}`	Specifies the anchor point that will be used to align the SDP group.
`-name sdp_name`	Specifies the name of the SDP object.
`-orient {R0 MX MY R180 NONE}`	Specifies the orientation of the SDP object.
`-origin {x y}`	Specifies the location of the top SDP group. It can be set only to the top group.

`-padding {x y}`

Specifies the edge extend value of the SDP bounding box in horizontal and vertical direction for the specified top SDP group. The tool uses the sum of the actual SDP bounding box and the extended value to place the SDP groups during global placement. This way, less SDP groups overlap because the tool can enlarge the SDP bounding box by using padding during global placement.

For example, the following command specifies a padding of `{5.0 1.0}` for the SDP top group named `top_group1`:

```
setSdpGroupAttribute -name top_group1 -padding {5.0 1.0}
```



Default: `{0 0}`

Note: The padding is an attribute of each top SDP group. If the specified SDP group name is not a top SDP group, the tool will give an error and return.

`-skipSpace` *spacing_pattern*	Specifies the spacing pattern of the SDP group. The value for row skipping represents the number of skipped rows. The value for column skipping represents the number of the first vertical layer pitch. If the SDP group for which attributes are being set is of type `space`, the tool will accept a value for `-skipSpace`.

Examples

- Consider the SDP group, `sub_group1`, with origin at {383.46 628.88}. The following command will update the origin of the SDP group:
  ```
  setSdpGroupAttribute -name sub_group1 -origin {500 500}
  ```
  If you now check, the origin will have been updated without the need for running the `placeSdpGroup` command:
  ```
  > puts "[dbGet top.fplan.topSdps.pt]"
  {500.28 497.84}
  ```

Related Information

- `createSdpGroup`
- `getSdpGroupAttribute`
- `getSdpMode`
- `placeSdpGroup`
- `setSdpMode`
- `sdp` object in *Innovus Database Object Information*
- Using Structured Data Paths chapter of the *User Guide*
- Floorplan Menu chapter of the *Menu Reference*
  - *Structured Data Path*

setSdpMode

```
setSdpMode
[-help]
[-clock_location {bottom|center}]
[-disable_extended_core {true|false}]
[-honor_dont_use {true|false}]
[-honor_orient {true|false}]
[-legalization {NONE|SW|SE|NW|NE|AUTO}]
[-legalization_effort {low|medium|high}]
[-max_move_distance value]
[-num_column numberOfCol]
[-place_report file_name]
[-pre_fixed_cells_blockage_direction {NONE|X|Y}]
[-reset]
```

Sets SDP-related sticky options before using commands like `placeSdpGroup` and `place_design`. You can use the `setSdpMode` command to disable extension of core boundary before running the `placeSdpGroup` command. You can also use this command to generate a detailed SDP placement report.

Before setting SDP options with `setSdpMode`, you should have:

- Imported the design

Parameters

`-help`	Prints a brief description that includes type and default information for each `setSdpMode` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setSdpMode`.
`-clock_location {bottom | center}`	Specifies where the Integrated Clock Gating (ICG) cell will be placed in an SDP register column. *Default*: `center`

`-disable_extended_core {true | false}`	Disables extension of the core boundary. If you set `-disable_extended_core` to `true` before running the `placeSdpGroup` command, the software does not adjust the core boundary to accommodate all SDP placements. Instead, the software places the SDP elements outside the core boundary if they do not fit within the boundary. *Default*: `true`
`-honor_dont_use {true|false}`	Specifies whether the `dont_use` attribute on base cells should be honored by the `placeSdpGroup` command during EEQ swapping in SDP legalization. By default, `placeSdpGroup` takes all cells into account. If `-honor_dont_use` is set to `true`, `placeSdpGroup` ignores cells with the `dont_use` attribute. *Default*: `false`
`-honor_orient {true|false}`	Honors user-specified orientation during legalization. User-specified orientation can be set using the `setSdpGroupAttribute` command. You can use the `getSdpGroupAttribute` command to check the current orientation setting. Note that the SDP writer writes out orientation information only if its value is defined by the user through the SDP file or TCL command. *Default*: `false`
`-legalization {NONE|SW|SE|NW|NE|AUTO}`	
	Specifies the corner of the SDP box that will be kept fixed while legalizing an SDP instance. *Default*: `NONE`
`-legalization_effort {low|medium|high}`	

	Specifies the legalization effort in placing SDP groups. When you run `placeSdpGroup`, the SDP groups are legalized on the basis of their order, which is determined by their size. Bigger SDP groups are placed first, and multiple iterations are used to place and align the remaining SDP groups. You can also control the legalization effort applied by using the `-legalization_effort` parameter. The higher the setting of this parameter, the more the number of iterations attempted to try and place the SDP groups legally. *Default*: `low`
`-max_move_distance` *`value`*	Specifies how far an SDP can be moved from its original clustering location to resolve overlaps. By default, this value is half the perimeter of the core box. The Manhattan distance between the new and original locations of the SDP must be less than the value of the `-max_move_distance` option. The `-max_move_distance` option is honored by the `refinePlace` command. SDP columns start at the center-of-mass of the instances and then try to find a legal location without overlaps. *Default*: 0
`-num_column` *`numberOfCol`*	Specifies the number of flip flop columns for each SDP group. *Default*: `2`
`-place_report` *`file_name`*	Generates a detailed SDP placement report when `placeSdpGroup` is run. *Default*: If `setSdpMode -place_report` has not been specified before running `placeSdpGroup`, this report is not generated. **Note:** To disable the `-place_report` option once it has been specified, specify *`file_name`* as a null string (`""`). The detailed SDP placement report will not be generated subsequently.
`-pre_fixed_cells_blockage_direction {NONE|X|Y}`	

	Creates temporary placement blockage internally over pre-fixed cells (that is, well tap or power switch cells) in `X` or `Y` direction to prevent SDP cells to be placed in the horizontal or vertical empty spaces when resolving overlapping. The illustration below shows the difference between SDP placement without this setting and with `-pre_fixed_cells_blockage_direction` set to `Y`.  *Default:* `NONE`
`-reset`	Resets all or specified options to default value

Examples

- The following command disables extension of the core boundary if the boundary cannot accommodate all SDP placements:

  ```
  setSdpMode -disable_extended_core true
  ```

- The following commands place elements or instances of all defined SDP groups and generate a detailed SDP placement report named `dtmf_chip.sdp.rpt`:

  ```
  setSdpMode -place_report dtmf_chip.sdp.rpt
  placeSdpGroup
  ```

- The following commands control SDP movement from its original cluster location to resolve overlaps:

  ```
  setSdpMode -max_move_distance 30
  place_design -sdp
  ```

Related Information

  - *Structured Data Path*

setSdpObjectStatus

```
setSdpObjectStatus
[-help]
-status {unplaced|placed|fixed|cover}
[-name object_name_list | -all]
```

Sets the placement status of all or specified SDP group/instances. With `setSdpObjectStatus`, you can make the placer move or prevent it from moving to adjust placement of SDP elements. For example, if you specify status as `unplaced`, the command unplaces the data path and moves its boundary outside the die area on the right hand side.

Use this command after placement to set SDP status to `fixed` so other applications will preserve SDP placement (don't touch). Use the `setSdpObjectStatus` command before running optimization to set SDP placement status to `placed` so `optDesign` can further resize instances of SDP.

Before setting object status with `setSdpObjectStatus`, you should have:

- Imported the design
- Defined the SDP group or instance

Parameters

`-help`	Outputs a brief description that includes type and default information for each `setSdpObjectStatus` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setSdpObjectStatus`.
`-all`	Changes the placement status of all members of all SDP groups. **Note:** If neither `-all` nor `-name` is specified, `setSdpObjectStatus` changes placement status of all SDPs.
`-name` *`object_name_list`*	Specifies the names of SDP groups or instances whose placement status needs to change.
`-status {unplaced|placed|fixed|cover}`	Specifies the new placement status.

Examples

The following command changes the placement status of all SDP groups/instances to `placed`:

```
setSdpObjectStatus -status placed
```

Related Information

- `addSdpObject`
- `createSdpGroup`
- `deleteSdpObject`
- `moveSdpObject`

    - *Structured Data Path*

setSdpTopGroup

```
setSdpTopGroup
[-help]
-group group_name
[-force]
{-location llx lly | -hierPath path}
```

Specifies the location or the hierarchical path of a data path. If you know where SDP will be placed in the design, use the`-location` option to specify SDP location. The advantage of using `setSdpTopGroup` is that you do not need to specify the hierarchical path for each member of an SDP group.

Before setting `setSdpTopGroup -hierPath`, you should have:

- Imported the design
- Created the SDP group using `createSdpGroup`

Before setting `setSdpTopGroup -location`, you should have:

- Imported the design
- Created the SDP group using `createSdpGroup`
- Added members to the SDP group using `addSdpGroupMember`

Parameters

`-help`	Outputs a brief description that includes type and default information for each `setSdpTopGroup` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setSdpTopGroup`.
`-group` *`group_name`*	Sets the specified SDP group as the SDP top group.
`-force`	Indicates that the specified location should be set even if it is outside the existing core boundary. `-force` automatically adjusts the core boundary to accommodate the specified location.
`-location` *`llx lly`*	Specifies the location of the SDP top group.
`-hierPath` *`path`*	Specifies the hierarchical path of the SDP top group.

Examples

- The following command specifies the location of the SDP group `tdsp_sdpGrp`:
  ```
  setSdpTopGroup -group tdsp_sdpGrp -location 848.82 586.75
  ```
- The following command sets the hierarchical path for the SDP group `column_GRP5` as `/DTMF_INST/EXECUTE_INST`. As a result, the specified instance names of all members of this SDP will have this hierarchical path.
  ```
  setSdpTopGroup -group column_GRP5 -hierPath /DTMF_INST/EXECUTE_INST
  ```

writeSdpFile

```
writeSdpFile
[-help]
-file file_name
[-template | -topGroup group_name]
[-template | -command]
[-template  | [-updateRelativePlaceConstraint | -updateOrientation]]
```

Saves the current SDP relative placement information into a file. By default, the output is in `.sdp` format. `writeSdpFile` enables you to save SDP relative information so it can be reloaded in another Innovus session.

The `writeSdpFile` command can be run any time after SDPs have been defined.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `writeSdpFile` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man writeSdpFile`.
`-command`	Specifies that the relative placement information should be saved in TCL commands format instead of `.sdp` format.
`-file` *file_name*	Specifies the name of the output file containing SDP relative information.
`-template`	Specifies that the file should be saved as a template in `.sdp` format. **Note:** This parameter cannot be used with `-command` or `-topGroup`.
`-topGroup` *group_name*	Indicates that the relative placement information of only the specified SDP group should be written.
`-updateOrientation`	Updates the orientation of SDP instances before writing them to the SDP file.
`-updateRelativePlaceConstraint`	Updates relative placement constraints of SDPs before writing out the SDP file. Use this parameter to write out the updated SDP/TCL file after any change in SDP relative placement due to `placeDesign` or manual changes. The `-updateRelativePlaceConstraint` option can be used with the `-command` and `-topGroup` options as well.

Examples

- The following command writes the current SDP information in SDP format in a file named `test.sdp`:

  ```
  writeSdpFile -file test
  ```

- The following command writes the SDP information for the `sdpGrpA` group in the SDP TCL command format to the output file `output.sdp`.

```
writeSdpFile -file output.sdp -command -topGroup sdpGrpA
```

Path Exception Priorities

The following are the path exception priorities if a path in the design matches more than one path exception:

1. `set_false_path`
2. `set_min_delay`, `set_max_delay`
3. `set_multicycle_path`

If there is more than one exception of a given type, for example the `set_multicycle_path` command, the path exception that is more specific has higher priority. A path exception has higher priority if it specifies more of the `-from`/`-through`/`-to` parameters. For example, the `-from -to` options would have priority over the `-from` option.

If the path has the same number of reference points:

- `-from` option has priority over the `-to` option
- `-to` option has priority over the `-through` option
- `-from` option has priority over the `-to` option

Note: To check for ignored path exceptions, use the `report_path_exceptions -ignored` command.

The following table shows the priorities for path exceptions applied to the same path.

Table 38-1 **Path Exception Priorities**

Priority	Path Exception
1. (Highest)	`set_false_path`
2.	`set_max_delay -from` *`pin_list`*
3.	`set_max_delay -to` *`pin_list`*
4.	`set_max_delay -through` *`pin_list`*
5.	`set_max_delay -from` *`clkwave_name`*
6.	`set_max_delay -to` *`clkwave_name`*
7.	`set_max_delay` (The most constraining adjustment has the higher priority over less constraining adjustments.)
8.	`set_multicycle_path -from` *`pin_list`*
9.	`set_multicycle_path -to` *`pin_list`*
10.	`set_multicycle_path -through` *`pin_list`*
11.	`set_multicycle_path -from` *`clkwave_name`*
12.	`set_multicycle_path -to` *`clkwave_name`*
13. (Lowest)	`set_multicycle_path` (The most constraining adjustment has the higher priority over less constraining adjustments.)

Examples of Path Exception Priorities

The following are examples of the path exception priorities for a path starting at `A`, going through `B`, and ending with `C`. The pairs of examples are ordered such that the highest priority constraint in one pair has precedence over the highest priority constraint in the next pair.

- In the following pair of constraints, the false path overrides the cycle addition for the path from `A` through `B` to `C`. For all other paths from `A`, the cycle addition applies.

  ```
  set_false_path -from A -through B -to C set_multicycle_path -from A 2
  ```

- In the following pair, the first constraint is applied (two cycles added) because the `-from` option has priority over the `-to` option:

  ```
  set_multicycle_path -from A 3 set_multicycle_path -to C 2
  ```

- In the following pair, the first constraint is applied (two cycles added) because it specifies a `-through` pin as well as a `-to` pin:

  ```
  set_multicycle_path -through A -to B 3 set_multicycle_path -to B 2
  ```

- In the following pair, the first constraint is applied (two cycles added) because the `-from` option has precedence over the `-to` option:

  ```
  set_multicycle_path -from CLKA 3 set_multicycle_path -to CLKB 2
  ```

- In the following pair, the second constraint is applied because the second constraint overwrites the first one:

  ```
  set_multicycle_path -from A 2 set_multicycle_path -from A 3
  ```

Bidirectional Pin Defaults

Bidirectional pins have both an input pin and an output pin type. This section explains the default pin type that the system uses for bidirectional pins.

Defaults for Pin (or Port) Constraints

The following defines the pin and port types that are used in the next table.

Table 38-2 **Bidirectional Pin (or Port) Type Definitions**
Bidirectional Pin (or Port) Type Definitions

Pin Type	Type 1	Type 2
Blackbox pins	out	in

Instance pins	out	in
Netlist (primary) ports	in	out
Hierarchical ports	in	out

Table 38-3 **Bidirectional Pin Type Defaults**

Pin or Port Constraint	Type	Hierarchical Port
set_input_delay	1	ignored
set_output_delay	2	ignored
set_clock_latency	1	ignored
create_generated_clock	1	used
set_input_transition	1	ignored
set_driving_cell	1	ignored
set_drive	1	ignored

Defaults for Port Constraints

The following table defines the port types that are used in the next table.

Table 10-4 **Bidirectional Port Type Definitions**

Pin Type	Type 1	Type 2
Netlist (primary) ports	in	out
Hierarchical ports	in	out

Table 10-5 **Bidirectional Port Type Defaults**

Port Constraint	Type	Hierarchical Port
set_fanout_load	2	ignored
set_load	2	ignored
set_max_transition	2	ignored

all_analysis_views

```
all_analysis_views
[-help]
[-type string]
```

Returns a Tcl list of analysis views in the design, according to `type`.

Use this command after creating analysis views using `create_analysis_view`.

Parameters

`-help`	Prints out the command usage.
`-type string`	Specifies the type of analysis views: `setup`, `hold`, `dynamic`, `leakage`, `active`, or `all`.

Examples

- The following commands create analysis views `missionSlow` and `missionFast`:

```
create_analysis_view \
  -name missionSlow \
  -constraint_mode missionSetup \
  -delay_corner dcWCCOM
create_analysis_view \
  -name missionFast \
  -constraint_mode missionHold \
  -delay_corner dcBCCOM
```

- The following command returns a list of the defined analysis views in the design:

```
all_analysis_views
```

The software returns the following results:

```
{missionSlow missionFast}
```

Related Information

- create_analysis_view
- set_analysis_view

all_constraint_modes

```
all_constraint_modes [-active | -active_setup | -active_hold]
```

Returns a Tcl list of all defined constraint modes in the design.

Use this command after creating multiple constraint modes (`create_constraint_mode`).

Parameters

`-active`	Returns a list of the defined constraint modes associated with all active analysis views.
`-active_setup`	Returns a list of the defined constraint modes associated with active setup analysis views only.
`-active_hold`	Returns a list of the defined constraint modes associated with active hold analysis views only.

Example

- The following commands create constraint modes `missionSetup` and `missionHold`:

  ```
  create_constraint_mode -name missionSetup
  -sdc_files [list io.sdc mission1-clks.sdc mission1-except.sdc]

  create_constraint_mode -name missionHold
  -sdc_files [list io.sdc mission1-clks.sdc mission1-except.sdc dont_use.sdc]
  ```

- The following command returns a list all the defined constraints modes in the design:

  ```
  all_constraint_modes
  ```

  The software returns the following results:

  ```
  {missionSetup missionHold}
  ```

- The following command returns a list of all the defined constraint modes associated with the active setup analysis views in the design:

  ```
  all_constraint_modes -active_setup
  ```

Related Information

- create_constraint_mode

all_delay_corners

```
all_delay_corners
[-help]
[-active]
```

Returns a Tcl list of all defined delay calculation corner objects in the design.

Use this command after creating delay calculation corner objects with create_delay_corner.

Parameters

`-help`	Prints out the command usage.
`-active`	Returns a list of the defined delay corners associated with all the active analysis views.

Examples

- The following commands create the delay calculation corners `dcWCCOM` and `dcBCCOM`:

```
create_delay_corner -name dcWCCOM \
  -library_set IsCOM-1V \
  -opcond_library stdcell_1V \
  -opcond WCCOM \
  -rc_corner rc-cworst
create_delay_corner -name dcBCCOM \
  -library_set IsCOM-1V \
  -opcond_library stdcell_1V \
  -opcond BCCOM \
  -rc_corner rc-cbest
```

- The following command returns a list of all the delay calculation corners in the design:

```
all_delay_corners
```

  The software returns the following information:

```
{dcWCCOM dcBCCOM}
```

Related Commands

- create_delay_corner

all_hold_analysis_views

```
all_hold_analysis_views
```

Returns a Tcl list of all active hold analysis views in the design.

Use this command after setting active hold analysis views for the design (set_analysis_view).

Parameters

None

Example

- The following command defines the active setup and hold analysis views for the design:
  ```
  set_analysis_view -setup {missionWCCOM mission2WCCOM} -hold {missionBCCOM testBCCOM}
  ```
- The following command returns a list of the active hold analysis views in the design:
  ```
  all_hold_analysis_views
  ```

  The software returns the following results:
  ```
  {missionBCCOM testBCCOM}
  ```

Related Commands

- set_analysis_view
- create_analysis_view

all_library_sets

`all_library_sets`

Returns a Tcl list of all currently defined library sets in the design.

Use this command after creating multiple library sets (create_library_set).

Parameters

None

Examples

- The following commands create the library sets `IsCOM-1V` and `IsCOM-2V`:

  ```
  create_library_set -name IsCOM-1V -timing [list stdcell_F_1V.lib ram_F.lib pad.lib]

  create_library_set -name IsCOM-2V -timing [list stdcell_F_2V.lib ram_F.lib pad.lib]
  ```

- The following command returns a list of all defined library sets in the design:

  ```
  all_library_sets
  ```

  The software returns the following results:

  ```
  {IsCOM-1V IsCOM-2V}
  ```

Related Information

- create_library_set

all_op_conds

`all_op_conds`

Returns a Tcl list of all operating conditions defined for the design.

Use this command after creating multiple operating conditions (`create_op_cond`).

Parameters

None

Examples

- The following commands create operating conditions called `myPVT1` and `myPVT2` for libraries `IsCOM-1V.lib` and `IsCOM-2V.lib`:

```
create_op_cond -name PVT1
   -library_file IsCOM-1V.lib
   -P 1.0
   -V 1.2
   -T 120

create_op_cond -name PVT2
   -library_file IsCOM-2V.lib
   -P 1.0
   -V 1.2
   -T 20
```

- The following command creates a collection called `myOpConds` that contains the operating conditions `myPVT1` and `myPVT2`:

```
set myOpConds [all_op_conds]
```

Related Information

- `create_op_cond`

all_rc_corners

```
all_rc_corners
[-help]
[-active]
```

Returns a Tcl list of all currently defined RC corner objects in the design.

Use this command after creating multiple RC corner objects (create_rc_corner).

Parameters

`-help`	Prints out the command usage.
`-active`	Returns a list of the defined RC corners associated with all active analysis views.

Examples

- The following commands create the RC corners `rc-cbest`, `rc-cworst`, and `rc-typical`:

  ```
  create_rc_corner -name rc-cbest -cap_table myTech_bc.CapTbl -T 50
  create_rc_corner -name rc-cworst -cap_table myTech_wc.CapTbl
  create_rc_corner -name rc-typical -cap_table myTech_typ.CapTbl
  ```

  The following command returns a list of all defined RC corners in the design:

  ```
  all_rc_corners
  ```

  The software returns the following results:

  ```
  rc-cbest rc-cworst rc-typical
  ```

- The following command reads a spef file for each defined RC corner in the design:

  ```
  set corners [all_rc_corners]
  foreach corner $corners { read_spef -rc_corner $corner $corner.spef.gz }
  ```

Related Information

- create_rc_corner

all_setup_analysis_views

```
all_setup_analysis_views
```

Returns a Tcl list of all active setup analysis views in the design.

Use this command after setting active setup analysis views for the design (set_analysis_view).

Parameters

None

Example

- The following command defines the active setup and hold analysis views for the design:
  ```
  set_analysis_view -setup {missionWCCOM mission2WCCOM} -hold {missionBCCOM testBCCOM}
  ```
- The following command returns a list of the active setup analysis views in the design:
  ```
  all_setup_analysis_views
  ```

  The software returns the following results:
  ```
  {missionWCCOM mission2WCCOM}
  ```

Related Information

- set_analysis_view

calNegSlack

`calNegSlack`

Reports the worst slack, total negative slack, and the number of violating paths.

Example

The `calNegSlack` command reports the total negative slack, worst negative slack, and the number of violating paths. You can also find this report in the log file.

calNegSlack

Total negative slacks(TNS)= xxx

Worst negative slacks(WNS)= xxx

Number of violating paths= xxx

check_instance_library_in_views

```
check_instance_library_in_views
```

Checks for missing libraries for instances in the active view.

This command checks whether the library for the cell associated with the instance is present in the associated power domain library set of the instance in the active views.

Parameters

None

Examples

- The following command displays a report showing missing libraries:

  ```
  check_instance_library_in_views
  ```

  The software displays the following information:

  ```
  Checking the Library binding for instance in active view 'vA'
  Pass. All instances have library definition in view 'vA'
  Checking the Library binding for instance in active view 'vB'
  No library found for instance 'U1', cell 'AND2X1', in powerdomain 'PD_BAD', of view
  'vB'
  Fail. Missing Library for some instance found in view 'vB'
  Checking the Library binding for instance in active view 'vAB'
  Pass. All instances have library definition in view 'vAB'
  ```

check_ldb_version

```
check_ldb_version
-ldb string
[-help]
```

Reports the LDB version, size, and the source of the software that is used to generate the library database (LDB) file. The LDB is Cadence binary library format.

Parameters

`-help`	Prints out the command usage.
`-ldb string`	Specifies the LDB (library database) file whose version is to be printed.

Examples

The following example displays the missing features/recommendations for the library database cell_w.db:

```
> check_ldb_version -ldb cell_w.ldb
```

The output is as shown below:

```
LDB file compiled with tool version: v15.20 ((64bit) mm/dd/yyyy 08:40 (Linux 2.6.18-371.el5))
File Size is xxxxx
Source Tool: Innovus
```

check_timing

```
check_timing
[-type type_list ]
[-verbose]
[-check_only warning_list]
[-clock_crossing_output_format {summary | csv}]
[-include_warning warning_list ]
[-exclude_warning warning_list ]
[-view analysis_view_name ]
[ port_or_pin_list ]
[-tcl_list]
[{> | >> } file_name [.gz]]
```

Performs a variety of consistency and completeness checks on the timing constraints specified for a design.

The checks include arrival time and external delay (or required time) for each clock in a multiple clock system. In addition, clock connectivity and data connectivity are checked to make sure the clock or data is propagated as expected. Clock gating points are also reported.

Use this command on generic or mapped netlists. The `check_timing` command considers constants applied to a pin while reporting warnings.

> Use the `check_timing` command before using any commands for timing analysis. Warnings are displayed when problems occur. Refer to check_timing warnings. For best results, rerun the `check_timing` command after resolving each warning. Redirecting the output to a file is the quickest run method.

Parameters

`-check_only` *warning_list*	Allows you to specify warning types. For example, the following command lists the specified warnings only: `check_timing -check_only {uncons_endpoint clock_crossing}` This list can also include warnings that are not listed by default. Valid entries in warning_list are: clock_clipping_freq, clock_clipping_gate, clock_crossing, clock_expected, clock_gating_controlling_edge_unknown, clock_gating_no_data, clock_missing_at_sequential_output, clock_not_propagated, clocks_masked_by_another_clock, const_collision, data_check_multiple_reference_signal, data_check_no_reference_signal, ideal_clock_waveform, invalid_pll_configuration, loop, master_clk_edge_not_reaching, missing_clock_groups, missing_drive, multiple_clock, no_drive, no_gen_clock_source, no_input_delay, partial_input_delay, pulse_non-pulse_clock_merge, signal_level, uncons_endpoint, uncons_endpoints_due_to_case_analysis
`-clock_crossing_output_format {summary | csv}`	Specifies the format of the clock crossing report to be generated - as a summary or in csv format.

{> | >>} *file_name*	When specified with >, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with >>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The *filename* parameter must be the last argument in the list. The *filename* and -tcl_list parameters are mutually exclusive; you cannot specify them together. **Note:** To write a compressed report, add the .gz extension to the file name. *Default:* Report is displayed on standard output without being saved.
-exclude_warning *warning_list*	
	Excludes the specified warning types when generating the report. Use this parameter to exclude any of the warnings included in the report by default. By default, the software includes the following warnings in the report: clock_expected, loop, ideal_clock_waveform, master_clk_edge_not_reaching, partial_input_delay, no_input_delay, no_drive, no_gen_clock_source, uncons_endpoint,uncons_endpoints_due_to_case_analysis. The complete list of warnings and their descriptions is given in check_timing warnings.
-include_warning *warning_list*	

	Includes the specified warning types when generating the report. Use this parameter to add any of the warnings not included in the report by default. By default, the software reports all warnings except the following: `clock_clipping_gate`, `const_collision`, `clock_crossing`, `clock_not_propagated`, `missing_drive`, `multiple_clock`, `data_check_multiple_reference_signal`, `data_check_no_reference_signal`, `clock_gating_no_data`, `clock_gating_controlling_edge_unknown`, `clock_missing_at_sequential_output`, `signal_level`, `clocks_masked_by_another_clock`. The complete list of warnings and their descriptions is given in check_timing warnings.
port_or_pin_list	Lists pins or ports. For example: `check_timing -verbose [get_ports in*]`
`-tcl_list`	Produces the report in Tcl list format instead of a tabular format. This is useful for integrating timing with custom Tcl functions, and also for customizing report generation. The `-tcl_list` and *`filename`* parameters are mutually exclusive; you cannot specify them together.
`-type` *type_list*	Limits the checks to the specified type. Valid types are: `clocks`, `endpoints`, `inputs`, `nets`, `loops`, `clock_clipping`, `clock_gating_inferred`, and `constant_collision`. *Default*: All types. Only check violations will be reported. To report all the checks you can use the `timing_check_timing_report_all_checks` global variable. When set to `true`, the software reports all the checks performed by the `check_timing` command, even if there are no violations. By default, this global variable is set to `false`.

	`clocks`: Reports the following clock warnings: • clock_crossing • clock_expected • clock_not_propagated • ideal_clock_waveform • master_clk_edge_not_reaching • no_gen_clock_source
	`endpoints`: For output ports, warns if no output delay constraint is applied to the port or if a specific (min/max rise/fall) output delay is missing. It also warns if an output delay constraint is applied with no clock information. For all endpoints (output ports and register data pins), it warns if any incoming signal is unconstrained. Also warns if a clock arrives where clock is not expected, or if multiple signals arrive at an endpoint.
	`inputs`: Reports the following input delay, arrival time assertion, and drive assertion warnings: • partial_input_delay • missing_drive • no_input_delay • no_drive
	`nets`:
	`loops`: Warns when a combinational loop is detected. Reports the loop and the arc used to break the loop. The `-pin` option is ignored in this case. Also reports loops caused by generated clocks.

	`clock_clipping`: Warns when there is a problem with clock gating that can result in clock clipping. Reports the following warnings: • clock_clipping_freq • clock_clipping_gate
	`clock_gating_inferred`: Warns when inferred clock gating checks are not analyzed by the software, even if a clock signal reaches and is used downstream the clock tree. Reports the following warnings. • clock_gating_controlling_edge_unknown • clock_gating_no_data
	`constant_collision`: Warns when there is a constant collision on a net connected to the pin or if there is a contradiction on a pin. Constant collision occurs when a net is driven simultaneously by conflicting values and a constant contradiction occurs when a constant constraint on a pin conflicts with the driven value.
`-verbose`	Gives detailed information about the warnings. When specified, warnings are grouped and sorted by warning type. *Default:* Gives a summary of how many warnings of each type exists.
`-view`	Reports warning(s) that belong to the specified analysis view.

Command Order

Use this command after setting all the constraints but before optimizing your design or generating any timing reports.

Warning Messages

The following table shows the `check_timing` warning messages.

check_timing Warning Messages

Warning	Description
`clock_clipping_gate`	**Warning**: Clock clipping possible due to wrong gate type or wrong trigger for data input.
`clock_clipping_freq`	**Warning**: Clock clipping possible due to incompatible clock signal and data signal frequencies.

`clock_crossing`	**Warning**: Clock domains interact. **Comments:** Checks clock interactions between multiple clock domains in the design. When you specify this parameter, the Timing Check Crossing Clocks report shows the interaction of clocks in the design and indicates whether the paths between the clocks are `False` or `Partial False`. If a clock launches one or more paths, which are captured by other clocks, the report lists all pairs of crossing clocks. • This includes inferred clock gating with different reference and signal clock. • If a path has been disabled using the `set_disable_timing` command, crossing clocks on that path are not reported. If all the paths between two clocks are false paths or they are exclusive/asynchronous clocks, the path is marked as `False`. The false path can be defined on clocks, for example, `set_false_path -clock_to CLK` or on pins or ports, such as, `-through buf1/Y`. If only part of paths are set as false paths or exclusive/asynchronous clocks, the path is marked as `Partial False`. • If a false path is defined only for one check type (say, setup), the crossing clocks are marked as `Partial False` if the simultaneous setup hold mode is set to `on`. The crossing clocks are marked `False` if the analysis type is setup and the simultaneous setup hold mode is set to `off`. • If only one edge (rise/fall) of a particular clock pair has false paths (say, using `-clock_fall`), then the path is marked as a `Partial False`.

`clock_expected`	**Warning:** Clock not found where clock is expected. **Comments:** Indicates that no clock signal is defined at the clock pin. See create_clock.
`clock_gating_controlling_edge_unknown`	**Warning:** Unknown controlling edge to perform clock gating check. **Comments:** Reports library cells with complex functions (MUX or AOI) where controlling edge of signal to perform clock gating check cannot be determined automatically. You need to specify correct edge by `-high`/`-low` option using the `set_clock_gating_check` command to resolve such warning. **Note:** The software does not report this warning when either: • `set_disable_clock_gatin g_check` command is applied on such pins, or • global settings to disable clock gating checks are on.

`clock_gating_no_data`	**Warning:** No data signal reaching clock gating enable pin **Comments:** Reports clock gating enable pins where no valid data signal arrives. You need to do either of the following: • specify valid data signal to reach enable pin of clock gating cells, or • remove any path exceptions or disabled checks that blocks valid data signal to reach enable pin **Note:** The software does not report this warning when either • `set_disable_clock_gatin g_check` is applied on such pins, or • global settings to disable clock gating checks are on.
`clocks_masked_by_another_clock`	**Warning:** Clock(s) in fanin cone are dropped due to another clock **Comments:** Reported timing pins on which creation of a regular or a generated clock causes clock(s) in fanins of such pins have been blocked or masked from propagating further. However, for pins having only master clock waveform on the fanin, this warning is not reported. You can use the detailed mode (`-verbose` option) to report names of all the incoming clock waveforms that have been blocked.

`clock_missing_at_sequential_output`	**Warning:** Found latency phase at sequential output on clock tree instead of clock phase **Comments:** Reports output pins of sequential elements that lie on source clock tree for the generated clocks created downstream and do not have any valid clock phase. This indicates possible missing clock related checks (e.g., clock gating) on downstream clock tree. You can add clocks on this pin or downstream clock tree only if no valid clock exists until downstream generated clock creation point.
`clock_not_propagated`	**Warning:** Clock not propagated **Comments:** Reports ideal clocks reaching the reference pin of a timing check.
`const_collision`	**Warning:** Constant collision **Comments:** See set_case_analysis.
`data_check_multiple_reference_signal`	**Warning:** Multiple clocked signals are reaching data check reference pin **Comments:** Reports on reference pins for non sequential timing check (data check) where more than one reference data arrives.
`data_check_no_reference_signal`	**Warning:** No clocked signal is reaching data check reference pin **Comments:** Reports reference pins for non-sequential timing check (data check) where no valid reference signal (data phase) arrives. You can do one of the following to resolve such warnings: • add valid reference signals to reach at such reference pins • remove path exceptions or disabled arcs that are blocking such reference signals

`ideal_clock_waveform`	**Warning:** Clock waveform is ideal. **Comments:** Reports clocks that are ideal and are not propagated. This warning type is reported by default (unless `-exclude_warning` or `-check_only` parameter is specified). You can use the set_propagated_clock command to avoid this warning.
`invalid_pll_configuration`	**Warning:** No valid path exists from output pin to feedback pin of PLL. **Comments**: Shows PLL (phase locked loop) check warnings. These checks allow you to identify and fix issues in the PLL flow.
`latch_fanout_clock_connectivity`	**Warning**: Latch and its fanout latch work on same clock. **Comments**: Checks for a latch and its fanout latch(es) that works on the same clock.
`loop`	**Warning:** Timing loop found in the design. **Comments:** Indicates that there are timing loops in the design. It also includes loops caused by generated clocks.
master_clk_edge_not_reaching	**Warning:** Master clock edge does not reach the generated clock target. **Comments:** This warning means that rise/fall latency edge is not reaching to create generated clock root from the master clock. You can verify if the path that is seeing this warning is actually broken, or edge is somewhere disabled earlier on this path. There is a global `timing_enable_genclk_edge_based_source_latency` that controls how the software chooses generated clock source latency paths. Details of this global can be found at Tempus text command reference.

`missing_clock_groups`	**Warning**: Set clock group related checking. **Comments:** Reports any potential issues with the defined clock grouping data.
`partial_input_delay`	**Warning:** Indicates that a rise or fall input delay assertion is not applied.
`missing_drive`	**Warning:** Missing specific (rise/fall) drive constraint **Comments:** Either a rise or fall drive constraint is applied and the other one is missing.
`multiple_clock`	**Warning:** Multiple clocks are reaching clock reference pin. **Comments:** Reports clock pins of sequential or clock gating cells where more than one clock waveform arrives. This warning is for information only and the software performs timing analysis with respect to all such clocks.
`no_input_delay`	**Warning:** No input delay assertion with or without `-clock` option specified. **Comments:** See set_input_delay.
`no_drive`	**Warning:** No drive constraint **Comments:** See set_driving_cell and set_drive.
`no_gen_clock_source`	**Warning:** No clock source found for generated clock. **Comments:** Indicates that the source pin of the clock generated by the create_clock command is not driven by a clock source.
`pulse_non-pulse_clock_merge`	**Warning**: Merge of pulse and non-pulse clock paths. **Comments**: Reports points where a pulse clock and a non-pulse clock merges.

`signal_level`	**Warning:** Driver pin voltage value do not match with sink pin voltage level **Comments:** Reports net driver/receiver pin pairs for which the pin voltage does not match.
`uncons_endpoint`	**Warning:** No constrained signal reaching pin. **Comments:** For output ports: Primary output port has no implicit timing check. Use set_output_delay, set_max_delay, or set_min_delay to create a valid constraint. For register data pins: There is no valid clock reaching the CK pin of the register data pin. Check for missing create_clock for the clock network. The endpoints are reported as unconstrained in both in early and late timing. This does not cover all the cases and scenarios because of which endpoint can become unconstrained. To cover all possible cases, you can use the `report_analysis_coverage` command.
`uncons_endpoints_due_to_case_analysis`	**Warning:** Unconstrained signal arriving at end point due to case analysis **Comments:** Reports unconstrained endpoints due to case analysis. To enable this warning, you must set the `timing_report_check_timing_unconstrained_endpoints_due_to_constants` global variable to `true`.

Examples

- Consider the following example:

```
in---------|>-----------|>---------out

buf1 buf2
```

The Timing Check Crossing Clocks reports False or Partial False in some of the scenarios given below:

a) `set_input_delay` with respect to CLK1 on in and set_output_delay with respect to CLK2 on out:

From Clock Crossing Clocks

CLK1 CLK2

b) `set_input_delay` with respect to CLK1 on in, set_output_delay with respect to CLK2 on out, and set_false_path -to CLK2 (clock-based false path):

From Clock Crossing Clocks

CLK1 CLK2 (False)

c) If the set_false_path becomes set_false_path -rise_to CLK2, the following is reported:

```
From Clock          Crossing Clocks
```

CLK1 CLK2 (Partial False)

The following command displays the default summary report:

```
tempus> check_timing

checkTimingLibrary

```
checkTimingLibrary
[-outfile string]
[-cellName string]
[-library string]
[-checkPower]
[-reportMissingPowerOnly]
```

Checks the contents of the timing library and reports any inconsistencies in a log file.

You can use the `checkTimingLibrary` command after importing the design and timing libraries.

Parameters

`-cellName` *string*	Checks if the timing is defined for all cells with the specified name, in all timing libraries. **Note:** In general, the `-cellName` parameter is optional. However, if you specify the `-library` parameter, then you *must* specify `-cellName`.
`-checkPower`	Checks if power constructs are defined for the cells, such as internal_power, leakage_power, or ecsm_power. **Note:** In general, the `-checkPower` parameter is optional. However, if you specify `-reportMissingPowerOnly`, then you *must* specify `-checkPower`. If you use the `-library` parameter, you do not have to specify the `-checkPower` parameter, because when a library-specific cell is given as input, the software automatically checks for power constructs. *Default:* Only checks if timing is defined for the cells.

`-library` *string*	Specifies the timing library in which to check a particular cell. You must specify the `-cellName` parameter with `-library`, to specify the particular library cell to check. **Note:** If you use the `-library` parameter, you do not have to specify the `-checkPower` parameter, because when a library-specific cell is given as input, the software automatically checks for power constructs.
`-outfile` *string*	Writes the report to the specified file.
`-reportMissingPowerOnly`	Reports only the cells that do not have internal_power (at pin level), or leakage_power defined. You must specify the `-checkPower` parameter with the `-reportMissingPowerOnly` parameter.

Examples

- The following command checks if timing is defined for all cells that have been read into the design, and writes a report to the log file:

  ```
  checkTimingLibrary
  ```

- The following command checks if timing is defined for all cells that have been read into the design, and writes a report to a file named `CheckTiming1`:

  ```
  checkTimingLibrary -outfile CheckTiming1
  ```

- The following command checks if timing and power constructs are defined for all cells that have been read into the design, and writes the report to the log file:

  ```
  checkTimingLibrary -checkPower
  ```

- The following command checks if timing and power constructs are defined for all cell that have been read into the design, and writes the report to a file named `CheckTiming2`:

  ```
  checkTimingLibrary -outfile CheckTiming2 -checkPower
  ```

- The following command checks if timing is defined for all cells with the name `A01` in all timing libraries, and writes the report to a file named `CheckTiming3`:

  ```
  checkTimingLibrary -outfile CheckTiming3 -cellName A01
  ```

- The following command checks if timing and power constructs are defined for all cells with the name `A01`, in all timing libraries, and writes the report to a file named `AllA01Check`:

  ```
  checkTimingLibrary -outfile AllA01Check -cellName A01 -checkPower
  ```

- The following command checks if timing and power constructs are defined for the cell with the name `A01` in the timing library `minFile1.lib`, and writes the report to a file named `A01Check`:

  ```
  checkTimingLibrary -outfile A01Check -cellName A01 -library minFile1.lib
  ```

  Note: When you use the `-library` parameter, you do not have to specify the `-checkPower` parameter, because when a library-specific cell is given as input, the software automatically checks for power constructs.

- The following command checks if the internal_power and/or leakage_power constructs are defined for all cells that have been read into the design, and reports only those cells that do not have the constructs defined. The software writes the report to a file named `MissingPower`:

  ```
  checkTimingLibrary -outfile MissingPower -checkPower -reportMissingPowerOnly
  ```

create_analysis_view

```
create_analysis_view
-name viewName
-constraint_mode modeName
-delay_corner dcCornerObj
```

Creates an analysis view object that associates a delay calculation corner with a constraint mode. An analysis view object provides all of the information necessary to control a single multi-mode multi-corner analysis.

After creating analysis views, use the set_analysis_view command to specify which views to use for setup and hold optimization or timing analysis.

Use this command after creating constraint modes (create_constraint_mode) and delay calculation corners (create_delay_corner).

Parameters

`-name` *viewName*	Specifies the name of the analysis view being defined.
`-constraint_mode` *modeName*	Specifies the name of the constraint mode to associate with this analysis view. A constraint mode groups a set of constraints to be used with any given analysis. To create the constraint mode, use the create_constraint_mode command.
`-delay_corner` *dcCornerObj*	Specifies the name of the delay calculation corner object to associate with this analysis view. A delay calculation corner object contains all of the information needed to control delay calculation for a specific analysis view. To create a delay calculation corner, use the create_delay_corner command.

Examples

- The following command creates an analysis view called `missionSlow` using the constraint mode `missionSetup` and the delay calculation corner `dcWCCOM`:

```
create_analysis_view
```

```
-name missionSlow
-constraint_mode missionSetup
-delay_corner dcWCCOM
```

- The following command creates an analysis view called `missionFast` using the constraint mode `missionHold` and the delay calculation corner `dcBCCOM`:

```
create_analysis_view
-name missionFast
-constraint_mode missionHold
-delay_corner dcBCCOM
```

Related Information

- `set_analysis_view`
- `create_constraint_mode`
- `create_delay_corner`

create_constraint_mode

```
create_constraint_mode
-name modeName
-sdc_files {file1.sdc file2.sdc ...}
[-ilm_sdc_files {file1.sdc file2.sdc ...}]
[-tcl_vars {{var_name1 value1} {var_name2 value2} {var_name3 value3} ...}]
```

Associates a list of SDC constraint files with a specified constraint mode name, for multi-mode multi-corner analysis. This constraint mode name can be referred to later when creating analysis views. A constraint mode defines one of possibly many different functional, test, or Dynamic Voltage and Frequency Scaling (DVFS) modes of a design. SDC files can be shared by many different constraint modes, and the same constraint mode can be associated with multiple analysis views.

SDC files typically contain timing analysis information, such as the clock specifications, case analysis constraints, I/O timings, and path exceptions that make each mode unique. If the ILM is being used, the timing system utilizes the files specified with `-ilm_sdc_files` during the flatten ILM mode (`flattenIlm`); otherwise, the system uses the files specified with `-sdc_files`.

Parameters

`-ilm_sdc_files {file1.sdc file2.sdc ...}`	Specifies a Tcl list of ILM SDC files to be included in the constraint mode.
`-name modeName`	Specifies the name of the constraint mode to be created.
`-sdc_files {file1.sdc file2.sdc ...}`	Specifies a Tcl list of SDC files to be included in the constraint mode.
`-tcl_vars {{var_name1 value1} {var_name2 value2} {var_name3 value3} ...}`	
	Specifies a list of tcl variables and values to be used in the constraint mode.

Examples

- The following command groups the SDC files `io.sdc`, `mission1-clks.sdc`, and `mission1-except.sdc` to create a mode object named `missionSetup`:

```
create_constraint_mode -name missionSetup

-sdc_files [list io.sdc mission1-clks.sdc mission1-except.sdc]
```

- The following command groups the SDC files `io.sdc`, `mission1-clks.sdc`, `mission1-except.sdc`, and `dont_use.sdc` to create a mode object named `missionHold`:

```
create_constraint_mode -name missionHold

-sdc_files [list io.sdc mission1-clks.sdc mission1-except.sdc      dont_use.sdc]
```

- The following command groups the SDC files `test-io.sdc`, `test-clks.sdc`, and `test-except.sdc` to create a mode object named `testHold`:

```
create_constraint_mode -name testHold

-sdc_files [list test-io.sdc test-clks.sdc test-except.sdc]
```

Related Information

- `update_constraint_mode`
- `create_analysis_view`

create_delay_corner

```
create_delay_corner
[-help]
[-early_estimated_worst_irdrop_factor <percent>]
[-late_estimated_worst_irdrop_factor <percent>]
-name delayCornerName
[-si_enabled true | false]
{ { [-library_set libSetObj] | [-late_library_set libSetObj -early_library_set libSetObj ]
}
[-opcond_library libName ]
[-opcond opcondName]
[-pg_net_voltages voltage_pairs]
[-rc_corner rcCornerObj | [-late_rc_corner rcCornerObj -early_rc_corner rcCornerObj]]
[-irdrop_file list_of_files | -irdrop_data files_or_directories]
[-late_opcond_library libName]
[-early_estimated_worst_irDrop_factor percent]
[-early_opcond_library libName]
[-late_opcond opCondName]
[-early_opcond opCondName]
[-late_estimated_worst_irDrop_factor percent]
[[-late_irdrop_file list_of_files -early_irdrop_file libSetObj] | [-
late_irdrop_data files_or_directories -early_irdrop_data files_or_directories]]
[-temp_file tempName | [-late_temp_file tempName -early_temp_file tempName]] }
```

Creates a named delay calculation corner object that can be referenced later when creating an analysis view. A delay calculation corner provides all of the information necessary to control delay calculation for a specific view. Each corner contains information on the libraries to use, the operating conditions with which the libraries should be accessed, and the RC extraction parameters to use for calculating parasitic data. Delay corner objects can be shared by multiple top-level analysis views.

The `-early_*` and `-late_*` parameters should not be used to represent best and worst case corners. Instead use separate delay corners to define Best-Case and Worst-Case differences. Use the -early_* and -late_* parameters within a single delay calculation corner to control on-chip variation. In this latter situation different conditions or libraries will be used for the launch and capture paths of individual timing paths.

Note: A single delay calculation corner object specifies the delay calculation rules for the entire

design. If a design includes power domains, the delay calculation corner can contain domain-specific subsections that specify the required operating condition information, and any necessary timing library rebinding for the power domain. Use the `update_delay_corner` command to add a power domain definition to a delay calculation corner.

Parameters

`-help`	Prints out the command usage.
`-early_estimated_worst_irDrop_factor` *`per cent`*	Specifies the early voltage derating factor. When this parameter is specified, the software performs delay calculations using the voltage = nomVolt * (1 – value). *Default*: 0.0
`-early_estimated_worst_irdrop_factor` *`percent`*	Specifies the early voltage derating factor.
`-early_irdrop_data` *`files_or_directories`*	Specifies the IR drop files or directories to apply when calculating the early arrival times at a single delay corner.
`-early_irdrop_file` *`list_of_files`*	Specifies the list of IR drop files to apply when calculating early arrival times at a single delay corner. This parameter is used primarily when configuring the multi-mode multi-corner environment for on-chip-variation (OCV) analysis. **Note**: This parameter is obsolete and will be removed in a future release. To ensure compatibility with future releases, you should update your scripts.
`-early_library_set` *`libSetObj`*	Specifies the library set to associate with this delay corner object for calculating early arrival times at a single delay corner. This parameter is used primarily when configuring the multi-mode multi-corner environment for on-chip-variation (OCV) analysis.

`-early_opcond` *opcondName*	Specifies the operating condition to use for calculating early arrival times at a single delay corner. This parameter is used primarily when configuring the multi-mode multi-corner environment for on-chip-variation (OCV) analysis. *Default:* Each library in the early library set uses its own default operating condition.
`-early_opcond_library` *libName*	Specifies the internal library name for the library in which the early operating condition is defined. This is *not* the library file name. This parameter is used primarily when configuring the multi-mode multi-corner environment for on-chip-variation (OCV) analysis. *Default:* The software searches the early library set for the specified operating condition (`-early_opcond`), starting with the master library.
`-early_rc_corner` *rcCornerObj*	Specifies the RC corner object to associate with the early corner object.
`-early_temp_file` *tempName*	Specifies the name of the temperature file for temperature aware delay calculation for early corner.
`-irdrop_data` *files_or_directories*	Specifies the IR drop files or directories to apply to both the early and late delay calculation for the specified delay corner object.
`-irdrop_file` *list_of_files*	Specifies the list of IR drop files to apply to both early and late delay calculation for this delay corner object. This parameter is used primarily to configure single-corner or Best-Case Worst-Case (BC-WC) analysis modes. **Note**: This parameter is obsolete and will be removed in a future release. To ensure compatibility with future releases, you should update your scripts.

`-late_estimated_worst_irDrop_factor` *percent*	Specifies the late voltage derating factor. When this parameter is specified, the software performs delay calculations using the voltage = nomVolt * (1 – value). *Default*: 0.0
`-late_irdrop_data` *files_or_directories*	Specifies the IR drop files or directories to apply when calculating the late arrival times at a single delay corner.
`-late_irdrop_file` *list_of_files*	Specifies the list of IR drop files to apply when calculating late arrival times at a single delay corner. This parameter is used primarily when configuring the multi-mode multi-corner environment for on-chip-variation (OCV) analysis. **Note**: This parameter is obsolete and will be removed in a future release. To ensure compatibility with future releases, you should update your scripts.
`-late_library_set` *libSetObj*	Specifies the library set to associate with this delay corner object for calculating late arrival times at a single delay corner. This parameter is used primarily when configuring the multi-mode multi-corner environment for on-chip-variation (OCV) analysis.
`-late_opcond` *opcondName*	Specifies the operating condition to use for calculating late arrival times at a single delay corner. This parameter is used primarily when configuring the multi-mode multi-corner environment for on-chip-variation (OCV) analysis. *Default:* Each library in the late library set uses its own default operating condition.

`-late_opcond_library` *libName*	Specifies the internal library name for the library in which the late operating condition is defined. This is *not* the library file name. This parameter is used primarily when configuring the multi-mode multi-corner environment for on-chip-variation (OCV) analysis. *Default:* The software searches the late library set for the specified operating condition (`-late_opcond`), starting with the master library.
`-late_rc_corner` *rcCornerObj*	Specifies the RC corner object to associate with the late corner object.
`-late_temp_file` *tempName*	Specifies the name of the temperature file for temperature aware delay calculation for late corner.

`-library_set` *libSetObj(s)*	Specifies the library set(s) to associate with this delay corner object. To configure an ECSM-based multi-library interpolation , you should specify a Tcl list of library_set, such as:
	`create_delay_corner -name dc_P1_T1`
	`-library_set {p1_v1_t1`
	`p1_v2_t1`
	`p1_v3_t1}`

`-name` *delayCornerName*	Specifies the name for the delay corner object being created.
`-opcond` *opcondName*	Specifies the operating condition to use for setup and hold analysis. This parameter is used primarily to configure single-corner or Best-Case Worst-Case (BC-WC) analysis modes. *Default:* Each library in the library set uses its own default operating condition.

`-opcond_library` *libName*	Specifies the internal library name for the library in which the operating condition is defined. This is *not* the library file name. This parameter is used primarily to configure single-corner or Best-Case Worst-Case (BC-WC) analysis modes. *Default:* The software searches the library set for the specified operating condition (`-opcond`), starting with the master library.
`-pg_net_voltages` *voltage_pairs*	Specifies the power/ground net voltages to be used for both early/late timing analysis.
`-rc_corner` *rcCornerObj*	Specifies the RC corner object to associate with this delay corner object. This parameter is used primarily to configure OCV and Best-Case Worst-Case (BC-WC) analysis modes.
`-si_enabled {true | false}`	Controls signal integrity (SI) analysis. When set to `true`, the analysis of all MMMC views will include SI analysis by default. You can use this parameter to further determine which analysis views receive SI analysis and which do not. When this parameter is set to `false` on a delay corner, the software will disable SI analysis for all the views that reference that corner. By default (or when this parameter is set to `true`), SI analysis is computed for all the views related to that corner - whenever SI is globally enabled. (The global control of signal integrity (SI) analysis is determined by the `setDelayCalMode -SIAware` setting.)
`-temp_file` *tempName*	Specifies the name of the temperature file for temperature aware delay calculation for single corner.

Examples

- The following command creates a delay calculation corner called `dcWCCOM`. This corner uses the libraries from `IsCOM-1V`, sets the operating condition to `WCCOM`, as defined in the `stdcell_1V` timing library, and uses the `rc-cworst` RCcorner:

```
create_delay_corner -name dcWCCOM
-library_set IsCOM-1V
-opcond_library stdcell_1V
-opcond WCCOM
-rc_corner rc-cworst
```

- The following command creates a delay calculation corner called `dcBCCOM`.This corner uses the libraries from `IsCOM-1V`, sets the operating condition to `BCCOM`, as defined in the `stdcell_1V` timing library, and uses the `rc-cbest` RC corner:

```
create_delay_corner -name dcBCCOM
-library_set IsCOM-1V
-opcond_library stdcell_1V
-opcond BCCOM
-rc_corner rc-cbest
```

- The following commands create best-case (`dcBBCOM-OCV`) and worst-case (`dcWCCOM-OCV`) delay calculation corners. The OCV variance in each corner is due to different early and late libraries and operating conditions within each delay corner.

```
create_delay_corner -name dcBCCOM-OCV
-late_library_set BCCOM-SLOW
-early_library_set BCCOM-FAST
-late_opcond_library BCCOM-SLOW
-early_opcond_library BCCOM-FAST
-late_opcond SLOW
-early_opcond FAST

create_delay_corner -name dcWCCOM-OCV
-late_library_set WCCOM-SLOW
-early_library_set WCCOM-FAST
-late_opcond_library WCCOM-SLOW
-early_opcond_library WCCOM-FAST
```

```
-late_opcond SLOW
-early_opcond FAST
```

Related Information

- update_delay_corner
- get_delay_corner

create_library_set

```
create_library_set
[-help]
[-aocv string]
[-library_side_file string]
-name libSetName
[-si string]
[-socv string]
[-timing string]
```

Associates a TCL list of timing and cdB/UDN libraries with a specified library set name. Library sets allow a group of library files to be treated as a single entity so that higher-level descriptions (delay calculation corners) can simply refer to the library configuration by name. The same library set can be referenced multiple times by different delay calculation corners.

Timing libraries can be in text format or Cadence binary library format (LDB). The LDB (library database) files generated from other tools, like Voltus, or Genus are read in to the software with an error message (TECHLIB-1249). The LDB files are not forward compatible, that is, a LDB generated from 15.2 version cannot be used with 15.1 or prior versions of the software.

Note: The `create_library_set` command determines the priority of ECSM vs CCS data (if both are present). The software first checks for ECSM construct, if it is missing then CCS construct is loaded.

> The order in which you define timing libraries is important. The software considers the first library you specify in the list as the master library, with each successive library having a lower priority.

Parameters

`-help`	Prints out the command usage.
`-aocv string`	Specifies the AOCV libraries to include in the library set.
`-library_side_file string`	Specifies the library side file.

`-name` *libSetName*	Specifies the name for the library set being created. This name is used to associate the library list with a specific delay calculation corner.
`-si` *string*	Specifies cdB libraries and/or user-defined noise (UDN) models to include in the library set. The cdB and/or UDN libraries are required for performing signal integrity analysis. **Note**: You cannot use this parameter for CCS-N or ECSM-N models, that is, for cdBs only.
`-socv` *string*	Specifies the SOCV libraries to include in the library set.
`-timing` *string*	Specifies the timing libraries to include in the library set. **Note:** Libraries intended for use in an ECSM-based multi-library interpolation must be grouped within an additional level of Tcl list structure to identify the intended usage to the library subsystem. Specify three timing libraries that are characterized at different voltages (typically the lower and upper voltage bounds, and a third intermediate point). All voltages required by the software will be interpolated from this set of libraries. The libraries in the set can differ only in the characterization voltage; they must be identical to each other in all other aspects. However, if you want to perform multi-temperature based library interpolation, you can use two library files that are characterized at different temperatures for each voltage value. See the examples for creating an ECSM-based multi-library set and multi-temperature based library interpolation in the Examples section.

The ECSM and CCS libraries can be very large and loading them may take significant time. You can convert the ASCII NLDM (Liberty .lib), ECSM, and CCS libraries to a binary version using the `write_ldb` command. For conversion of libraries to a binary version, refer to `write_ldb`.

Instead of the original ASCII libraries, you can specify these binary libraries in the configuration file:

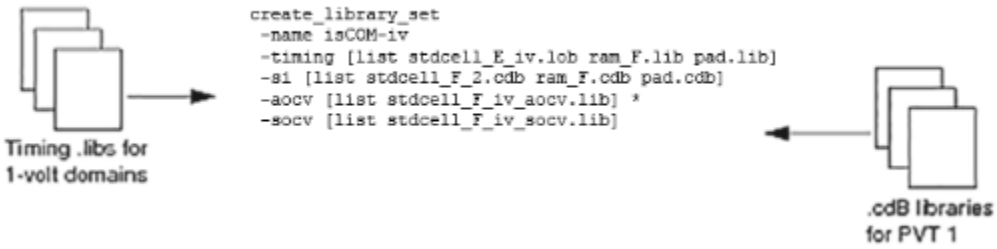
- **Original MMMC setup file**:

```
create_library_set -name libName -
timing "AAA.lib BBB.ecsm CCC.ccs"
```

- **New MMMC setup file**:

```
create_library_set -name libName -
timing "AAA.ldb BBB.ldb CCC.ldb"
```

The library sets can be created only after the top module is set. The following figure shows the creation of a library set that associates timing libraries and cdB libraries with a nominal voltage of 1 volt with the library name isCOM-1V.



Note: Either AOCV or SOCV libraries can be specified at a time. The AOCV and SOCV files can also be added to the library set by either `-aocv [list aocv1.lib aocv2.lib]` or `-socv [list socv1.lib socv2.lib]` in the `create_library_set` settings.

Examples

- The following command creates a library set that associates timing libraries and cdB libraries with a nominal voltage of 1 volt with the library name `IsCOM-1V`:

```
create_library_set
-name IsCOM-1V -timing [list stdcell_F_1V.lib ram_F.lib pad.lib]
-si [list stdcell_F_2.cdb ram_F.cdb pad.cdb]
```

- The following command creates a library set that can be used to specify the 2-volt version of a core cell library, which could be associated later with a 2-volt MSMV power domain specified in the design:

```
create_library_set
-name IsCOM-2V
-timing [list stdcell_F_2V.lib]
```

Related Information

- `get_library_set`
- `update_library_set`

create_op_cond

```
create_op_cond
-name virtualOpcondName
-library_file libraryFileName
-P processValue
-V voltageValue
-T temperatureValue
```

Creates a set of virtual operating conditions in the specified library without actually modifying the library. These virtual operating conditions can then be referenced by a delay calculation corner (`create_delay_corner`) as if they actually exist in the library.

Parameters

`-library_file` *libraryFileName*	Specifies the library for which to create the virtual operating conditions.
`-name` *virtualOpcondName*	Specifies the name for the operating condition being created.
`-P` *processValue*	Specifies the process value for the operating condition.
`-T` *temperatureValue*	Specifies the temperature value for the operating condition.
`-V` *voltageValue*	Specifies the voltage value for the operating condition.

Examples

- The following command creates a virtual operating condition called `PVT1` for the library `IsCOM-1V`.lib:

```
create_op_cond -name PVT1
   -library_file IsCOM-1V.lib
   -P 1.0
   -V 1.2
   -T 120
```

- The following command creates a virtual operating condition called `PVT2` for the library `IsCOM-2V.lib`:

```
create_op_cond -name PVT2
   -library_file IsCOM-2V.lib
   -P 1.0
   -V 1.2
   -T 20
```

Related Information

- `get_op_cond`
- `create_delay_corner`

create_property_alias

```
create_property_alias
[-help]
-map <alias_propery_name_pairs>
-obj_type {pin port cell net clock lib_cell lib_pin design lib timing_path timing_point
timing_arc path_group lib_timing_arc si_victim si_attacker lib_pg_pin pg_pin pg_net}
```

Creates a property alias for the selected objects.

Parameters

`-help`	Prints out the command usage.
`-map <alias_propery_name_pairs>`	Specifies pair list of alias and property to be associate with that alias, such as, {alias1 prop1} or {{ialias1 prop1}{alias2 prop2}...}.
`-obj_type {pin port cell net clock lib_cell lib_pin design lib timing_path timing_point timing_arc path_group lib_timing_arc si_victim si_attacker lib_pg_pin pg_pin pg_net}`	Specifies the object type for which a property alias needs to be created.

create_rc_corner

```
create_rc_corner
-help
[-T temperatureValue]
[-cap_table capTableFile]
-name rcCornerName
[-postRoute_cap {capFactor1 capFactor2 capFactor3}]
[-postRoute_clkcap {capFactor1 capFactor2 capFactor3}]
[-postRoute_clkres {resFactor1 resFactor2 resFactor3}]
[-postRoute_res {resFactor1 resFactor2 resFactor3}]
[-postRoute_xcap {xcapFactor1 xcapFactor2 xcapFactor3}]
[-preRoute_cap capFactor]
[-preRoute_clkcap capFactor]
[-preRoute_clkres resFactor]
[-preRoute_res resFactor]
[-qx_tech_file fileName]
[-via_variation_file viaVariationFile]
```

Creates a named RC corner object that can be referenced later when creating a delay calculation corner object. An RC corner object provides the software with all of the information necessary to properly extract, annotate, and use the RCs for delay calculation.

Note: You must use the RC corner scaling attributes when running the software in multi-mode multi-corner analysis mode. Use the `setExtractRCMode` command to set the extraction mode for all RC corner objects in the design.

Note: In multi-mode multi-corner mode, only the default RC corners created by the software inherit the derating factor values defined in the configuration file.

You can set different postroute scale factors for the postroute engine variants by specifying them as duplets and triplets. For example,

resFactor1 resFactor2 resFactor3

Where:

- Single value: If you specify one value, the scale factor applies to effort level `low`. Scale factor value of `1` is used for `medium` and `high` by default.
- Duplet: If you specify two values, the first value is used for effort level `low` and the second value is used for `medium`. Scale factor value of `1` is used for `high` by default.
- Triplet: If you specify three values, the first value is used for effort level `low`, the second value is used for `medium`, and the third value is used for `high`.

Parameters

`-help`	Outputs a brief description that includes type and default information for each create_rc_corner parameter. For a detailed description of the command and all of its parameters, use the man command: `man create_rc_corner`.
`-cap_table` *capTableFile*	Specifies the capacitance table to use for extraction when using this RC corner. *Default:* The Innovus extraction system uses internal rules for extracting resistances and capacitances.
`-preRoute_cap` *capFactor*	Specifies the capacitance scale factor for RC Extraction in preRoute mode. *Default:* `1.0`
`-preRoute_clkcap` *capFactor*	Specifies the scale factor for capacitance of clock nets in preRoute mode. *Default:* `0` When this parameter is not specified, the value specified with the `-postRoute_cap` parameter is used for preRoute extraction. When specified, this parameter overrides the value specified with the `-postRoute_cap` parameter for clock nets.
`-preRoute_clkres` *resFactor*	Specifies the scale factor for resistance of clock nets in prerRoute mode. *Default:* `0` When this parameter is not specified, the value specified with the `-postRoute_res` parameter is used for preRoute extraction. When specified, this parameter overrides the value specified with the `-postRoute_res` parameter for clock nets.

`-preRoute_res` *resFactor*	Specifies the resistance scale factor for RC extraction in preRoute mode.
`-postRoute_cap` {*capFactor1 capFactor2 capFactor3*}	Specifies the capacitance scale factor for RC extraction in postRoute mode. *Default:* `1.0`
`-postRoute_clkcap` {*capFactor1 capFactor2 capFactor3*}	Specifies the scale factor for capacitance of clock nets in the postRoute extraction mode. *Default:* `0` When this parameter is not specified, the value specified with the `-postRoute_cap` parameter is used for postRoute extraction. When specified, this parameter overrides the value specified with the `-postRoute_cap` parameter.
`-postRoute_clkres` {*resFactor1 resFactor2 resFactor3*}	Specifies the scale factor for resistance of clock nets in the postroute extraction mode. *Default:* `0` When this parameter is not specified, the value specified with the `-postRoute_res` parameter is used for postRoute extraction. When specified, this parameter overrides the value specified with the `-postRoute_res` parameter for clock nets.
`-postRoute_res` {*resFactor1 resFactor2 resFactor3*}	Specifies the resistance scale factor for RC extraction in post-route mode.
`-postRoute_xcap` {*xcapFactor1 xcapFactor2 xcapFactor3*}	Specifies the coupling capacitance scale factor for RC extraction in postroute mode. *Default:* `1.0`
`-name` *rcCornerName*	Specifies the name for the RC corner object being created. You can choose any name for an RC corner object, but it is recommended that you use a name that can be easily recognized as referring to a specific RC corner (for example, rc-min, rc-max, c-min, c-max, and so on).

`-qx_tech_file` *fileName*	Specifies the name of the Quantus technology (`.tch`) file used by TQuantus/IQuantus or Quantus sign-off RC extraction. The technology file is generated by TechGen, a built-in functionality of Quantus. For most technologies you can get this file from technology vendors. For technologies that are not available through the technology vendors, you enter the fabrication process information into an ASCII-format interconnect technology (ICT) input file. The ICT file is then used as input to IceCaps, which in turn generates the technology file. For more information on creating the ICT files, see the chapter, "Creating the ICT File", in the *Innovus User Guide*.
`-T` *rcTemperatureValue*	Specifies the temperature, in units of Celsius, to use to derate resistance values. Use this parameter when you want to override the default temperature specified in the capacitance table or the Quantus technology file. **Note:** The software does not require that the temperature specified by the PVT operating condition at the delay calculation corner level be the same as the RC nominal or user-specified temperature value. *Default:* The Innovus extraction system uses the default temperature of 25 degrees Celsius, unless it is overridden by the capacitance table or the Quantus technology file.

`-via_variation_file` *viaVariationFile*	Specifies a file for modeling via variation. The VIA variation file lists up all the VIA layer names with the corresponding multiplier. Each RC corner can have its own VIA variation file.
	For example:
	`create_rc_corner`
	`-rc_corner rcCornerName1 \`
	`-via_variation_file viaVariationFileName1`
	`create_rc_corner`
	`-rc_corner rcCornerName2 \`
	`-via_variation_file viaVariationFileName2`

Examples

- The following command creates an RC corner called `rc-cbest` that uses the capacitance table `myTech_bc.CapTbl`, and derates the resistance values based on the temperature of 50 Celsius:
  `create_rc_corner -name rc-cbest -cap_table myTech.4_bc.CapTbl -T 50`

Related Commands

- `update_rc_corner`

createUserDisableForCombLoopBreak

```
createUserDisableForCombLoopBreak
-input_file fileName
-outfile fileName
```

Generates SDC file containing constraints for combinational loop breaking. The command selects the disable arc (s) with flag set to 1 from the report file, and generates the equivalent SDC commands in an output file.

Note: You need to set `set_interactive_constraint_modes` command before sourcing the SDC file.

Parameters

`-input_file` *fileName*	Specifies the disabled time arcs report that you generate. To generate the report, use the following command: `report_disbale_timing -nosplit > pt_disable_arcs.rpt`
`-outfile` *fileName*	Specifies the name of the output SDC file.

Command Order

Use this command after generating the disable arcs report.

Example

The following command generates an `encCombLoopBreak.sdc` file when the input is a `pt_disable_arcs.rpt` file:

```
createUserDisableForCombLoopBreak -input_file pt_disable_arcs.rpt
           -outfile encCombLoopBreak.sdc
```

The contents of `pt_disable_arcs.rpt` file are as follows:

Cell or Port	From To Sense Flag Reason
----------	
uchip_core/u_s5_power	oLpcSd_4_ orig_oSmAcpiSd_4_ * 1

The contents of output file `encCombLoopBreak.sdc` are as follows:

```
:
set_disable_timing -from {oLpcSd_4_} -to {orig_oSmAcpiSd_4_}
                [get_cells {uchip_core/u_s5_power}]:
```

display_timing_map

```
display_timing_map
[-help]
{[-step float  -threshold float ] -check_type {setup | hold}] | -clear}
```

Sets color-coded slack threshold values for worst timing paths.

Parameters

`-help`	Prints a brief description that includes type and default information for each `display_timing_map` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man display_timing_map`
`-check_type {setup | hold}`	Specifies the check type for timing paths. The possible arguments are `setup` and `hold`.
`-clear`	Clears the timing slack threshold values.
`-step`	Sets the step value.
`-threshold`	Sets color-coded slack threshold values for worst timing paths. You can specify a range of threshold values. When specified, the instances as seen on the Timing Debug form are color-coded according to the worst timing slack threshold value. For information on timing map, see "Display Timing Map" in the *Innovus Menu Reference Guide* .

Examples

- The following example sets a threshold value of -1, for setup timing check:
  ```
  display_timing_map -step 0.2 -threshold -1 -check_type setup
  ```

get_analysis_view

```
get_analysis_view
viewName
{-constraint_mode | -delay_corner}
```

Returns the constraint mode or delay calculation corner associated with the specified analysis view.

Use this command after creating at least one analysis view (create_analysis_view).

Parameters

`-constraint_mode`	Returns the constraint mode associated with the specified analysis view.
`-delay_corner`	Returns the delay calculation corner associated with the specified analysis view.
viewName	Specifies the name of the analysis view to query.

Examples

- The following command creates the analysis view `missionSlow`:

  ```
  create_analysis_view
  -name missionSlow
  -constraint_mode missionSetup
  -delay_corner dcWCCOM
  ```

- The following command returns the delay calculation corner associated with the `missionSlow` analysis view:

  ```
  get_analysis_view missionSlow -delay_corner
  ```

  The software returns the following result:

  ```
  dcBCCOM
  ```

Related Information

- setAnalysisMode

get_capacitance_unit

`get_capacitance_unit`

Returns the session capacitance unit in picofarads.

Example

The following command returns the session capacitance unit:

get_capacitance_unit

1.000000pf

Related Information

- `setLibraryUnit`

get_clock_network_objects

```
get_clock_network_objects
[-help]
[-clocks clock_list]
[-type {cell | pin}]
```

Returns the cells or pins that exist in the clock network of the specified clocks.

Parameters

`-help`	Prints out the command usage.
`-clocks` *`clock_list`*	Returns the cells or pins present in the clock network of the specified clock(s).
`-type {cell | pin}`	Returns the specified cells or pins in the clock network.

Examples

- The following command returns the pins present in the clock network of all the clocks:
  ```
  get_clock_network_objects
  ```
- The following command returns the pins that exist in the clock network of CLK and CLK2 clocks:
  ```
  get_clock_network_objects -clocks {CLK CLK2}
  ```
- The following command returns the cells that exist in the clock network of CLK clock.
  ```
  get_clock_network_objects -clocks {CLK} -type cell
  ```

get_constant_for_timing

```
get_constant_for_timing
[-bidi_input | -bidi_output]
pin_name
```

Queries the design database for the state of the specified pin or the state propagated through the combinational logic cone to that pin. The returned value is `0` for logic 0, `1` for logic 1, `X` for undefined, and `Z` for tristate.

Note: Constants on hierarchical ports are not computed.

The `get_constant_for_timing` command returns the state for one pin only. If you want to know the state on all ports that have a constant set, use the `-type constant` option with the report_ports command. For example:
`report_ports -type constant`. Use the `-tcl_list` option to process the list in Tcl.

See report_net examples for an example of the `-tcl_list` output.

Parameters

`-bidi_input | -bidi_output`	Returns the constant that is set on the input or output part of bidirectional pins. *Default*: Returns the constant on the output part.
pin_name	Specifies the name of the single pin to query for pin state. The pin must be an instance pin or primary I/O port.

Examples

- The following command sets the value of the specified pin(s) to either a 1 or 0 for use by the timing engine: `set_case_analysis 0 J_block/zbuf0/A`
- The following command queries the design database for the state of the specified pin or the state

propagated through the combinational logic cone to that pin: `get_constant_for_timing J_block/zbuf0/A`

Related Information

- `report_ports`
- `set_case_analysis`
- `report_case_analysis`

get_constraint_mode

```
get_constraint_mode
modeName
{-sdc_files | -ilm_sdc_files | -tcl_vars}
```

Returns a Tcl list of the regular SDC constraint files, or the ILM SDC constraint files associated with the specified constraint mode.

Use this command after creating constraint modes (create_constraint_mode).

Parameters

`-ilm_sdc_files`	Returns the ILM SDC files associated with the specified constraint mode.
modeName	Specifies the name of the constraint mode to query.
`-sdc_files`	Returns SDC files associated with the specified constraint mode.
`-tcl_vars`	Returns a list of tcl variables associated with the specified constraint mode.

Example

- The following command creates the constraint mode `missionSetup`:

  ```
  create_constraint_mode -name missionSetup

  -sdc_files [list io.sdc mission1-clks.sdc mission1-except.sdc]
  ```

- The following command returns the SDC constraint files associated with `missionSetup`:

  ```
  get_constraint_mode missionSetup -sdc_files
  ```

  The software returns the following Tcl list:

  ```
  {io.sdc mission1-clks.sdc mission1-except.sdc}
  ```

Related Information

- create_constraint_mode
- update_constraint_mode

get_delay_corner

```
get_delay_corner
[-help]
delayCornerName
[-early_irdrop_data]
[-early_irdrop_file]
[-early_library_set]
[-early_opcond]
[-early_opcond_library]
[-early_rc_corner]
[-early_temp_file]
[-irdrop_data]
[-irdrop_file]
[-late_irdrop_data]
[-late_irdrop_file]
[-late_library_set]
[-late_opcond]
[-late_opcond_library]
[-late_rc_corner]
[-late_temp_file]
[-library_set]
[-opcond]
[-opcond_library]
[-power_domain powerDomainName]
[-power_domain_list]
[-rc_corner]
[-si_enabled]
[-supply_set supplySetName]
[-supply_set_list]
[-temp_file]
```

Returns attribute information for the specified delay calculation corner object, or for one of its power domains.

Use this command after creating at least one delay calculation corner object (`create_delay_corner`). The delay calculation corner must include a power domain definition in order to query power domain information (`update_delay_corner`).

Parameters

`-help`	Prints a brief description that includes type and default information for each `get_delay_corner` parameter. For a detailed description of the command and all of its parameters, use the man command: `man get_delay_corner`.
`parameter_names`	See `create_delay_corner` for descriptions of the parameters that you can specify.

Examples

- The following command creates the delay calculation corner `dc1`:

```
create_delay_corner -name dc1
-library_set libs-2volt
-opcond_library delayvolt_2V
-opcond slow_2V
-rc_corner rc-cworst
```

- The following command returns the operating condition for the delay calculation corner `dc1`:

```
get_delay_corner dc1 -opcond
```

  The software returns the following results:

```
slow_2V
```

- The following commands add definitions for power domains `domain-3V` and `domain- 5V` to the delay calculation corner `dc1`:

```
update_delay_corner -name dc1
-power_domain domain-3V
-library_set libs-3volt
-opcond_library delayvolt_3V
-opcond slow_3V
update_delay_corner -name dc1
-power_domain domain-5V
-library_set libs-5volt
-opcond_library delayvolt_5V
```

```
-opcond slow_5V
```

- The following command returns a list of all the power domains associated with the delay calculation corner `dc1`:

  ```
  get_delay_corner dc1 -power_domain_list
  ```

  The software returns the following results:

  ```
  {domain-3V domain-5V}
  ```

- The following command returns the name of the library set associated with the power domain `domain-5V`:

  ```
  get_delay_corner dc1 -power_domain domain-5V -library_set
  ```

  The software returns the following results:

  ```
  libs-5volt
  ```

Related Information

- `create_delay_corner`
- `update_delay_corner`

get_equivalent_cells

```
get_equivalent_cells
[-help]
-cell string
[ [ { { -delay_corner string [ -early_only | -late_only ] } | -max |-min } [ -power_domain
string ] ] | -library string ]
```

Returns equivalent cells from minimum/maximum libraries or from libraries of specific power domains.

Parameters

`-cell` *string*	Specifies the cell name for which equivalent cells will be fetched.
`-delay_corner` *string*	Specifies delay corner for which equivalent cells from libraries will be fetched.
`-early_only`	Fetches cells only for early libraries of the specified delay corner.
`-late_only`	Fetches cells only for late libraries of the specified delay corner.
`-library` *string*	Specifies the library for which cells will be fetched.
`-max`	Fetches equivalent cells for max libraries only.
`-min`	Fetches equivalent cells for min libraries only.
`-power_domain` *string*	Fetches cells for libraries of a specific power domain.

Examples

- The following command will return all the cells equivalent to BUF_X4 (buffers) present in the power domain PD1 in the max libraries:

  ```
  > get_equivalent_cells -cell BUF_X4 -max -power_domain PD1
  ```

  Output:

  ```
  CORELIB/BUF_X1 CORELIB/BUF_X16 CORELIB/BUF_X2 CORELIB/BUF_X32 CORELIB/BUF_X4
  ```

- The following command will return all the AND cells of different drives present in the library USERLIB:

  ```
  > get_equivalent_cells -cell AND_X8 -library USERLIB
  ```

get_interactive_constraint_modes

```
get_interactive_constraint_modes
[-help]
```

Returns a list of the multi-mode multi-corner constraint modes that are in interactive constraint entry mode.

When the software is in interactive constraint entry mode (`set_interactive_constraint_modes`), any timing constraints you specify take effect immediately on all active analysis views that are associated with these constraint modes.

Note: Interactive constraint mode only works when the software is in multi-mode multi-corner timing analysis mode.

Related Information

- `set_interactive_constraint_modes`

get_lib_cell_leakage_power

```
get_lib_cell_leakage_power
[-help]
-cell string
[-file string]
[-stateleakagegrp]
[ {-view string | -delay_corner string}
[-power_domain string]]
[ -early  | -late  ]
```

Returns the default leakage power of a cell.

Parameters

`-help`	Prints out the command usage
`-cell` *string*	Specifies the cell Name for which Leakage Power need to be fetched (string, required)
`-delay_corner` *string*	Selects cell from specified delay corner
`-early`	Selects cell from early library of the specified delay corner. If this option is not specified by default late will be used. (bool, optional)
`-file` *string*	Specifies a.Name of the output file. (string, optional)
`-late`	Selects cell from late library of the specified delay corner. If this option is not specified by default late will be used. (bool, optional)
`-power_domain` *string*	Selects cell from the library of the specified power domain (string, optional)
`-stateleakagegrp`	Reports state dependent leakage power information.
-view *string*	Selects the cell from the specified view.

Examples

- The following example reports state independent cell leakage power along with return value:
  ```
  get_lib_cell_leakage_power -cell xyz
  ```

- The following command shows state dependent groups:

  ```
  get_lib_cell_leakage_power -cell xyz -stateleakagegrp
  ```

Related Information

- report_power

get_library_set

```
get_library_set
libSetName
{-timing  | -si | -aocv | -socv}
```

Returns a Tcl list of the timing or cdB libraries for the specified library set.

Use this command after creating at least one library set (`create_library_set`).

Parameters

`-aocv`	Returns AOCV library names for the specified library set.
libSetName	Specifies the name of the library set.
`-si` *libSetName*	Returns the cdb library names for the specified library set.
`-socv`	Returns the SOCV library names for the specified library set.
`-timing`	Returns a list of the timing libraries for the specified library set. This list contains the names of files from where the libraries were sourced from.

Examples

- The following commands create the library sets `IsCOM-1V`:

  ```
  create_library_set -name IsCOM-1V -timing [list stdcell_F_1V.lib ram_F.lib pad.lib]
   -si [list stdcell_F_2.cdb ram_F.cdb pad.cdb}]
  ```

- The following command returns a TCL list of the timing libraries for library set `IsCOM-1V`:

  ```
  get_library_set -timing IsCOM-1V
  ```

  The software returns the following results:

```
{stdcell_F_1V.lib ram_F.lib pad.lib}
```

Related Information

- create_library_set

get_op_cond

```
get_op_cond
virtualOpcondName
{-library_file | -P | -V | -T}
```

Returns the process, voltage, or temperature value for the specified operating condition.

Use this command after creating at least one operating condition (`create_op_cond`).

Parameters

`-library_file`	Specifies the library file in which the operating condition is defined.
`-P`	Returns the process value for the operating condition.
`-T`	Returns the temperature value for the operating condition.
`-V`	Returns the voltage value for the operating condition.
`virtualOpcondName`	Specifies the name of the operating condition to query

Examples

- The following command creates an operating condition called `myPVT2` for the library `IsCOM-2V.lib`:

  ```
  create_op_cond -name myPVT2
     -library_file IsCOM-2V.lib
     -P 1.0
     -V 1.2
     -T 20
  ```

- The following command creates a collection called myPVT2-temp that contains the temperature

value of the `myPVT2` operating condition:

```
set myPVT2-temp [get_op_cond myPVT2 -T]
```

Related Information

- `create_op_cond`

get_pba_mode

```
get_pba_mode
[-help]
[-epba_bounded_mode]
[-quiet]
[-nonDefault]
```

Displays information for the IPBA mode set using the `set_pba_mode` command.

Parameters

`-help`	Prints out the command usage.
`-epba_bounded_mode`	Enables/disables the IPBA mode with exhaustive PBA analysis (enabled using the `report_timing -retime_mode exhaustive` command).
`-quiet`	Displays the current settings in Tcl list format only.
`-nonDefault`	Displays the current settings which are not default settings.

Related Commands

- `set_pba_mode`
- `report_timing`

get_propagated_clock

```
get_propagated_clock
[-clock clock_list] [-pin pin_list]
[> filename]
```

Returns the clock propagation mode, either `ideal` or `propagated`, for the specified clocks or pins.

Parameters

`> filename`	Specifies the name of a file in which to save the report. You can add the `.gz` extension to the file name to generate a compressed report. **Note:** The file name must be the last argument in the list.
`-clock clock_list`	Specifies one or more clock waveforms for which you want to retrieve the clock propagation mode information.
`-pin pin_list`	Specifies one or more pins or ports for which you want to retrieve the clock propagation mode information. You cannot specify hierarchical pins.

Example

- The following command gets the clock propagation mode information for all clock waveforms:
  ```
  get_propagated_clock -clock {*}
  ```

Related Information

- `set_propagated_clock`
- `reset_propagated_clock`

get_rc_corner

```
get_rc_corner
rcCornerName
-rcCornerAttribute
```

Returns attribute information for the specified RC corner object.

Use this command after creating at least one RC corner object (create_rc_corner).

Parameters

-rcCornerAttribute	Returns the setting for the specified RC corner attribute. You can query one of the following attributes: `-cap_table`, `-T`, `-preRoute_res`, `-postRoute_res`, `-preRoute_cap`, `-postRoute_cap`, `-postRoute_xcap`, `-qx_tech_file`. For attribute information, see the create_rc_corner command.
rcCornerName	Specifies the name of the RC corner to query.

Examples

- The following commands create the RC corners `rc-cbest` and `rc-cworst`:

  ```
  create_rc_corner -name rc-cbest -cap_table myTech_bc.CapTbl -T 50
  create_rc_corner -name rc-cworst -cap_table myTech_wc.CapTbl
  ```

- The following command returns the capacitance table specified for `rc-cworst`:

  ```
  get_rc_corner rc-cworst -cap_table
  ```

  The software returns the following results:

  ```
  myTech_wc.CapTbl
  ```

Related Information

- create_rc_corner
- update_rc_corner

get_resistance_unit

```
get_resistance_unit
```

Returns the resistance unit for the current session.

Example

The following command returns the resistance unit for the current session:

```
get_resistance_unit
```

1.000000 kohm

get_socv_rc_variation_factor

```
get_socv_rc_variation_factor
[-help]
-view viewName
{-early | -late }
```

Displays the variation factor for interconnect delays.

Parameters

`-help`	Prints out the command usage.
`-early`	Displays the variation factor for early interconnect delays.
`-late`	Displays the variation factor for late interconnect delays.
`-view viewName`	Displays the SOCV interconnect variation factor for specified view.

Related Commands

- set_socv_rc_variation_factor

get_socv_reporting_nsigma_multiplier

```
get_socv_reporting_nsigma_multiplier
[-help]
-view viewName
{[-setup | -hold ]}
```

Allows you to query sigma multiplier setting for the specified view in setup or hold mode.

Parameters

`-help`	Prints out the command usage.
`-hold`	Returns the sigma multiplier for hold mode.
`-setup`	Returns the sigma multiplier for setup mode.
`-view viewName`	Returns the sigma multiplier value for the specified view. **Note**: Applies to active views only.

Examples

- The following command displays the sigma multiplier setting for the specified view:

```
innovus > set_socv_reporting_nsigma_multiplier -hold 2.5 -view
default_emulate_view_hold
innovus > get_socv_reporting_nsigma_multiplier -view default_emulate_view_hold -hold
2.500000
```

Related Commands

- set_socv_reporting_nsigma_multiplier

get_time_unit

```
get_time_unit
```

Returns the current time unit for the session.

Example

- The following command returns the time unit for the session:
  get_time_unit

  1.000000ns

Related Information

- setLibraryUnit

getAnalysisMode

```
getAnalysisMode
[-analysisType]
[-aocv]
[-asyncChecks]
[-caseAnalysis]
[-checkType]
[-clkNetsMarking]
[-clkSrcPath]
[-clockGatingCheck]
[-clockPropagation]
[-cppr]
[-enableMultipleDriveNet]
[-honorActiveLogicView]
[-honorClockDomains]
[-log]
[-multi_input_switching_mode]
[-propSlew]
[-nonDefault]
[-quiet]
[-sequentialConstProp]
[-skew]
[-socv]
[-timeBorrowing]
[-timingEngine]
[-timingSelfLoopsNoSkew]
[-usefulSkew]
[-useOutputPinCap]
[-warn]
```

Returns the following information about a specified timing analysis mode parameter in the System log file and in the System console:

- Parameter name
- Current value
- Type (Boolean, string, and so on)
- Whether the current value was set by the user

If you do not specify a parameter, the software returns information for all timing analysis mode parameters.

Parameters

parameter_names	Returns information for the specified parameters. You can specify one or more parameters. See `setAnalysisMode` for descriptions of the timing analysis mode parameters you can specify.
`-quiet`	Returns the current settings for the specified parameters in Tcl list format only. If you specify `-quiet` without any parameters, the software returns the current settings of all `setAnalysisMode` parameters in Tcl list format.

Examples

- The following command returns the current setting of the `-checkType` parameter:

  ```
  getAnalysisMode -checkType

  The software returns the following information:

  -checkType setup # enums={setup hold}, default=setup

  setup
  ```

- The following command returns the current setting of the `-checkType` parameter in Tcl list format:

  ```
  getAnalysisMode -checkType -quiet
  ```

  The software returns the following information:

  ```
  setup
  ```

- The following command returns the current settings for the `-checkType`, `-skew`, and `-analysisType` parameters:

  ```
  getAnalysisMode -checkType -skew -analysisType

  The software returns the following information:
  ```

```
-checkType setup # enums={setup hold}, default=setup

-skew true # bool, default=true

-analysisType bcwc # enums={single bcwc onChipVariation}, default=bcwc

{checkType setup} {skew true} {analysisType bcwc}
```

- The following command returns the current settings for the `-checkType`, `-skew`, and `-analysisType` parameters in Tcl list format:

  ```
  getAnalysisMode -checkType -skew -analysisType -quiet
  ```

  The software returns the following information:

  ```
  {checkType setup} {skew true} {analysisType bcwc}
  ```

Related Information

- `setAnalysisMode`

getTimeLibFile

```
getTimeLibFile
library_name
```

Reports the library files that match the specified library name.

Parameters

library_name	Specifies the library name for which to check.

read_path_descriptions

```
read_path_descriptions
[-help]
filename
[-hpin]
[-path_type {end summary full full_clock end_slack_only summary_slack_only}]
[-retime {aocv ssta path_slew_propagation aocv_path_slew_propagation
waveform_propagation}]
```

Reads the file created by the `write_path_descriptions` command. This command reads the complete description of the paths specified in the file in another Tempus session.

The paths description when read back can be saved as a collection that can be used as a regular path collection for any reporting command or queried using the `get_property` command.

Parameters

`-help`	Prints out the command usage.
`filename`	Specifies the name of the input file.
`-hpin`	Prints all the hierarchical crossings of an arc under the "hpin" column in the `report_timing` table.
`-path_type {end | summary | full | full_clock | end_slack_only | summary_slack_only}`	Allows you to choose the format of the report based on the path type.
`-retime {aocv | ssta | path_slew_propagation | aocv_path_slew_propagation | waveform_propagation}`	Reanalyzes the specified set of paths using the specified analysis method.

Examples

- The following example command reads out the pathfile1.txt. The file contains details of the collection of timing paths with hierarchical pins (`-hpin`) format based on timing and exact path availability in the session in which the path description is read:

  ```
  read_path_descriptions pathfile1.txt -hpin
  ```

Related Information

`write_path_descriptions`

read_sdf

```
read_sdf
[-help]
sdf_file_name
[-continue_on_error]
[-ilm_filter]
[-increment]
[-overwrite_incremental_delay]
[-path instanceName]
[-persistent]
[-print_summary]
[-scale float]
[-strict_cond_matching]
[-view viewName]
[-sdf_field {min|typ|max} | [-early_sdf_field {min|typ|max}] [-late_sdf_field
{min|typ|max}]]
```

Reads an OVI Standard Delay Format (SDF) file and annotates user-specified delay information from the SDF file into the timing system. You can use the `read_sdf` command to supply pre-calculated delays and timing check values from an external delay calculator, or from a previous Innovus session.

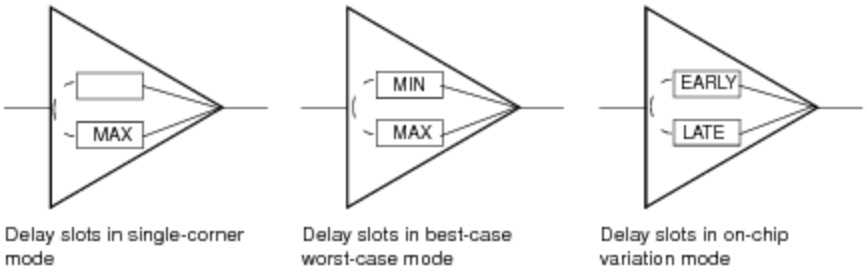
The `read_sdf` command can read version 2.1 and 3.0 of the SDF files, and can read both plain-text and GNU zipped (`.gz`) format files. The command and the Innovus software do not support the Timing Environment section of the SDF specification.

The SDF file can provide one, two, or three different values for each timing arc delay or timing check value. These values are passed in the min, typ, or max SDF delay fields, represented as min:typ:max.

Innovus provides multiple delay place holders to store the calculated or annotated delay information:

- In single-corner (`setAnalysisMode -analysisType single`) analysis mode, only max delays are available.
- In best-case worst-case (`setAnalysisMode -analysisType bcwc`) mode, a min delay slot is provided for storing min delays used for hold analysis. A max delay slot stores delays used for setup analysis.
- In on-chip variation (`setAnalysisMode -analysisType onChipVariation`) mode, the early delay slots store delays used for calculated early arrival times. The late delay slot stores delays used for calculated late arrival times.
- In multi-corner mode, an early and a late delay slot are provided for each multi-mode multi-corner analysis view.

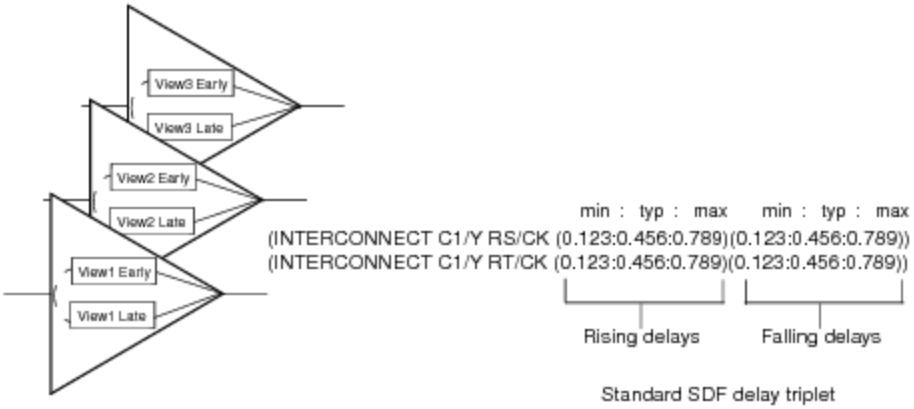
The `read_sdf` command provides parameters for controlling how the SDF min:typ:max triplet values are mapped into the Innovus software's delay slots. The correct mapping depends on how the delay information in the SDF file was created, and what type of analysis you are performing.



Delay slots in single-corner mode

Delay slots in best-case worst-case mode

Delay slots in on-chip variation mode



Delay slots in multi-corner mode

Standard SDF delay triplet

The timing system provides special handling for annotating incremental delays. These delays typically represent plus or minus offsets due to crosstalk effects. Incremental delay annotation to the Innovus software can be done by:

- Importing an incremental SDF file (SDF has an internal `INCREMENT` keyword) using the `read_sdf` command.
- Tcl sourcing a file of `set_annotated_delay -net -delta_only` constraints.

The incremental delay annotations can be viewed in the `report_timing` report by adding the `incr_delay` option to the `report_timing -format` list, or to the `report_timing_format` global variable.

Parameters

`-help`	Prints out the command usage.

`-continue_on_error`	Continues to read the file if an error occurs. By default, when an error occurs, the `read_sdf` command stops reading the file. Use this parameter to attempt to continue reading the file, if possible. **Note**: If you continue some annotations may be missing due to the errors. You can use the `report_annotated_parasitics` command to find the missing annotations. If the SDF file is corrupted, you can obtain a file.
`-early_sdf_field {min | typ | max}`	Annotates the early delay from the specified SDF field. In single-corner mode, all setup and hold analysis use maximum delays. The software ignores any minimum or early delay information. In best-case worst-case mode, use this parameter to specify which SDF field to use for hold analysis. In on-chip variation mode, the software uses the early delay for calculation of fast paths.
`-ilm_filter`	Ignores ILM-related errors. By default, the `read_sdf` command does not ignore errors reported due to missing arcs in core ILM.
`-increment`	Increments the total delay without affecting the delta delay. By default, when the SDF file contains the INCREMENT delay type, the `read_sdf` command will perform an adjustment on the delta delay slot which models SI cross-talk push-out/pull-in effects. When this option is used, the INCREMENT delays will be applied against the static base delay values instead.

`-late_sdf_field {min | typ | max}`	Annotates the late delay from the specified SDF field. In single-corner mode, use this parameter to specify which of the SDF triplet values to annotate for both setup and hold checks. In best-case worst-case mode, use this parameter to specify which SDF field to use for setup analysis. In on-chip variation mode, the software uses the late delay for the calculation of slow paths.
`-overwrite_incremental_delay`	When annotating an incremental SDF file, replaces any pre-existing delta delays with the new SDF values. The total delay will be equivalent to the original base delay, plus the new delta delay. If the delays in the incremental SDF file represent crosstalk delay push-outs from a signal integrity analysis, use the `-overwrite_incremental_delay` parameter to ensure that any stale data from a previous analysis is removed. By default, when an incremental SDF file (SDF has an internal `INCREMENT` keyword) is annotated, the delays are added to the base delay, and also stored separately as delta delays. If an additional incremental SDF file is annotated, the software adds the existing base and delta delays with the new values.
`-path` *instanceName*	Specifies the instance in the design to which the specified SDF file should be applied.
`-persistent`	Keeps the delays from certain SDF files persistently in use during various steps of the timing optimization . Use this parameter to support pre-timed structures, such as clock meshes.
`-print_summary`	Outputs the summary information of annotated delays.

`-scale` *float*	Overrides the automatic scaling of SDF delays to the library units by the value given. To disable all scaling, use a value of 1.0.
`-sdf_field {min | typ | max}`	Annotates the delay from the specified SDF slot. In single-corner and best-case worst-case modes, the software uses this value for both setup and hold analysis. In on-chip variation mode, the software uses the same value from the specified SDF slot for both the early and late delays of the specified arc.
sdf_filename	Specifies the name of the SDF file that has the back annotation data.
`-strict_cond_matching`	Annotates only the conditions that are an exact syntax-to-syntax match between the SDF file and the `.lib` file. *Default:* Uses looser conditional matching rules between the `.lib` and SDF arc specifications.
`-view` *viewName*	Annotates the specified analysis view(s) with the delays from the SDF file. You can use this parameter only when you are in multi-mode multi-corner analysis mode.

Examples

- The following command annotates delay information from the SDF min field to the min/early slots, and maps the SDF max field data to the max/late delay slots:

  ```
  read_sdf sdf_filename
  ```

  Given the following SDF, the default annotation would be:

  (INTERCONNECT C1/Y RS/CK (0.123:0.456:0.789) (0.123:0.456:0.789))

  - In single-corner analysis mode, a delay of 0.789 ns is annotated to the max delay slot.
  - In best-case worst-case mode, a delay of 0.123 ns is annotated to the min delay slot, and a value of 0.789 ns is placed in the max delay slot.

    - In on-chip variation mode, a delay of 0.123 is used for early delays, and a value of 0.789 ns is used for late delays.
- The following command annotates the SDF typ field to both the early and late delay slots:
  `read_sdf -sdf_field typ sdf_filename`
- The following command annotates the SDF typ field to the early delay slot, and the SDF max field to the late delay slot:
  `read_sdf -early_sdf_field typ -late_sdf_field max sdf_filename`
- The following command annotates the SDF typ field to the late delay slot. The early delay slot is annotated with the default min SDF field:
  `read_sdf -late_sdf_field typ sdf_filename`

Related Information

- set_annotated_delay
- report_timing
- report_annotated_parasitics
- setAnalysisMode

read_spdf

```
read_spdf
{-help]
SPDF_file_name
```

Reads the statistical parameter distribution format (SPDF) file. An SPDF file contains statistics of variation of process parameters. The SPDF file is required for statistical static timing analysis (SSTA).

Parameters

`-help`	Prints out the command usage.
`SPDF_file_name`	Specifies the name of a SPDF file - that contains statistics of variation of process parameters.

read_twf

```
read_twf
[-help]
[filenames]
[-cell string]
[-prefix string]
[-quiet]
[-reset]
[-scope string]
[-skipconst]
[-skiptw]
[-strip_prefix string]
[-verbose]
[-view string]
```

Reads the external timing window file (TWF) for noise (Signal Integrity) and power calculation (Common Power Engine - CPE). This file is used to obtain clocks, constants, external load, slews, timing windows, and slack information. The external TWF specification is optional. In the absence of a TWF, this information is automatically derived using the Common Timing Engine (CTE), if timing constraints are read.

Note: If the `VOLTAGE_THRESHOLD` construct is missing from the TWF file header, the values 10 and 90 are automatically assigned as the minimum and maximum threshold values, respectively. For example:

```
VOLTAGE_THRESHOLD (10 90)
```

Parameters

`-help`	Prints out the command usage.
`-cell string`	Specifies the master cell for the timing window file.
filenames	Specifies the names of the timing window files.
`-prefix string`	Adds a prefix to the net or pin name.
`-quiet`	Skips information and warning messages.
`-reset`	Clears the previously read TWF files.

`-scope` *string*	Specifies the scope for the given hierarchical timing window file.
`-skipconst`	Skips constant processing.
`-skiptw`	Skips timing windows processing.
`-strip_prefix`	Removes hierarchical path name.
`-verbose`	Prints the command progress details.
`-view` *string*	Specifies the view for the timing window file.

Examples

- The following command reads the timing window file TW.in for the view 'view01', while skipping the constant processing from the timing window file:

  ```
  read_twf TW.in -skipconst -view view01
  ```

- The following command clears the previously read TWF file:

  ```
  read_twf -reset
  ```

Related Commands

- `write_timing_windows`

report_analysis_coverage

```
report_analysis_coverage
[-help]
[pin_port_list]
[-check_type check_type_list]
[-exclude_untested reason_list]
[-include_dyn_checks]
[-include_parallel_check_arcs]
[-include_when_cond]
[-max_paths{type integer}]
[-nworst <integer>]
[-retime {aocv | ssta | path_slew_propagation | aocv_path_slew_propagation}]
[-sort {pin | refpin | checktype | slack | reason}]
[-tcl_list]
[-unsorted]
[-verbose check_status_list]
[-view view_name]
[> <filename[.gz]>]
[>> <filename[.gz]>]
```

Provides information about the timing checks in the design. Valid check types are clock_gating_hold, clock_gating_pulse_width, clock_gating_setup, clock_period, clock_separation, external_delay, hold, no_change_hold, no_change_setup, path_delay, pulse_width, recovery, removal, setup, skew, and time_borrow. Valid status types are: met, untested, and violated.

For each type of timing check, the command reports the number of checks that meet constraints, violated constraints, or that are untested in the `SUMMARY` section. The `DETAILS` section includes information about the signal pin, reference pin, check type, slack, and the reason for being untested.

A `met` check shows as a positive value in the `Slack` column. A `violated` check shows as a negative value in the `Slack` column. An `untested` check shows as `UNTESTED` in the `Slack` column and the reason is given in the `Reason` column. The `Reason` column is blank when a `Slack` number is given because the check has been tested.

Note: If there are no timing checks in the design of the type specified by `-check_type`, the report shows "No timing checks found."

Use `check_timing` to look for missing constraints.

Parameters

{> | >>} *file_name*	When specified with >, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with >>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The *filename* parameter must be the last argument in the list. The *filename* and -tcl_list parameters are mutually exclusive; you cannot specify them together. **Note:** To write a compressed report, add the .gz extension to the file name. *Default:* Report is displayed on standard output without being saved.

`-check_type` *check_type_list*	Limits the report to the type of check(s) in the *check_type_list*. *Default*: All (all types of check(s) are reported) Valid check types are: • `setup`: Reports paths with setup timing checks. • `hold`: Reports paths with hold timing checks. • `pulse_width`: Reports paths with pulse width timing checks. • `clock_period`: Reports paths with clock period timing checks. • `clock_gating_setup`: Reports paths with clock gating setup timing checks. • `clock_gating_hold`: Reports paths with clock gating hold timing checks. • `clock_gating_pulse_width`: Reports paths with clock gating pulse width checks. • `recovery`: Reports paths with recovery timing checks. • `removal`: Reports paths with removal timing checks. • `clock_separation`: Reports paths with clock separation timing checks. • `skew`: Reports paths with skew checks. • `data_setup`: Reports paths with data to data setup checks. • `data_hold`: Reports paths with data to data hold checks.

`-exclude_untested` *reason_list*	Excludes from the report endpoints that are unconstrained due to a specific reason. Valid reasons are: • `const`: Constant reaching signal/reference pin of any timing check. • `false_path`: Path disabled due to `set_false_path`. • `no_endpoint_clock`: Missing clock at the reference pin of the timing check. • `no_startpoint_clock`: Missing clock at the signal pin of the timing check. This may happen if the clock signal does not reach the launching register. • `unknown`: None of the known reasons are identified for an untested path. • `user_disable`: Checks arc disable due to `set_disable_timing`.
`-include_dyn_checks`	Reports the dynamic checks (data_to_data, path_delay) on pins that are constrained by set_data_check, set_max_delay, or set_min_delay constraints. By default, these checks will not be reported and the command only reports the pins constrained by all library checks, set_output_delay or inferred clock gating checks. The dynamic checks, such as set_data_check or set_max_delay are not reported by default, when `-include_dyn_checks` parameter is not specified.
`-include_parallel_check_arcs`	Reports all the parallel check arcs that have been merged.
`-include_when_cond`	Reports the when condition of check arcs.
`-max_paths{type` *integer}*	Enumerates the specified number of worst paths in the design, regardless of the endpoint.

`-nworst` *integer*	Enumerates the specified number of paths for each endpoint.
`-retime {aocv | ssta | path_slew_propagation | aocv_path_slew_propagation}`	Reanalyzes the set of paths using the specified method.
pin_port_list	Limits the report to timing checks on specified pins or ports.

`-sort {pin | refpin | checktype | slack | reason}`	Sorts the checks by the specified method while reporting detailed information using the `-verbose` option. The `-sort` option does not change the order of the columns. The criteria by which sorting is attempted for the `slack`, `pin`, and `checktype` arguments is as follows: • When sorting by slack, if the slack values are the same, the software then attempts to sort the checks by pin name. If the pin names are the same, the software attempts to sort by timing check type. When you sort by `slack`, the slack value is reported in order of least negative to most negative (worst slack last). • When sorting by pin name, if the pin names are the same, the software then attempts to sort the checks by slack value. If the slack values are the same, the software attempts to sort by timing check type. • When sorting by timing check type, if the check types are the same, the software then attempts to sort by slack value. If the slack values are the same, the software attempts to sort by pin name. *Default*: By default, checks are sorted by slack value (`slack`). Improve usability of the report for debugging purposes by using the -verbose and -sort options as shown in these examples: `report_analysis_coverage -verbose untested -sort reason report_analysis_coverage -verbose violated -sort slack`

`-tcl_list`	Produces the report in Tcl list format instead of a tabular format. This is useful for integrating timing with custom Tcl functions, and also for customizing report generation. The `-tcl_list` and *`filename`* parameters are mutually exclusive; you cannot specify them together.
`-unsorted`	Reports unsorted slacks with untested end points at the end of the report.
`-verbose` *`check_status_list`*	Limits the detailed information to only the checks with the status specified. Valid status types are: `met`, `violated`, and `untested`. Reduce the number of lines in the `DETAILS` section and improve usability of the report by using the `-verbose` option to filter out the `met` checks as shown in this example: `report_analysis_coverage -verbose {violated untested}` **Note**: The `-verbose` parameter supports multi-threading.
`-view` *`view_name`*	Generates a timing check report for the specified analysis view only. You can specify this parameter only when the software is in multi-mode multi-corner analysis mode.

Examples

- The following command filters from the report all endpoints that are unconstrained because of the reason `const`:

```
> report_analysis_coverage -exclude_untested const -verbose untested
-------------------------------------------------------------
TIMING CHECK COVERAGE SUMMARY
-------------------------------------------------------------
Check Type             No. of     Met      Violated    Untested
                       Checks
-------------------------------------------------------------
Clock Gating Hold      1          0 (0%)    1 (100%)   0 (0%)
Clock Gating Setup     1          1 (100%)  0 (0%)     0 (0%)
ClockPeriod            28         24 (85%)  0 (0%)     4 (14%)
ExternalDelay (Early)  1          0 (0%)    0 (0%)     1 (100%)
ExternalDelay (Late)   1          0 (0%)    0 (0%)     1 (100%)
Hold                   13         8 (61%)   1 (7%)     4 (30%)
PulseWidth             28         24 (85%)  0 (0%)     4 (14%)
Setup                  13         8 (61%)  1 (7%)      4 (30%)
-------------------------------------------------------------

TIMING CHECK COVERAGE DETAILS
-----------------------------------------------------------
Pin     Reference Pin      Check Type      Slack            Reason
-----------------------------------------------------------
out1       -               ExternalDelay(Early)  UNTESTED    No data signal
out1       -               ExternalDelay(Late)   UNTESTED    No data signal
u99/CK ^   u99/CK ^        ClockPeriod           UNTESTED    No endpoint clock
u99/CK ^   u99/CK v        PulseWidth            UNTESTED    No endpoint clock

seg1/u9/D  seg1/u9/CK ^    Setup                 UNTESTED    No data signal
seg2/u9/D  seg2/u9/CK ^    Hold                  UNTESTED    No data signal
seg2/u9/D  seg2/u9/CK ^    Setup                 UNTESTED    No data signal
-------------------------------------------------------------------------------
```

When the software is in multi-mode multi-corner timing analysis mode, You can specify the -view

parameter to generate a timing check report for the specified analysis view only:

```
> report_analysis_coverage -view view1
-----------------------------------------------------
TIMING CHECK COVERAGE SUMMARY (Analysis View: view1)
-----------------------------------------------------------
Check Type          No. of     Met       Violated      Untested
                    Checks
-----------------------------------------------------------------

Clock Gating Hold     1         0 (0%)     1 (100%)     0 (0%)
Clock Gating Setup    1         1 (100%)   0 (0%)       0 (0%)
ClockPeriod           28        24 (85%)   0 (0%)       4 (14%)
ExternalDelay (Early) 1         0 (0%)     0 (0%)       1 (100%)
ExternalDelay (Late)  1         0 (0%)     0 (0%)       1 (100%)
Hold                  14        8 (57%)    1 (7%)       5 (35%)
PulseWidth            28       24 (85%)    0 (0%)       4 (14%)
Setup                 14        8 (57%)    1 (7%)       5 (35%)
-----------------------------------------------------------------
```

report_analysis_summary

```
report_analysis_summary
[-help]
[-csv string]
[-merged_views]
[-retime {path_slew_propagation | aocv_path_slew_propagation}]
[-retime_mode {exhaustive}]
[-view viewName]
[> <filename[.gz]>]
[>> <filename[.gz]>]
[-early | -late ]
[-expanded_summary_clocks | -merged_groups]
```

Generates timing slack summary reports for specified analysis view(s). This command categorizes the slack summary in terms of groups - In2reg, Reg2reg, Reg2Out, and In2Out. A column "ALL" is displayed that regroups in2reg, in2out, reg2reg, and reg2out details.

By default, the slack is categorized in terms of worst negative slack (WNS), total negative slack (TNS), and the total number of violations in group-based mode.

The `report_analysis_summary` command is supported in path-based analysis (PBA) mode.

Parameters

`-help`	Prints out the command usage.
{> | >>} *filename*	When specified with >, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with >>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. **Note:** To write a compressed report, add the .gzextension to the file name. *Default:* Report is displayed on standard output without being saved.
`-csv` *string*	Specifies the name of the CSV output file.
`-early`	Generates report for hold analysis mode for early paths.
`-expanded_summary_clocks`	Generates report in terms of each possible clock domain pair separately.
`-late`	Generates report for setup analysis mode for late paths.
`-merged_groups`	Merges all the clock groups for a consolidated timing summary.
`-merged_views`	Generates merged reports across all the views.
`-retime {path_slew_propagation | aocv_path_slew_propagation}`	Reanalyzes the defined set of paths using the specified method. By default, the timing report shows a maximum of 2 million paths for retime PBA analysis.
`-retime_mode {exhaustive}`	Reanalyzes the specified set of paths using the specified retime mode.
`-view` *viewName*	Generates report for the specified analysis views only. By default, all the active views are analyzed.

Example

- The `report_analysis_summary` command shows the following report output:

```
REPORT ANALYSIS SUMMARY (View:default_emulate_view) (EL:Setup)

Related Information

- set_default_view
- set_analysis_view

report_analysis_views

```
report_analysis_views
-help
[-type {all | setup | hold | active}]
```

Generates a hierarchical report of the current multi-mode multi-corner configuration. By default, the `report_analysis_views` command generates a report of all defined views in the design. Use the `-type` parameter to generate a report on a specific type of analysis view.

Use this command after creating analysis views (`create_analysis_view`), and setting active setup and hold views (`set_analysis_view`) for the design.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `report_analysis_views` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_analysis_views`.
`-type {all | setup | hold | active}`	Specifies the type of report to generate. *Default:* `all` • active: Generates a report of all active setup and hold views in the design. • all: Generates a report of all defined views in the design, including those that are currently inactive. • hold: Generates a report of all active hold views in the design. • setup: Generates a report of all active setup views in the design.

Examples

Examples

- The following command generates a hierarchical report of the active setup analysis views in the design:

  ```
  report_analysis_views -type setup
  ```

  The software reports the following results:

  ```
  Multi-Mode Analysis View Report

report_annotated_assertions

```
report_annotated_assertions
-type {load | transition}
[-list_annotated]
[-list_non_annotated]
[-view viewName]
[-max_lines number]
[-min | -max | -min_max]
object_list
[{> | >>} file_name]
```

Reports information for annotated assertions, set using the `set_load` or `set_annotated_transition` command, according to the specified assertion type. You can select load or transition reporting.

Note: The `report_annotated_assertions` command is now obsolete. This command will continue to be supported in the current release, but will be removed in the next major release of the software.

Parameters

`{> | >>} file_name`	Writes the report to the specified file name. When specified with >, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with >>, writes the report to the specified filename. If the file already exists, the software concatenates the report to the end of the file.
`-list_annotated`	Lists the detailed information for the specified assertion types.
`-list_non_annotated`	Lists information for non-annotated assertions.

`-min	-max	-min_max`	Specifies to report minimum, maximum, or both values of the specified assertion type. When input assertions are applied using both -min and -max parameters, you can specify the -min_max parameter to report both the assertion values. In this case, you do not need to specify this command twice, that is, separately with -min and -max parameters. *Default*: max
`-max_lines` *number*	Controls the number of output lines reported by `-list_annotated` or `-list_non_annotated` parameter. By default, the specified net, pin, or port names are reported.
object_list	Specifies the list of nets, pins, or ports to be reported.
`-type {load	transition}`	Specifies the assertion type, load or transition, to be reported.
`-view` *viewName*	Reports the annotations for the specified analysis view. In multi-mode multi-corner timing analysis mode, annotations are reported for the specified mode or corner.

Examples

- The following command reports all the load annotated assertions:
  ```
  report_annotated_assertions -type load -list_annotated -min_max
  ```

Related Information

- `set_load`
- `set_annotated_transition`

report_annotated_check

```
report_annotated_check
[-check_type check_type_list]
[-max_line number]
[instance_list]
[-list_annotated]
[-list_non_annotated]
[-view viewName]
[> | >> filename[.gz] | -tcl_list]
```

Reports coverage of annotated timing checks.

Parameters

`-check_type` *check_type_list*	Allows you to specify the check type. The valid check types are `setup`, `hold`, `pulse_width`, `clock_period`, `clock_gating_setup`, `clock_gating_hold`, `clock_gating_pulse_width`, `data_setup`, `data_hold`, `recovery`, `removal`, `clock_separation`, `no_change_setup`, `no_change_hold`, and `skew`.

`> filename`	When specified with `>`, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with `>>`, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The *`filename`* parameter must be the last argument in the list. The *`filename`* and `-tcl_list` parameters are mutually exclusive; you cannot specify them together. **Note:** To write a compressed report, add the `.gz` extension to the file name. *Default:* Report is displayed on standard output without being saved.
`instance_list`	Specifies instance names for which annotations of check arcs are to be reported.
`-list_annotated`	Lists the detailed annotation information for the following timing checks: • setup • hold • recovery • removal • pulse-width • nochange-setup • clock-period • skew **Note**: If the software is in multi-mode multi-corner timing analysis mode, you need to specify the `-view` parameter.

`-list_non_annotated`	Lists the timing checks that do not have annotated delay information. The software checks for the following timing checks: • setup • hold • recovery • removal • pulse-width • nochange-setup • clock-period • skew **Note**: If the software is in multi-mode multi-corner timing analysis mode, you need to specify the `-view` parameter.
`-max_line` *number*	Controls the number of output lines reported by the `-list_annotated` or `list_non_annotated` parameter.
`-tcl_list`	Produces the report in Tcl list format instead of a tabular format. This is useful for integrating timing with custom Tcl functions, and also for customizing report generation. The `-tcl_list` and *`filename`* parameters are mutually exclusive; you cannot specify them together.
`-view` *viewName*	Reports coverage of annotated timing checks for the specified analysis view. You can specify this parameter only when the software is in multi-mode multi-corner timing analysis mode. *Default:* Reports annotated timing checks for the default analysis view.

Examples

- The `report_annotated_check` command shows the following report output in simultaneous setup and hold analysis mode:

```
tempus> report_annotated_check

------------------------------------------------------------------

| Check arc type         | Total | Annotated | Not       |Percentage|
|                        |       |           | Annotated |Arcs      |
|                        |       |           |           |Annotated |

report_annotated_delay

```
report_annotated_delay
[-help]
[-ignore_tied_low_high_net_arcs]
[-list_annotated]
[-list_non_annotated]
[-view viewName]
[-max_line number]
[{> | >>} filename[.gz] | -tcl_list]
[pin_port_list]
```

Reports coverage of annotations on a design. These annotations include SDF delay arc annotations. Besides SDF annotations, the command also reports annotations that are set using the `set_annotated_delay` command.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `report_annotated_delay` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_annotated_delay`.

`>	>> filename`	When specified with >, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with >>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The *filename* parameter must be the last argument in the list. The *filename* and `-tcl_list` parameters are mutually exclusive; you cannot specify them together. **Note:** To write a compressed report, add the `.gz` extension to the file name. *Default:* Report is displayed on standard output without being saved.
`-ignore_tied_low_high_net_arcs`	Ignores timing arcs of power and ground nets.
`-list_annotated`	Lists detailed annotation information for the following annotated arcs: • annotated internal net arcs • annotated input port arcs • annotated output port arcs • annotated cell arcs
`-list_non_annotated`	Lists the arc information for the non-annotated arcs corresponding to the following types of arcs: • non-annotated internal net arcs • non-annotated input port arcs • non-annotated output port arcs • non-annotated cell arcs
`-max_line` *number*	Controls the number of output lines reported by `-list_annotated` or `-list_non_annotated` parameter.

`-tcl_list`	Produces the report in Tcl list format instead of a tabular format. This is useful for integrating timing with custom Tcl functions, and also for customizing report generation. The `-tcl_list` and *`filename`* parameters are mutually exclusive; you cannot specify them together.
`-view` *`viewName`*	Generates the report for the specified analysis view only. You can specify this parameter only when the software is in multi-mode multi-corner timing analysis mode.

Examples

If your SDF has only cell arcs, and net delays are included in the cell delays, you can report the status of annotation for cell arcs, internal net arcs, net arcs from primary inputs, and net arcs to primary outputs, and all timing arcs separately. The following report is generated for `report_annotated_delay` for delay arcs types:

```
report_annotated_delay
------------------------------------------------------------
Delay Arc Type     Total    Annotated    Not Annotated    Percentage Annotated
------------------------------------------------------------------------------
Cell arcs          128      0            128              0.000000
Input net arcs     14       0            14               0.000000
Internal net arcs  107      0            107              0.000000
Output net arcs    7        0            7                0.000000
------------------------------------------------------------------
All timing arcs    256      0            256              0.000000
------------------------------------------------------------------
```

Related Information

- `set_annotated_delay`

report_annotated_parasitics

```
report_annotated_parasitics
[-help]
[-net_file string]
[-nets string]
[-view {viewName}]
[> {write_fileName}]
[>> {append_fileName}]
[{[-list_annotated]
[-list_broken_net]
[-list_extra_pin_net]
[-list_float_net]
[-list_nodriver_net]
[-list_noload_net]
[-list_not_annotated]
[-list_real_net]
[-list_supply_net]
[-list_zero_cap_net]
[-max_missing {max_missing_int}]}]
```

Reports the back-annotated parasitics of the design. By default only summary report is generated. The software groups all the nets by net-types and annotation-status (annotated or not-annotated).

Parameters

`-help`	Outputs a brief description that includes type and default information for the `report_annotated_parasitics` parameters. For a detailed description of the command and all of its parameters, use the `man` command: `man report_annotated_parasitics`.
`>> {append_fileName}`	Appends the report to the specified file name.
`-list_annotated`	Generates a list of annotated nets.
`-list_broken_net`	Reports broken nets in the design.

`-list_extra_pin_net`	Generates a list of nets that have extra pins in the SPEF but not in the Verilog.
`-list_float_net`	Generates a list of floating nets.
`-list_nodriver_net`	Lists all the terminal nets that have no driver.
`-list_noload_net`	Lists all the terminal nets that have no load.
`-list_not_annotated`	Generates a list of not annotated nets.
`-list_real_net`	Lists all real nets.
`-list_supply_net`	Lists all supply nets.
`-list_zero_cap_net`	Generates a list of zero capacitance nets.
`-max_missing {max_missing_int}`	Limits the number of missing annotations to the specified number of annotations. *Default*: 1000
`-net_file` *string*	Accepts a file name, which contains a list of net names, as input. When this parameter is specified, the parasitic annotation summary is provided only for the listed nets. The net names in the file can be specified as one net per line.
`-nets` *string*	Specifies the list of net names for which annotation summary is required.
`-view` *viewname*	Reports the back-annotated parasitics for the specified analysis view. You can specify this parameter only when the software is in multi-mode multi-corner timing analysis mode. *Default*: Reports against the default analysis view
`> {write_fileName}`	Writes the report to the specified file name.

Examples

- The following command generates a list of annotated and not-annotated nets:

```
report_annotated_parasitics -list_annotated -list_not_annotated -list_real_net -
list_float_net -list_nodriver_net \ + -list_noload_net -list_supply_net -max_missing
```

```

report_annotations

```
report_annotations
[-missing_resistances]
[-missing_capacitances]
[-missing_rc]
[-missing_delays]
[-missing_spf]
[-max_missing integer ]
[-tcl_list]
[-ignore_floating_nets]
[-ignore_tied_low_high_nets]
[-ignore_tied_low_high_net_arcs]
[-list_annotated]
[-list_non_annotated]
[-view viewName ]
[> filename ]
```

Reports the coverage of the annotations on a design. These annotations include SDF delay arc annotations, SPF annotations, wire resistances, and wire capacitances.

Use the `-missing_*` options to get a detailed report of all delay arcs and wires that are missing annotations. You can use the information in a Tcl program.

Note: The `report_annotations` command reports only the first 1000 nets, which is the default value of the `-max_missing` option. Set this option to a higher value if needed, for example: `report_annotations -max_missing 1000000`.

Command `report_annotations` is obsolete. Use `report_annotated_parasitics` for RC annotation report and `report_annotated_delay` for delay arc annotation instead.

Parameters

`> filename`	Writes the report to the specified file name. If the file already exists, the software overwrites it. The *filename* parameter must be the last argument in the list. The *filename* and `-tcl_list` parameters are mutually exclusive; you cannot specify them together. **Note:** To write a compressed report, add the `.gz` extension to the file name. *Default:* Report is displayed on standard output without being saved.
`-ignore_floating_nets`	
	Ignores nets without drivers, power, and ground nets.
`-ignore_tied_low_high_net_arcs`	Ignores timing arcs of power and ground nets.
`-ignore_tied_low_high_nets`	Ignores nets connected to `tied_low` and `tied_high` cells.
`-list_annotated`	Lists detailed annotation information for the following annotated arcs: • annotated internal net arcs • annotated input port arcs • annotated output port arcs • annotated cell arcs

`-list_non_annotated`	Lists the arc information for the non-annotated arcs corresponding to the following types of arcs: • annotated internal net arcs • annotated input port arcs • annotated output port arcs • annotated cell arcs
`-max_missing` *integer*	Limits the number of missing annotations to the number specified. *Default*: 1000
`-missing_capacitances`	Reports the nets that are missing capacitances. *Default*: Only a summary of the coverage is reported.
`-missing_delays`	Reports the arcs that are missing SDF annotations. *Default*: Only a summary of the coverage is reported.
`-missing_rc`	Reports the nets that are missing resistances and capacitances. *Default*: Only a summary of the coverage is reported.
`-missing_resistances`	Reports the nets that are missing resistances. *Default*: Only a summary of the coverage is reported.
`-missing_spf`	Reports the nets that are missing SPF data. *Default*: Only a summary of the coverage is reported.

`-tcl_list`	Produces the report in Tcl list format instead of a tabular format. This is useful for integrating timing with custom Tcl functions, and also for customizing report generation. The `-tcl_list` and *`filename`* parameters are mutually exclusive; you cannot specify them together. See report_net for an example of the `-tcl_list` output.
`-view` *viewName*	Reports the coverage of annotations for the specified analysis view. You can specify this parameter only when the software is in multi-mode multi-corner timing analysis mode. *Default:* Reports against the default analysis view.

Examples

- The following command reports the nets that are missing capacitances: report_annotations -missing_capacitances
  Default: Only a summary of the coverage is reported.
- The following commands show the difference between the summary and the `-missing_spf` reports:

report_annotations Summary Report

```
+-------------------------------------------------------------------------------+
| Total |  Total C  | Percentage |  Total R  | Percentage | Total SPF | Percentage |
|  Nets | Annotated|     C      | Annotated |     R      | Annotated |    SPF     |
|       |          | Annotated  |           | Annotated  |           | Annotated  |
|-------+----------+------------+-----------+------------+-----------+------------|

report_aocv_derate

```
report_aocv_derate
[-help]
[-check_global_derating]
[-clock]
[-data]
-file <string>
[-list_cell_not_annotated]
[-mesh]
[-voltage <float>]
[-design | -cell <string> ]
[{-delay_corner <string> [-power_domain <string>] } | -max | -min ]
[-early | -late]
[-rise | -fall]
```

Reports the AOCV derating tables from AOCV libraries. The command generates the output report in AOCV library format.

Parameters

`-help`	Prints out command usage.
`-cell` *string*	Reports the table for the specified library cell name. You can specify a regular expression corresponding to library cell names.
`-check_global_derating`	Reports the list of cells for which derating table or global derating table was not specified.
`-clock`	Reports derate tables read for clock paths.
`-delay_corner` *string*	Reports the derating tables from the specified delay corner. For a MMMC design, if a delay corner specific table is read using the `create_library_set -aocv` command, that derating table is reported. Otherwise the default table is reported. For a non-MMMC design, no details are reported. The `-delay_corner` and `-min`/`-max` parameters are mutually exclusive.
`-data`	Reports derate tables read for data paths.
`-design`	Reports the default cell or net derating tables.
`-early` | `-late`	Reports the early/late derating table.
`-file` *string*	Reports all the derating tables. This parameter is mandatory.
`-list_cell_not_annotated`	Reports the list of cells for which derating table is not specified. This parameter reports an error when specified with `-voltage`, `-design`, or `-cell` parameters.
`-max`	Reports derate tables from max AOCV libraries.
`-mesh`	Reports derate tables read for mesh.
`-min`	Reports derate tables from min AOCV libraries.

`-power_domain` *string*	Reports derate tables from the specified power domain. This option should always be specified with delay corner.
`-rise` | `-fall`	Reports the rise/fall table for specified transition.
`-voltage` *float*	Reports derating tables for the specified voltage value.

Examples

Here are some examples.

- The following command reports derating tables for the specified cells:

```
report_aocv_derate -cell "BUF" -delay_corner default_emulate_delay_corner -file
report.lib

report_case_analysis

```
report_case_analysis
[-all]
[-nosplit]
[-dir]
[-view view_name]
[-propagated]
[-verbose]
[pins_and_ports_list]
[{> | >>} filename | -tcl_list]
```

Generates a User Case Analysis table, which reports ports and pin that have a set_case_analysis constraint. These ports and pins are constant only for timing analysis. You can optionally generate a Logic Constant Value table, which reports ports and pins whose constant status is part of the design. Information from this table includes ports or pins with `set_logic` constraints (`set_logic_zero` and `set_logic_one`), netlist explicit constants, and output pins with constant output functions.

Parameters

`{> | >>} filename`	When specified with `>`, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with `>>`, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The *`filename`* parameter must be the last argument in the list. The *`filename`* and `-tcl_list` parameters are mutually exclusive; you cannot specify them together. **Note:** To write a compressed report, add the `.gz` extension to the file name. *Default:* Report is displayed on standard output without being saved.

`-all`	Specifies that the Logic Constant Value table report pins or ports with `set_logic` constants, constants in the netlist, and output pins with a constant function. These output pins are from library cells or netlist modules.
`-nosplit`	Specifies that reports with long names will not be split into multiple lines. **Note:** The `-nosplit` parameter works if `set_table_style -no_frame_fix_width` command is specified.
`-dir`	Specifies that the report include the direction of the pin or port, which is reported as input, output, or inout (internal pins may not have constant constraints).
`pins_and_ports_list`	Generates a report only for the pins and ports in the specified list. *Default:* Generates a report for all pins and ports in the design.
`-propagated`	Generates a report that includes all constant pins, including pins with propagated constants. When specified, the report column header for constant values changes to `Constant value`. *Default:* Generates a report that includes only pins with a `set_case_analysis` constraint. (The column header for the constant values is labeled as `User case analysis value`.)
`-tcl_list`	Produces the report in Tcl list format instead of a tabular format. This is useful for integrating timing with custom Tcl functions, and also for customizing report generation. The `-tcl_list` and *`filename`* parameters are mutually exclusive; you cannot specify them together.

`-verbose`	Generates a report in which each pin is listed on a separate line with a cause. If the pin is a propagated constant, a table is included that reports a chain of constants from an original cause to the reported pin. *Default:* All pins are reported in a table.
`-view` *view_name*	Generates a User Case Analysis table for the specified analysis view only. To specify this parameter, the software must be in multi-mode multi-corner (MMMC) analysis mode. *Default:* When in MMMC analysis mode, generates a table for all active analysis views

Examples

- The following command uses the `-dir` option, which shows that 1 is on the input part of the `timing_const_on_Z/Z` pin:

  ```
  report_case_analysis -dir
  ```

  The following report is generated:

  ```
  ------------------------------------------------
  Pin name        Dir               User case
                                   Analysis value
  ------------------------------------------------
  gscanmode       input             0
  gscanenable     input             0
  ------------------------------------------------
  ```

- The following command generates a report that includes all constant pins, including pins with propagated constants. When specified, the report column header for constant values changes to `Constant value`.

  ```
  report_case_analysis -propagated
  ```

  The following report is generated:

  ```
  ----------------------------------------
  Pin name                  Constant value
  ```

```
-----------------------------------------
clockandlatch/U8/TE         0
clockandlatch_dup1/U8/TE    1
clockandlatch_dup2/U8/TE    1
clockandlatch_dup3/U8/TE    0
-----------------------------------------
```

- The following command generates a report in which each pin is listed on a separate line. The report includes all constant pins, including pins with propagated constants. The pin `clockandlatch_dup3/U8/TE` is reported because of a `set_case_analysis 0` assertion on pin `gscanenable`.

  ```
  report_case_analysis -propagated -verbose clockandlatch_dup3/U8/TE
  ```

  The following report is generated:

  ```
  -----------------------------------------------
  Pin name                       Constant value
  -----------------------------------------------
  gscanenable                   0
  FE_OFC306_gscanenable/I       0
  FE_OFC306_gscanenable/ZN      1
  FE_OFC307_gscanenable/I       1
  FE_OFC307_gscanenable/ZN      0
  FE_OFC315_gscanenable/I       0
  FE_OFC315_gscanenable/Z       0
  coreclockandlatch_dup3/U8/TE  0
  -----------------------------------------------
  ```

- The following report shows that there are no `set_case_analysis` constraints but there are logical constraints:

  ```
  report_case_analysis -propagated -verbose core_q_reg_1_/SI
  ```

  ```
  -------------------------------------------
  Pin name              Logic constant value
  -------------------------------------------
  ram256x10/TEST1       0
  ram1024x32/TEST1      0
  core_q_reg_2_/SI      1
  core_q_reg_11_/SI     0
  core_q_reg_1_/SI      1
  -------------------------------------------
  ```

Related Commands

- set_case_analysis

report_cell_instance_timing

```
report_cell_instance_timing
[-help]
list_of_cell_instances
[-early | -late]
[-clock_timing]
[-tcl_list]
[-view view_name]
[{> | >>} filename]
```

Reports the following information about the timing context for all the pin and delay arcs of the specified instances:

- Arrival time
- Required time
- Slack
- Delays

Note: Internal pins (pins inside the instance boundary) are also reported.

This command uses the results of earlier timing analysis runs; therefore, you must run the `report_timing` command before using `report_cell_instance_timing`.

To analyze the setup (maximum) paths, you must use the `setAnalysisMode -checkType setup` command and run the `report_timing` command before using the `-late` parameter. Similarly, to analyze the hold (minimum) paths, you must use the `setAnalysisMode -checkType hold` command and run the `report_timing` command before using the `-early` parameter.

The `report_cell_instance_timing` timing report contains the following tables:

- The first table in the report contains information about the pins of the instance.
  The propagated slew is the slew that is propagated to the pin, based on the slew propagation mode.
- The second table contains information about the arcs through the instance.
  The slew out is the slew calculated at the arc output from the arc input slew, using the timing model.
- The third table, generated for sequential devices, contains information about the timing checks, if present, on the cell.
  Only checks that are from the library are shown in this table. Automatic checks, such as clock gating setup and hold, are not reported.

The *Phase* column of each table can contain the following symbols:

- `D` indicates it is a data signal in the clock domain.
- `C` indicates it is a clock signal in the clock domain.
- `P` indicates it is a positive phase.
- `N` indicates it is a negative phase.
- `L` indicates it is a latency phase.
- Asterisk (`*`) indicates there is a timing exception associated with the signal.

  Note: Currently, it is not possible to expand the asterisk to determine which exception is associated with the reported timing phase.

When the software is in multi-mode multi-corner timing analysis mode, the timing context information is reported for each active analysis view, with the view name listed in the *Phase* column.

Parameters

`-help`	Prints out the command usage.
`{> | >>} filename`	When specified with `>`, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with `>>`, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The *`filename`* parameter must be the last argument in the list. The *`filename`* and `-tcl_list` parameters are mutually exclusive; you cannot specify them together. **Note:** To write a compressed report, add the `.gz` extension to the file name. *Default:* Report is displayed on standard output without being saved.
`-clock_timing`	Specifies to report slack for clock style checks.

`-early	-late`	Reports the information for early (maximum) path (data hold/clock setup) or late (minimum) path (data setup/clock hold). You must use the `setAnalysisMode -checkType hold` command and run the `report_timing` command before using the `-early` parameter. Similarly, you must use the `setAnalysisMode-checkType setup` command and run the `report_timing` command before using the `-late` parameter. *Default*: If you do not specify any of the parameters, the software uses the `-late` parameter.
list_of_cell_instances	Specifies a flat (non-hierarchical) cell instance or list of cell instances. Use curly braces (`{}`) to enclose the list and separate the instance names with white space.
`-tcl_list`	Produces the report in Tcl list format instead of a tabular format. This is useful for integrating timing with custom Tcl functions, and also for customizing report generation. The `-tcl_list` and *`filename`* parameters are mutually exclusive; you cannot specify them together.
`-view` *view_name*	Specifies the analysis view in which to query the object attribute.

Examples

- The following example reports information about the timing context of instance `seg1/u9`:

  Example: report_cell_instance_timing seg1/u9

```
------------------------------------------------------------------------
                  Instance seg3/u14 of DFF
------------------------------------------------------------------------

Related Information

- report_net
- report_timing

report_clock_gating_check

```
report_clock_gating_check
[object_list]
[-view view_name]
[{> | >>} file_name]
```

Reports information of all or specific clock gating checks of the current design. If you specify a list of pins, cells, or clocks, the clock gating check information is reported for the specified objects only. If you use the `report_clock_gating_check` command without an object list, all clock gating check information is reported.

The `Type` column of the generated report (see examples below) can contain one of the following abbreviations:

- `I` indicates that the clock gating check is inferred.
- `L` indicates that the clock gating check is from the library (integrated clock gating check).

Set the `report_precision` global variable using the `set_global` command to specify the accuracy of the result in terms of number of significant digits.

Parameters

object_list	Specifies a list of pins, instances, or clocks. A collection of these can also be specified. • Pin: Any pin of a clock gating cell can be specified and the check information will be reported for that pin. • Instance: Any instance name of a clock gating cell can be specified and the check information will be reported for that instance. • Clock: Only a clock at a given clock (reference) pin of a cell can be specified for reporting the check information. Check information about the clocks at enable (signal) pin cannot be reported. If the *object_list* parameter is not specified, all the clock gating check points (inferred and library) of the current design are reported.
-view *view_name*	Specifies a view for which clock gating check is to be reported. The default is worst of all the views.
{> | >>} *filename*	When specified with >, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with >>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file.

Examples

The following command returns a clock gating check report for the current design:

```
report_clock_gating_check

The clock gating check report returned by this command is as follows:

+--------------------------------------------------------------------------+
```

```
|                              Clock Gating Check Report                  |
|-------------------------------------------------------------------------|
| Instance | Enable | Clock | Type | Level | Setup | Setup | Hold | Hold |
|          |        |       |      |       | Rise  | Fall  | Rise | Fall |
|----------+--------+-------+------+-------+-------+-------+------+----|
|    i1    |    A   |   B   |   I  |   L   | 0.000 | 0.000 |   -  |  -   |
|    i2    |    B   |   A   |   I  |   H   | 0.000 | 0.000 |   -  |  -   |
|   icg    |  CEN   |  CLK  |   L  |   H   | 0.149 | 0.181 |   -  |  -   |
+-------------------------------------------------------------------------+
```

Related Information

- report_precision
- set_global

report_clock_propagation

```
report_clock_propagation
[-help]
-clock clock_list
[-max_paths number of paths]
-to pin_port_list
[-verbose]
[-view viewName]
[> filename[.gz]]
[>> filename[.gz]]
```

This command provides the ability to determine clocks that do not propagate to a particular node in the network, and report the causes for such occurrences.

Parameters

`-help`	Prints out the command usage
`-clock clock_list`	List or collection of clocks that are to be checked.
`-max_paths number of paths`	Reports number of maximum clock paths per clock.
`-to pin_port_list`	Specifies the pin/port list.
`-verbose`	Generates a verbose report for clock propagation stop reason.
`-view viewName`	Generates a report for the specified analysis view.
`> filename[.gz] | >> filename[.gz]`	When specified with >, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with >>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. **Note**: To write a compressed report, add the .gz extension to the file name.

Examples

- The following command shows that clock propagation stops due to an inactive timing arc from b12/A to b12/Y

```
set_disable_timing -from A -to Y b12
report_clock_propagation -to u99/CK -clock CLK_W_4

Clock: CLK_W_4
Point: u99/CK
Reason 1: The clock 'CLK_W_4' propagation stops due to the inactive timing arc:
(b12/A->b12/Y)

The partial clock path:

-------------------------------------------------
Source    Sink      ArcType         ArcSense
-------------------------------------------------
CLK4     b11/A   (net)           (net)
b11/A    b11/Y   combinational   positive_unate
b11/Y    b12/A   (net)           (net)
b12/A    b12/Y   combinational   positive_unate
-------------------------------------------------
```

- The following command shows that clock propagation stops due to no clock source found:

```
report_clock_propagation -to launchff/Q -clock [get_clocks gen_clk]
report_clock_propagation -to seg3/u15/Q -clock CLK_W_5_gen

Clock: CLK_W_5_gen
Point: seg3/u15/Q
Reason 1: The generated clock ‘CLK_W_5_gen could not be created on its root pin
‘seg3/u15/Q’ because no clock source found for it
```

- The following command shows that clock propagation stops at the register clock pin as all the arcs from the clock pin of the register have been disabled:

```
set_disable_timing -from A -to Y seg3/u17_a
report_clock_propagation -to seg3/u14/CK -clock CLK_W_3

Clock: CLK_W_3
Point: seg3/u14/CK
Reason 1: The clock 'CLK_W_3' propagation stops due to the inactive timing arc:
(seg3/u17_a/A->seg3/u17_a/Y)
```

```
The partial clock path:
-------------------------------------------------------------
Source          Sink          ArcType         ArcSense
-------------------------------------------------------------
CLK3           seg3/u16/A     (net)           (net)
seg3/u16/A     seg3/u16/Y     combinational   positive_unate
seg3/u16/Y     seg3/u17/A     (net)           (net)
seg3/u17/A     seg3/u17/Y     combinational   positive_unate
seg3/u17/Y     seg3/u17_a/A   (net)           (net)
seg3/u17_a/A   seg3/u17_a/Y   combinational   positive_unate
-------------------------------------------------------------
```

```

Generates a clock analysis report for the current design. The software generates a separate report for each specified clock or pair of clocks. You specify the clocks using the `-clock` parameter, and clock pairs using the `-from_clock` and `-to_clock` parameters. You can use the `-nworst` and `-greater_than` parameters with the `-from_clock` and `-to_clock` parameters to generate reports with skew to the specified sink pins. You can use the `-early` and `-late` parameters to specify the type of skew to be reported.

Note: To remove common path pessimism from the reported skew, use the `setAnalysisMode -cppr both` command before using the `report_clock_timing` command. The report contains a separate column for common path adjustment values.

You can use the `report_clock_timing` command to perform MMMC based SSTA analysis. In MMMC mode, the command reports the latency and clock skew for all individual views. You can use the `report_clock_timing -view` parameter to report clock timing for a user-specified view.

Parameters

{> | >>} *filename*	When specified with >, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with >>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The *filename* parameter must be the last argument in the list. The *filename* and -tcl_list parameters are mutually exclusive; you cannot specify them together. **Note:** To write a compressed report, add the .gz extension to the file name. *Default:* Report is displayed on standard output without being saved.
-absolute_compare	Reports skews with values compared in absolute form.
-clock *clock_list*	Specifies the list of clocks to be reported.
-cppr_relative	Reports the latency in skew reports from the CPPR common pin. When specified, the reports are printed with latency measured from branch point to the register's CK pin. The CPPR value is no longer required in reports.
-early	Uses hold skew to generate the report. Hold skew is the difference between minimum latency at the start point flip-flop and the maximum latency at the end point flip-flop. Default: Uses the setup skew.

`-format` *column_list*	Specifies which columns to display for path reports, and the order in which they should appear. For example: `-format {instance arc pin cell slew load}` The `-format` parameter can be used only for latency or skew reports (`-type skew`, `-type interclock_skew`, or `-type latency`), and if the `-verbose` parameter is specified.
`-from` *from_list*	Specifies the list of sequential device clock pins or ports to consider as from-pins in the generated report. If any pin in the *from_list* is not a sequential device clock pin, it is replaced with all the sequential device clock pins in the transitive fanout of the named pin. If there are no sequential pins in the transitive fanout of the pin, the software drops the pin from the list and generates a warning message.
`-from_clock` *from_clock_list*	Specifies the list of from-clocks to be used in generating the current interclock skew report. You can use this option only in an interclock skew report. *Default:* Report is generated considering all clocks as from-clocks.
`-greater_than` *lower_limit*	Reports skews with values greater than the lower_limit value.

`-histogram`	Generates a textual histogram of the latency report. The `-histogram` parameter can be used only when `-type latency` is specified. When specified in conjunction with the `-clock` parameter, the software limits the latency reporting to the specified clocks only. When specified with the `-greater_than` parameter, the software limits the latency reporting to clocks with a latency value that is greater than the specified value. **Note:** The `-histogram` parameter cannot be specified in conjunction with the following parameters: `-launch`,`-capture`, `-from`, `-to`, `-from_clock`, `-to_clock`, `-verbose`, `-nworst`.
`-histogram_range` *`interval_size`*	Generates the histogram report at the specified intervals. The interval size specified must be a positive integer or decimal values. For example, if the maximum latency value is 437, and you specify `-histogram_range 50`, the histogram would be generated with intervals of: 0-50, 50-100, 100-150, ... 400-450. **Note:** The unit of *`interval_size`* will be the same as that used for generating the timing report. This parameter can be used only when the `-histogram` parameter is specified.
`-late`	Uses setup skew to generate the report. Setup skew is the difference between the maximum latency at the start point flip-flop and minimum latency at the end point flip-flop.
`-latency_greater_than <`*`lower_limit`*`>`	Reports are filtered based on the specified -type option. When specified with: • `-type skew` or `interclock_skew`: Reports are filtered for latency greater than the provided value or depth. • `-type cppr_stage_count`: Reports are filtered for depth greater than the provided value.

`-launch	-capture`	When specified with `-type latency`, generates a report of either the launch latency values (`-launch`), or the capture latency values (`-capture`). **Note:** You can specify these parameters only with `-type latency`. *Default*: `-launch`
`-logic_level`	Reports the levels (the stage count of gates) between the clock root, or generated clock root, and the capturing register. The `-logic_level` parameter can be used only when `-type latency` is specified. The `-logic_level` parameter cannot be specified in conjunction with the following parameters: `-launch`,`-capture`, `-from`, `-to`, `-from_clock`, `-to_clock`, `-verbose`, `-nworst`.
`-nworst` *worst_entries*	Specifies the number of entries to be reported per clock domain. *Default:* `1`
`-rise	-fall`	Specifies active transition at sequential devices clock pins. The `-rise` and `-fall` parameters are mutually exclusive and cannot be specified together. **Note:** You can specify these parameters only with the `-type latency` parameter.

`-source {clock_root | generated_clock}`	Reports the latency from either the master clock, or the generated clock that was derived from it. The `-source` parameter can be used only when `-logic_level` is specified. The `-source` parameter cannot be specified in conjunction with the following parameters: `-launch`,`-capture`, `-from`, `-to`, `-from_clock`, `-to_clock`, `-verbose`, `-nworst`. *Default:* Reports the latency from the master clock (`-source clock_root`)
`-tcl_list`	Produces the report in Tcl list format instead of a tabular format. This is useful for integrating timing with custom Tcl functions, and also for customizing report generation. The `-tcl_list` and *`filename`* parameters are mutually exclusive; you cannot specify them together.
`-to` *`to_list`*	Specifies the list or collection of sequential device clock pins or ports to be considered for reporting. If any pin in the *`to_list`* is not a sequential device clock pin, it is replaced with all the sequential device clock pins in the transitive fanout of the named pin. If there are no sequential pins in the transitive fanout of the pin, the software drops the pin from the list and generates a warning message.
`-to_clock` *`to_clock_list`*	Specifies the list of to-clocks to be used in generating the current interclock skew report. You can use this option only in an interclock skew report. *Default:* Report is generated considering all clocks as to-clocks.
`-type {skew interclock_skew jitter summary latency cppr_stage_count}`	Specifies the type of report to generate. The `-type` options are described below: • `skew`: Reports the skew for all clocks, or for clocks that you specify using the -clock

parameter.

- `interclock_skew`: Reports the skew between all clocks in the design, or between clocks that you specify using the `-from_clock` and `-to_clock` parameters.
- `jitter`: Reports the difference in late and early arrival times of a clock phase at a clock end point. When specified, the software generates a clock jitter report for one clock end point, for each clock in the design.
  You can generate a jitter report for all clocks, or for clocks specified with the `-clock` parameter. You can limit the report to a specific clock end point using the `-to` parameter.
  Note: The `report_clock_timing -type jitter` option can be used only when the software is in On-Chip Variation (OCV) timing analysis mode. Jitter analysis does not remove any common path pessimism.
- `summary`: Generates a summary report for each analyzed clock that includes the following information:
  - When setup skew is used (`-late`):
    - maximum launch latency
    - minimum capture latency
    - maximum setup skew
  - When hold skew is used (`-early`):
    - minimum launch latency
    - maximum capture latency
    - maximum hold skew
- `latency`: Reports the network and source latency values for all the clock pins in the

	design, or for clock pins that you specify using the `-clock` parameter.
	• `cppr_stage_count`: The generated report is arranged in terms of difference of stages from common pin to CK pin. The reports are generated on the basis of logical CPPR points derived between each pair of phases reaching the launch/capture CK pins. Only same clock pairs (similar to type skew) are picked. For example,
	`Branch Point Difference Depth Clock Pin`
	`----------------------------------------`
	`-`
	`inv2/Y`
	`5 r ff2/CK`

`-verbose`	Generates a report that contains the full clock path from the clock source to the sink pin (the clock pin of the flop or latch). You can specify the `-verbose` parameter only for skew or latency reports (`-type skew`, `-type interclock_skew`, or `-type latency`). When this parameter is specified in SOCV mode, the intermediate arrival times of pins are shown as "-" in the report output.
`-view` *view_name*	Generates a report for the specified analysis view only. You can specify this parameter only when the software is in multi-mode multi-corner timing analysis mode.

Examples

- The following command reports worst case skew for all clocks in a design:

```
report_clock_timing -type skew -nworst 4

  Clock: CLK_W_4
  Skew    Latency   Clock Pin
  ---------------------------
```

```
        0.150 r   u99/CK
0.000   0.150 r   u55/CK

Clock: CLK_W_3
Skew   Latency   Clock Pin
-----------------------------
        0.682 r seg3/u9/CK
0.061   0.621 r seg3/u14/CK

Clock: CLK_W_2
Skew    Latency Clock Pin
-----------------------------
        0.682 r seg2/u9/CK
0.061   0.621 r seg2/u14/CK

Clock: CLK_W_1
Skew    Latency Clock Pin
------------------------------
        0.682 r seg1/u9/CK
0.061   0.621 r seg1/u14/CK
```

Here 'r' indicates the transition (r - rise, f - fall) at the reported register clock pin.

- The following command reports interclock skew with -from_clock, -to_clock, -from, and -to parameters defined:

```
report_clock_timing -type interclock_skew -nworst 10 -from CLK4 -to u5/CK -from_clock
CLK_W_4 -to_clock CLK_W_4_gen2

  Clocks: CLK_W_4 -> CLK_W_4_gen2
  Skew       Latency Clock Pin
  -----------------------------
                     CLK4
             0.180 r u99/CK
                     u2/Q
                     u8/Q
  -0.205    0.386 ri u5/CK
```

Here 'r' indicates the transition (r - rise, f - fall) at the reported register clock pin. The 'i' refers to the 'inverted' polarity of the clock signal at the reported register clock pin.

- The following command reports skew for all clocks in the design including common path pessimism removal:

```
set_analysis_mode -cppr both
report_clock_timing -type skew -nworst 10

  Clock: CLK_W_4
```

```
Skew    Latency    CPPR    Clock Pin
-----------------------------------------
        0.180              r u99/CK
0.000   0.120       -0.060 r u55/CK

Clock: CLK_W_3
Skew     Latency  CPPR    Clock Pin
-----------------------------------------
         0.818            r seg3/u9/CK
0.139    0.496 -0.183     r seg3/u14/CK

Clock: CLK_W_2
Skew    Latency  CPPR     Clock Pin
-----------------------------------------
        0.818             r seg2/u9/CK
0.139   0.496    -0.183   r seg2/u14/CK

Clock: CLK_W_1
Skew     Latency   CPPR     Clock Pin
-----------------------------------------
         0.818              r seg1/u9/CK
0.139    0.496    -0.183    r seg1/u14/CK
```

- The following command generates a summary report for the clock:

```
report_clock_timing -type summary -nworst 10 -clock CLK_W_1

Clock: CLK_W_1
                  Skew    Latency    Clock Pin
-----------------------------------------------
Maximum launch latency:   0.818 r    seg1/u9/CK
Minimum capture latency:  0.000 r    u2/CK
Maximum skew:             0.818 r    seg1/u9/CK
                  0.322   0.496 r    seg1/u14/CK
-----------------------------------------------
```

- The following command reports the Network and source latency values for the clock CLK_W_1:

```
report_clock_timing -type latency -nworst 10 -clock CLK_W_1

Clock: CLK_W_1
---Latency---
Source  Network  Total   Clock Pin
-----------------------------------------
0.000   0.818    0.818   r seg1/u9/CK
0.000   0.000    0.000   r u2/CK
-----------------------------------------
```

- The following command reports the Network and source latency values for the clock GCLK1, as well as the full clock paths:

```
report_clock_timing -type latency -verbose -clock CLK_W_1
```

```
  Clock: CLK_W_1
  ---Latency---
  Source Network Total Clock Pin
  ----------------------------------------
  0.000 0.818 0.818 r seg1/u9/CK

  Clock latency Path
  Clock Rise Edge 0.000
  = Beginpoint Arrival Time 0.000
  Other End Path:
  ----------------------------------------
  Instance       Arc      Cell     Delay   Clock
  Latency
  ------------------------------------------------
  -            CLK1 ^       -      -       0.000
  seg1/u16     A ^ -> Y ^  CLKBUF   0.111  0.111
  seg1/u17     A ^ -> Y ^  CLKBUF   0.126  0.236
  seg1/u17_a   A ^ -> Y ^  CLKBUF   0.107  0.343
  seg1/and1    B ^ -> Y ^  AND      0.071  0.818
  seg1/u9      CK ^        DFF      0.000  0.818
  ------------------------------------------------
```

- When the software is in multi-mode multi-corner timing analysis mode, the software generates a report for every active analysis view in the design:

```
report_clock_timing -type latency
```

```
  Clock: EJ_TCK
  Analysis View: hold_view1
  ---Latency---
  Source Network Total Clock Pin
  ----------------------------------------
  0.000 0.000 0.000 r cregister_q_reg_3_/CP

  Clock: EJ_TCK
  Analysis View: hold_view2
  ---Latency---
  Source Network Total Clock Pin
  ----------------------------------------
  0.000 0.000 0.000 r cregister_q_reg_3_/CP
```

```
  Clock: EJ_TCK
  Analysis View: setup_view1
  ---Latency---
  Source Network Total Clock Pin
  ----------------------------------------
  0.000 0.000 0.000 r cregister_q_reg_3_/CP
```

- Specify the `-view` parameter to generate a report only for a specific analysis view:

```
report_clock_timing -view setup_view1 -type latency
```

```
  Clock: EJ_TCK
  Analysis View: setup_view1
  ---Latency---
  Source    Network    Total    Clock       Pin
  ----------------------------------------
  0.000     0.000      0.000    r    cregister_q_reg_3_/CP

  Clock: SI_ClkIn
  Analysis View: setup_view1
  ---Latency---
  Source   Network   Total    Clock        Pin
  ----------------------------------------
  0.000    0.000     0.000     r     cregister_q_reg_13_/CP
```

- The following command generates a textual histogram of the latency report:

```
report_clock_timing -type latency -histogram
```

```
[Delay Chart: CLK4(CLK_W_4_gen2)]
************************************
Min Delay : 0.778
Max Delay : 0.778
Count : 1
************************************
----------------------------------------

Min      Max      Count   1
----------------------------------------
0.000  100.000 1          |o
```

- The following command generates the histogram report at intervals of `0.5`:

```
report_clock_timing -type latency -histogram -histogram_range 0.5
```

```
[Delay Chart: CLK4(CLK_W_4_gen2)]
*************************************
Min Delay : 0.778
Max Delay : 0.778
Count : 1
*************************************
-------------------------------------

Delay   Count   End Point
1.018   8       seg2/u9/CK r
1.018   8       seg2/u3/CK r
0.945   7       seg2/u14/CK r

************************************************
Start point:CLK3(CLK_W_4_gen2(CLK_W_4))
-----------------------------------------------
Delay   Count  End Point
1.345   8      seg3/u6/CK r
1.345   8      seg3/u1/CK r
1.218   7      seg3/u12/CK r
```

- The following command generates a latency report starting from the generated clock, and includes the stage gate counts between the generated clock and the capturing register:

```
report_clock_timing -type latency -logic_level -source generated_clock
```

```
************************************************
Start point:CLK2(CLK_W_4_gen1(CLK_W_3))
-----------------------------------------------
Delay   Count   End Point
0.818   8       seg2/u9/CK r
0.818   8       seg2/u3/CK r
0.745   7       seg2/u14/CK r
```

```
  ************************************************
  Start point:CLK3(CLK_W_4_gen2(CLK_W_4))
  -----------------------------------------
  Delay   Count   End Point
  0.845   8       seg3/u6/CK r
  0.845   8       seg3/u1/CK r
  0.718   7       seg3/u12/CK r
```

- The following command generates a latency report starting from the generated clock CLK_W_4_gen2, and includes the stage gate counts between the generated clock and the capturing register:

```
report_clock_timing -type latency -logic_level -source generated_clock -clock
CLK_W_4_gen2
```

```
  ************************************************

  Start point:CLK3(CLK_W_4_gen2(CLK_W_4))
  -----------------------------------------

report_clocks

```
report_clocks
[-description]
[-arrival_points]
[-phase_shift_table]
[-total_shift_table]
[-uncertainty_table]
[-adjustment_table]
[-delay_adjustment_table]
[-source_insertion]
[-insertion]
[-hierarchy]
[-groups]
[-clocks clk_signame | clk_signame_list]
[-view view_name]
[{> | >>} filename | -tcl_list]
```

Reports information on clocks created with the `create_clock` and `create_generated_clock` command. The report includes information about all clock waveforms, clock arrival points, and clock uncertainties.

Use the `-description`, `-arrival_points`, `-uncertainty_table`, and the `*_table` parameters to specify different parts of the report. If one of these options is supplied, only the section that the option corresponds to is reported. If other options are supplied, those sections are also reported.

Based on the current setup or hold analysis mode, the following parameters report only one of the late or early tables:

- `-phase_shift_table`
- `-total_shift_table`
- `-uncertainty_table`
- `-adjustment_table`
- `-delay_adjustment_table`

However, in simultaneous (setup and hold) mode both the tables are reported.

The `report_clocks` command only reports constraints with respect to clock waveforms. Use the `report_ports -type` command for constraints applied to clock pins.

Parameters

{> | >>} *filename*	When specified with >, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with >>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The *filename* parameter must be the last argument in the list. The *filename* and -tcl_list parameters are mutually exclusive; you cannot specify them together. **Note:** To write a compressed report, add the .gz extension to the file name. *Default:* Report is displayed on standard output without being saved.
-adjustment_table	Reports two tables that detail the hold and setup cycle adjustments between clock waveforms as set by the set_multicycle_path command. **Note:** If specific ideal (or generated) clocks are requested with the -clocks *clock_name_list* option, then only the relationships between those clock signals are reported.
-arrival_points	Reports only the clock arrival points. A clock arrival point is the pin where the create_clock or create_generated_clock command has been asserted. **Note:** This parameter is obsolete and will be removed in a future release.

`-clocks` *`clk_signame`* | *`clk_signame_list`*	Requests information on a specific ideal (or generated) clock. If a list is given, only information about those clocks is reported. You can use wildcards in the names. *Default*: All clocks, except generated clocks, are reported. Use the `-generated` option to report generated clocks.  This parameter is obsolete and will be removed in a future release. Cadence recommends that you specify clock names without the `-clocks`parameter.
`-delay_adjustment_table`	Reports two tables that detail the early and late path delay adjustments between clock waveforms as set by the `set_max_delay` and `set_min_delay` commands. **Note:** If specific ideal (or generated) clocks are requested with the `-clocks` *`clock_name_list`* option, then only the relationships between those clock signals are reported.
`-description`	Reports only the description of the specified clock waveform(s).
`-generated`	Includes information on generated clocks in the report, such as source and master clock of the generated clock, and other information specified in the `create_generated_clock` constraints. The report uses the internal clock names created by the system, if you did not specify new clock names while creating these clocks. ⓘ This parameter is obsolete and will be removed in a future release. The software now reports generated clocks by default.
`-groups`	Reports the existing clock groups.

`-hierarchy`	Reports the inter-clock relationship in tree style format.
`-insertion`	Reports the network insertion delays specified on clock waveforms. The values in the table are in `min:typ:max` format.
`-phase_shift_table`	Reports the table that details the phase shift between clock waveforms. Based upon the current analysis mode, the table shows the phase shifts either in late or early mode. In case of simultaneous setup hold mode, both the tables are reported for phase shift in late and early mode. **Note:** If specific ideal (or generated) clocks are requested with the `-clocks` *`clock_name_list`* option, then only the relationships between those clock signals are reported.
`-source_insertion`	Reports the source insertion delays specified on clock waveforms.
`-tcl_list`	Produces the report in Tcl list format instead of a tabular format. This is useful for integrating timing with custom Tcl functions, and also for customizing report generation. The `-tcl_list` and *`filename`* parameters are mutually exclusive; you cannot specify them together.
`-total_shift_table`	Based on the current analysis mode, reports one of the tables (late or early mode) that details the total relationship between clock waveforms. In case of simultaneous setup hold mode both the tables are reported. **Note:** If specific ideal (or generated) clocks are requested with the `-clocks` *`clock_name_list`* option, then only the relationships between those clock signals are reported.

`-uncertainty_table`	Based on the current analysis mode, reports one of the tables (late mode or early mode) that detail the uncertainty between clock waveforms as specified using the `set_clock_uncertainty` command. In case of simultaneous setup hold mode both the tables are reported. The tables report only those clock waveforms for which uncertainty has been defined using the `set_clock_uncertainty` command. **Note:** If specific ideal (or generated) clocks are requested with the `-clocks` *`clock_name_list`* option, then only the relationships between those clock signals are reported.
`-view` *`view_name`*	Generates a clock report for the specified analysis view only. You can specify this parameter only when the software is in multi-mode multi-corner timing analysis mode.

Examples

Here are some examples.

- `report_clocks`

```

```

- The following command displays only the uncertainty information:

```
set_clock_uncertainty 5 CLK_W_1
set_clock_uncertainty 4 -from CLK_W_1 -to CLK_W_4_gen1
set_clock_uncertainty 6 -from CLK_W_2 -to CLK_W_4_gen2
report_clocks -uncertainty_table

-------------------------------------------------------
Clock To Clock Uncertainty (Late)
-------------------------------------------------------
From    To           L->L    L->T    T->L     T->T
-------------------------------------------------------
*       CLK_W_1      5.000  5.000   5.000     5.000
CLK_W_1 CLK_W_4_gen1 4.000  4.000   4.000     4.000
CLK_W_2 CLK_W_4_gen2 6.000  6.000   6.000     6.000
-------------------------------------------------------
Clock To Clock Uncertainty (Early)
-------------------------------------------------------------
From     To            L->L   L->T   T->L   T->T
-------------------------------------------------------------
*        CLK_W_1      -5.000 -5.000 -5.000 -5.000
CLK_W_1  CLK_W_4_gen1 -4.000 -4.000 -4.000 -4.000
CLK_W_2  CLK_W_4_gen2 -6.000 -6.000 -6.000 -6.000
```

```
-------------------------------------------------------
```

- Consider the following clock definition:
  create_clock -name "CLK_W_1" -add -period 60 -waveform {0 30}
  report_clocks CLK_W_1 -phase_shift_table

```
-----------------------------------------------------
Clock To Clock Phase Shift (Late)
-----------------------------------------------------
From    To      L->L    L->T  T->L   T->T
-----------------------------------------------------
CLK_W_1 CLK_W_1 60.000  0.000 60.000 60.000
-----------------------------------------------------
-----------------------------------------------------
Clock To Clock Phase Shift (Early)
-----------------------------------------------------
From    To      L->L   L->T   T->L  T->T
-----------------------------------------------------
CLK_W_1 CLK_W_1 0.000 -60.000 0.000 0.000
-----------------------------------------------------
```

- You can use the following command to add uncertainty:
  `set_clock_uncertainty 2 CLK_W_1`

  The phase shift and total shift table values will be different. The following command displays the changed shift values as given below:
  `report_clocks -total_shift_table CLK_W_1`

```
-----------------------------------------------------
Total Clock To Clock Phase Shift Required (Late)
-----------------------------------------------------
From    To      L->L    L->T  T->L   T->T
-----------------------------------------------------
CLK_W_1 CLK_W_1 58.000 -2.000 58.000 58.000
-----------------------------------------------------
-----------------------------------------------------
Total Clock To Clock Phase Shift Required (Early)
-----------------------------------------------------
From    To      L->L   L->T   T->L  T->T
-----------------------------------------------------
CLK_W_1 CLK_W_1 2.000 -58.000 2.000 2.000
-----------------------------------------------------
```

You can see that the uncertainty is subtracted from the phase shift.
Consider the following example path:

```
Path 1: MET Setup Check with Pin u2/CK
Endpoint: u2/D (v) checked with leading edge of 'CLK_W_1'
Beginpoint: CLK2 (v) triggered by trailing edge of 'CLK_W_2'
Path Groups: {CLK_W_1}
Other End Arrival Time 0.000
- Setup 0.188
+ Phase Shift 15.000
- Uncertainty 2.000
= Required Time 12.812
- Arrival Time 12.463
= Slack Time 0.349
Clock Fall Edge 12.500
= Beginpoint Arrival Time 12.500
-------------------------------------
Load  Slew    Delay   Arrival   Cell  Arc          Pin
                      Time
-----------------------------------------------------
0.034  0.003  12.500                  CLK2 v       CLK2
0.003  0.003  -0.037  12.463   BUF    A v -> Y v   u10999/Y
0.003  0.003  0.000   12.463   DFF    D v          u2/D
-----------------------------------------------------
```

Here the begin point CLK_W_2 to end point CLK_W_1 shows a phase shift value of 15.00. This means that if a path starts from the falling edge of CLK_W_2 , and ends at the rising edge of CLK_W_1, the phase shift is 15.00. In other words, when the timing (setup time) is reported, the required time at the end point begins with 15.00 (in addition to adjustments like setup time, time borrowing, uncertainty, etc). However, the arrival time of this path starts at 12.500.

- When the software is in multi-mode multi-corner timing analysis mode, the software reports the clock information for each active analysis view:

```
report_clocks -total_shift_table -description

------------------------------------------------------------
Clock Descriptions
------------------------------------------------------------
Attributes
-------------------------------------------------------------------------
Clock Name Source  View       Period  Lead   Trail Generated Propagated
-------------------------------------------------------------------------
EJ_TCK     EJ_TCK  hold_view2 17.400  0.000  8.700  n         n
```

```
EJ_TCK     EJ_TCK  hold_view1 17.400  0.000  8.700  n         n
EJ_TCK     EJ_TCK  setup_view117.400  0.000  8.700  n         n
------------------------------------------------------------------------
-------------------------------------------------------------
Total Clock To Clock Phase Shift Required (Late)
-------------------------------------------------------------
From      To        View        L->L   L->T   T->L    T->T
-------------------------------------------------------------
EJ_TCK    EJ_TCK    hold_view2  17.400  0.000 17.400  17.400
EJ_TCK    EJ_TCK    hold_view1  17.400  0.000 17.400  17.400
EJ_TCK    EJ_TCK    setup_view2 17.400  0.000 17.400  17.400
------------------------------------------------------------------------
```

- Specify the `-view` parameter to generate clock information for a specific analysis view only:

```
report_clocks -total_shift_table -description -view setup_view1 > clk_sv1

-------------------------------------------------------------
Clock Descriptions
-------------------------------------------------------------
Attributes
-------------------------------------------------------------
Clock Name      Source  View         Period  Lead  Trail  Generated Propagated
-------------------------------------------------------------------------------
EJ_TCK          EJ_TCK  setup_view1  17.400  0.000 8.700  n         n
virt_in_EJ_TCK  -       setup_view1  17.400  0.000 8.700  n         n
-------------------------------------------------------------------------------
-----------------------------------------------------------------
Total Clock To Clock Phase Shift Required (Late)
-----------------------------------------------------------------

```

Reports constraint information of current design. The constraints information includes information such as whether or not constraint is violated, by how much amount, and the worst violator object.

The following timing checks are reported when you use the `report_constraint` command:

- All setup and hold checks
- DRV
- Clock and asynchronous checks including pulse_width, min_period, recovery, removal, clock_gating_setup, clock_gating_hold, skew

The `report_constraint` command does not honor the `report_timing_format` global variable by default. To honor this global you need to set the `timing_report_constraint_use_report_timing_format` global variable to `true`.

The `report_constraint` command supports DRV constraints (`set_min_fanout`, `set_max_fanout`, `set_min_transition`, `set_max_transition`, `set_min_capacitance`, and `set_max_capacitance`) applied on library pins.

The `report_constraint` command supports multi-threaded reporting. You can make the following settings to enable multi-threaded reporting:

```
setMultiCpuUsage -localCpu number_of_CPU
set_table_style -no_frame_fix_width
```

By default, the `report_constraint` command reports only the mean slews. You can enable DRV checking to use mean as well as the n-sigma slew values (in SOCV mode), with the following setting:

```
set timing_report_max_transition_check_using_nsigma_slew true
```

Parameters

`{> | >>}` *`filename`*	When specified with `>`, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with `>>`, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The *`filename`* parameter must be the last argument in the list. **Note:** To write a compressed report, add the `.gz` extension to the file name. *Default:* Report is displayed on standard output without being saved.

`-all_violators`	Reports negative slack values for timing checks. The supported check types are: • setup • hold • clock_gating_setup • clock_gating_hold • recovery • removal • clock_period • pulse_width • max_capacitance • max_transition • max_fanout • min_capacitance • min_transition • min_fanout • skew • pulse_clock_max_width • pulse_clock_min_width • pulse_clock_max_transition • pulse_clock_min_transition You can use the `-all_violators` parameter for reporting specific check types to generate report for that particular check type only. For example, you can use `-all_violators` with `-late` to report setup checks and path delays from set_max_delay.
`-check_type`	Reports setup or hold checks. The supported check types are: • clock_gating_setup: Reports only the paths that end at the clock_gating_setup timing check. • clock_gating_hold: Reports only the paths that end at the

clock_gating_hold timing check.

- `electromigration`: Reports signal EM analysis related violations. When high density current passes through a thin metal wire, the high energy electrons exert forces on atoms causing them to migrate. Electromigration (EM) can drastically reduce the lifetime of a chip by increasing the resistivity of a metal wire or creating a short circuit between adjacent lines. When this option is specified, the software reports standard cell level electromigration violations.
- recovery: Reports paths that end at the recovery timing check.
- removal: Reports paths that end at the removal timing check.
  Note: The check types - recovery, removal, clock_gating_setup, and clock_gating_hold are also supported in AOCV mode.
- pulse_width: Reports only the paths that end at the pulse_width timing check.
  If you do not specify the `-all_violators` parameter, then the `pulse_width` option reports only one entry of the most critical pulse_width check. The DRV checks also report only the most critical entry.

  To report all the violated pulse_width checks, you need to specify `report_constraint -check_type pulse_width -all_violators` command (which is consistent with other check types of the `report_constraint` command).

  To report both violating and met entries, you can use the `report_min_pulse_width` command.
- clock_period: Reports only the paths that end at the clock_period timing check.
- skew: Reports skew checks.
  The `report_constraint` command performs skew checks by default. Skew checks are implemented as setup checks that are reported in the late analysis or simultaneous mode. These checks are not reported in the early mode. Skew checks are performed assuming the signal and reference clocks have the same frequency. If the frequencies of the signal and reference clocks are different, a warning message is displayed.
- pulse_clock_max_width: Reports the maximum pulse clock width checks

	set using the set using `set_pulse_clock_max_width` command. • pulse_clock_min_width: Reports the minimum pulse clock width checks. • rail_swing: Reports details related to the rail swing checks. For rail swing check settings, you can use the following global variables: ○ `timing_rail_swing_checks_low_voltage_threshold` ○ `timing_rail_swing_checks_high_voltage_threshold`
`-clock`	Specifies that the DRV checks will be restricted to the clock network. If any pin is part of both the clock and data network, it will be reported as a clock.
`-connection_class`	Reports violations if the connection class attributes of the driving pin and receiving pin of a net are different.
`-data`	Specifies that the DRV check will be restricted to the data network. If any pin is part of both the clock and data network, it will be reported as a clock network pin. By default, the DRV checks are applied to both clock and data networks.
`-drv_fields {field list}`	Allows only the specified fields to be included in the DRV report - in the same order as defined.
`-drv_output_format {txt | csv}`	Specifies that DRV output format – txt or CSV. The default value is “txt”.

`-drv_violation_type`	Reports DRV violations. The supported DRV check types are: • max_capacitance: Reports pins having the worst `max_capacitance` constraint. If you specify the `-all_violators` parameter, you can see all the pins whose actual capacitance is greater than the `max_capacitance` value specified in library and timing constraints file. • min_capacitance: Reports pins having the worst `min_capacitance` constraint. If you specify the `-all_violators` parameter, you can see all the pins whose actual capacitance is less than the `min_capacitance` value specified in the library and timing constraints file. • max_transition: Reports pins having the worst `max_transition` constraint. If you specify the `-all_violators` parameter, you can see all the pins whose actual transition is greater than the `max_transition` value specified in the library and timing constraint file. **Note:** These checks are not reported in hold analysis mode. The `set_si_mode -enable_drv_with_delta_slew true` setting is required for max_transition DRV violations with SI slew. • min_transition: Reports pins having the worst `min_transition` constraint. If you specify the `-all_violators` parameter, you can see all the pins whose actual transition is less than the `min_transition` value specified in the library and timing constraints file. • max_fanout: Reports pins having the worst `max_fanout` constraint. If you specify the `-all_violators` parameter, you can see all the pins whose actual fanout is greater than the `max_fanout` value specified in the library and timing constraints file. • min_fanout: Reports pins having the worst `min_fanout` constraint. If you specify the `-all_violators` parameter, you can see all the pins whose actual fanout is less than the `min_fanout` value specified in the library and timing constraints file. • pulse_clock_max_transition: Reports maximum pulse clock transition checks. • pulse_clock_min_transition: Reports minimum pulse clock transition checks.

`-early`	Reports all of the hold checks, including regular, clock_gating_hold, and data-to-data hold checks. Also reports path delays from set_min_delay. **Note:** This parameter does not report removal checks.
`-late`	Reports all of the setup checks, including regular, clock_gating_setup, and data-to-data setup checks. Also reports path delays from set_max_delay. **Note:** This parameter does not report recovery checks.
`-max_pins_per_drv`	Reports the specified number of top worst violations per DRV category, such as, max_transition, max_capacitance. If this parameter is not specified, then by default 1000 entries per DRV category will be reported.
pin_port_list	Controls the output of DRV constraints. When specified, all DRV violations are reported for the specified pins or ports only.
`-retime {aocv | path_slew_propagation | aocv_path_slew_propagation}`	
	Reanalyzes the specified set of paths using the specified method. **Note**: The parameter supports setup/hold check types only. `aocv`: Re-evaluates the given set of graph-based analysis (GBA) paths by reverting back graph-based AOCV derate factors and applying path- based AOCV derates instead of less pessimistic derates. In this case the slew (and respective delays) values are worst that are propagated during graph-based analysis. `aocv_path_slew_propagation`: Re-evaluates the given set of graph-based analysis (GBA) paths by using path-based AOCV derates and delays using actual path- based propagated slew. `path_slew_propagation`: Re-evaluates the given set of graph-based analysis (GBA) paths by recalculating the delay values based upon actual propagated slew across the path. In this case the AOCV derates are the ones that are reported during graph-based analysis.

`-retime_mode {path | exhaustive}`	Allows the `report_constraint` command to be run in exhaustive path-based analysis (PBA) mode. In this mode, the software will exhaustively examine nworst paths of the selected endpoints and then select the true worst path to be reported - based on retimed slacks of all the examined paths. To enable exhaustive mode, the use model is given below: `report_constraint -all_violators -retime path_slew_propagation -retime_mode exhaustive` When you use this parameter, reporting can be run time intensive as the software needs to do an exhaustive search for true worst paths. Therefore, it is recommended to use this option in the later phases of sign-off stage when there are very few violations left for analysis. *Default*: `path`
`-verbose`	Generates a report that displays the full data path with accompanying required time and slack calculation.
`-view viewName`	Generates a report containing endpoint and other constraint information for the specified analysis view. You can only specify this parameter when the software is in multi-mode multi-corner analysis mode. *Default:* Generates a report containing the worst endpoint and constraint information based on all of the analysis views.
`-worst_drv_per_net`	Reports only the worst DRV violation per net.

Examples

- Consider a design having 3 sequential endpoints:
  - setup_pin: Having a setup check with slack equal to -9.000
  - recovery_pin: Having a recovery check with slack equal to -8.000
  - both_setup_recovery_pin: Having both setup check (slack = -6.000) and recovery check (slack = -7.000)
    In this case, the report_constraint -late -all_violators command will display the

following output:

```
max_delay/setup
-------------------------------------------------------
End Point                  Slack          Cause
-------------------------------------------------------
setup_pin f                -9.000         VIOLATED
both_setup_recovery_pin    -6.000         VIOLATED
-------------------------------------------------------
```

- The `report_constraint -check_type recovery -all_violators` command will display the following output:

```
Check type : recovery
-------------------------------------------------------------
End Point                     Slack          Cause
-------------------------------------------------------------
recovery_pin r                -8.000         VIOLATED
both_setup_recovery_pin       -7.000         VIOLATED
-------------------------------------------------------------
```

- The `report_constraint -late -check_type recovery -all_violators` command displays the following output:

```
max_delay/setup
-------------------------------------------------------------------------------
End Point                   Slack           Cause
-------------------------------------------------------------------------------
setup_pin f                 -9.000          VIOLATED
recovery_pin r              -8.000          VIOLATED
both_setup_recovery_pin     -7.000          VIOLATED
-------------------------------------------------------------
```

- The `report_constraint` command displays the following output:

```
max_delay/setup
-------------------------------------------------------------
End Point             Slack                 Cause
-------------------------------------------------------------
out2 r              -4111.834               VIOLATED
```

report_cppr

```
report_cppr
[-help]
[-check_type {setup | hold | clock_gating_setup | clock_gating_hold |
clock_gating_pulse_width | data_setup | data_hold | recovery | removal | pulse_width |
clock_period | clock_separation | skew | no_change_setup | no_change_hold | time_borrow}]
-from pin_or_port
-to pin_or_port
[-from_clock clkname]
[-to_clock clkname]
[-early | -late]
[-view view_name]
[> filename]
```

Reports the clock reconvergence pessimism value at the common branching point of the early and late paths in the clock network of the specified data path.

The `report_cppr` command reports separate values for both opening and closing edges for paths with latches as destinations. If both source and destination flops are triggered by multiple clocks, then one report is generated for each separate clock.

When the software is in multi-mode multi-corner analysis mode, `report_cppr` reports the results for each active analysis view.

To use the `report_cppr` command, you must first set the following global variables:

- `timing_cppr_transition_sense`
- `timing_cppr_threshold_ps`

Parameters

`-help`	Prints out the command usage.

`-check_type {setup | hold | clock_gating_setup | clock_gating_hold | clock_gating_pulse_width | data_setup | data_hold | recovery | removal | pulse_width | clock_period | clock_separation | skew | no_change_setup | no_change_hold | time_borrow}`	Reports the CPPR for the paths that end at the specified timing check. The following check types are reported when the software is in setup analysis mode: `setup`, `pulse_width`, `clock_period`, `clock_gating_setup`, `clock_gating_pulse_width`, `data_setup`, `recovery`, skew, `clock_separation`, `time_borrow`, and `no_change_setup`. The following check types are reported when the software is in hold analysis mode: `hold`, `clock_gating_hold`, `data_hold`, `removal`, and `no_change_hold`. If the software is in simultaneous setup and hold analysis mode, all of the check types listed above are reported.
`> filename`	Writes the report to the specified file name. If the file already exists, the software overwrites it. The *`filename`* parameter must be the last argument in the list. **Note:** To write a compressed report, add the `.gz` extension to the file name. *Default:* Report is displayed on standard output without being saved.
`-early`	Reports the hold analysis clock reconvergence pessimism value. You can specify this parameter when the software is in hold analysis mode, or in simultaneous setup and hold analysis mode (`set_global timing_enable_simultaneous_setup_hold_mode true`).
`-from` *`pin_or_port`*	Reports the clock reconvergence pessimism value for paths starting from the specified clock pin of the source flop, or from the specified port.

`-from_clock` *clkname*	Reports the clock reconvergence pessimism value for paths with the specified triggering clock. Use this parameter when there is more than one clock triggering the source flop.
`-late`	Reports the setup analysis clock reconvergence pessimism value. You can specify this parameter when the software is in setup analysis mode, or in simultaneous setup and hold analysis mode (`set_global timing_enable_simultaneous_setup_hold_mode true`).
`-to` *pin_or_port*	Reports the clock reconvergence pessimism value for paths ending at the specified clock pin of the destination flop, or at the specified port.
`-to_clock` *clkname*	Reports the clock reconvergence pessimism value for paths with the specified capturing clock. Use this parameter when there is more than one clock capturing the destination flop.
`-view` *view_name*	Reports the clock reconvergence pessimism values for paths in the specified analysis view only. You can specify this parameter only when the software is in multi-mode multi-corner timing analysis mode.

Examples

Here are some examples.

- When the software is in multi-mode multi-corner timing analysis mode, you can specify the `-view` parameter to report the CPPR values for a specific analysis view:

```
report_cppr -from CLK3 -to seg3/u14/CK

Start Clock Pin: CLK3 (Triggered by rising edge of clock CLK_W_3)
End Clock Pin: seg3/u14/CK (Triggered by rising edge of clock CLK_W_3)
Analysis Type: Setup
Analysis View: setup_view1
```

```
Common Branch Point : seg3/u17_c/Y
Launching Edge Type At Common Point : Rising
Capturing Edge Type At Common Point : Rising
Pessimism Threshold Value : 0.020
-------------------------------------
Arrival   Late    Early   Pessimism
Times
-------------------------------------
Rise      0.549   0.366   0.183
Fall      0.400   0.267   0.133
-------------------------------------
Edge Selection Mode : Normal
Edge Selection : Match, Using Rise
CPPR Adjustment : 0.183
```

- The following report shows sigma and mean values:

```
report_cppr -from FF01/CP -to FF02/CP

Start Clock Pin: FF01/CP (Triggered by rising edge of clock CK)
End Clock Pin: FF02/CP (Triggered by rising edge of clock CK)
Analysis Type: Setup
Analysis View: view1
Common Branch Point : CK
Launching Edge Type At Common Point : Rising
Capturing Edge Type At Common Point : Rising
Pessimism Threshold Value : 0.020
+-------------------------------------------------------------------------------+
| Arrival | Late  | Late  | Early | Early | Pessimism | Pessimism | Pessimism |
| Times   | Mean  | Sigma | Mean  | Sigma | Mean      | Sigma     |           |
|---------+-------+-------+-------+-------+-----------+-----------+-----------|
| Rise    | 0.000 | 0.000 | 0.000 | 0.000 | 0.000     | 0.000     | 0.000     |
| Fall    | 0.000 | 0.000 | 0.000 | 0.000 | 0.000     | 0.000     | 0.000     |
+-------------------------------------------------------------------------------+
Edge Selection Mode : Normal
Edge Selection : Match, Using Rise
CPPR Adjustment : 0.000 (+3.00S) | 0.000 | 0.00
```

Related Information

- report_timing

report_design

```
report_design
[-view viewName]
[{> | >>} filename | -tcl_list]
[-early | -late]
```

Reports the minimum and/or maximum operating conditions and active design rules for the current design.

When `setAnalysisMode -analysisType single` option is specified, the `report_design` command reports only the maximum operating conditions.

When `setAnalysisMode -analysisType bcWc` option is specified, the `report_design` command reports the minimum operating conditions, if `setAnalysisMode -checkType hold` option is specified.

Both minimum and maximum operating conditions are available for on-chip variation analysis mode.

When simultaneous setup hold analysis mode is set to `on`, the minimum or maximum conditions can be reported using the `-early`/`-late` parameters.

Parameters

{> | >>} *filename*	When specified with >, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with >>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The *filename* parameter must be the last argument in the list. The *filename* and -tcl_list parameters are mutually exclusive; you cannot specify them together. **Note:** To write a compressed report, add the .gz extension to the file name. *Default:* Report is displayed on standard output without being saved.
-early | -late	The -early parameter reports minimum operating condition in bcwc or onChipVariation analysis mode. The -late parameter reports maximum operating condition. The -late and -early parameters are mutually exclusive.
-tcl_list	Produces the report in Tcl list format instead of a tabular format. This is useful for integrating timing with custom Tcl functions, and also for customizing report generation. The -tcl_list and *filename* parameters are mutually exclusive; you cannot specify them together.
-view *viewName*	Reports view specific operating conditions.

Examples

- The following is a sample report generated using the `report_design` command:
  `report_design`

Design Property	Value
Design Name	dsp_core
Operating Condition Name	slow
Process	1.000
Voltage	1.620
Temperature	125.000
Tree Type	balanced

Design Rule	Value
Max Transition	NA
Min Transition	NA
Max Capacitance	NA
Min Capacitance	NA
Max Fanout	24.000

- The following sample report shows both the minimum and maximum operating condition details in simultaneous mode:
  `report_design`

Design Property	Value	
Design Name	dsp_test	
	MAX	**MIN**
Operating Condition Name	tdsp_core/%NOM_PVT	tdsp_core/%NOM_PVT

Process	1.000	1.000
Voltage	1.800	1.800
Temperature	25.000	25.000
Tree Type	worst_case	worst_case

Design Rule	Value
Max Transition	NA
Min Transition	NA
Max Capacitance	NA
Min Capacitance	NA
Max Fanout	NA
Min Fanout	NA

Related Commands

- `report_timing`
- `setAnalysisMode`

report_fanin

```
report_fanin
-to pin_port_net_list
[-trace_through {case_disable | user_disable | all}]
[-pin_levels numOfPinLevels]
[-view viewName]
[-nosplit]
[{> | >> } filename]
```

Allows a cone traversal that is not tied to the timing graph, that is, not blocked by `set_disable_timing` and case analysis. By default, the trace matches the timing view and the reports generated using the `all_fanin` and `all_fanout` commands. The reports indicate whether disabled or case analysis arcs were traversed.

Parameters

`> | >>` *filename*	When specified with >, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with >>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file.
`-nosplit`	Specifies that reports with long names will not be split into multiple lines. **Note**: You should use the `-nosplit` parameter after specifying the `set_table_style -no_frame_fix_width` parameter.
`-pin_levels` *numOfPinLevels*	Specifies the desired depth of the output.
`-trace_through {case_disable | user_disable | all}`	Allows traversal through disabled arcs. You can specify one of the following options: • `case_disable`: Arcs which are disabled because of set_case_analysis are traversed but because of set_disable_timing are not traversed • `user_disable`: Arcs disabled because of set_disable_timing are traversed but because of set_case_analysis are not traversed • `all`: Trace through all arcs
`-to` *pin_port_net_list*	Specifies a list or collection of pins, ports, or nets. A mixed list or heterogeneous collection is also allowed.
`-view` *viewName*	Specifies disabled arcs in the specified view.

Examples

- The report_fanin -to h0/A command shows the following output:

```
Fanin Network for Pin: h0/A
-------------------------------------------------------------------------------
Source Pin    Sink Pin     Cell Type    Timing Sense   Arc          Case
                                                       Disabled     Analysis
-------------------------------------------------------------------------------
 u1/Y          h0/A         (net)         -               -         -
 -----------------------------------------------------------------------------
 u1/A          u1/Y          BUFX2        positive_unate   -        -
 -----------------------------------------------------------------------------
 in            u1/A          (net)         -               -        -
 -----------------------------------------------------------------------------
```

Related Information

- set_disable_timing
- set_case_analysis
- all_fanin
- all_fanout

report_fanout

```
report_fanout
{-from pin_port_net_list | -clock_tree}
[-trace_through {case_disable | user_disable | all}]
[-pin_levels numOfPinLevels]
[-view viewName]
[-nosplit]
[{> | >> } filename]
```

Allows a cone traversal that is not tied to the timing graph, that is, not blocked by `set_disable_timing` and case analysis. By default, the trace matches the timing view and the reports generated using the `all_fanin` and `all_fanout` commands. The reports indicate whether disabled or case analysis arcs were traversed.

Parameters

`> | >> filename`	When specified with >, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with >>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file.
`-clock_tree`	Reports the fanout of the source pin, one after the other for all the clocks in the design.
`-nosplit`	Specifies that reports with long names will not be split into multiple lines. **Note**: You should use the `-nosplit` parameter after specifying the `set_table_style -no_frame_fix_width` parameter.
`-pin_levels numOfPinLevels`	Specifies the desired depth of the output.

`-trace_through {case_disable | user_disable | all}`	Allows traversal through disabled arcs. You can specify one of the following options: • `case_disable`: Arcs which are disabled because of set_case_analysis are traversed but because of set_disable_timing are not traversed • `user_disable`: Arcs disabled because of set_disable_timing are traversed but because of set_case_analysis are not traversed • `all`: Trace through all arcs
`-from` *`pin_port_net_list`*	Specifies a list or collection of pins, ports, or nets. A mixed list or heterogeneous collection is also allowed.
`-view` *`viewName`*	Specifies disabled arcs in the specified view.

Examples

- Suppose arc seg1/u1 is disabled due to following constraint:
  `set_disable_timing -from A -to Y seg1/u1`
  `report_fanout -from IN1` (command will show the following output):

```
Fanout Network for Port: IN1
-----------------------------------------------------------------------
Source Pin  Sink Pin    Cell Type   Timing Sense   Arc       Case
                                                   Disabled  Analysis
-----------------------------------------------------------------------
IN1         seg1/u1/A   (net)       -              -         -
-----------------------------------------------------------------------
```

- The following command will show the output below:
  `report_fanout -from IN1 -trace_through user_disable`

```
Fanout Network for Port: IN1
-----------------------------------------------------------------------
Source Pin    Sink Pin   Cell Type  Timing Sense    Arc       Case
                                                    Disabled  Analysis
-----------------------------------------------------------------------
IN1           seg1/u1/A  (net)      -               -         -
-----------------------------------------------------------------------
seg1/u1/A     seg1/u1/Y  CLKBUF     positive_unate  Y         -
-----------------------------------------------------------------------
seg1/u1/Y     seg1/u2/A  (net)      -               -         -
-----------------------------------------------------------------------
```

Related Commands

report_inactive_arcs

```
report_inactive_arcs
[-help]
[instance_or_port_list]
[-exclude_type {const snipped disable library_disable global_disable conditional_disable
Library_Mode}]
[-include_net_arcs]
[-include_when_cond]
[-type {const snipped disable library_disable global_disable conditional_disable
Library_Mode power_mode_disable}]
[-view view_name]
[> <filename[.gz]>]
[>> <filename[.gz]>]
[-delay_arcs_only | -check_arcs_only]
```

Reports information about disabled timing and timing check arcs in the design. Reports all arcs disabled due to user-specified exceptions such as `set_disable_timing` or `set_case_analysis`, as well as information about arcs disabled by constant propagation during timing analysis, snipped loop arcs, and arcs disabled in the timing library.

The report output prints only the 'from' and 'to' information of arcs, and not the full instance name for each arc.

Parameters

`-help`	Prints out the command usage.
instance_or_port_list	Reports disabled timing arcs for the specified list of instances or ports. If you specify a list of instances, the software reports all disabled arcs of the specified cells. If you specify a list of ports, the software reports all disabled arcs directly connected to the ports. *Default:* Reports all disabled net and cell arcs.
`-check_arcs_only`	Lists only disabled check arcs. The `check_arcs` are disabled by using the `set_disable_timing` command. *Default*: Both disabled timing delay arcs and check arcs are listed.

`-delay_arcs_only`	Lists only disabled timing delay arcs.
`-exclude_type {const snipped disable library_disable global_disable conditional_disable Library_Mode}`	Excludes the disabled arcs that belong to the specified category of disabled arcs. The valid options are: const, snipped, disable, library_disable, global_disable, conditional_disable, and, Library_Mode.
`-include_net_arcs`	Includes disabled net arcs in the report.
`-include_when_cond`	Shows the when_cond of arcs in the output report.
`-type {const snipped disable library_disable global_disable conditional_disable Library_Mode power_mode_disable}`	Lists only the disabled arcs that belong to the specified category of disabled arcs. The `-type` options restrict the report to only those arcs which are disabled due to a particular timing analysis step, such as constant propagation, specified disables, or loop arc disables. The valid type options are: • `const`: Propagated constant -- arcs disabled due to a constant value. The constant value can apply to one of the arc nets/pins, to side inputs which disable a condition for the arc, to nets that disable an active mode for the arc, or disable a default conditional arc. • `snipped`: Loop snipped arcs -- arcs automatically disabled by the software as part of a feedback loop. • `disable`: Defined by using the `set_disable_timing` command. • `library_disable`: Delay arc disabled due to library disables. These disables may be caused by the following conditions: ◦ Disables specified using the `set_disable_timing` command. ◦ The arc is an asynchronous arc and the `timing_enable_preset_clear_arcs` global

	variable is set to `false`. • `global_disable`: Lists the arcs that are disabled through user-specified global variable settings. • `conditional_disable`: Arcs disabled if a `when` condition is specified. There is no constant on sink or source pin and arc is disabled due to the `when` condition. • `Library_Mode`: Displays library mode of disabled arcs. • `power_mode_disable`: Reports the arcs for which power mode is disabled.
`-view` *`view_name`*	Generates the report for the specified analysis view only. You can specify this parameter only when the software is in multi-mode multi-corner timing analysis mode.
`{> | >>}` *`filename`*	When specified with `>`, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with `>>`, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The *`filename`* parameter must be the last argument in the list. **Note:** To write a compressed report, add the `.gz` extension to the file name. *Default:* Report is displayed on standard output without being saved.

Examples

- The following command reports all disabled arcs in the design:

  ```
  report_inactive_arcs > Report
  ```

  The following example shows the report generated:

  ```
  ------------------------------------------------
  Flags :   const                propagated constant
            snipped              loop snipped arcs
            disable              set_disable_timing
            disable_clock_gating set_disable_clock_gating
            library_disable      set_disable_cell_timing
            Missing_Phase        No Arc Phase Data
  From         To           DisableType ArcType              Reason
  ------------------------------------------------------------------------
  u8/CK ^      u8/D ^       const       hold_rising_clk_rise  u8/D = 1
  u8/CK ^      u8/D v       const       hold_falling_clk_rise u8/D = 1
  seg3/u12/A ^ seg3/u12/Y v disable     combinational         User Disable
  ------------------------------------------------------------------------
  ```

- When the software is in multi-mode multi-corner analysis mode, the report generated lists the disabled arcs by active analysis view, as shown in the following example:

  ```
  ------------------------------------------------
  Flags : const propagated constant
  snipped loop snipped arcs
  disable set_disable_timing
  disable_clock_gating set_disable_clock_gating
  library_disable set_disable_cell_timing
  Missing_Phase No Arc Phase Data
  From        To                 DisableType ArcType  Reason         View
  ------------------------------------------------------------------------------

  gscanmode ^ FE_O305_gmode/I ^  const       net_arc  gscanmode = 0  setup_view2
  gscanmode v FE_O305_gmode/I v  const       net_arc  gscanmode = 0  setup_view2
  gscanmode ^ FE_O305_gmode/I ^  const       net_arc  gscanmode = 0  hold_view1
  gscanmode v FE_O305_gmode/I v  const       net_arc  gscanmode = 0  hold_view1
  gscanmode ^ FE_O305_gnmode/I ^ const       net_arc  gscanmode = 0  hold_view2
  ------------------------------------------------------------------------------
  ```

report_instance_library

```
report_instance_library
-file fileName
[-instance instanceName]
[-view viewName | -delay_corner delayCornerName]
[-power_domain domainName]
[-early | -late]
```

Reports library related information for an instance(s). The report prints the following information about an instance:

- Instance name
- Cell type
- View name or delay corner
- Power domain name
- Library/Libset (early/late)
- Library file (early/late)
- Operating conditions
- Binding Status : Prints out the status for the matched voltage library available. If the user setting is `True`, then the binding status is not displayed.

Parameters

`-delay_corner` *delayCornerName*	Specifies the delay corner from which an instance library is to be selected. If no delay corner is specified, then all the instance libraries will be printed.
`-early` | `-late`	Specifies the library set (early/late) from which a library instance is to be printed. If either of these options are not specified then both the early and late library sets are used.

`-file` *fileName*	Specifies the name of the output file. If no file is specified, the report will be printed on standard output file.
`-instance` *instanceName*	Specifies the instance(s) for which the report is to be printed. If no instance is provided the report will print information of all the instances. The value of instance can be a list of regular expressions.
`-power_domain` *domainName*	Specifies the power domain from which instance(s) are to be selected. This option should be specified with the `-delay_corner` or `-view` options.
`-view` *viewName*	Specifies the view from which instance library is to be selected.

Examples

- The `report_instance_library` command displays the following information about instance `ff2` :

```
Instance              : ff2
Analysis View         : view1
Power Domain          : Default
Library/Libset(early) : locv/libCom
Library File (early)  : locv/locv2.lib
Library/Libset(late)  : locv/libCom
Library File (late)   : locv/locv2.lib
Op Cond               : P->1.000000, V->3.300000, T->25.000000 (locv/%NOM_PVT)
Cell Type             : gateCell
```

- The following command displays the following information about instance AO1/g1080:

```
report_instance_library -instance AO1/g1080

Instance : AO1/g1080
Cell : INVXL
Analysis View : AV_bc_on
Power Domain : Default
Library/Libset : slow/INV.lib
Library File : INV.lib
User Setting : True
Op Cond : P->1.000000, V->1.500000, T->0.000000 (fast)
Cell Type : gateCell
```

Related Commands

report_lib_arcs

```
report_lib_arcs
[-help]
-arc <string>
[-fall]
[-nldm]
[-quiet]
[-rise]
[-lvf  [-early]]
[-lvf  [-late]]
[-moments  [-mean_shift]]
[-moments  [-std_dev]]
[-moments  [-skewness]]
[-input_net_transition <float> | -constrained_pin_transition <float>]
[-input_net_transition <float> | -related_pin_transition <float>]
[-total_output_net_capacitance <float> | -constrained_pin_transition <float>]
[-total_output_net_capacitance <float> | -related_pin_transition <float>]
[-constrained_pin_transition <float> | -delay ] [-constrained_pin_transition <float> | -
transition ]
[-related_pin_transition <float> | -delay ]
[-related_pin_transition <float> | -transition ]
```

Reports the library arc data. The command also returns the data in a Tcl object, which can be used in scripts.

This command uses a collection of arcs as input, which can be queried using the `get_lib_arcs` command.

The units for the input and output data can be obtained using the `get_time_unit` and `get_capacitance_unit` commands.

Parameters

`-help`	Prints out the command usage.
`-arc <string>`	Specifies the arc(s) for which the report is to be printed.

`-constrained_pin_transition <float>`	Specifies the constrained pin slew (valid for constraint arcs) at which the parameters need to be reported. The slew units must be specified using the `get_time_unit` command.
`-delay`	Specifies if delay is to be reported.
`-early`	Specifies if early LVF data is to be reported. This parameter can be used only in conjunction with the `-lvf`.
`-fall`	Specifies if details of fall tables are to be reported.
`-input_net_transition <float>`	Specifies the slew at which the parameters need to be reported. The slew units must be specified using the `get_time_unit` command.
`-late`	Specifies if late LVF data is to be reported. This parameter can be used only in conjunction with the `-lvf`.
`-lvf`	Specifies if LVF data is to be reported.
`-mean_shift`	Specifies if the mean shift data is to be reported. This parameter can be used only in conjunction with the `-moments`.
`-moments`	Specifies if moments data is to be reported.
`-nldm`	Specifies if NLDM data is to be reported.
`-quiet`	Disables output to be displayed on the screen.
`-related_pin_transition <float>`	Specifies the related pin slew (valid for constraint arcs) at which the parameters need to be reported. The slew units must be specified using the `get_time_unit` command.
`-rise`	Specifies if details of rise tables are to be reported.

`-skewness`	Specifies if skewness data is to be reported. This parameter can be used only in conjunction with the `-moments`.
`-std_dev`	Specifies if standard deviation data is to be reported. This parameter can be used only in conjunction with the `-moments`.
`-total_output_net_capacitance <float>`	Specifies the load at which the parameters need to be reported. The load must be specified using the `get_capacitance_unit` command.
`-transition`	Specifies if the output slew is to be reported.

Examples

- The following command reports the library arc data containing mean shift rise tables:

```
report_lib_arcs -arc [get_lib_arcs -from cell_w/DFF/CK -to cell_w/DFF/Q] -
input_net_transition 0.08 /
       -total_output_net_capacitance 0.055 -mean_shift -rise -delay -moments -nldm

Units of Report:- Time: '1000ps', Capacitance: '1000fF'.
input_net_transition:0.080000, total_output_net_capacitance:0.055000
-------------------------------------------------------------------
| Index | Timing Arc | Value(s) |
| ------------------------------------------------------------------------------|
|       | Cell       | Source/Sink Pin | Timing Sense | Timing Type | cell_rise |
-------------------------------------------------------------------------------
| 1     | cell_w/DFF | CK -> Q         | non_unate    | rising_edge | 0.258444  |
-------------------------------------------------------------------------------
{{cell_rise 0.258444279432} {ocv_mean_shift_cell_rise NA}}
```

- The following command reports the library arc data containing fall tables for moments data:

```
report_lib_arcs -arc [get_lib_arcs -from cell_w/BUF/A -to cell_w/BUF/Y] /
```

```
    -input_net_transition 0.055 -total_output_net_capacitance 0.15 -fall -delay -
moments -nldm

Units of Report:- Time: '1000ps', Capacitance: '1000fF'.
input_net_transition:0.055000, total_output_net_capacitance:0.150000
-------------------------------------------------------------------------------
| Index | Timing Arc                                                  | Value(s)   |

 | 0.258444  |
-------------------------------------------------------------------------------
--------------
{{cell_rise 0.258} {rise_transition 0.216} {ocv_mean_shift_cell_rise NA}
{ocv_mean_shift_rise_transition NA}}
```

This command also returns the data in a Tcl object that can be parsed and used in scripts. A 3-Dimensional Tcl List will return the following information:

{{TableName Value} {TableName Value}} {{TableName Value} {TableName Value}}

Here, the first list (left column) indicates the Table-Value pair in one arc. The second list indicates the various tables present per arc. And the third list (last column) indicates the list of total arcs in the collection.

- The following command reports the slew and capacitance load:

```
set items [report_lib_arcs -arc [ get_lib_arcs -from sc_cmoslp/AO22X/clk -to
sc_cmoslp/AO22X /out1] /
     -input_net_transition 0.003 -total_output_net_capacitance 0.021]

Units of Report:- Time: '1000ps', Capacitance: '1000fF'.
input_net_transition:0.003, total_output_net_capacitance:0.021

report_min_pulse_width

```
report_min_pulse_width
[-verbose]
[-clock <object_list>]
[-path_type {summary | short | full_clock}]
[-pins object_list]
[-net]
[-violation_only]
[-view view_name]
[-waveform_aware_type {regular | waveform_aware | both}]
[ { > | >> } filename | -tcl_list]
```

Reports a set of minimum pulse width violations on pins and ports on the clock network. The report shows the required pulse width, the actual pulse width, and by how much the constraint is violated or met. This is reported separately for sequential elements and instances on the clock tree.

You can customize pulse width reporting format by using the `report_timing_format` global variable.

The report header shows clock edge information to make it more intuitive for clock style checks.

Parameters

`{> | >>} filename`	When specified with `>`, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with `>>`, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The *`filename`* parameter must be the last argument in the list. The *`filename`* and `-tcl_list` parameters are mutually exclusive; you cannot specify them together. **Note:** To write a compressed report, add the `.gz` extension to the file name. *Default:* Report is displayed on standard output without being saved.

`-clock <object_list>`	Specifies a set of clocks to for which to report the minimum pulse width.
`-net`	Reports the net arcs. This parameter can be specified with the `-path_type full_clock` option only.
`-path_type {summary | short | full_clock}`	Specifies the type of report to generate. *Default:* `summary` • `summary`: Generates a summary report for each pulse width check that shows the required width, the actual width, and the resulting slack. • `short`: Generates a path report for each pulse width check that lists the latency of each edge of the pulse as a single lumped value, instead of reporting a detailed path report. • `full_clock`: Generates a path report for each pulse width check that shows the detailed pin-to-pin path for each edge of the pulse. **Note:** The `-path_type full_clock` parameter may cause an increased runtime. In that case you can use the `-path_type short` parameter.
`-pins` *object_list*	Specifies a set of ports and pins on the clock network. If this list is not specified, then the report contains all the pins and ports in the current design.
`-tcl_list`	Produces the report in Tcl list format instead of a tabular format. This is useful for integrating timing with custom Tcl functions, and also for customizing report generation. The `-tcl_list` and *`filename`* parameters are mutually exclusive; you cannot specify them together.

`-verbose`	Provides detailed information about minimum pulse width calculations. **Note:** This parameter is obsolete. The parameter still works in this release, but to ensure compatibility with future releases, use the `-path_type` parameter instead.
`-view` *view_name*	Generates the report for the specified analysis view only. You can specify this parameter only when the software is in multi-mode multi-corner timing analysis mode.
`-violation_only`	Reports only the negative slack minimum pulse width violations.
`-waveform_aware_type {regular | waveform_aware | both}`	Reports the waveform-aware pulse width checks. You can specify the following options: • `waveform_aware`: Reports only the waveform-aware pulse width checks. • `both`: Reports waveform-aware as well as regular pulse width checks. • `regular`: Reports regular pulse width checks. This is the default setting.

Examples

- The `report_min_pulse_width` will generate a summary report as shown below:

```
report_min_pulse_width

--------------------------------------------------
SEQUENTIAL CLOCK PULSE WIDTH
--------------------------------------------------
Pin                Required     Actual Pulse   Slack
                   Pulse Width  Width
--------------------------------------------------
seg3/u14/CK (high) 0.169        0.860         0.691

- reset_min_pulse_width

report_mode

```
report_mode
instance_list
[-view viewName]
```

Reports the status of library modes associated with a specified instance. The report includes the status of each mode and its condition, for each mode group defined in the timing library.

Parameters

instance_list	Generates a report for the specified instances.
-view viewName	Reports the status of library modes in the specified active analysis view. Default: Reports the status of library modes in all active analysis views.

Examples

- The following command activates the `tst_mode_disable` library mode for instances of `i_ram`:
  ```
  set_mode tst_mode_disable [get_cells i_ram]
  ```

- The following command sets the active setup and hold analysis views:
  set_analysis_views -setup {v1 v2} -hold {v3}

- The following command reports the status of all modes associated with m4k_top:
  ```
  report_mode m4k_top

  ------------------------------------------------
  Mode Group tets_mode of m4k_top
  ------------------------------------------------
  Mode Name         Status    Condition     View Name
  ------------------------------------------------
  test_mode_enable  ACTIVE    TST_BYPASS    View1
  test_mode_disable INACTIVE  !(TST_BYPASS) View2
  ------------------------------------------------
  ```

- The following command reports the status of all modes in the analysis view `View1`:
  ```
  report_mode m4k_top -view View1

  ------------------------------------------
  Mode Group tets_mode of m4k_top
  ------------------------------------------
  Mode Name        Status  Condition  View Name
  ------------------------------------------
  test_mode_enable ACTIVE  TST_BYPASS View1
  ------------------------------------------
  ```

report_net

```
report_net
[-min_fanout int]
[-max_fanout int]
{-net list_of_net_name_or_id | -pin list_of_pin_name_or_id}
[-tcl_list]
[-hier]
[[{> | >>} filename | -output filename]
 | -tcl_list]
```

Reports the net information on the current module. The information includes the net name, the number of source pins, sink pins and bidirectional pins on the net, wire capacitance, and total capacitance.

Electrical information such as pin capacitance, and wire capacitance with which the net is associated are also included.

Use the `-pin` option to report the net that is connected to the specified pin (or port). Both `-net` and `-pin` cannot be specified at the same time. The net (or pin) names can be hierarchical names that are unique relative to the top cell.

This command only searches for the defined nets and does not modify any object in database.

Parameters

{> | >>} *filename*	When specified with >, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with >>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The *filename* parameter must be the last argument in the list. The *filename*, -output, and -tcl_list parameters are mutually exclusive; you cannot specify them together. **Note:** To write a compressed report, add the .gz extension to the file name. *Default:* Report is displayed on standard output without being saved.

`-hier`	Reports all of the nets in the design hierarchy. Without this argument, only the nets in the current level of hierarchy are reported.
`-max_fanout` *`int`*	Reports the net whose number of fanouts is less than or equal to the maximum number specified by *`integer`*.
`-min_fanout` *`int`*	Reports the net whose number of fanouts is greater than or equal to the minimum number specified by *`integer`*.
`-net` *`list_of_net_name_or_id`*	Reports the set of nets on the list of net names. This argument cannot be specified at the same time as `-pin`. If neither `-net` or `-pin` is specified, all nets are listed by default. **Note:** This argument also reports the capacitance of the net and the input pins.
`-output` *`filename`*	Dumps the report to the specified file instead of to the standard output. The *`filename`* argument must be the last argument in the list. This parameter cannot be used simultaneously with the `-tcl_list` option.
`-pin` *`list_of_pin_name_or_id`*	Reports the set of nets to which the pins on the list *`list_of_pin_name_or_id`* are connected. This argument cannot be specified at the same time as `-net`.
`-tcl_list`	Produces the report in Tcl list format instead of a tabular format. This is useful for extracting information from the report in a Tcl program. The `-tcl_list`, *`filename`* and `-output` parameters are mutually exclusive; you cannot specify them together.

Examples

- Control the `report_net` table fields, such as setting the minimum and maximum column width using the `set_table_style` command. The table names are `report_net_source_table`, `report_net_sink_table`, `report_net_summary_table`, `report_net`, and `report_net_header`.
- For example, the following command sets an indentation of six columns for the table and disables printing of the first column:

```
set_table_style -name report_net_source_table -indent 6 -max_widths {0,}
report_net
```

- The format of the `report_net` report is the same for all the examples, as shown in the first example. The following command reports information about net named `in`, as shown in the following example:

```
report_net -net n5

Net Name : n5
Number of Sources : 1

(P)
-------------------------------------------------------------------------------
```

- The following command reports the net to which the pin interesting_pin is connected:
  ```
  report_net -pin interesting_pin
  ```
- The following command reports all the nets in the current module:
  ```
  report_net -net *
  ```
- The following command reports all nets with a fanout greater than 16:
  ```
  report_net -net * -min_fanout 16
  ```

Related Information

- report_path_exceptions
- report_timing

report_path_exceptions

```
report_path_exceptions
[-early | -late]
[-ignored]
[-view view_name]
[{> | >>} filename | -tcl_list]
```

Generates a report about path exceptions specified using the `set_false_path`, `set_min_delay`, `set_max_delay`, and `set_multicycle_path` commands.

By default, the `report_path_exceptions` command only reports activated path exceptions. To report only the path exceptions that have been ignored by timing analysis, specify the `-ignored` parameter.

If more than one path exception is applied on a timing path, multiple path exceptions that match a given path are prioritized. The adjustment on the path honors the path exception with the highest priority.

When the software is in multi-mode multi-corner timing analysis mode, the report generates path exception information for every active analysis view.

The `report_path_exceptions` command output also includes 2 columns that show the file name and line number. The report output shows the exact file name and line number of the applied/ignored constraints. The compressed constraints will be decompressed first and then shown as individual constraints as written in the SDC file.

Parameters

{> | >>} *filename*	When specified with >, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with >>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The *filename* parameter must be the last argument in the list. The *filename* and -tcl_list parameters are mutually exclusive; you cannot specify them together. **Note:** To write a compressed report, add the .gz extension to the file name. *Default:* Report is displayed on standard output without being saved.
-early | -late	Generates the path exception report for either early paths or late paths. *Default:* Generates a report based on the current timing analysis mode.

-ignored	Reports only the path exceptions that have been ignored by timing analysis. This parameter can be used for debugging constraints that may be ineffective or incorrectly entered. A path exception may be ineffective if it is covered by, or overridden by, another path exception. For example:
	
	`set_false_path -to OUT`
	`set_multicycle_path -to OUT 2`
	
	In the above scenario, the set_multicycle_path command will be ignored as false paths have higher priority over cycle addition on the same timing paths.

`-tcl_list`	Produces the report in Tcl list format instead of a tabular format. This is useful for integrating timing with custom Tcl functions, and also for customizing report generation. The `-tcl_list` and *`filename`* parameters are mutually exclusive; you cannot specify them together.
`-view` *`view_name`*	Generates a path exception report for the specified analysis view only. You can specify this parameter only when the software is in multi-mode multi-corner timing analysis mode.

Examples

- The following commands shows that a false path has priority over cycle addition on the same path:

```
set_false_path -from seg1/u3/q -to seg1/u9/d
set_multicycle_path -from seg1/u3/Q -to seg1/u9/D 2

> report_path_exception -ignored
-----------------------------------------------------
From       To          Early           Late
-----------------------------------------------------
seg1/u3/Q  seg1/u9/D   false ignored   false ignored
seg1/u3/Q  seg1/u9/D   -               add 1 ignored
seg1/u3/Q  seg1/u9/D   add 0 ignored   -
-----------------------------------------------------
```

  The following command shows how edges are handled:

```
set_false_path -rise_from {IN1} -through {OUT1}
set_false_path -rise_from {IN1 IN2} -fall_to {OUT1}
set_false_path -rise_from {IN1}

tempus> report_path_exceptions -ignored
-------------------------------------------------------------
From        Through    To      Early            Late
-------------------------------------------------------------
^ IN1 IN2   -          v OUT1  false ignored   false ignored
^ IN1       OUT1       -       false ignored   false ignored
-------------------------------------------------------------
```

```
> report_path_exceptions -early
-----------------------------------
From       Through    To  Early
-----------------------------------
^ IN1      -          -   false
-----------------------------------

tempus> report_path_exceptions -late
-----------------------------------
From   Through  To  Late
------------------------------
^ IN1  -       -    false
------------------------------
```

When the software is in multi-mode multi-corner timing analysis mode, the software generates path exception information for every active analysis view:

```
set_analysis_view -setup {setup1 setup2} -hold {hold1 hold2}

> report_path_exceptions
----------------------------------------
From              Early  Late     View
                                  Name
----------------------------------------
test_mode reset  false           setup2
test_mode reset  false           setup1
test_mode reset         false    hold1
test_mode reset         false    hold2
----------------------------------------
```

Specify the -view parameter to generate a report only for a specific active analysis view:

```
> report_path_exceptions -view setup1
-------------------------------------------
From       Early    Late     View
                             Name
-------------------------------------
test_mode reset    false     setup1
-------------------------------------
```

Related Information

- report_timing

report_path_groups

```
report_path_groups
[-name group_name]
[{> | >>} filename | -tcl_list]
```

Lists the names of all path groups with the corresponding paths.

Parameters

`{> | >>} filename`	When specified with `>`, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with `>>`, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The *`filename`* parameter must be the last argument in the list. The *`filename`* and `-tcl_list` parameters are mutually exclusive; you cannot specify them together. **Note:** To write a compressed report, add the `.gz` extension to the file name. *Default:* Report is displayed on standard output without being saved.
`-name group_name`	Limits the report to the specified path group. *Default*: All path groups are reported.
`-tcl_list`	Produces the report in Tcl list format instead of a tabular format. This is useful for integrating timing with custom Tcl functions, and also for customizing report generation. The `-tcl_list` and *`filename`* parameters are mutually exclusive; you cannot specify them together.

Example

The following command shows a sample report:

```
> report_path_groups
---------------------------------
From    To         Group Name
---------------------------------
CLK1    seg1/u3/D  path1
---------------------------------
```

Related Information

- set_clock_groups
- reset_clock_groups

report_ports

```
report_ports
[-type {[input] | [source_insertion] | [insertion] | [clock_root]
| [uncertainty] | [arrival] | [required] | [external] | [clk_arrival]
| [port_cap] | [fanout_load] | [fanout_load_limit] | [drive_resistance]
| [drive_cell] | [slew_time] | [slew_limit] | [constant] | external_detail
| drive_resistance_detail}]
[-include_pins]
[-pins port_name_list ]
[-view viewName ]
[> filename | -tcl_list]
```

Reports timing constraints on ports. By default, the command reports all timing constraints on all ports of the current module.

The direction (*DIR*) column of the generated report can contain one of the following abbreviations:

- `IN` indicates that the pin is an input pin.
- `OUT` indicates that the pin is an output pin.
- `INTL` indicates that the pin is an internal pin (a pin inside the instance boundary).

The *Clock Name* column of the report can contain the following symbols:

- `D` indicates it is a data signal in the clock domain.
- `C` indicates it is a clock signal in the clock domain.
- `P` indicates it is a positive phase.
- `N` indicates it is a negative phase.
- Asterisk (`*`) indicates there is a timing exception associated with the signal.

  Note: Currently, it is not possible to expand the asterisk to determine which exception is associated with the reported timing phase.

Parameters

`> filename`	Writes the report to the specified file name. If the file already exists, the software overwrites it. The *filename* parameter must be the last argument in the list. The *filename* and `-tcl_list` parameters are mutually exclusive; you cannot specify them together. **Note:** To write a compressed report, add the `.gz` extension to the file name. *Default:* Report is displayed on standard output without being saved.
`-include_pins`	Reports timing constraints on instance pins, as well as on ports. *Default:* Reports timing constraints on ports only.
`-pins port_name_list`	Specifies the pins or ports to be reported. Pins can be specified by name, or by object ID in a Tcl list.
`-tcl_list`	Produces the report in Tcl list format instead of a tabular format. This is useful for integrating timing with custom Tcl functions, and also for customizing report generation. The `-tcl_list` and *filename* parameters are mutually exclusive; you cannot specify them together.
`-type {assertion_type | assertion_type_list}`	Specifies the constraints to be reported. *Default*: All constraints are reported. The following are valid assertion_type values: • `arrival`: Reports arrival time constraints as set by `set_input_delay` command. • `clk_arrival`: Reports clock arrival time constraints as set by the `set_clock_latency` command. • `clock_root`: Reports the clock root as set by the `create_clock` command.

- `constant`: Reports constant constraints as set by the `set_case_analysis` command.
- `drive_cell`: Reports drive cell constraints as set by the `set_driving_cell` command.
- `drive_resistance`: Reports drive resistance constraints as set by the `set_drive` command.
- `drive_resistance_detail`: Reports detail about the input ports with drive resistance constraints.
- `external`: Reports external delay constraints as set by the `set_output_delay` command.
- `external_detail`: Reports detail about the output ports with external delay constraints.
- `fanout_load`: Reports fanout load constraints as set by the `set_fanout_load` command.
- `fanout_load_limit`: Reports fanout load limit constraints as set by the `set_max_fanout` command.
- `input`: Reports the input delay constraints as set by the `set_input_delay` command.
- `insertion`: Reports the network insertion delay as set by the `set_clock_latency` command.
- `port_cap`: Reports port capacitance constraints as set by the `set_load` command.
- `required`: Reports required time constraints as set by the `set_output_delay` command.
- `slew_limit`: Reports slew time limit constraints as set by the `set_max_transition` command.
- `slew_time`: Reports slew time constraints as set by the `set_input_transition` command.
- `source_insertion`: Reports the source insertion

	delay as set by the `set_clock_latency -source` command. • `uncertainty`: Reports the clock uncertainty as set by the `set_clock_uncertainty` command.
`-view` *viewName*	Specifies the view name.

Examples

- The following command shows a port report, as shown in the following example:

```

report_socv_interconnect_variation

```
report_socv_interconnect_variation
[-help]
[-delay_corner string]
[-power_domain string]
```

Reports the RC variation multiplier data provided in the SOCV files.

Parameters

`-help`	Prints out the command usage.
`-delay_corner` *string*	Specifies the name of the delay corner.
`-power_domain` *string*	Specifies the name of the power domain.

report_socv_library

```
report_socv_library
[-help]
[-categories string]
[-coverage_verbose]
[-list_not_annotated]
[ -libset string | { -delay_corner string [ -power_domain string] }| { -view string [-
power_domain string]}] [ -libs string | -lib_cellsstring]
[-coverage]
```

Reports the coverage of SOCV library(s) loaded in the design.

Parameters

`-help`	Prints out the command usage.
`-categories string`	Allows you to control the types of table data to be used to check delay arcs, transition arcs, and check arcs. *Default*: all
`-coverage`	Reports coverage library data.
`-coverage_verbose`	Generates detailed report table for each cell.
`-delay_cornerstring`	Checks all the libraries defined in the specified library set.
`-lib_cells string`	Specifies library cells. The allowed format is \u201clibrary/cell\u201d name or pattern or collection. This is typically used for debugging purpose.
`-libs string`	Specifies the name of the library. If -library_set, or -delay_corner parameter is not specified then all libraries matching the library name across the MMMC configuration will get checked.
`-libset string`	Checks all the libraries defined in the specified library set.
`-list_not_annotated`	Control the types of table data to be used to check delay arcs, transition arcs, and check arcs. *Default*: all

`-power_domain` *string*	Checks and reports the specified power domain.
`-view` *string*	Checks all the delay corners associated with a view.

report_statistical_timing_derate_factors

```
report_statistical_timing_derate_factors
-type {arrival_time_based
      | slack_time_based}
-ssta_view ssta_view_name
-sta_view sta_view_name
-path_group groupname_list
-derate_cell
-derate_net
-derate_cell_check
-early | -late]
[-path_based_ssta]
[-clock_factor | -data_factor]
[-max_paths integer]
[-max_slack float]
[-max_points integer]
```

Generates design specific OCV factor. The scaling factor (hold or setup) is computed either by using the arrival time or slack time approach.

Parameters

`-clock_factor	-data_factor`	Specifies if the user-defined factor value is for clock or data. If you specify the `-clock_factor` parameter, then the `-data_factor` parameter is calculated by the software, and vice versa. These parameters are applicable to type `slack_time_based`. **Note:** The `-clock_factor` parameter and the `-data_factor` parameter are mutually exclusive. You cannot specify them together.
`-derate_cell`	Applies user-specified scaling factors on cell delays.
`-derate_cell_check`	Applies user-specified scaling factors on timing checks.
`-derate_net`	Applies user-specified scaling factors on net delays.

`-late	-early`	Specifies early or late mode analysis. Default is `late`.
`-max_paths`	Reports the specified number of worst paths in the design, regardless of the endpoint.
`-max_points` *integer*	Reports the worst path that is found to each endpoint up to the number specified by the `-max_points` option.
`-max_slack` *float*	Reports only those paths with slack equal to or less than the specified float value.
`-path_based_ssta`	Enables generation of the statistical OCV factor using path based SSTA analysis.
`-path_group` *groupname_list*	Considers only the path contained in the groups in the specified *groupname_list* for computing the statistical timing derate factor.
`-ssta_view` *ssta_view_name*	Specifies view for SSTA run.
`-sta_view` *sta_view_name*	Specifies view for STA run.
`-type arrival_time_based	slack_time_based`	
	Specifies if the OCV factor needs to be generated using the arrival time or slack time approach. In the arrival time approach, the SSTA arrival time values are used to compute the statistical OCV factor for clock and data. In the slack time approach, the STA and SSTA slacks are used to generate the statistical OCV factor for either clock or data depending on whether you specify the factor for data or clock. *Default:* `arrival_time_based` You can use the `-type arrival_time_based` parameter with the following parameters only: • `-late` • `-early` • `-path_based_ssta`

	You can use the `-type slack_time_based` parameter with the following parameters only: • `-ssta_view` • `-sta_view` • `-late` • `-early` • `-clock_factor` • `-data_factor` • `-derate_cell` • `-derate_net` • `-derate_cell_check` • `-max_paths` • `-max_slack`

Examples

- The following example computes the factors for setup analysis using the arrival time based approach:
  ```
  report_statistical_timing_derate_factors -type arrival_time_based -late
  ```
- The following example computes the data factor for setup analysis using the slack time based approach applying a user defined clock factor of 0.95:
  ```
  report_statistical_timing_derate_factors -type slack_time_based -ssta_view viewname -sta_view viewname -clock_factor 0.95
  ```
- The following example computes the clock factor for hold analysis using the slack time based approach applying a user defined data factor of 1.05:
  ```
  report_statistical_timing_derate_factors -type slack_time_based -ssta_view viewname -sta_view viewname -data_factor 1.05 -early
  ```

report_timing

[-to pin_list | -to_rise pin_list | -to_fall pin_list]
[-clock_to clk_signame_list [-edge_to {lead trail}]]]
```

Generates a timing report that provides information about the various paths in the design.

The reports typically contain data on the delay through the entire path. The start node and the end node of each path is identified.

The timing report contains the following information:

- The slack times of the arriving signal at the end node
- The start node
- The associated transitions
- The signal required times and the actual signal arrival times
- Summary of propagated vs ideal status of launching and capturing clocks
- Any phase shifts applied when evaluating timing checks
- Any CPPR values applied to timing check evaluation

The `report_timing` command output accomadates both the instance pin names and net names in the same column. Since both instance pin names and net names can be long, to save screen space alternating instance pin and net names (depending on whether the row displays gate delay or net delay) are reported in a single column.

When the `timing_report_timing_header_detail_info` timing global variable is set to `extended`, the software generates timing reports with additional header information, that includes the following details:

- The analysis mode - best case worst case or on chip variation
- The active views (displayed only in MMMC mode)
- The clock reconvergence pessimism (CPPR)
- The latch slack mode
- The specified clock propagation value
- The delay calculation
- The specified delay calculation engine

When `timing_report_group_based_mode` global variable is set to `true`, paths are grouped by clock domain. In this mode, the `report_timing` command will have the following four types of groups:

- Clock gating group: This is an internal group. This group reports the clock gating check type paths.
- Asynchronous group: This is also an internal group and reports the asynchronous check type paths.
- Groups for all the clocks in the design: These are also internal groups, classified on the basis of each reference clock. Paths belonging to each reference clock are reported separately under each clock name's group. These groups do not honor the clock gating/asynchronous check types. Suppose there are three clocks C1, C2, and C3 in the design, then three groups will be reported for each of these clocks. The endpoint sharing the same reference clock will be part of the same group. In case the endpoint belongs to multiple groups then it will be reported separately in each group.
- Default group: This is an internal group - for combinational max delay or min delay paths.
- User-Defined Groups: These are user-defined path groups. These are created by users with single or multiple constraints. These groups honor all the check types. These groups are now reported by default.

By default, the `timing_report_group_based_mode` global variable is set to `false`.

Note: The global does not honor user-defined path groups so the paths will still be grouped by different clocks.

In this mode, the following commands will have the same behavior and can be used interchangeably:

`report_timing -path_group` *`Clock_Name`*

`report_timing -clock_to` *`Clock_Name`*

The `report_timing` command supports multi-threaded reporting. You can make the following settings to enable multi-threaded reporting:

`setMultiCpuUsage -localCpu` *`number_of_CPU`*

`set_table_style -no_frame_fix_width`

Note: When `timing_allow_input_delay_on_clock_source` global variable is enabled and the `set_input_delay` command is applied to a clock input, the specified delay value will be considered as the source clock latency for clock paths and as regular data path arrival time for clock source paths.

This page provides the following `report_timing` details:

- Parameters
- Use of Informational Flags
- Reporting Timing Checks Between Various Types of Clocks

- Retime Analysis Report Header Description
- SPD (Sequential Path Delay) Examples
- Sample Reports
- Related Information

Parameters

`{> | >>} filename`	When specified with >, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with >>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The *filename* parameter must be the last argument in the list. The *filename* and -tcl_list parameters are mutually exclusive; you cannot specify them together. **Note:** To write a compressed report, add the .gz extension to the file name. *Default:* Report is displayed on standard output without being saved. **Note:** The last argument specified in the `report_timing` command is not considered a filename.
`-analysis_summary_csv_extended_file <string>`	Generates the CSV file to be used for merging.
`-analysis_summary_csv_file <string>`	Generates the analysis summary CSV file.
`-analysis_summary_file <string>`	Generates the analysis summary file.

`-begin_end_pair`	Reports all violating paths between unique source and target register pairs. To report other paths, specify this parameter with the -max_slack parameter. Paths are not sorted by slack; instead, paths with the same source pins are reported adjacent to each other. When specified with the `-from`, `-through`, or `-to` parameters, the software only reports the unique register pair paths that match the path description. **Note:** You cannot specify this parameter with the `-max_paths`, `-nworst`, `-unique_pins`, or `-min_slack` parameters. The `report_timing -begin_end_pair` parameter will always report the paths grouped by path_groups irrespective of `timing_report_group_based_mode` global variable setting.
`-check_clocks`	Generates reports based on timing paths on the clock network instead of the standard timing to data endpoints. This report includes clock paths that end at the reference end of a check or a clock gating end point. *Default*: Data paths and all the other clock paths (for example, a clock path ending at a D pin of a register) are reported.
`-check_type` *check_type*	Reports only the paths that end at the specified timing check. The following check types can be reported when the software is in setup analysis mode: setup, skew, pulse_width, clock_period, clock_gating_setup, clock_gating_pulse_width, data_setup, recovery, clock_separation, and no_change_setup. The following check types can be reported when the software is in hold analysis mode: hold, clock_gating_hold, data_hold, removal, and no_change_hold. If the software is in simultaneous setup and hold

	analysis mode, all of the check types listed above can be reported. By default, the following checks are reported: • setup • hold • clock_gating_setup • clock_gating_hold • data_setup • data_hold • recovery • removal • no_change_setup • no_change_hold You can use the `-check_type` parameter to specify the following clock style checks: • pulse_width • clock_gating_pulse_width • clock_period • Skew • clock_separation Do not use this parameter with the `-unconstrained`, `-early`, or `-late` parameters. **Note:** The `report_timing` command does not perform skew checks by default.
`-clock_from` *clk_signame_list*	Generates reports based on source clock waveform(s). Reports only those paths whose source clocks are the clock signals in *clk_signame_list*.

`-clock_to` *clk_signame_list*	Generates reports based on target clock waveform(s). Reports only those paths whose target clocks are the clock signals in *clk_signame_list*.
`-collection`	Returns a collection of timing paths. This is useful for performing Tcl queries on selected timing reports. To generate a collection of paths analyzed by Path Based Analysis (PBA), you can use the `-retime` parameter. **Note** : This parameter is not supported in DMMMC mode.
`-debug {unconstrained | time_borrow | cppr_point}`	You can specify the following option for debugging: • `unconstrained`: Determines the reasons for a path to be unconstrained. The report output will list all the applicable arcs/constraints that could not constrain the paths, along with the reasons. • `time_borrow`: Reports time borrowing calculations. Time borrowing is the amount of time borrowed by a previous logic. • `cppr_point`: Reports the CPPR point information for the reported paths.
`-delay_limit` *float*	Specifies the path delay limit for unconstrained paths (`-unconstrained` option). For early paths (-early option), reports only those paths with path delay less than the delay limit. For late paths (-late option) reports only those paths with path delay more than the delay limit. **Note:** The `-delay_limit` option only can be used in conjunction with the `-unconstrained` option.
`-derate_summary`	Generates an AOCV derating summary table for the launch and capture paths, in addition to the timing report.

`-early	-late`	Generates the timing report for early paths (hold checks) or late paths (setup checks). *Default*: `-late` **Note:** If you specify a check, setup or hold, using the set_analysis_mode command, the report_timing command reports that check by default.
`-edge_from {lead	trail}`	Generates reports based on source clock edge, either leading or trailing. **Note:** The `-edge_from` parameter only can be used in conjunction with the -clock_from parameter. *Default*: Generates reports based on both source clock edges
`-edge_to {lead	trail}`	Generates reports based on the target clock edge, either leading or trailing. **Note:** The `-edge_to` parameter only can be used in conjunction with the -clock_to parameter. *Default*: Generates reports based on both target clock edges
`-format` *column_list*	Formats the report according to the *column_list*. The *column_list* specifies which columns to display in the timing report and the order in which they appear. You can use the `-format` parameter to customize the reports to your needs by requesting the exact fields in which you have an interest. The valid format columns are: adjustment, abs_delay_err, abs_slew_err, annotation, aocv_adj_stages, aocv_derate, aocv_weight, arc, arrival, arrival_mean, arrival_sigma, cell, delay, delay_mean, delay_sigma, direction, edge, fanin, fanout, flags, hpin, incr_delay, instance, instance_location, latch_window, load, module, net, pct_delay_err, pct_slew_err, phase, phys_info, pin, pin_load, pin_location, power_domain, required, retime_delay, retime_delay_mean, retime_delay_sigma, retime_slew,

	retime_slew_mean, retime_slew_sigma, stage_count, slew, slew_mean, slew_sigma, socv_derate, spice_arrival, spice_delay, spice_slew, stolen, timing_point, total_derate, user_derate, voltage, when_cond, wire_load, wlmodel For more details on the 'flags' column, refer to the section on Use of Informational Flags. For example: `-format {hpin cell delay required arrival required edge}` See Table for a list of valid options. The default net format (with -net option) for the full path is: {hpin edge net cell delay arrival required}. If the `-unconstrained` option is specified, the required column is not displayed. The adjustment column is automatically added to the timing report. To disable this feature you can set the `report_timing_default_adjustment_column` global variable to `false`. You can also use a combination of the -format and -tcl_list parameters to integrate the timing reports into your Tcl scripts. You can use the `-from` parameter to limit the number of paths reported, and to find specific paths in the design. The `-format` option cannot be used with the `-path_type end` or `-path_type summary` options. You can change the re-timing columns by using the `timing_report_retime_formatting_mode` global variable.
`-gui`	Displays the timing report in a GUI window.

{-from | -from_rise | -from_fall} *pin_list*	Reports paths starting from the object(s) specified in the *pin_list*. The supported objects are pins and ports. Using -from_rise (or -from_fall) specifies that the rising (or falling) edge of the signals on the pins/ports in the *pin_list* are the start of the paths. You can use this option with the -through and -to parameters for specifying particular paths in the design. **Note** : These parameters do not allow clock objects. You can use the -clock_from and -clock_to parameters to reference clock waveforms.
-hpin	Prints all hierarchical crossings of an arc under hpin column in report_timing table.
-machine_readable	Generates detailed timing report in machine-readable format. This report is used for debugging timing results using the timing debug feature.
-max_paths *integer*	Reports the specified number of worst paths in the design, with maximum of nworst (-nworst) paths to any single endpoint (default 1). In case of group based mode (when timing_report_group_based_mode is set to true), the -max_paths parameter specifies the number of worst paths reported per clock group. *Default*: 1

`-max_slack` *float*	Reports only those paths with slack less than the value of the *float*. The `-max_slack` option limits the report to paths that fall into the specified range. A positive slack value indicates that timing was met. A negative value for slack indicates a timing violation. The `-max_slack` option cannot be used with the -unconstrained option. When the `-retime_mode exhaustive` option is specified, the `-max_slack` is set to `0` by default.
`-min_slack` *float*	Reports only those paths whose slack is greater than the value of float. The `-min_slack` option cannot be used with the `-unconstrained` option. You can generate a timing report showing paths with slack greater than the specified slack by using the `-max_paths` option. For example, to report all paths with slack greater than 2ns, you can issue the following command: `min_slack 2.0 -max_paths 1000` In this case the maximum number of paths reported will be 1000. When the `-min_slack` parameter is specified, the total numbers of paths processed will be as determined by the `max_path`s/`nworst` settings and only those paths satisfying the `-min_slack` criteria will be reported. The software will not process paths beyond the `max_paths`/`nworst` limit to find other paths satisfying the `-min_slack` limit. In the below diagram, if `-min_slack` is 0 and `-max_paths 4 -nworst 2` is specified, then only 3 paths will be reported; path with slack value of -1 will be ignored. Here, even if there is another path with slack that is greater than or equal to 2, then it will not be reported because worst max_paths have been processed.

	`-net`	Adds a row for the net arc. This parameter also separates the cell delay from the wire delay. *Default*: The net arc is not shown, and the net delay is added to the following delay. **Note**: The report_timing -net command displays the net delays separate from the cell delays. However, the net delay is sometimes shown as 0.0.To get the net delays to show up, increase the report precision using the following global: `set_global report_precision 5`

{-not_through | -not_rise_through | -not_fall_through} *object_list*	-not_through: Reports paths that do not traverse through the specified nets, ports, or pins of a cell. By default the parameter will be ignored when an object has already been specified. In this case the parameter shows the following behavior: • If a collection of all the input ports has been specified (using the all_inputs command), then the report will show paths to the inout part, and paths starting from the internal part of inout will be excluded. • If a collection of all output ports has been specified (using the all_outputs command), then the report will show paths starting from the internal part of inout, and paths ending at inout part will be excluded. • If any other collection (not specified using the all_inputs and all_outputs commands) is specified, then paths to both the parts will not be reported.
	-not_rise_through: Excludes paths with rise transition.
	-not_fall_through: Excludes paths with fall transition.

`-nworst` *integer*	Specifies the maximum number of paths which can be reported for a particular endpoint (the total number of paths reported is specified by the `-max_paths` parameter). In case of group based mode (when `timing_report_group_based_mode` global variable is set to `true`), the `-nworst` parameter specifies the maximum number of paths for a particular endpoint per clock group. You can use the `-nworst` option to report all the checks at an endpoint or use the `-check_type` option to report a specific check. *Default*: 1
`-output_format {text | csv | gtd | binary}`	Generates a detailed timing report in the specified format - text, CSV, GTD, or binary.

`-path_exceptions {applied | ignored | all}`	Includes information of path exceptions applied and considered for the reported path. If multiple from, through, or to pins are specfied, the exception report for that path will show only those pins that are part of the current path. **Note:** You cannot use this parameter with the following report_timing parameters: • `-point_to_point` • `-collection` • `-path_type end | end_slack_only | summary | summary_slack_only` • `-tcl_list` In addition, you cannot use this parameter with block-based SSTA. **Note**: If a path is already unconstrained, then all further path exceptions applied on that particular path will be reported as ignored exceptions. The `-path_exception` parameter also reports -start/-end options with multi-cycle paths. Without start or end specification, by default, the setup check is relative to the end clock and the hold check is relative to the start clock. The `report_timing -path_exception all` command will report all the non-default -start/-end specifications.
	applied: Reports the honored exception on the reported path.
	ignored: Reports the ignored exceptions on the reported path.
	all: Reports both applied and ignored set of exceptions on the reported. **Note:** Analyzing all the exceptions for a path will cause increase in runtime.

`-path_group` *groupname_list*	Reports only paths contained in the groups specified in *groupname_list*. Report paths belonging to the default path group by using -path_group default. The paths that do not belong to any user-specified path group belong to the default path group named default. In group-based mode, the internal groups - clock gating, clock names, asynchronous - and user defined path groups can be selected using the `-path_group` parameter.
`-path_type {end | summary | full | full_clock | end_slack_only | summary_slack_only}`	The `path_type` option lets you choose the format of the report by path type. The default format, if the `-path_type` option is not specified is `full`. You can choose one of the following options: • `end`: Generates an end point report for each path consisting of an endpoint, cause, slack, arrival time, required time, and phase. This option generates a very fast report. The -format option does not have any impact on this report format. • `summary`: Generates a summary report for each path consisting of a start point, endpoint, cause, slack, arrival time, required time, and phase. The `-format` option does not have any impact on this report format. • `full`: Generates a report that displays the full path with accompanying required time and slack calculation. This is the default path type. Control the report format using the `-format` option. • `full_clock`: If the path reported ends at a timing check, this option also reports the full clock path (Other End Path) in addition to the full data path (Timing Path). • `end_slack_only`: Generates an end point report, similar to `-path_type end` report, for each path

	consisting of an endpoint, slack and cause (as Violated/Met). This option generates a very fast report. The `-format` option does not have any impact on this report format. **Note**: When the `-path_type end_slack_only` option is used, the path collections will not be reported. • `summary_slack_only`: Generates a summary report, similar to `-path_type summary`, for each path consisting of a start point, endpoint, slack and cause (as Violated/Met). The `-format` parameter does not have any impact on this report format. In MMMC mode, when you specify the `report_timing -path_type` parameter (with `end`, `end_slack_only`, `summary`, or `summary_slack_only` options), the output report displays a view column for all the reported paths. **Note**: The paths contained in a collection are not reported with upgraded path type.
`-point_to_point`	Traces the worst delay path between a pair of from-to pins. Paths reported with this parameter only include the cumulative delay of the path. You must specify either the -from or -to parameter, to define the begin and end points of the path. If you do not specify a `-from` pin, the standard definition of the begin point of a path applies. If you specify a `-from` pin, it is treated as the begin point of the path. If you specify a -from pin that is not a valid begin point, the arrival time of the first pin starts from 0. If you do not specify a `-to` pin, the standard definition of the end point applies. If you specify a `-to` pin, it is treated as the end point, and only those paths ending in -to pins are reported. If you specify

	more than one -to pin, the worst path to each pin-to-pin is reported. When from-to pins are specified, the software will trace across the trigger arcs and report a path, if there is a clock reaching the CK pin of the trigger arc. However, if there is a begin or end point present between the `-from` and `-to` pins, the software will not trace beyond it. If there is no clock reaching the CK pin of the trigger arc, the software cannot trace across the trigger arc, and no path is reported. Additionally, clock path delay is included only when the clock is in propagated mode. The `-point_to_point` parameter can be used with the `-max_paths` and `-nworst` parameters. **Note:** The `-point_to_point` and `-through` parameters are mutually exclusive; you cannot specify them together. **Note**: The `-point_to_point` parameter supports a single `-from` and `-to` pin; a list of pins is not supported. See Sample Reports.
`-retime_delaycal_pins <pin_list>`	Reports the PBA delay calculation details for timing arcs that fanin to the user-specified to-pin list. You can specify multiple pins in the pin list. The delay calculation report will be printed at the end of each timing path for the arcs, which are retimed in that path. The PBA delay calculation report format is similar to the `report_delay_calculation` output in GBA mode, however, the results may be vary because this output is based on path-based analysis. When a cell output pin list is provided, the generated report is for the cell arcs; the cell input pin list generates the net arc report. This parameter is supported for PBA reporting only.

`-retime_format {manual | retime_compare | retime_replace}`	Allows you to set the format of timing reports for retime related fields. You can specify one of the following options: • `manual`: Does not change the `report_timing` format. • `retime_compare`: If GBA columns are present in the report format, then the corresponding retime options are added. If PBA columns are already present, then there is no change in the format. • `retime_replace`: If GBA columns are present in the report format, then the GBA columns are replaced by the corresponding PBA columns. If PBA columns are already in the report, then there is no change in the format. **Note**: The timing report format is also controlled using the `timing_report_retime_formatting_mode` global variable. The `report_timing` command setting has precedence over this global variable.

`-retime_mode {path | exhaustive}`	Reanalyzes the specified set of paths using the specified method. You can use one of the following options: • `path`: Reanalyzes the specified set of paths. By default, the software uses `-retime_mode path` setting, when the `-retime path_slew_propagation` option is specified. • `exhaustive`: Enables exhaustive path-based analysis mode. In this mode, the software will exhaustively examine nworst paths of the selected endpoints and then select the true worst path to be reported - based on retimed slacks of all the examined paths. When you use this option, reporting can be run time intensive as the software needs to do an exhaustive search for true worst paths. Therefore, it is recommended to use this option in the later phases of the sign-off stage when there are very few violations left for analysis. *Default*: `path`
`-retime {aocv | |path_slew_propagation | aocv_path_slew_propagation}`	Reanalyzes the specified set of paths using path based analysis (1 path per endpoint). **Note:** This feature is not meant to be run on all the paths of a design.

	aocv: Computes AOCV stage count based on specific paths and applies the AOCV derate values to GBA (graph-based analysis) delays. The `-retime aocv` option can be used with the following parameters only: • `-clock_from` • `-edge_from` • `-clock_to` • `-edge_to` • `-rise/-fall` • `-early/-late` • `-check_type` • `-max_paths` • `-begin_end_pair` • `-from/-from_rise/-from_fall` • `-through/-through_rise/-through_fall` • `-to/-to_rise/-to_fall`

	• `-path_group` • `-path_exceptions` • `-net` • `-path_type` • `-max_slack` • `-min_slack` • `-view` • `-format` *`column_list`* • `-derate_summary` • `-machine_readable` • `-nworst`
	`path_slew_propagation`: Re-evaluates the given set of graph-based analysis (GBA) paths by recalculating the delay values based upon actual propagated slew across the path. In this case the AOCV derates are the ones that are reported during graph-based analysis. The default timing analysis uses worst-case slew propagation to calculate the delays at each stage. As a result, timing analysis results can be pessimistic. **Note:** This feature should be run only on paths that are not meeting the slack margin criteria, to help identify actual failing paths from those that are simply failing due to the conservative delay calculation. Signal integrity incremental delays can be recomputed for the entire path. You can use the following command to perform path based signal integrity analysis: `report_timing -retime path_slew_propagation` In the report_timing command output, the Retime

	Incr Delay column reports recomputed signal integrity delays. To view this column, specify the `report_timing -format retime_incr_delay` option or use `set_global report_timing_format` timing global variable. The `-retime` option also supports retiming a collection of paths. This option does not retiming an already retimed path collection. This feature works in graph-based analysis (GBA) mode for path collections. You can use the following use model to retime collections: `report_timing $collection -retime path_slew_propagation` A path collection stores context dependent data, that is, a delay property in GBA will reflect delay data of the timing path report generated in GBA mode. The same property in PBA will reflect the re-time delay data of the timing path report in PBA mode. The delay column in timing reports is also context dependent - under the `timing_report_retime_formatting_mode retime_replace` global variable. **Note**: For memory optimization purposes, both the delays will not be stored in the same path collection. You can use this setting for comparison purposes.
	`aocv_path_slew_propagation`: Re-evaluates the given set of graph-based analysis (GBA) paths by using path-based AOCV derates and delays using actual path- based propagated slew. This option is a combination of `-aocv` and `-path_slew_propagation`. For retime report header details, see Retime Analysis Report Header Description.
`-skip_io_paths`	Specifies whether the input/output paths are to be ignored.

`-rise	-fall`	Reports the path with the specified edge on the endpoint. If an endpoint is specified using -to_rise (or -to_fall) option, the -rise (or -fall) option is ignored and paths with edge specified by `-to_rise` (or `-to_fall`) are reported. The `-rise` option applies to end point only.
`-tcl_list`	Produces the report in Tcl list format instead of a tabular format. This is useful for integrating timing with custom Tcl functions, and also for customizing report generation. The -tcl_list and *filename* parameters are mutually exclusive; you cannot specify them together.
`{-through	-through_rise	-through_fall}` *pin_list*	Reports paths that pass through pin(s) or net(s) specified by the *pin_list*. Any number of -through pins or nets can be specified. Using -through_rise (or `-through_fall`) specifies that the paths go through the rising (or falling) edge of the signals on the pins/nets in *pin_list*. The *pin_list* is a logical OR function. The resulting path may pass through any of the pins or nets in the -through *pin_list*. To force the report to pass through multiple pins or nets, separate -through statements are needed. You can use these parameters with the `-net` option.
`-to	-to_rise	-to_fall` *pin_list*	Reports paths leading to the pin(s) specified by the *pin_list*. Pins in the *pin_list* can be either pins on the design boundary (ports) or pins on an instance. Only one list of -to pins can be specified per report. Using -to_rise (or -to_fall) specifies that the rising (or falling) edge of the signals on the pins in *pin_list* are at the end of the paths. The `-to_rise` option applies to end point as well as intermediate pins.

`-unconstrained`	Reports only the unconstrained paths (paths with no slack). Each signal arriving at the path end node which does not have a matching required time, results in an unconstrained path. The `report_timing` command without the `-unconstrained` parameter reports only constrained paths. If no constrained path is found, there may be unconstrained paths or the path may not exist. **Note**: The `-min_slack` and `-max_slack` cannot be specified with the `-unconstrained` parameter. See Sample Reports for the conditions under which a path is reported as constrained or unconstrained.
`-unique_pins`	Reports paths through unique set of pins. When this parameter is specified, in group-based mode for a given begin-end point pair, the software will consider all different launch clock paths for reporting unique paths. If for a given begin-end pair and a given capture clock, there is a possibility of different launch clock paths, then each such path will be reported. **Note**: Using this option may significantly affect runtime and memory usage if the number of paths to be reported is high.
`-view {`*`viewName`*`}`	Generates report for the specified analysis view. You must be in multi-mode multi-corner analysis mode in order to use this parameter. To create a view, you use the `create_analysis_view` command. To set an active view for analysis, you use the `set_analysis_view` command. *Default:* Reports the worst path to each endpoint across all analysis views. The report_timing command to performs block based analysis in MMMC mode. By default, the command reports the worst end-point(s) across all views. You can use the -view parameter to report for individual views.

-worst_rc_corner	Identifies worst interconnect parameter combination that leads to minimum slack (desired) and generates a report for the corner.

Use of Informational Flags

Informational tags are used providing additional details. The following informational tags are supported:

Flags	Description
(i)	Net is ideal
(P)	Instance is preserved / don't_touch
(p)	Instance is preserved / don't_touch but may be resized

The output format uses the flag keys on the timing report and adds a description at the end of the report for reference. A sample output is as shown below:

```
#-------------------------------------------------------------------------
# Timing Point  Delay (ns) Latch  Window   Arrival   Arc   Flags   Adjustment
# (ns)
#-------------------------------------------------------------------------
f0/CP           -          -    1.000000            CP       -       -
f0/Q            0.254100   -    1.254100            CP->Q    -       -
b32/Z           0.598446   -    1.852546            I->Z     -       -
...
b4/Z            0.086940   -    2.502181            I->Z     -       -
f1/D            0.000000   -    2.502181            D        <<<     -
#-------------------------------------------------------------------------

(P) : Instance is preserved
(p) : Instance is preserved but may be resized
(i) : Net is ideal.
(b) : Timing paths are broken.
```

Report Timing- Column List Options

Option	Description
adjustment	Reports generated clock adjustment values. When reporting the detailed path for a generated clock, there are circumstances where the arrival time needs to be adjusted when a `create_generated_clock` assertion is encountered along the path. The adjustment argument can be used to provide a clearer indication of why a "jump" in the arrival time is seen in the path report. When the `create_generated_clock -edge_shift` parameter is specified, the adjustment column will show the amount of shift specified.
abs_delay_err	Reports the absolute delay difference of Tempus from Spice.
abs_slew_err	Reports the absolute slew difference of Tempus from Spice.
annotation	Reports RC parasitic annotations for net arcs, and delay annotations for either gate or net arcs. The following annotations are reported: • SDF: SDF back-annotation. The annotation status reflects the gate arc, not the interconnect arc. • SPEF: This entry appears if parasitic extraction has been done or annotated using SPEF. • LumpedRC: Lumped RC annotation • DlyAssert: Assertion set with set_annotated_delay command • WLM: Wire load model back-annotation • <none>: All others
aocv_adj_stages	Shows up "Aocv Adjust Stages" column. This column reports the AOCV adjustment stages that indicate the total effective stage count.

aocv_derate	Reports the graph-based AOCV derating factor used for cells/nets in AOCV mode. In retime mode, this column will report graph-based derating for cells/nets before the AOCV branch point and path-based derating.
aocv_weight	Reports AOCV weight values for the path elements.
arc	Reports the arc as described by the from pin, from pin edge, to pin, and to pin edge. For example, the arc from the rising edge of pin A to the falling edge of pin Z is reported as `A -> Z`.
arrival	Reports the arrival time on the pin.
arrival_mean	Reports mean of the arrival time on a pin.
arrival_sigma	Reports standard deviation of the arrival time on a pin.
cell	Reports the cell name of the given pin's instance.
delay	Reports the arc delay. If the stolen slack at the arc output pin (output of transparent latches) is not zero, the stolen column is also displayed along with this column.
delay_mean	Reports the mean of each arc's delay.
delay_sigma	Reports the standard deviation of each arc's delay. **Note**: In the absence of correlated and uncorrelated components of variation, the individual delay sigma values will not be summed up.
direction	Reports the pin direction (IN, OUT).
edge	Reports the edge of a pin (^=R, v=F).
fanin	Reports the number of source nodes of a net connected to a timing pin.
fanout	Reports the number of sinks of a net connected to a timing pin.

flags	Indicates the size_only, dont_use, dont_touch, and ideal attributes. When the 'flags' option is specified, a capacitance group entry (if it exists) will be displayed under the "Flags" column. This value indicates the input capacitance group being used for delay calculations – C1C2 (2-piece model) or C1CN (n-piece model).
hpin	Reports the hierarchical name for a given pin. **Note**: The hpin, pin, and timing_point will print the same values in the report output.
incr_delay	Reports the incremental delay of a pertaining arc. The software reads the incremental delay from an incremental SDF file using the `read_sdf` command.
instance	Reports the hierarchical name of a given pin's instance.
instance_location	Reports the location (x,y) of an instance. If a design is not placed, this column will be blank. This option displays the `instance` column automatically.
latch_window	Reports the available window for latch to sample the data.
load	Reports the total capacitance load on a given pin.
module	Reports the module name of the corresponding block hierarchy. This hierarchical module name will be reported only when the `-hpin` parameter of the `report_timing` command is specified.
net	Reports the hierarchical name of a net connected to a given pin.
pct_delay_err	Reports the percent delay difference of Tempus from Spice.
pct_slew_err	Reports the percent slew difference of Tempus from Spice.

phase	Reports the phase name of a pin.
phys_info	Shows minimum/maximum assigned layer, and non-default rule name information.
pin	Reports the reference name for the given pin.
pin_load	Reports the pin load data. The pin load refers to the sum of pin capacitance of all the pins connected to the current net.
pin_location	Reports the location (x,y) of a pin. If a design is not placed, this column will be blank.
power_domain	Reports power domain details of the specified path instance.
required	Reports the required time on a pin.
retime_delay	Reports the recalculated arc delay based on the path being reanalyzed with the specified retime method.
retime_delay_mean	Reports the mean of the recalculated arc delay on the path being reanalyzed with the specified retime method.
retime_delay_sigma	Reports the standard deviation of each parameter of an arc's retimed delay.
retime_slew	Reports the recalculated slew based on the path being reanalyzed with the specified retime method.
retime_slew_mean	Reports the mean of each parameter of an arc sink pin's retimed slew.
retime_slew_sigma	Reports the standard deviation of each parameter of an arc sink pin's retimed slew.
stage_count	Displays the aggregate stage count of a specific instance in graph-based analysis (GBA) mode, and the actual stage count in path-based analysis (PBA) mode.
slew	Reports the propagated slew at the given pin.

slew_mean	Reports mean of each parameter of an arc sink pin's slew.
slew_sigma	Reports the standard deviation of each parameter of an arc sink pin's slew.
socv_derate	Reports the SOCV or the spatial derating factor applied on the cells or nets in SOCV analysis mode.
spice_arrival	Reports the Spice arrival time at the timing point.
spice_delay	Reports the Spice delay of a timing arc.
spice_slew	Reports the Spice slew of a timing point.
stolen	Reports the slack stolen (or the time given to the previous stage) at the given pin. If the slack is not zero and the `delay` column is specified, then this column is displayed by default (but only visible on the output of transparent latches).
timing_point	Reports the hierarchical names for the given points.
total_derate	Reports the total derating factor applied on the corresponding cell or nets that reflect the combined impact of all the derates (OCV/AOCV/spatial) applied on each stage of the timing path.
user_derate	Reports the derating scale factors set with the `set_timing_derate` command. **Note:** The timing system cannot provide an accurate derating factor for the lumped gate and wire delay when the `set_timing_derate` factors for `-cell_delay` and `-net_delay` are not equivalent. In this case, an asterisk (*) is reported in the SSI Derate column.
voltage	Returns the voltage that is used during delay calculations.
when_cond	Reports the "when" condition of the arc specified in the library.

wire_load	Reports the wire load.
wlmodel	Reports the kind of parasitic used by a pin or net, such as SPEF. If the wire load model is derived from a Liberty file, the information is reported in the following format: `Wireload model (.lib model_name library_name)`

Reporting Timing Checks Between Various Types of Clocks

The following table summarizes the timing checks and the min/max delay checks that are performed based on the types of launching and capturing clocks:

- NZ (Non Zero Period Clock - Regular Clock)
- Z (Zero Period Clock - Regular clock whose period is equal to zero)
- @ (Asynchronous Clock - Clock which triggers the default input delay and the input delay without a clock)
- CPD (Combinational Path Delay)

Launching Clock	Capturing Clock	Timing Checks	Path Delay Checks
@	@	NO	CPD
Z	@	NO	CPD
NZ	@	NO	CPD
@	Z	YES	SPD
@	NZ	YES	SPD
NZ	Z	NO	SPD
Z	NZ	YES	SPD
Z	Z	YES	SPD
NZ	NZ	YES	SPD

Retime Analysis Report Header Description

AOCV(default)	Indicates that the selected retime analysis includes recalculation of path depths and AOCV derates. The AOCV retime is enabled with the `-retime aocv` or `aocv_path_slew_propagation` parameter. The AOCV stage counting mode (set using the `timing_aocv_analysis_mode` global variable) is indicated in the parenthesis. The stage counting modes are given below: • `launch_capture(default)` `(Default)` • `combine_launch_capture` `(Combine)` • `separate_clock_data` `(Separate)` • `clock_only` `(Clock)`
Corr	Indicates that the current SOCV accuracy mode considers correlation of variation between stages. Starting with SOCV accuracy mode `medium` (specified using `setDelayCalMode -socv_accuracy_mode` parameter), it is assumed that some portion of the variation is not completely uncorrelated random variation, so the software tracks a correlated and uncorrelated component for each of the applicable moments.
Data Clock	Indicates the portion of the path that has been retimed. By default, only the data path is retimed. When the `timing_disable_retime_clock_path_slew_propagation` global variable is set to `false`, then the clock path will also be retimed, and “Clock” will be added to the retime status.
GP	Indicates that graph-based PBA mode settings are enabled.

GS	Indicates that GBA skewness mode settings are enabled.
Path-Slew	Indicates the selected retime analysis is set to use path correct slew rates to reduce the pessimism from slew merging. This can be controlled with the `report_timing -retime` parameter. The path slews are recalculated in `path_slew_propagation` and `aocv_path_slew_propagation` modes.
RC	Indicates that RC variation is enabled with the `timing_socv_rc_variation_mode` setting, and an SOCV format RC variation side file library is available.
SI	Indicates that SI analysis was enabled during the retime analysis. The path-based analysis will recompute SI effects using path-correct victim timing windows.
SOCV(Ultra)	Indicates that SOCV analysis is enabled and has been incorporated into the retiming. The SOCV analysis mode (specified using the `setDelayCalMode -socv_accuracy_mode` parameter) is shown in parenthesis. The accuracy modes are mapped as follows: • `low` `<not shown>` • `medium` `Medium` • `high` `High` • `ultra` `Ultra`

Spatial (CS)	Indicates that spatial derating side files have been loaded and an explicit spatial derate factor will be calculated. This is not shown for AOCV 2D derate tables, where the spatial and depth derates are combined. The GBA spatial derate mode (specified with the `timing_spatial_derate_distance_mode` setting) is shown in parenthesis with the possible values below: • `chip_size (CS)` • `bounding_box (BB)` The GBA spatial derate mode does not affect the path-based analysis bounding box calculation.
WP	Indicates that waveform propagation is enabled (`setDelayCalMode -equivalent_waveform_model propagation` setting). The path-based retime will also use this delay calculation accuracy setting when recomputing delays and transitions for the path.

SPD (Sequential Path Delay) Examples

- The following command reports paths leading to the pin(s) specified by the *pin_list* :

```
report_timing -to u55/D

Path 1: MET Setup Check with Pin u55/CK
Endpoint: u55/D (^) checked with leading edge of 'CLK_W_4'
Beginpoint: u55/QN (^) triggered by leading edge of 'CLK_W_4'
Path Groups: {CLK_W_4}
Other End Arrival Time 0.152
- Setup 0.306
+ Phase Shift 10.000
= Required Time 9.845
- Arrival Time 1.902
= Slack Time 7.943
Clock Rise Edge 0.000
```

```
+ Clock Network Latency (Prop) 0.152
= Beginpoint Arrival Time 0.152
-------------------------------------------------------------------------
Pin      Arc            Cell      Delay     Arrival    Required    Instance
                                              Time      Time
-------------------------------------------------------------------------
            -
u55/CK    CK ^           -       - 0.151    8.094                  u55
u55/QN    CK ^ -> QN ^   DFF      1.750     1.901       9.844      u55
u55/D ->  D ^            DFF      0.001     1.902       9.845      u55
-------------------------------------------------------------------------
```

- The following command shows a report similar to the first with the addition of net arc information.

```
report_timing -to u55/D -net

Path 1: MET Setup Check with Pin u55/CK
Endpoint: u55/D (^) checked with leading edge of 'CLK_W_4'
Beginpoint: u55/QN (^) triggered by leading edge of 'CLK_W_4'
Path Groups: {CLK_W_4}
Other End Arrival Time 0.152
- Setup 0.306
+ Phase Shift 10.000
= Required Time 9.845
- Arrival Time 1.902
= Slack Time 7.943
Clock Rise Edge 0.000
+ Clock Network Latency (Prop) 0.152
= Beginpoint Arrival Time 0.152
-------------------------------------------------------------------------
Pin        Arc           Cell    Delay    Arrival    Required    Instance
Time Time
-------------------------------------------------------------------------
u55/CK     CK ^           -      -        0.151     8.094       u55
u55/QN     CK ^ -> QN ^   DFF     1.750    1.901     9.844       u55
u55/D ->   -              DFF     0.001    1.902     9.845       u55
-------------------------------------------------------------------------
```

- The `report_timing` command also accepts `-collection` as an argument. For example,

```
report_timing [report_timing -collection]
```

```
set rpt [report_timing -collection]
report_timing $rpt
```

- The following command displays the worst late path in the design. The format of the report is similar to the first example:
  ```
  report_timing
  ```
- The following command displays the worst late path to each violating endpoint that has a slack less than -1.0:
  ```
  report_timing -max_slack -1.0
  ```
- The following command displays all the late paths that end at port `out[2]` and that have negative slack up to a maximum of 1000 worst paths. If there are more than 1000 paths, only the 1000 worst paths are reported:
  ```
  report_timing -to out[2] -max_paths 1000 -max_slack 0.0
  ```
- The following command reports the worst late path that starts at `in[0]` and ends at `out[1]`:
  ```
  report_timing -from in[0] -to out[1]
  ```
- The following command displays the three worst paths that start at `in[1]` and end at `out[3]`. With reconvergent fanout, more than one path may exist:
  ```
  report_timing -from in[1] -to out[3] -max_paths 3
  ```
- The following command displays the ten worst paths. Only the paths between the specified pins are enumerated.With reconvergent fanout, more than one path may exist: `report_timing -from i102/Z -to i123/A -max_paths 10`
- The following command enumerates the worst ten paths through the given two pins, starting at the beginning points in the design and ending at the endpoints, similar to using the `-from` option: `report_timing -through i102/Z -through i123/A -max_paths 10`
- The following command reports the ten worst paths through blocks A and C, or blocks B and C. The path only has to satisfy one element in a through list, but all through lists must be satisfied. The example can be thought of as ((A or B) and C):
  ```
  report_timing -through {A/*B/*} -through {C/*} -max_paths 10
  ```
- The following command forces a path through pin A and pin B. Use the syntax shown in the example. Do not use `-through {A B}`:
  ```
  report_timing -through A -through B
  ```
- The following command displays the clock path through the clock root to Launch flop: `report_timing -through aBC_bs/bs_mex1/r2_00_q1_reg_10_/CK -to .... -path_type`

```
full_clock
```

- You will not see the path for the launch clock if you specify the following command because the report_timing command starts reporting from the CK pin:

```
report_timing -from aBC_bs/bs_mex1/r2_00_q1_reg_10_/CK
```

- The first command displays the path leading to the `CK` pin.
- The following command shows the `-unconstrained` option:

```
report_timing -unconstrained

Path 1:Endpoint: OUT4 (^) (unconstrained output)
Beginpoint: u55/Q (^) triggered by leading edge of 'CLK_W_4'
Arrival Time 0.365
+ Clock Network Latency (Prop) 0.150
= Beginpoint Arrival Time 0.150
-------------------------------------
Load Slew Delay Arrival Cell Arc Pin
Time
-------------------------------------
0.013 0.116 - 0.150 - CK ^ u55/CK
0.011 0.072 0.215 0.365 DFF CK ^ -> Q ^ u55/Q
0.011 0.131 0.000 0.365 - OUT4 ^ OUT4 ->
-------------------------------------
```

- The following command shows the `-unconstrained -path_type end` report:

```
report_timing -nworst 5 -unconstrained -path_type end -format {pin arrival phase}

-------------------------------------------------------------------
Path No. Pin           Cause               Arrival  Phase
-------------------------------------------------------------------
1        seg3/u9/CK ^  Unconstrained Path  0.682    CLK_W_3(D)(P) *
2        seg3/u9/CK ^  Unconstrained Path  0.682    CLK_W_3(D)(P) *
3        seg3/u3/CK ^  Unconstrained Path  0.682    CLK_W_3(D)(P) *
4        seg3/u3/CK ^  Unconstrained Path  0.682    CLK_W_3(D)(P) *
5        seg2/u9/CK ^  Unconstrained Path  0.682    CLK_W_2(D)(P) *
-------------------------------------------------------------------
```

- The following command sets a false path from u99/Q to u55/D:

```
set_false_path -from u99/Q -to u55/D
```

```
set_false_path -through u4/Y
report_timing -from u99/Q -to u55/D -unconstrained -path_exceptions all

Path 1:Endpoint: u55/D (^) (unconstrained output)
Beginpoint: u99/Q (v) triggered by leading edge of 'CLK_W_4'
Arrival Time 0.827
+ Clock Network Latency (Prop) 0.150
= Beginpoint Arrival Time 0.150
------------------------------------------------------------
Load    Slew    Delay   Arrival   Cell   Arc   Pin

```

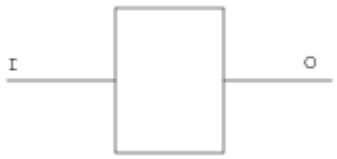
- The following examples refer to the figure shown below:

Conditions for Unconstrained and Constrained Paths



- Shows the path from `I` to `O` is reported as an unconstrained path under the following conditions (constraints on `I` and `O`):
- No constraints on either `I` or `O`
- `set_input_delay -clock ck1 1.0 I`
  No `set_output_delay` constraint on `O`
- `set_input_delay 1.0 I`

```
set_output_delay 1.1 O
```

- Shows the path from `I` to `O` is reported as a constrained path under the following conditions (constraints on `I` and `O`):

- ```
  set_input_delay  -clock ck1 1.0 I
  set_output_delay  -clock ck1 1.0 O
  ```

- ```
  set_input_delay  -clock ck1 1.0 I
  set_output_delay  -clock ck2 1.0 O
  ```

- ```
  set_output_delay  -clock ck1 1.0 O
  ```
  No `set_input_delay` constraint on I. It uses default delay of zero.
  Default: `-late`

- The following command reports AOCV weight details of path elements:
  ```
  report_timing -from in3 -to Top_I9/D -format {instance cell arc delay

Abbreviative attacker status and filtered reason:
------------------------------------------------------------
SY : Synchronous
INF: Attacker with infinite timing window
PE : Filtered due to physical exclusion
UF : Filtered by user
CN : Filtered because it is a constant net
SB : Filtered due to small bump
TA : Filtered because of timing window does not overlap
LC : Filtered due to logical correlation
ACT: Attacker is Active.
------------------------------------------------------------
```

Scenarios for Group Path Reporting for User-Defined Groups

- A user-defined group is created with the same name as any of the defined reference clocks and with the same constraint as for the "to" clock. For example, `group_path -name CLK -to CLK`.

  In this case only one group named `CLK` will be displayed in the timing report. This will be the same default group with reference clock `CLK`. Note that default groups - clock gating and asynchronous checks - will not be honored for this group.

- A user-defined group is created with the same name as any of the reference clocks but with different constraint as specified for the "to" clock. E.g., `group_path -name CLK - from pin1 -to CLK`.

  In this case the two groups named `CLK` will be displayed in the timing report. One group will be the same as the default group with reference clock `CLK` (which will not honor clock gating or asynchronous checks) and the other will be the user-defined path group with name `CLK`, which will honor all the checks.

report_timing_derate

```
report_timing_derate
[-delay_corner delayCornerName]
[-include_inherited]
[object_list]
[{> | >>} filename[.gz]]
```

Reports delay scaling or derating factors for early and late clock and data paths in the current design.

By default, the `report_timing_derate` output shows pulse_width_check and clock_period_check details for instance objects (see `set_timing_derate`).

If you specify this command without any parameters, reports are generated for global derating factors for each instance, net, or cell for which derating is asserted.

The following reports are also generated:

- In best case worst case, maximum and minimum corner
- Early values from minimum corner and late values from maximum corner in on-chip variation mode
- In MMMC mode, specified corners, or for all corners when corner is not specified
- Power domains (if present in the design)

Parameters

`> | >> filename`	When specified with `>`, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with `>>`, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. **Note:** To write a compressed report, add the `.gz` extension to the file name.
`-delay_corner delayCornerName`	Reports derating factors for the specified delay calculation corner only. *Default:* Reports derating factors for all delay calculation corners.
`-include_inherited`	Reports the object names from which the derating factor values are inherited. When specified, the report displays the name of the cell for each instance from which derate values are inherited.
object_list	Specifies the list of cells, nets, or library cells.

Examples

- The following commands display global derating factors:

```
set_timing_derate 1.2
set_timing_derate -clock -early 1.1
set_timing_derate -data -late 1.2

report_wire_load

```
report_wire_load
[-inst name_or_collection_of_hierarchical_instances]
[-ports name_or_collection_of_ports]
[-late | -early]
[> | >> filename]
```

Reports the wireload name, library, wire load mode and selection type for all hierarchical instances in the design.

Note: To enable wireload mode, you are required to set the following global:

set soceSupportWireLoadMode 1

Note: To use the wireload model functionality, you must enable the `enable_wire_load_model_support` global variable using the following command:

```
set_var enable_wire_load_model_support 1
```

Parameters

`>|>> filename`	When specified with `>`, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with `>>`, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. The *`filename`* parameter must be the last argument in the list. **Note:** To write a compressed report, add the `.gz` extension to the file name. *Default:* Report is displayed on standard output without being saved.

`-inst` *`name_or_collection_of_hierarchical_instances`*	Specifies the name of an instance or collection for which the `report_wire_load` command reports the wireload name, library, wire load mode, and selection type. The `report_wire_load` command also supports wildcard names such as U*.
`-late	-early`	Reports wireload models in setup or hold analysis mode. By default, the software reports wireload models for the mode that you set using the command.
`-ports` *`name_or_collection_of_ports`*	Reports wireload information for the specified ports.

Examples

- The following example shows the default report when wireload mode is set to top:

```
report_wire_load
---------------------------------------------------------------------
Design Name top_chip
Wire Load Mode top

Instance Module WireLoadModel Library SelctionType
---------------------------------------------------------------------
- top_chip model4 fast library-default
---------------------------------------------------------------------
```

- The following example shows the report when wireload mode is set to enclosed to report lower hierarchy:

```
set_wire_load_mode enclosed

report_wire_load
---------------------------------------------------------------------
Design Name top_chip
Wire Load Mode enclosed
Instance Module WireLoadModel Library SelctionType
---------------------------------------------------------------------
```

```
- top_chip model4 fast library-default
U1 randr model4 fast library-default
U2 randr model4 fast library-default
------------------------------------------------------------------------
```

- The following example shows model assertions using the `set_wire_load_model` command the corresponding reports using the `report_wire_load` command:

```
set_wire_load_model -name model3
report_wire_load
------------------------------------------------------------------------
Design Name top_chip
Wire Load Mode enclosed

Instance Module WireLoadModel Library SelctionType
------------------------------------------------------------------------
- top_chip model3 fast user-asserted
U1 randr model3 fast user-asserted
U2 randr model3 fast user-asserted
------------------------------------------------------------------------
set_wire_load_model -name model2 [get_cells U1]

set_wire_load_model -name model4 [get_cells U2]

report_wire_load
------------------------------------------------------------------------
Design Name top_chip
Wire Load Mode enclosed

Instance Module WireLoadModel Library SelctionType
------------------------------------------------------------------------
- top_chip model3 fast user-asserted
U1 randr model2 fast user-asserted
U2 randr model4 fast user-asserted
------------------------------------------------------------------------
```

- The following example shows the report including port information:

```
report_wire_load -ports [get_ports XYZ/A]

-------------------------------------------------------------------------
Design Name   randr

Wire Load Mode   enclosed

Port     Module WireLoadModel Library    SelctionType
-------------------------------------------------------------------------

P1     randr model2               slow   user-asserted

P2     randr model4              slow   user-asserted
-------------------------------------------------------------------------
```

- setAnalysisMode

reportTimingLib

```
reportTimingLib
-outfile fileName
[-byLib]
[-all | -pin | -threshold | -sibling]
[-lib library_name]
[cellName]
```

Reports the contents of the timing library.

Parameters

`-all	-pin	-threshold	-sibling`	Specifies the parameter for which the software should report the timing data. `-all` prints all the pin properties, siblings of a cell, the libraries where they are defined, and the voltage. `-pin` reports the pin properties, such as the pin name, direction, capacitance, max load, max fanout, and fanout load. `-threshold` reports the input thresholds, output thresholds, and slew thresholds of a cell. `-sibling` reports sibling cells, the libraries where they are defined, and the voltage. *Default:* `-all`
`-byLib`	Organizes the generated report by libraries. If you do not specify this parameter, the `reportTimingLib` command prints out cells with the same name together. Use this parameter to support multi-supply multi-voltage feature of the software, where you can define same cell names in more than one library with different voltage values and timing data.
cellName	Specifies the individual cell name to be reported.

`-lib` *`library_name`*	Reports a specified library. If you do not specify this parameter, all the library names are reported.
`-outfile` *`fileName`*	Specifies the name of the file to which the results are written.

Command Order

Use this command after importing the design when the timing library is also loaded.

Example

The following command reports the cell information in the timing library, and writes the results to the file `xyz.dump.lib`:

reportTimingLib -outfile xyz.dump.lib

reset_instance_library

```
reset_instance_library
[-help]
```

Resets the settings/binding done using the `set_instance_library` command.

Parameters

`-help`	Prints out the command usage.

Related Commands

- `set_instance_library`

reset_path_adjust_group

```
reset_path_adjust_group
[-help]
[-name <group_name> | -all]
```

Removes all path adjust groups that are set using the `set_path_adjust` command for setting path slack adjustment values.

Parameters

`-help`	Prints out the command usage.
`-all`	Removes all the path adjust groups.
`-name` *`group_name`*	Removes the named path adjust group completely.

Related Commands

- `set_path_adjust_group`
- `set_path_adjust`

reset_sdf_assertions

`reset_sdf_assertions`

Resets the sdf delays to the values defined in the library. When you perform timing analysis using the timing engine, the software uses sdf values that you define using the `read_sdf` command earlier in the flow. You use the `reset_sdf_assertions` commands to discard delay values specified using the sdf files, and use the delays defined in the library.

Note: You do not need to read in the sdf delays every time you perform delay calculation. The software uses the sdf files specified earlier in the flow.

Parameter

None

Related Information

- `read_sdf`

reset_timing_derate

```
reset_timing_derate
[-delay_corner delayCornerName]
[-increment]
[object_list]
```

Resets derate factors specified on a design or a list of instances (cells, net, or library cells). All the derating factors that are set globally or on specific instances are reset to a default value of `1.0`.

The derating factors for early or late paths in the design are set using the `set_timing_derate` command.

Parameters

`-help`	Prints out the command usage.
`-delay_corner delayCornerName`	Specifies the delay corner or a list of delay corners on which reset derating is to be applied.
`-increment`	Incrementally adds the derate value to the total derate value in all the modes - OCV, AOCV, and SOCV mode.
object_list	Specifies the list of cells, nets, or library cells to reset. If the *object_list* contains hierarchical cells then all cells within the hierarchical cells and across lower hierarchies have reset derate factors.

Examples

- The following example resets all the object-specific and global derating factors:
  ```
  reset_timing_derate *
  ```
- The following example resets only global derating factors:
  ```
  reset_timing_derate [current_design]
  ```

- The following example resets derating factor values for the specified delay corner:
  `reset_timing_derate -delay_corner` *`delayCornerName`*
- The following example resets the global derating values for the specified delay corner:
  `reset_timing_derate -delay_corner` *`delayCornerName`* `[current_design]`
- The following example resets timing derate on instance `u1`:
  `reset_timing_derate [get_cells u1]`

Related Information

- `set_timing_derate`

reset_wire_load_mode

```
reset_wire_load_mode
```

Resets the wire-load mode to the default mode of `top`.

Note: To enable wireload mode, you are required to set the following global:

```
set soceSupportWireLoadMode 1
```

Note: To use the wireload model functionality, you must enable the `enable_wire_load_model_support` global variable using the following command:

```
set_var enable_wire_load_model_support 1
```

Related Information

- `set_wire_load_mode`

reset_wire_load_model

```
reset_wire_load_model
[-help]
[{ list_of_instances_or_ports }]
```

Resets wireload models for the specified list of objects. The list of objects can include designs, hierarchical cells, or ports.

When objects are not specified, the software removes the wireload model specified using the `set_wire_load_model` command from the current instance only.

Note: To enable wireload mode, you are required to set the following global:

```
set soceSupportWireLoadMode 1
```

Note: To use the wireload model functionality, you must enable the `enable_wire_load_model_support` global variable using the following command:

```
set_var enable_wire_load_model_support 1
```

Parameters

`-help`	Outputs a brief description that includes type and default information for each `reset_wire_load_model` parameter. For a detailed description of the command and all of its parameters, use the man command: `man reset_wire_load_model`.
`list_of_instances_or_ports`	Specifies the list of instances or ports for which to remove the wireload models.

Example

- The following command removes the wireload model for `clk1`:

  ```
  reset_wire_load_model clk1
  ```

Related Commands Information

- set_wire_load_model

reset_wire_load_selection_group

```
reset_wire_load_selection_group [{ list_of_objects }]
```

Removes the wireload selection group for the specified list of objects. The list of objects can include designs, hierarchical cells, or ports. When objects are not specified, wireload selection groups are removed for all objects.

Note: To enable wireload mode, you are required to set the following global:

```
set soceSupportWireLoadMode 1
```

Note: To use the wireload model functionality, you must enable the `enable_wire_load_model_support` global variable using the following command:

```
set_var enable_wire_load_model_support 1
```

Parameters

list_of_objects	Specifies the list of object names for which to remove the wireload selection groups.

Example

- The following command removes the wireload selection group for `clk1`:

  ```
  reset_wire_load_selection_group clk1
  ```

Related Information

- `set_wire_load_selection_group`

set_analysis_view

```
set_analysis_view
[-help]
[-drv string]
[-dynamic string]
-hold list_of_views
[-inactive string]
[-leakage string]
-setup list_of_views
[-update_timing]
```

Defines the analysis views to use for setup and hold analysis and optimization.You must define at least one setup and one hold analysis view. The "active" views represent the different design variations that will be analyzed. These views can be changed throughout the flow to utilize different subsets of views. The libraries and data are loaded into the system that are required to support the selected set of active views.

When the `set_analysis_view` command is issued, it will cause a full timing reset. During a timing reset, all the interconnect parasitics, delays, and timing slacks will be recalculated.

The order in which you specify the views with the `-setup` and `-hold` parameters is important. By default, the first views defined in the `-setup` and `-hold` lists are the default views. The default views serve two purposes:

- Provide the library data that is used during the design initialization process.
- Indicate to parts of the application, that are not MMMC-aware, which view's information to use for a particular analysis step (in most cases, the default view is the first setup or hold view). You can use the `set_default_view` command to change the default view to any currently active view without incurring a timing reset. This control is not frequently used since most applications either support MMMC or provide a direct control for selecting the appropriate view to use for that specific analysis.

Using the `set_default_view` command does not affect software performance because it only uses views that are already active in the design. If you use the `set_analysis_view` command to change the default views, the existing timing and delay calculation data is reset.

Use this command after creating multiple analysis views (`create_analysis_view`).

Note: The `set_analysis_view` command does not work in an incremental manner for setting parameters. Each invocation of this command must include the full specification of all the active views required for analysis.

Parameters

`-help`	Prints out the command usage.
`-drv` *string*	Selects specific views for DRV analysis, e.g., max_transition and max_capacitance checking. When this parameter is specified, additional analysis views are specified for DRV analysis, so the timing system efficiently computes the required data for these checks. This methodology is efficient with respect to memory and performance, because all the views as full Setup views are not included. The following guidelines should be followed when selecting DRV views: • Any setup views that require DRV analysis should not be specified as DRV views. The setup views are automatically considered for DRV. • If a subset of hold-only views require DRV analysis, they should be specified as DRV views as well. The timing system will augment the timing information normally computed for Hold views with additional data required for the DRV analysis. • Additional views that are not active setup or hold views can be specified as DRV only views. The system will efficiently compute the required data for performing accurate DRV checks.

`-dynamic` *string*	Sets a view as a dynamic view. Delay calculation is required to provide transition times. Delay calculation should not perform SI analysis if the delay corner is only required for the dynamic power. The timer is not required to propagate required times or perform slack computations.
`-hold` *list_of_views*	Sets the active views for hold analysis.
`-inactive` *string*	Sets views as inactive for timing analysis.
`-leakage` *string*	Sets a view as a leakage view. The Timing libraries must be loaded, if not already in use. The Timer constant propagation is required, whereas delay calculation is not required.
`-setup` *list_of_views*	Sets the active views for setup analysis.
`-update_timing`	Reloads the configuration described by the MMMC view and mode objects. When the timing global `timing_defer_mmmc_object_updates` is set to `true`, this parameter is required to update the MMMC timing environment. The `-update_timing` parameter may be specified without any `-setup` or `-hold` arguments. In this case, the data associated with the current set of setup and/or hold views will be loaded. If no active setup or hold views exist, then using this parameter alone may display an error. The `-update_timing` parameter may also be used in conjunction with the `-setup` and `-hold` options. In this case, the newly specified setup/hold view configuration will be loaded with the updated MMMC object information.

When you issue the `set_analysis_view` command, the software will perform a timing reset, so that only the new active view information is loaded up. The software requires the `-setup` and `-hold` view parameters to be explicitly specified for each `set_analysis_view` command run. If these parameters are not specified, the software issues an error message. Any optional settings, such as, `-leakage` or `-dynamic` views will be reset if they are not specified with the

new `set_analysis_view` command.

Note: It is recommended to use the same power view for both leakage and dynamic, that is, both the `-dynamic` and `-leakage` parameters should have the same user-specified view settings.

Examples

- The following command sets `missionWCCOM` and `mission2WCCOM` as the active views for setup analysis, and `missionBCCOM` and `testBCCOM` as the active views for hold analysis:

```
set_analysis_view -setup {missionWCCOM mission2WCCOM}

  -hold {missionBCCOM testBCCOM}
```

- `set_default_view`

set_aocv_thresholds

```
set_aocv_thresholds
[-help]
[-min_stage_count_setup <int>]
[-min_stage_count_hold <int>]
[-reset]
[-slack_pruning_threshold <float>]
-view <list_of_views>
```

Limits the minimum AOCV stage depth in graph-based analysis (GBA) mode.

Parameters

`-help`	Prints out the command usage
`-min_stage_count_setup <int>`	Applies the AOCV stage count floor, during Setup analysis, so that all the instances are guaranteed to have a stage depth no less than the specified value. A value of '0' will remove the assertion.
`-min_stage_count_hold <int>`	Applies the AOCV stage count floor, during Hold analysis, so that all the instances are guaranteed to have a stage depth no less than the specified value. A value of '0' will remove the assertion.
`-reset`	Removes/sets to default all of the AOCV threshold assertions for specified views.
`-slack_pruning_threshold <float>`	Controls the slack threshold (in two-pass/slack-based AOCV analysis mode), at which paths are removed from consideration for the next phase of AOCV stage counting.
`-view <list_of_views>`	Applies the specified thresholds to the list of analysis views.

set_default_view

```
set_default_view
{-setup newDefaultSetupView | -hold newDefaultHoldView}
```

Temporarily changes the default active analysis view to a different active view.

Some Innovus applications can function only on a single analysis view at a time. By default, these single-view applications use the default analysis view. If an application or flow step does not provide a native option for specifying which view to use, the `set_default_view` command can be used to temporarily change the default view to a different active view that is better suited to that flow step.

Note: Using the `set_default_view` command does not affect software performance because it only uses views that are already active in the design. If you use the set_analysis_view command to change the default views, the existing timing, delay calculation, and RC data is reset.

Use this command after defining active views for the design (set_analysis_view).

Parameters

`-hold` *newDefaultHoldView*	Changes the default active hold analysis view to the specified analysis view.
`-setup` *newDefaultSetupView*	Changes the default setup analysis view to the specified analysis view.

Examples

- The following command sets `missionWCCOM`, `mission2WCCOM`, and `missionSlow` as the active views for setup analysis, and `missionBCCOM` and `testBCCOM` as the active views for hold analysis. The default active setup view is `missionWCCOM`, and the default active hold view is `missionBCCOM`.

  ```
  set_analysis_view -setup {missionWCCOM mission2WCCOM missionSlow}
  -hold {missionBCCOM testBCCOM}
  ```

- The following command changes the default active setup view to `missionSlow`:

  ```
  set_default_view -setup missionSlow
  ```

- The following command changes the default active hold view to `testBCCOM`:

  ```
  set_default_view -hold testBCCOM
  ```

Related Commands

- create_analysis_view
- update_analysis_view
- set_default_view

set_instance_library

```
set_instance_library
[-help]
-library string
-instance string
[-early | -late]
```

Binds a cell library to an instance. When specified, the software overrides the default binding mechanism for a cell from the library set.

Note: The `set_instance_library` command cannot be used at the command prompt - this command can be specified in the ViewDefinition file.

Parameters

`-help`	Prints out the command usage.
`-early`	Uses the library binding for early timing analysis.
`-instance <string>`	Specifies the instance for which the library binding needs to be done.
`-late`	Uses the library binding for late timing analysis.
`-library <string>`	Specifies the library file path.

Examples

The following commands specify the instance for which the library binding will be done:

- `set_instance_library -library newcell.lib -instance {i1}`
- `set_instance_library -library mysil.lib -instance {i1 i2}`
- `set_instance_library -library {new.lib mysil.lib} -instance {i1} -early`
- `set_instance_library -library {mynew.lib mysil.lib} -instance {i1 i2} -late`

Related Commands

- `reset_instance_library`

set_interactive_constraint_modes

`set_interactive_constraint_modes {list_of_constraint_modes}`

Puts the software into interactive constraint entry mode for the specified multi-mode multi-corner constraint mode objects. Any timing constraints that you specify after this command take effect immediately on all active analysis views that are associated with the specified constraint modes. By default, no constraint modes are considered active.

The software stays in interactive mode until you exit by specifying the `set_interactive_constraint_modes` command with an empty list:

```
set_interactive_constraint_modes { }
```

All new assertions are saved in the SDC files of the specified constraint modes when you save the design (`saveDesign`).

The `all_constraint_modes` command can be used to generate a list of constraint modes as the argument for this command.

Use the `get_interactive_constraint_modes` command to return a list of the constraint mode objects in interactive constraint entry mode.

Note: Interactive constraint mode only works when the software is in multi-mode multi-corner timing analysis mode. In min/max analysis mode, constraints are always accepted interactively.

Parameters

{*list_of_constraint_modes*}	Specifies the constraint mode objects to update with the new assertions.

Examples

- The following commands put the software into interactive constraint entry mode, and apply the `set_propagated_clock` assertion on all views in the current session that are associated with the constraint mode `func1`:

  ```
  set_interactive_constraint_modes func1

  set_propagated_clock [all_clocks]
  ```

  When you specify `saveDesign`, the updated constraints file for the `func1` constraint mode will include the `set_propagated_clock`.

- The following commands put the software into interactive constraint entry mode, and apply the `set_propagated_clock` assertion on all active analysis views in the current session.

  ```
  set_interactive_constraint_modes [all_constraint_modes -active]

  set_propagated_clock [all_clocks]
  ```

  When you specify `saveDesign`, the `set_propagated_clock` assertion will be saved persistently as part of a new `.sdc` file.

Related Information

- `get_interactive_constraint_modes`

set_io_thresholds

```
set_io_thresholds
[-slew_lower_threshold_pct pctValue]
[-slew_upper_threshold_pct pctValue]
[-input_threshold_pct pctValue]
[-output_threshold_pct pctValue]
[-slew_lower_threshold_pct_rise pctValue]
[-slew_lower_threshold_pct_fall pctValue]
[-slew_upper_threshold_pct_rise pctValue]
[-slew_upper_threshold_pct_fall pctValue]
[-input_threshold_pct_rise pctValue]
[-input_threshold_pct_fall pctValue]
[-output_threshold_pct_rise pctValue]
[-output_threshold_pct_fall pctValue]
```

Sets the threshold trip-points used for delay calculation to and from the primary I/Os. The `set_io_thresholds` command does not affect the interpretation of threshold settings in the Liberty timing libraries; the effect is strictly limited to the I/O ports.

If you do not specify I/O thresholds with the `set_io_thresholds` command, delay calculation assumes that the I/O thresholds are equivalent to those of the logic gates to which they are connected.

The `set_io_thresholds` command supports separate rise and fall slew thresholds as normally found in Liberty timing libraries.

Note: Some third-party applications derive the I/O threshold values from the first Liberty timing library in the library search path. The software currently does not support this methodology. Explicit setting of I/O thresholds with the `set_io_thresholds` command should be used to complete a compatible analysis environment.

Parameters

`-input_threshold_pct` *pctValue*	Specifies the slew input threshold value.
`-input_threshold_pct_fall` *pctValue*	Specifies the measurement point for a falling signal that will be used for calculating the interconnect delay from a primary input to internal logic. *Value:* `0` - `100` *Default:* `50`

`-input_threshold_pct_rise` *pctValue*	Specifies the measurement point for a rising signal that will be used for calculating the interconnect delay from a primary input to internal logic. *Value:* `0 - 100` *Default:* `50`
`-output_threshold_pct` *pctValue*	Specifies the slew output threshold value.
`-output_threshold_pct_fall` *pctValue*	Specifies the measurement point for a falling signal that will be used for calculating the interconnect delay from internal logic to a primary output. *Value:* `0 - 100` *Default:* `50`
`-output_threshold_pct_rise` *pctValue*	Specifies the measurement point for a rising signal that will be used for calculating the interconnect delay from internal logic to a primary output. *Value:* `0 - 100` *Default:* `50`
`-slew_lower_threshold_pct` *pctValue*	Specifies the slew lower threshold value.
`-slew_lower_threshold_pct_fall` *pctValue*	Specifies the lower trip-point for a falling signal that will be used to measure transition times. *Value:* `0 - 100` *Default:* `20`

`-slew_lower_threshold_pct_rise` *pctValue*	Specifies the lower trip-point for a rising signal that will be used to measure transition times. *Value:* `0 - 100` *Default:* `20`
`-slew_upper_threshold_pct_fall` *pctValue*	Specifies the upper trip-point for a falling signal that will be used to measure transition times. *Value:* `0 - 100` *Default:* `80`
`-slew_upper_threshold_pct_rise` *pctValue*	Specifies the upper trip-point for a rising signal that will be used to measure transition times. *Value:* `0 - 100` *Default:* `80`
`-slew_upper_threshold_pct` *pctValue*	Specifies the slew lower rise threshold value.

Examples

The following command specifies trip-points for measuring delay and transition times:

```
set_io_thresholds -slew_lower_threshold_pct_rise 10

-slew_upper_threshold_pct_fall 80
-slew_upper_threshold_pct_rise 90
-slew_lower_threshold_pct_fall 20
-input_threshold_pct_rise 40
-input_threshold_pct_fall 70
-output_threshold_pct_rise 60
-output_threshold_pct_fall 30
```

set_normalized_driver_waveform_lib

```
set_normalized_driver_waveform_lib
[-help]
[-fall_waveform string]
[-rise_waveform string]
-ref_lib string
-libs string
```

Specifies normalized driver waveform for a library. The normalized driver waveform given in the reference library is applied to all the specified libraries.

Note: For this command to take effect, you should set the `timing_generate_normalized_driver_waveform` global variable to `false` before loading libraries.

Parameters

`-help`	Prints out the command usage.
`-fall_waveform string`	Specifies the name of the fall normalized driver waveform.
`-libs string`	Specifies a list of space separated libraries to which normalized driver waveform is to be applied.
`-ref_lib string`	Specifies the reference library from which normalized driver waveform is to be selected.
`-rise_waveform string`	Specifies the name of the rise normalized driver waveform.

Examples

- The following example shows that normalized driver waveform given in `$libDir/libs/ref.lib` will be applied to all the cells in `$libDir/1.lib $testDir/2.lib $libDir/libs/3.lib`:

  ```
  set_normalized_driver_waveform_lib -libs "$libDir/1.lib $testDir/2.lib
  $libDir/libs/3.lib" -ref_lib $libDir/libs/ref.lib
  ```

set_path_adjust

```
set_path_adjust
[-help]
adjust_value
[-path_adjust_group path_adjust_group_name]
[-view string]
[-setup | -hold]
```

Defines the slack adjustment value for timing paths. The defined adjustment value is added to the slack of a path specified by the path adjust group, referred to by the `-path_adjust_group` parameter. You can specify a path adjust group by using the `set_path_adjust_group` command.

If multiple path adjustment values are applicable on the same pin, which is on the path specified by multiple `set_path_adjust_group` constraints, then the smallest adjustment value will be applied.

Note: The `set_path_adjust` command is not allowed to be used inside the SDC constraints file. It is only allowed in the software run script.

Parameters

`-help`	Prints out the command usage.
adjust_value	Specifies the value of slack adjustment.
`-hold`	Specifies to apply the adjust value to early paths.
`-path_adjust_group` *path_adjust_group_name*	Specifies the name of path adjust group that defines the path for which the adjustment will be applied.
`-setup`	Specifies to apply the adjust value to late paths. **Note**: If you do not specify `-setup` or `-hold` parameter, the software sets the adjust value to both setup and hold analysis.
`-view` *string*	Specifies a list of analysis views for which adjustment will be applied. This parameter accepts multiple views as argument.

Examples

- The following commands define the slack adjustment values for the specified views:

```
set_path_adjust 0.44 -path_adjust_group AG1 -view view1 -hold
set_path_adjust 0.44 -path_adjust_group AG2 -view view2 -setup
set_path_adjust 0.44 -path_adjust_group AG3 -view view3
```

Related Commands

- set_path_adjust_group
- reset_path_adjust_group

set_path_adjust_group

```
set_path_adjust_group
[-help]
-name <path_adjust_group_name>
[-from <from_list>]
[-to <to_list>]
[-through <through_list>]
```

Allows you to specify the path that is used by the `set_path_adjust` command for setting path slack adjustment values.

The `set_path_adjust_group` command is not allowed to be used inside the SDC constraints file. It is only allowed in the tool run script.

If path group definitions are matching/overlapping (when the `-from`/`-through`/`-to` parameters are used), then path group resetting is applied. The path group overwriting and prioritization rules are similar to path exceptions.

For more details, refer to `group_path`.

Parameters

`-help`	Prints out the command usage.
`-from <from_list>`	Specifies a list of pins, instances, or clocks that are the start of the paths.
`-name <path_adjust_group_name>`	Specifies the name of the path adjust group.
`-through <through_list>`	Specifies a list of pins or instances where the paths go through.
`-to <to_list>`	Specifies a list of pins, instances, or clocks where the path ends.

Examples

The following commands specify the adjusted path groups:

- `set_path_adjust_group -name AG1 -from in1 -through buf1/A -to out1`
- `set_path_adjust_group -name AG2 -from [get_clocks CK1] -through buf1/A -to [get_clocks CK2]`

- `set_path_adjust_group -name AG3 -from [get_clocks {CK1 CK2}] -to [get_clocks {CK1 CK2}]`

Related Commands

- `set_path_adjust`
- `reset_path_adjust_group`
- `group_path`

set_pba_mode

```
set_pba_mode
[-help]
[-reset]
```

Enables IPBA infinite depth path-based analysis (IPBA).

This feature runs faster analysis (vs full depth exhaustive PBA (EPBA)) and attains PBA design coverage with no depth limit per endpoint.

Parameters

-help	Prints out the command usage.
-reset	Resets specified or all the options to the default value.

Related Commands

- report_timing

set_socv_constraint_config

```
set_socv_constraint_config
[-help]
[-hold_folding float]
-libs string
[-nochange_hold_folding float]
[-nochange_setup_folding float]
[-setup_folding float]
```

Enhances the built-in sigma pessimism of check values for setup and hold constraints in the library. The folding factor attribute records the amount of on-chip-variation pessimism added during cell characterization to the nominal setup/hold tables in the libraries. The folding factor attributes are library level attributes.

Notes

- The `set_socv_constraint_config` command does not reset the timing; so it should be used before the `report_timing` command.
- To change the setting later in the flow, you need to use the `update_timing -full` command.
- You cannot use this command, if any of the following global variables are specified:
  `timing_library_setup_sigma_multiplier`
  `timing_library_hold_sigma_multiplier`

Parameters

`-help`	Prints out the command usage.
`-hold_folding` *float*	Specifies a number of additional sigma units added on top of the existing nominal hold value. *Min* = -100 *Max* = 100
`-libs` *string*	Specifies a list of library names (not library paths) or collection objects.
`-nochange_hold_folding` *float*	Specifies a number of additional sigma units added on top of the existing nominal hold value for no-change timing arcs. *Min* = -100 *Max* = 100
`-nochange_setup_folding` *float*	Specifies a number of additional sigma units added on top of the existing nominal setup value for no-change timing arcs. *Min* = -100 *Max* = 100
`-setup_folding` *float*	Specifies a number of additional sigma units added on top of the existing nominal setup value. *Min* = -100 *Max* = 100

Examples

- The following command is used when an additional margin of 10 sigma units is applied to the nominal hold tables in the library collection test.lib:

```
set_socv_constraint_config -hold_folding 10 -libs [get_libs test.lib]
```

Related Commands

- report_timing
- update_timing

set_socv_rc_variation_factor

```
set_socv_rc_variation_factor
[-help]
variation_factor
[-early]
[-late]
[-view list_of_views]
```

Defines the value of interconnect delay variation factor.

This command applies global variation as percentage of the nominal delay.

To enable this feature, you can set the `timing_socv_rc_variation_mode` global variable to `true`.

Parameters

`-help`	Prints out the command usage
`variation_factor`	Specifies the value of the interconnect delay variation factor to be used.
`-early`	Specifies the variation factor for early interconnect delays.
`-late`	Specifies the variation factor for late interconnect delays.
`-view` *`list_of_views`*	Apply the SOCV interconnect variation factor to the specified list of analysis views.

Related Commands

- `get_socv_rc_variation_factor`

set_socv_reporting_nsigma_multiplier

```
set_socv_reporting_nsigma_multiplier
[-help]
[-view list_of_views]
{[-setup float] [-hold float]}
[-transition float]
```

Controls n-sigma value for reporting purposes.

This command supports n-sigma specification per view per setup/hold combination.

Parameters

`-help`	Prints out the command usage.
`-hold float`	Specifies the sigma multiplier for hold mode.
`-setup float`	Specifies the sigma multiplier for setup mode.
`-transition float`	Specifies the sigma multiplier to use for transition related DRV checks – including max_transition, min_transition, pulse_clock_max_transition, and pulse_clock_min_transition. When this parameter is not specified, the sigma multiplier specified for setup will be used for transitions. When the `-transition` parameter is specified, you can set the `timing_report_max_transition_check_using_nsigma_slew` global variable to `true` to report transition related DRV checks, such as, max_transition, min_transition, pulse_clock_max_transition, and pulse_clock_min_transition. This setting enables the `report_constraint` command to use mean and sigma slew values for reporting transition values in DRV checks.
`-view list_of_views`	Applies the sigma multiplier factor to the specified list of analysis views. **Note**: The specified views should be active.

Examples

- The following command applies the sigma multiplier to the specified view in setup mode :
  ```
  set_socv_reporting_nsigma_multiplier -setup 2.5 -view std_max_setup
  ```
- The following command applies the sigma multiplier to the specified view in for hold mode:
  ```
  set_socv_reporting_nsigma_multiplier -hold 3.0 -view std_min_hold
  ```

Related Commands

- get_socv_reporting_nsigma_multiplier

set_table_style

```
set_table_style
-help
-name string
[-reverse_rows]
[-major_sort integer]
[-minor_sort integer]
[-max_widths integer]
[-min_widths integer]
[-indent integer]
-frame | -no_frame_fix_width [-nosplit]
```

Disables printing of specific columns and allows for specifying the minimum and maximum size of each column in a report. It allows for reversing the data, for controlling the left indent, and for controlling the sorting of the columns.

Note: Do *not* include a blank space between commas "*,* " when specifying widths. If you are specifying a value for the width(s), make sure there is *no* leading or trailing blank space.

The `-frame`, `-no_frame`, and `-no_frame_fix_width` parameters work in a global manner. If you specify one of these parameters, it will affect all reports that can be formatted with this command. You cannot specify them with the -name parameter, to change the format of a specific report.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `set_table_style` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_table_style`.
`-frame`	Specifies that the table columns have a fixed frame or border, based on the minimum and maximum width settings. Any data that is longer than the maximum width for its column is wrapped within the same column. This is the default format for tables.
`-indent integer`	Specifies the number of spaces to leave on the left for that particular table.

`-major_sort` *integer*	Specifies the column to be used in the major sort. If the column number is negative, it reverses the sort.

`-max_widths` *integer*	Specifies the maximum width for each table column in the report specified by the `-name` parameter. **Note**: You cannot specify `-max_widths` parameter without `-name`. You can separate each specified width value with a comma (,). For example, if you specify: -max_widths `{10,20,30}` The first column will have a maximum width of 10, the second column will have a maximum width of 20, and the third column will have a maximum width of 30. The fourth and fifth columns will remain the default width spacing. Commas are also specified as column "placeholders", when you want to change the spacing of a column without changing the spacing of the preceding column. For example, if you specify: -max_widths {,,20,30} The third column will have a maximum width of 20, the fourth column will have a maximum width of 30, and the first, second, and fifth columns will remain the default width spacing. If you specify: `-max_widths {20,,30}` The first column will have a maximum width of 20, the third column will have a maximum width of 30, and the second, fourth and fifth columns will remain the default width spacing. Each column resizes itself to be between the range of the maximum and minimum widths specified for that column, based on the data in that column. Overruns are wrapped within the same column, unless otherwise specified. *Default:* `{50,50,50,50,50}`

`-min_widths` *integer*	Specifies the minimum width for each table column in the report specified by the `-name` parameter. **Note**: You cannot specify `-min_widths` parameter without `-name`. You can separate each specified width value with a comma (,). For example, if you specify: -min_widths `{7,10,15}` The first column will have a minimum width of 7, the second column will have a minimum width of 10, and the third column will have a minimum width of 15. The fourth and fifth columns will remain the default width spacing. Commas are also specified as column "placeholders", when you want to change the spacing of a column without changing the spacing of the preceding column. For example, if you specify: -min_width {,,10,15} The third column will have a minimum width of 10, the fourth column will have a minimum width of 15, and the first, second, and fifth columns will remain the default width spacing. If you specify: -min_width {7,,10} The first column will have a minimum width of 7, the third column will have a width of 10, and the second, fourth and fifth columns will remain the default width spacing. Each column resizes itself to be between the range of the maximum and minimum widths specified for that column, based on the data in that column. Overruns are wrapped within the same column, unless otherwise specified. *Default:* `{5,5,5,5,5}`

`-minor_sort` *integer*	Specifies the column to be used in the minor sort. It applies to *all* rows that have the same values in the `major_sort` column. If the column number is negative, the software reverses the sort.
`-name` *string*	Changes the formatting for the specified table. See Table for a list of table names you can use, and the commands with which they work.
`-no_frame_fix_width`	Specifies that the table columns have a fixed minimum width, but no maximum width (the data does not wrap). Column data that fits within the column's minimum width will left-justify and pad its location to fill the specified column space. Column data that is longer than the column's minimum width will take as much space in the table as needed. If a column is overwritten by the data from the preceding column, its data will begin on a new line at the correct column location. *Default:* `-frame`
`-nosplit`	Specifies that each column follows the preceding column without splitting to a new line, if the data in one column overruns the next column. The wrapping behavior for data is controlled by the size of the display window. This format is useful for machine parsing the report. **Note:** You must specify `-no_frame_fix_width` in order to use this parameter.
`-reverse_rows`	Reverses the data rows. This is useful, for example, if you want to trace back from an end point and the default report traces forward from the end point.

The timing report formatting depends on the specified `set_table_style` parameters. These are described below:

- When `set_table_style -no_frame_fix_width` parameter is specified, the timing report displays long inst/hpin names and the rest of the column values are shown on the next line.

- When `set_table_style -no_frame_fix_width -nosplit` is specified, the timing report displays long inst/hpin names and rest of the column values are shown on the same line, because `-nosplit` table style is specified. In this case, other column headers (beyond inst/pin) may not be aligned properly.
- The following settings are specified:

  ```
  set_table_style -no_frame_fix_width -nosplit
  set_table_style -name report_timing -max_width {50,50,,,,,}
  ```

  The generated report will show properly aligned column headers and end-point/begin-points are not split.
- The following settings generate a report displaying longer (than above reports) inst/pin names:

  ```
  set_table_style -no_frame_fix_width -nosplit
  set_table_style -name report_timing -max_width {120,120,,,,,}
  ```

  In this report output, the column headers are aligned properly and are not split.

Table: **List of Table Names**

Table Name	Formats Reports Generated by
`report_cell_instance_delays_arcs`	`report_cell_instance_timing`
`report_cell_instance_delays_checks`	`report_cell_instance_timing`
`report_cell_instance_delays_pins`	`report_cell_instance_timing`
`report_inactive_arcs`	`report_inactive_arcs`
`report_net`	`report_net`
`report_net_header`	`report_net`
`report_net_sink_table`	`report_net`
`report_net_source_table`	`report_net`
`report_net_summary_table`	`report_net`
`report_path_exceptions`	`report_path_exceptions`
`report_port`	`report_ports`

report_timing	report_timing
report_timing_summary	report_timing

Examples

- The following command resizes the first column to a maximum range of 70 and specifies a default width of 50 for the second column. The default for the maximum width is 50 and the default for the minimum width is 5:

  ```
  set_table_style -name report_timing -max_widths {70,}
  ```

  Note: Do *not* include a blank space between commas ",*,* " when specifying widths. If you are specifying a value for the width(s), make sure there is *no* leading or trailing blank space.

- The following command specifies a default width of 50 for the first and second column:
  set_table_style -name report_timing -max_widths {,}

  The following sample timing report shows the table style generated with the `-frame` parameter:

  ```
  set_table_style -frame

  report_timing -format {cell arc delay arrival required instance}

```

Sets delay scaling or derating factors for early and late paths in the current design. You use this command to perform scaled on-chip variation around best-case and worst-case corners. The timing scaling factors affect the delay values generated in the timing reports. You can set scaling factors for data paths, clock paths, minimum and maximum operating conditions.

If you do not specify the `-clock` or `-data` parameter, the software applies the scaling factors to both clock and data paths. If you specify only one of the two parameters, `-data` or `-clock`, the software uses the last defined value for the other.

Similarly, if you do not specify the `-min` or `-max` parameter, the software applies the scaling factor to both minimum and maximum operating conditions. You should only use the `-min` or `-max` parameter for best-case worst-case analysis. If you specify them in on-chip variation (OCV) mode, the software will

use the `-min -early` derating factor for early path scaling, and the `-max -late` derating factor for late path adjustments.

When there are separate max and min libraries specified, only those `set_timing_derate` constraints are honored that are specified with max library. The constraints specified with min library are ignored.

In MMMC mode, for delay corners having different late and early library sets, only those `set_timing_derate` constraints are honored that are specified with late library set of the delay corner. The constraints specified with early library set are ignored.

Note: The `set_timing_derate` command can only be used on the command line. You cannot import it as part of an SDC file.

Parameters

`-add`	Incrementally adds or subtracts derates. You can also apply derates on specific leaf instances.
`-cell_check`	Specifies scaling on timing checks. Use the `-cell_check` option with the `-early` option to specify scaling on hold arcs and use with the `-late` option to specify scaling on setup arcs. When you specify this parameter, derating factors are also applied to user constraints such as `set_output_delay`, `set_data_check`, and `set_clock_gating_check`. The `-cell_check` parameter by default does not apply check derate to output external delay (e.g., `set_output_delay`). To enable this feature, you can set the `timing_apply_check_derate_to_external_output_delay` timing global variable to `true`. When set to `true`, this global applies cell derate to the top boundary port.
`-cell_delay`	Specifies scaling on cell delays. If neither the `-cell_delay` nor the `-net_delay` option is specified, the specified scaling factor applies to both types of delays.

`-clock`	Applies the derating factors to clock paths only.
`-clock_period_check`	Specifies derate values for clock period checks.
`-corner`	Applies derating on cells or nets that are modeled as corner data elements. The specified derating factor is applied to both the mean and sensitivities of the delays (corner objects can have propagated sensitivities). A cell with no timing arc data in a library that has any sensitivity information with respect to any parameter defined in SPDF are considered as a corner object. All cells that do not qualify are considered to be statistical objects. A net with parasitic data that has no sensitivity information with respect to any parameter defined in SPDF is considered as a corner object. All nets that do not qualify are considered to be statistical objects.
`-data`	Applies the derating factors to data paths only.
`-delay_corner` *`delayCornerName`*	Applies the derating factor to the specified delay calculation corner or a list of delay corners. **Note**: The timing derate can be applied to corners associated with active views only.
`derate_value`	Specifies the derating value to be used.
`-dynamic`	Applies the specified derating factor to the delta portion of net delays only. You can specify `-net_delay` or `-cell_delay` parameter with the `-dynamic` parameter. You cannot specify `-dynamic` with `-mean` or `-sigma` parameters.

`-early`	Specifies that the derating factor applies to early paths. Early paths are launching clock during hold analysis, receiving clock during setup analysis and datapath during hold analysis. For definition of early and late paths, see "Definition of Early Late Paths" in *Innovus User Guide*. **Note**: To use this parameter, you must specify `-delay_corner`.
`-fall`	Applies the derating factor to falling delay and check arcs based on the transition direction at the arc's sink pin. This parameter can be used to selectively apply timing derates for the fall arcs (cell, net, or check arcs).
`-increment`	Incrementally adds the derate value to the total derate value in all the modes - OCV, AOCV, and SOCV mode.
`-input_switching`	Considers the given derate as simultaneous switching input (SSI) derate that is applicable to early paths only.
`-late`	Specifies that the derating factor applies to late paths. Late paths are receiving clock during hold analysis, launching clock during setup analysis and datapath during setup analysis. **Note**: To use this parameter, you must specify the `-delay_corner` parameter.
`-max`	Applies the derating factor to the maximum operating condition during best-case worst-case analysis. This parameter is ignored during on-chip variation analysis. **Note:** You cannot use the `-max` parameter when the software is in multi-mode multi-corner (MMMC) mode. You must use the `-delay_corner` parameter instead.

`-min`	Applies the derating factor to the minimum operating condition during best-case worst-case analysis. This parameter is ignored during on-chip variation analysis. **Note:** You cannot use the `-min` parameter when the software is in multi-mode multi-corner (MMMC) mode. You must use the `-delay_corner` parameter instead.
`-mean`	Controls nominal derating. You can apply separate derating the mean components of the delay.
`-multiply`	Incrementally multiplies derates. You can also apply derates on specific leaf instances.
`-net_delay`	Specifies scaling on net delays.
`object_list`	Specifies the list of instances, library cells, or nets to which the derating will be applied.
`-power_domain` *`string`*	Allows you to specify a specific power domain for the timing derate factors to be applied.
`-pulse_width_check`	Specifies derate values for pulse width checks. **Note:** The `-pulse_width_check` and `-clock_period_check` parameters are mutually exclusive. To apply check derating to pulse width checks, set the `timing_enable_derating_for_pulsewidth_checks` global variable to `true`. By default, the global is set to `false`.
`-retain_delay`	Specifies scaling on retain constructs. If you specify both `-retain_delay` and `-cell_delay` parameters, the software uses the retain_delay value for retain construct scaling. If you do not specify the `-retain_delay` parameter, retain constructs are scaled in the same manner as cell delays.

`-rise`	Applies the derating factor to rising delay and check arcs based on the transition direction at the arc's sink pin. This parameter can be used to selectively apply timing derates for the rise arcs (cell, net, or check arcs).
`-sigma`	Controls derating on the variation component. You can apply separate derating to the sigma components of the delay.
`-static`	Applies the specified derating factor to the non-delta portion of net delays only. You can specify `-net_delay` or `-cell_delay` parameter with the `-static` parameter. You cannot specify `-static` with `-mean` or `-sigma` parameters.
`-statistical`	Applies derating on cells or nets that are modeled as statistical data elements. The specified derating factor is applied to both the mean and sigma of delays. If both `set_timing_derate -corner` and `-statistical` options are not specified, the derating factor is applied on variation and corner objects equally. This is equivalent to issuing to two separate `set_timing_derate` commands, one with `-statistical` option and the other with `-corner` option.
`-transition`	Specifies scaling on transitions. When specified, the software allows derate transition and stretch waveforms.

Examples

- The following command (1) can be used when the software is in on-chip variation analysis mode to add pessimism to both the setup and hold analyses by making the early paths 20 percent faster:

```
setAnalysisMode -analysisType onChipVariation
    ...
(1) set_timing_derate -early 0.8 -late 1.0
```

- The following example uses two set_timing_derate commands to set the scaling factors independently for the min and max corners. When the software is in best-case worst-case analysis mode:
  - Command (1) adds pessimism to the setup analysis by making the latching clock path 20 percent faster.
  - Command (2) adds pessimism to the hold analysis by making the latching clock path 10 percent slower.

```
(1) set_timing_derate -max -early 0.8 -late 1.0
(2) set_timing_derate -min -early 1.0 -late 1.1
```

- When the software is in on-chip variation analysis mode, there is only one active delay corner; therefore, the `-min` and `-max` parameters should not be used. The following command sequence will generate a warning:

```
setAnalysisMode -analysisType onChipVariation
...
set_timing_derate -min -early 0.8 -late 0.9
set_timing_derate -max -early 1.1 -late 1.2
```

  In this situation, the software uses `0.8` for derating early paths, and `1.2` for derating late paths.

- When the software is in on-chip variation analysis mode, there is only one active delay corner; therefore, the `-min` and `-max` parameters should not be used. The following command sequence will generate a warning:

```
setAnalysisMode -analysisType onChipVariation
...
set_timing_derate -min -early 0.8 -late 0.9
set_timing_derate -max -early 1.1 -late 1.2
```

  In this situation, the software uses `0.8` for derating early paths, and `1.2` for derating late paths.

- The following example uses two `set_timing_derate` commands to set the scaling factors

independently for the min and max corners. When the software is in best-case worst-case analysis mode:

  - Command (1) adds pessimism to the setup analysis by making the latching clock path 20 percent faster.

- The following command sets the early path scaling factor of 0.85 for instance `MULT_9` cell delays:

  ```
  set_timing_derate -early -cell_delay 0.85 [get_cells {MULT_9}]
  ```

- The following command sets the early path scaling factor of 0.75 for the net named `MUX2/Z`:

  ```
  set_timing_derate -net_delay -early 0.75 [get_nets {MUX2/Z}]
  ```

- The following command specifies power domain `PD1` for derating instances:

  ```
  set_timing_derate -power_domain PD1 -cell_delay 1.1
  ```

- In the following example, a design having max library as 'slow' and min library as 'fast', only the first two `set_timing_derate` constraints are honored:

  ```
  set_timing_derate -late 1.2 [get_lib_cells {slow/BUFX1}] -cell_delay
  set_timing_derate -early 0.8 [get_lib_cells {slow/BUFX1}] -cell_delay
  set_timing_derate -late 1.1 [get_lib_cells {fast/BUFX1}] -cell_delay
  set_timing_derate -early 0.9 [get_lib_cells {fast/BUFX1}] -cell_delay
  ```

- Consider the following library sets in MMMC mode:

  ```
  create_library_set -name libset1 -timing slow.lib
  create_library_set -name libset2 -timing fast.lib
  create_delay_corner -name corner1 -late_library_set libset1 -early_library_set
  libset2
  ```

  From the following `set_timing_derate` constraints the first and last are honored:

  ```
  set_timing_derate -late 1.2 -cell_delay [get_lib_cells slow/*] -delay_corner corner1
  set_timing_derate -early 2.3 -cell_delay [get_lib_cells slow/*] -delay_corner corner1
  set_timing_derate -late 3.4 -cell_delay [get_lib_cells fast/*] -delay_corner corner1
  set_timing_derate -early 4.5 -cell_delay [get_lib_cells fast/*] -delay_corner corner1
  ```

- The following command can be used when the software is in on-chip variation analysis mode to add pessimism to both the setup and hold analyses by making the early paths 20 percent faster:

  ```
  setAnalysisMode -analysisType onChipVariation
  ...
  set_timing_derate -early 0.8 -late 1.0
  ```

  This command adds pessimism to the setup analysis by making the latching clock path 20

percent faster.

- The following example uses two `set_timing_derate` commands to set the scaling factors independently for the min and max corners. When the software is in best-case worst-case analysis mode:
  - The following command sets the early path scaling factor of 0.85 for instance MULT_9 cell delays:
    ```
    set_timing_derate -early -cell_delay 0.85 [get_cells {MULT_9}]
    ```
  - The following command sets the early path scaling factor of 0.75 for the net named MUX2/Z:
    ```
    set_timing_derate -net_delay -early 0.75 [get_nets {MUX2/Z}]
    ```
- The following command specifies power domain PD1 for derating instances:
  ```
  set_timing_derate -power_domain PD1 -cell_delay 1.1
  ```
- The following command shows library object level support for clock (and pulse width) check options:
  ```
  set_timing_derate -delay_corner [all_delay_corners] -clock_period_check 1.05
  [object_list]
  ```

set_wire_load_mode

```
set_wire_load_mode
[-help]
{top | enclosed | segmented}
```

Controls how the software searches through the design hierarchy to find the appropriate wire load model for a net, or a hierarchical part of a net.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `set_wire_load_mode` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_wire_load_mode`.
*`{top	enclosed	segmented}`*	Specifies the wire load model. You can specify one of the following options. • `enclosed` • `segmented` • `top`

	`enclosed`: Selects the wire load model using an area lookup table for the module that is at the lowest level in the design hierarchy and contains the entire net. When you set the mode to `enclosed`, the software uses the area of the smallest block enclosing the net to select the wire load model. In the `enclosed` mode, the software uses the following order of precedence to search the wire load model in: • The inner-most block enclosing the net on which you set the wire load selection group using the `set_wire_load_selection_group` command, if the `auto_wire_load_selection` global variable is enabled. Or: The inner-most block enclosing the net on which you set the wire load model using the `set_wire_load_model` command. • Each higher level hierarchical block for a `set_wire_load_selection_group` assertion, all the way up to the top-level block, if the `auto_wire_load_selection` global variable is enabled. Or: Each higher level hierarchical block for a `set_wire_load_model` assertion, all the way up to the top-level block. • The `default_wire_load_selection` field in the first timing library. Or, The `default_wire_load` field in the first timing library. **Note:** If even the default values are not present in the timing library, you will not be able to use the wire load model functionality.

	`segmented`: Selects the wire load model in a way similar to the `enclosed` mode except that each hierarchical segment of the net is treated separately. In the `segmented` mode: • A segment is defined by pins (including hierarchical pins) connected to a particular net. • When counting the drivers and receivers, only the pins connected to the segment are considered. This information along with the wire load models determine the parasitic information for the segment. • The parasitics of each segment sum up to form the parasitics for the entire net. **Note:** Each segment may have different wire load models.
	`top`: Selects the wire load model in a way similar to `enclosed` and `segmented` except that all nets use the wire load selection or wire load models defined by the top-level (largest) block enclosing the net. **Note:** If the first library read in does not define the default wire load mode, the software uses `top` as the default mode.

Examples

- The following command sets the wire load mode to `enclosed`:

```
set_wire_load_mode enclosed
```

Related Commands

- `reset_wire_load_mode`

set_wire_load_model

```
set_wire_load_model
[-help]
[list_of_instances_or_ports]
[-library library_name]
[-max]
[-min]
-name wireload_model
```

Specifies the wire load model to be used from the technology library, and sets the wire load model on the design or on a hierarchical object (instance). If the list of instances is not specified, the wire load model is set on the current instance. Otherwise, the wire load model is set on all the specified instances or ports.

Use wire load models for estimating delays before the actual wire loads are back annotated. A technology library contains different wire load models, previously computed based on the analysis of several designs differing in area.

Parameters

`-help`	Prints out the command usage.
`-library` *library_name*	Specifies the technology library to use when searching for the name of the wire load model. You can specify a library name, or a collection of libraries. *Default:* All technology libraries are searched.
list_of_instances_or_ports	Specifies the list of objects - designs, ports, or hierarchical instances.
`-max`	Sets the wire load model only for the maximum PVT (process, voltage, temperature) corner. *Default*: The specified wire load model applies to all three PVT corners if neither the `-min` nor the `-max` parameter is specified.
`-min`	Sets the wire load model only for the minimum PVT (process, voltage, temperature) corner. *Default*: The specified wire load model applies to all three PVT corners if neither the `-min` nor the `-max` parameter is specified.
`-name` *wireload_model*	Specifies the name of the wire load model in the library.

Examples

- The following command sets the `COM3_LV_WLM_0.0` wire load model from the `COM3_LV_WIRE` library on the current module for all PVT corners:
  ```
  set_wire_load_model -library COM3_LV_WIRE -name COM3_LV_WLM_0.0
  ```
- The following command sets the `B1X1` wire load from the `lca500kv` library on the `clk1` port for the minimum PVT corner:
  ```
  set_wire_load_model -library lca500kv -min -name B1X1 clk1
  ```
- The following command sets the `3M_TO_4500K`wire load from the `c13tsmc_slow2s108v125c` library on the current module for the minimum PVT corner:
  ```
  set_wire_load_model -library c13tsmc_slow2s108v125c -min -name 3M_TO_4500K
  ```

Related Commands

- report_wire_load
- reset_wire_load_model

set_wire_load_selection_group

```
set_wire_load_selection_group
[-help]
wireload_selection_group_name
[list_of_instances]
[-library library_name]
[-max]
[-min]
```

Overrides the wire load selection table in the specified library.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `set_wire_load_selection_group` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_wire_load_selection_group`
`-library` *library_name*	Specifies the name of the technology library to search for the wire load selection table. When this parameter is not specified, the software searches all the libraries.
list_of_instances	Specifies the list of instances.
`-max`	Controls the choice of a wire load selection table only for the PVT max corner. *Default*: Selects the table for all PVT corners if neither the `-min` nor the `-max` parameter is specified.

`-min`	Controls the choice of a wire load selection table only for the minimum PVT corner. *Default*: Selects the table for all PVT corners if neither the `-min` nor the `-max` parameter is specified.
`wireload_selection_group_name`	Specifies the name of the wire load selection group.

Examples

- The following command selects `TLM` as the selection table used by the library:
  ```
  set_wire_load_selection_group TLM
  ```
- The following command selects `ASPEC1` as the selection table used by the `sm333s` library; only the minimum PVT corner is affected:
  ```
  set_wire_load_selection_group -min -library sm333s ASPEC1
  ```

```

Sets global analysis modes for timing analysis. The software uses these modes for all timing analysis commands unless you specify specific modes in the reporting commands. The modes that you specify in the reporting commands override these modes.

When you use the `setAnalysisMode` command, the software sets the following defaults:

- Sets the constants to be propagated while building the timing graph. The software reads the constants from the timing constraints file or the netlist.
- Sets the analysis mode to accept the module-level timing constraints of the internally specified *`set_input_delay`* and *`set_output_delay`* variables for the I/Os of the module for running timing analysis and timing optimization.
  The software applies the `set_input_delay` command and the `set_output_delay` command on internal pins during timing analysis.

- Treats the latches as latches.
- Reports the end points as many times as the number clocks that control that end point.

Running "`timeDesign -postRoute -si [-hold]`" with "`setAnalysisMode -analysisType bcwc`" might lead to incorrect timing analysis results. This is because the SI delay push-outs (or pull-ins for -hold mode) on the clock nets get annotated to both the launch and the capture clock paths resulting in optimistic slacks to be reported. To get accurate timing analysis results, use "`setAnalysisMode -analysisType onChipVariation`", which requires the design to be run either in multi-mode multi-corner (MMMC) or single-mode single-corner (SMSC) mode. For more information, see the Specifying the MMMC Environment section in the Optimizing Timing chapter of the *Innovus User Guide*.

Parameters

`-help`	Prints out the command usage.

`-analysisType {single | bcwc | onChipVariation}`	Sets the timing analysis type to single, best case worst case, or on-chip variation. *Default*: If you read in one library and do not specify any timing analysis type, the software uses `single` by default. If you read in two libraries and do not specify any timing analysis type, the software uses `bcwc` by default. Scales the delay values based on one operating condition. For more information, see "Single Timing Analysis Mode," in the Innovus User Guide. Checks the design for two extreme operating conditions. The software uses the maximum delays for all paths during setup checks and minimum delays for all paths during hold checks. For more information, see "Best-Case Worst-Case (BC-WC) Timing Analysis Mode," in the Innovus User Guide. `onChipVariation` Calculates the delay for one path based on maximum operating condition while calculating the delay for another path based on minimum operating condition for setup or hold checks. For more information, see "On-Chip Variation (OCV) Timing Analysis Mode," in the Innovus User Guide.
`-aocv {true | false}`	Sets the analysis mode to advanced on-chip variation (AOCV) analysis.
`-asyncChecks {async | noAsync | asyncOnly}`	Reports timing violations for asynchronous timing checks, including recovery and removal, and other checks on pins defined as preset or clear in the Liberty file. *Default:* `async` Reports timing checks on pins that are defined as preset or clear in the Liberty file. Reports timing violations while ignoring the two time arc attributes. Reports only recovery and removal checks.

`-caseAnalysis {true | false}`	Determines whether constants supplied from the constraint file and netlist should be applied to the analysis. Specifying `-caseAnalysis false` parameter blocks the application of constants from the timing constraints file. However, constants that are introduced through the netlist and timing library are still applied and propagated. *Default:* `true`
`-checkType {setup | hold}`	Checks the design for setup or hold violations in the current analysis. *Default:* `setup` **Note:** When simultaneous setup/hold mode analysis is on, this parameter does not have any impact. You can use the `report_timing -late/-early` parameter to report setup/hold timing reports.
`-clkNetsMarking {beforeConstProp | afterConstProp}`	**Note:** This parameter is not available in CTE timing analysis mode. Marks clock nets before or after propagating the constants. *Default:* `markClkNetsBeforeConstProp`

`-clkSrcpath {true | false}`	Reports combinational paths from the clock source to the timing checks on data pins. **Note:** If `-clkSrcPath false` is specified and the clock portion of the path is considered as ideal (due to the SDC constraints or the `-clockPropagation forcedIdeal` parameter setting), the delay calculation software treats the clock nets as ideal nets when calculating the delays and slews along the data path. For all pre-clock tree synthesis (CTS), `optDesign`, and `timeDesign` steps, the software uses `-clkSrcPath false` in combination with `-clockPropagation forcedIdeal` to calculate the delays and slews along the data path. For all post-CTS flow steps, the software uses the default `-clkSrcPath true` in combination with `-clockPropagation sdcControl` to calculate the delays and slews along the data path. *Default:* `true`
`-clockGatingCheck {true | false}`	Reports the gating checks. *Default:* `true`

`-clockPropagation {sdcControl | forcedIdeal | autoDetectClockTree}`	Specifies how to determine whether clock end points are interpreted as having either ideal or propagated clock timing. *Default:* `sdcControl` Reports the timing violations considering clock tree and enables propagating clocks to report clock latency. You must set the `set_propagated_clock` constraint to propagate the clocks. **Note**: By default, CTS will instruct the timer to make all of the clock roots propagated. In this case, you do not need to set the `set_propagated_clock` constraint. Does not report the timing violations considering the clock tree. `autoDetectClockTree` **Note:** The `autoDetectClockTree` parameter is obsolete. The timing system will revert to `sdcControl`, if this parameter is specified.

`-cppr {none | both | setup | hold}`	Removes pessimism from clock paths that have a portion of the clock network in common between the clock source and clock destination paths. The pessimism is introduced when the timing analysis tools assume that the common path has different delay values for two different paths in case of on-chip variation. The pessimism can also be because of clock reconvergence in the clock network. The pessimism effects all analysis modes including single, best case-worst case (`bcwc`), and on-chip variation. For more information, see "Clock Path Pessimism Removal" in "Timing Analysis", chapter in the Innovus User Guide. **Note:** If you use the `-cppr` parameter to do optimization, the run time might increase slightly. Disables removal of clock reconvergence pessimism. *Default:* `none` Enables removal of clock reconvergence pessimism for both setup and hold modes. When `setAnalysisMode -cppr` is specified (without any arguments), the value is set to `both`. Enables removal of clock reconvergence pessimism in setup mode only. Enables removal of clock reconvergence pessimism in hold mode only.
`-help`	Outputs a brief description that includes type and default information for each `setAnalysisMode` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setAnalysisMode`.

`-honorActiveLogicView {true | false}`	Sets the timing analysis mode to honor Active Logic View (previously referred to as CDTV and Virtual Partition). Instead of analyzing the whole chip, the software analyzes only the nets related to interface paths between the partitions. The `createActiveLogicView` command sets `-honorActiveLogicView` by default, so there is no need to specify `setAnalysisMode -honorActiveLogicView true` explicitly after specifying `createActiveLogicView`. **Note:** This parameter applies to pre-CTS mode only. *Default:* `false`

`-honorClockDomains {true | false}`	Controls whether the software uses clock domains or path groups for timing optimization. When set to `true`, `optDesign` uses standard and user-specified clock domains during timing optimization. The following clock domain related commands are enabled: `setClockDomains`,`clearClockDomains`, and `reportClockDomains`. This setting is backward compatible with the behavior of releases prior to 7.1. When set to `false`, `optDesign` uses path groups during timing optimization. Clock domain related commands are disabled, and any active clock domains are cleared. Path groups can be created and modified using the following commands:`group_path`, `reset_path_group`,`createBasicPathGroups`,`setPathGroupOptions`,`resetPathGroupOptions`,`reportPathGroupOptions`. If no path groups are explicitly created, the software acts as though the basic path groups were created. However, as soon as you create one path group, the basic groups are then cleared. **Note:** Path groups and clock domains are mutually exclusive: enabling one methodology disables the other. *Default:* `false` **Note**: The `-honorClockDomains` parameter is now obsolete - support for this flow will be discontinued in a future release of the software. You should update your scripts to be compatible with the path group based flow.
`-log {true | false}`	Writes warning messages to the log file. *Default:* `true`

`-multi_input_switching_mode {0 | 1 | 2}`	Sets the multiple input switching (MIS) mode. You can specify one of the following options. When set to: • 0: Simultaneous input switching is not considered. • 1: MIS analysis considers cells for which multiple inputs of a cell are tied together (tied-inputs). • 2: MIS analysis considers both the tied-inputs and inputs of cells switching independent to each other. *Default*: 0
`-propSlew {true | false}`	Controls whether slews in early path delay calculation are degraded as they pass across the interconnect from driver to receiver. You can specify a value of `false` to turn off interconnect slew degradation for early paths and have the driver slews copied to the receivers. Early path delay calculation affects all Hold paths in best-case/worst-case analysis mode, capture clock paths in on-chip variation Setup analysis, and clock launch and data paths in on-chip variation Hold analysis. *Default:* `true`
`-reset`	Resets parameters to their default values. The `-reset` parameter *must* be the first parameter specified. If you specify `-reset` by itself, the software resets all `setAnalysisMode` parameters to their default values. If you specify parameters after `-reset`, the software resets only those parameters to their default values. **Note**: Any values that do not already match the default value and are reset will be reported.

`-sequentialConstProp {true | false}`	Propagates constants through sequential elements. If you specify `-sequentialConstProp false`, constants will stop at sequential elements. *Default:* `false`
`-skew {true | false}`	Reports clock skew. The `-skew false` setting treats all clock latency as 0. *Default:* `true` With the `-skew true` setting, you can specify the `-clockPropagation` parameter. • Using the default `-skew true -clockPropagation sdcControl` setting accounts for the clock latency during timing analysis and proceeds as follows: ◦ If the `set_propagated_clock` command is specified in the timing constraint file, the clock latency is computed from the netlist (propagated mode). ◦ If the `set_clock_latency` command is specified in the timing constraint file, the clock latency specified in the constraint is used. Otherwise, no latency is reported (ideal mode).
`-socv {true | false}`	Enables SOCV analysis. *Default*: `false`
`-timeBorrowing {true | false}`	Considers time borrowing during timing analysis. Time borrowing is the amount of time borrowed by a previous logic. *Default:* `true`

`-timingEngine {statistical | static}`	Specifies the type of timing analysis to perform. • `statistical`: Sets analysis mode to SSTA (statistical static timing analysis). • `static`: Performs static timing analysis. *Default:* `static` **Note:** This parameter is obsolete. This still works in this release, and will be removed in a future release.
`-timingSelfLoopsNoSkew {true | false}`	Eliminates clock skew due to clock uncertainty for a path starting and ending at the same register. If the clock skew is not eliminated, the timing for such paths is pessimistic. **Note:** Use this parameter before building the timing graph. *Default:* `false`
`-usefulSkew {true | false}`	Considers the latency file (*`latency_file`*`.sdc`) during timing analysis. The latency file is generated when you run the `skewClock` command. *Default:* `false`
`-useOutputPinCap {true | false}`	Includes the output pin capacitance when calculating delay values. When you specify `-useOutputPinCap false`, the software excludes only the pin capacitance of the driver for which you are calculating the delay. *Default:* `true`
`-warn {true | false}`	Displays warning messages as the timing constraints file is read. *Default:* `true`

Examples

- The following command sets timing analysis to report clock skew, suppresses warning messages, and check for setup timing:

  ```
  setAnalysisMode -checkType setup -skew true -warn false
  ```

- The following commands set the mode for timing analysis to consider latency files, and generate a timing report based on timing with latencies from pre-CTS useful skew:

  ```
  setAnalysisMode -usefulSkew true

  restoreDesign mydesign

  report_timing
  ```

- The following commands sets the mode for timing analysis to ignore latency files, and generate a timing report based on timing without latencies from pre-CTS useful skew:

  ```
  setAnalysisMode -usefulSkew false

  report_timing
  ```

- The following command reset the `-checkType` parameter to its default value:

  ```
  setAnalysisMode -reset -checkType
  ```

- The following command resets all of the `setAnalysisMode` parameters to their default values:

  ```
  setAnalysisMode -reset
  ```

signoffTimeDesign

```
signoffTimeDesign
[-help]
[-noEcoDB]
[-noExpandedViews]
[-outDir string]
[-prefix string]
[-reportFullClockPath]
[-reportOnly]
```

Runs signoff timing analysis using extraction (Quantus) and Tempus in batch mode, and generates timing reports and ECO DB for each view. The command prints out a timing summary table per view and all the views combined.

Parameters

`-help`	Prints out the command usage.
`-noEcoDB`	Disables generation of ECO timing DB.
`-noExpandedViews`	Disables printing of expanded timing per view.
`-outDir string`	Specifies the directory to save reports.
`-prefix string`	Specifies prefix for timing report file names.
`-reportFullClockPath`	When this parameter is specified, the detailed timing report that is generated contains the full clock path.
`-reportOnly`	Skips parasitic extraction and use the parasitics in memory.

timeDesign

```
timeDesign
[-help]
[-drvReports]
[-expandReg2Reg]
[-expandedViews]
[-hold]
[-idealClock]
[-numPaths integer]
[-outDir string]
[-pathreports]
[-prefix string]
[-proto]
[-reportOnly]
[-slackReports]
[-timingDebugReport]
[-useTransitionFiles]
[-prePlace | -preCTS | -postCTS | -postRoute]
```

Runs Early Global Route, extraction, and timing analysis, and generates detailed timing reports. The generated timing reports are saved in `./timingReports` directory or the directory that you specify using the `-outDir` parameter.

The following timing reports are generated:

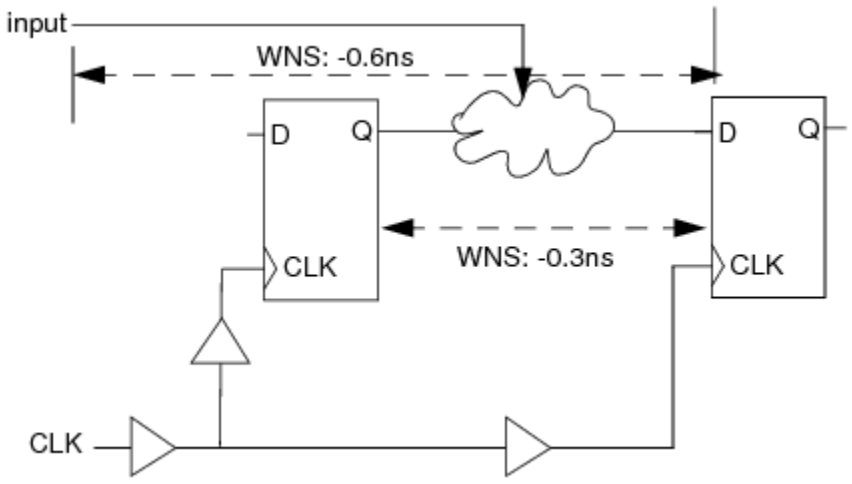
- Setup and hold time for the following path groups:
  - Register to register (*TopCellName_DesignStage*`_reg2reg.tarpt`)
  - Input to register - This report also includes the clock source paths (if applicable to the design). The clock source paths are included even if the clock source is an internal pin.
  - Register to output
  - Input to output
  - All paths ending in clock gate (*TopCellName_DesignStage*`_reg2cgate.tarpt`)
  - Groups in2reg, reg2out and in2out will be merged into a default group (`default.tarpt`)
- Setup and hold time without using path groups:
  - Setup analysis (*TopCellName_DesignStage*`_all.tarpt`)
  - Hold analysis (*TopCellName_DesignStage*`_all_hold.tarpt`)
- Density

Note: The density value reported by the `timeDesign` command might differ from the effective utilization value reported by the checkPlace command because `timeDesign` does not consider padding when calculating density, but `checkPlace` does consider it when calculating effective utilization.

- Maximum transition time violation (*`TopCellName_DesignStage`*`.tran`): The maximum transition value reported is the maximum value from `set_max_transition` command from SDC or the max_transition value specified in the library.
- Maximum capacitance violation (*`TopCellName_DesignStage`*`.cap`): The maximum capacitance value reported is the maximum value from the `set_max_capacitance` command from SDC or or max_capacitance value specified in the library.
- Maximum fanout violation (*`TopCellName_DesignStage`*`.fanout`)
- Glitch violations in the *`outDir`*/*`prefix_hold`*/`setup` directory.
- Summary (*`TopCellName_DesignStage`*`.summary` and *`TopCellName_DesignStage`*`_hold.summary`)
  Note: The ID number displayed in the Summary report refers to long path group names.

The overall total negative slack (TNS) and number of violating paths of a design might not be equal to the total of the TNS and violating paths of the individual path groups. This is because the TNS and number of violating paths are based on end-point of the path and are not path based.

For example, the following figure has a register with two paths, one from a primary input with a slack of `-0.6ns` and other from another register with a slack of `-0.3ns`.



In that case the overall TNS will be `-0.6ns` with `1` violating path (end point-based). But the individual reg2reg TNS will be `-0.3ns` with `1` violating path and in2reg with a TNS of `-0.6ns` with `1` violating path. Therefore, the sum total of individual path group TNS is not the same as overall TNS.

Similarly, when you run the `timeDesign` command while performing multi-mode multi-corner analysis,

overall TNS is not the sum of TNS of each view considered separately. The command sums the worst-case slack at each endpoint across all views. Therefore, each endpoint contributes only in overall worst-slack in the calculation of TNS.

Parameters

`-help`	Prints out the command usage.
`-drvReports`	Generate design rule violation (DRV) reports only. *Default:* Generates DRV and path reports.
`-expandedViews`	Generates detailed view-specific timing reports when the software is in multi-mode multi-corner analysis mode. For multi-mode multi-corner analysis, the software creates a separate directory for each view. For example, if your design has two analysis views, `view1` and `view2`, the output reports are generated in the `./timingReports/view1` and `./timingReports/view2` directories. If some of the active views have been pruned by auto view pruning then this command will restore those and give view-specific reports for all of the active views in the design.
`-expandReg2Reg`	Specifies that the register to register path groups are divided into the following detailed path groups for generating reports: • Flop to flop • Macro to flop • Flop to macro • Macro to macro
`-hold`	Reports hold violations only. Before ending the `timeDesign` run, the software reverts back to the initial analysis mode that was set by the `setAnalysisMode` command (either setup or hold). *Default:* Reports only setup violations

`-idealClock`	Performs ideal clock analysis irrespective of the design stage. Default: The software performs propagated clock analysis with the `-postCTS` and `-postRoute` parameters. The software performs ideal clock analysis with the `-prePlace` and `-preCTS` parameters. **Note**: This parameter is not honored when used with `-reportOnly`.
`-numPaths` *integer*	Specifies the number of paths to report in the detailed path violations. *Default:* `50`
`-outDir` *out_dir*	Specifies the name of the output directory that contains all the generated reports. *Default:* `timingReports`
`-pathReports`	Generate path reports only. *Default:* Generates DRV and path reports.
`-preCTS`	Generates timing reports before the clock tree is built. By default, in this mode the software runs early global route, native default extraction, and timing analysis for generating timing reports. The `-preCTS` parameter sets `setAnalysisMode` to `-clkSrcPath false` and `-clockPropagation forcedIdeal`.
`-prePlace`	Generates timing reports before the design is placed. In this mode, the software ignores the net load while building the timing graph and runs timing analysis for generating timing reports. The DRV report files are not generated in this mode, and the DRV numbers are not reported in the summary for this parameter. The `-prePlace` parameter sets `setAnalysisMode` to `-clkSrcPath false` and `-clockPropagation forcedIdeal`. **Note:** The `-reportOnly` parameter is not honored when used with this parameter.
`-proto`	Supports flex models. **Notes:** • The `-proto` parameter supports `set_proto_mode -timing_net_delay_model option`. • The `-proto` parameter honors the `-postCTS` option.

`-postCTS`	Generates timing reports for a design whose clock tree has been created. By default, in this mode the software runs early global route, native default extraction, and timing analysis for generating timing reports. The `-postCTS` parameter sets `setAnalysisMode` to `-clkSrcPath true` and `-clockPropagation sdcControl`.
`-postRoute`	Generates timing reports for a design whose routing is complete. By default, in this mode the software runs native detailed extraction, and timing analysis for generating timing reports. The `-postRoute` parameter sets `setAnalysisMode` to `-clkSrcPath true` and `-clockPropagation sdcControl`.
`-prefix` *`file_name_prefix`*	Specifies a prefix for the timing report file names. *Default:* *`DesignName_DesignStage`*
`-reportOnly`	Specifies the use of existing extraction and timing analysis data to generate timing reports. When you use this parameter, the software does not run extraction; instead it uses data that is already in memory. • `-reportOnly` is not honored when used with `-prePlace`. • `-idealClock` is not honored when used with `-reportOnly`. **Note:** The `-preCts`, `-postCts`, or `-postRoute`with `-reportOnly`. **Note**: If you restore a Innovus database (saved with `saveDesign -rc` before the `timeDesign -reportOnly` command is specified), a full extraction will still be performed if the database is in the pre-route stage. This is because the `preRoute` extraction RCDB cannot be saved into an Innovus database.
`-slackReports`	Generate slack reports only. *Default:* Generates DRV and path reports.
`-timingDebugReport`	Generates a compressed (`.gz`) detailed timing report in ASCII format. This report is used for debugging timing results using the timing debug feature in Innovus. For more information on debugging timing results, see Debugging Timing Results in *Innovus User Guide*.
`-useTransitionFiles`	Reports the maximum transition violations when using external transition files specified by the `readTransitionFile` command.

Command Order

Use this command after loading the design.

Examples

- The following command runs early global route, preRoute parasitic extraction, and timing analysis to generate timing reports before clock tree synthesis:
  `timeDesign -preCTS`
- The following example shows a summary report generated by `timeDesign`:

```
------------------------------------
timeDesign Summary

update_analysis_view

```
update_analysis_view
[-help]
-name <existingAnalysisViewName>
{[-constraint_mode <newModeName>]
[-delay_corner <newDelayCornerObj>]
[-latency_file <string>]}
```

Changes attribute values for the specified existing analysis view.

You can update an analysis view before the multi-mode multi-corner definition file is loaded into the design, or after. However, after the software processes the file, any change to an existing object when the software is in multi-mode multi-corner mode results in the timing, delay calculation, and RC data being reset.

Parameters

`-constraint_mode` *newModeName*	Specifies the name of the new constraint mode to associate with this analysis view.
`-delay_corner` *newDelayCornerObj*	Specifies the name of the new delay calculation corner to associate with this analysis view.
`-latency_file <`*string*`>`	Specifies the latency file name.
`-name` *existingAnalysisViewName*	Specifies the name of the existing analysis view to update.

Examples

- The following command creates an analysis view called missionSlow using the constraint mode missionSetup and the delay calculation corner dcWCCOM:

```
create_analysis_view
-name missionSlow
-constraint_mode missionSetup
```

```
-delay_corner dcWCCOM
```

- The following command changes the delay calculation corner associated with the analysis view `missionSlow` to `dcMax`:

```
update_analysis_view -name missionSlow -delay_corner dcMax
```

Related Information

- `create_analysis_view`
- `set_analysis_view`

update_constraint_mode

```
update_constraint_mode
[-help]
[-ilm_sdc_files {file1.sdc file2.sdc ...}]
[-name modeName]
{[[-sdc_files {file1.sdc file2.sdc ...}]
[-tcl_vars {{var_name1 value1} {var_name2 value2} {var_name3 value3} ...}]
[-reset_latency_files]]}
```

Updates the SDC constraint file information for the specified existing constraint mode object.

Note: The `update_constraint_mode` command overwrites the previous constraint mode settings. However, by default, this command updates a constraint mode without affecting other constraint modes, including interactive constraints, such as, `set_dont_use` and `set_dont_touch`.

ⓘ You can update a constraint mode object before the multi-mode multi-corner definition file is loaded into the design, or after. However, after the software processes the file, any change to an existing object when the software is in multi-mode multi-corner mode results in the timing, delay calculation, and RC data being reset.

Parameters

`-help`	Prints out the command usage.
`-ilm_sdc_files {file1.sdc file2.sdc ...}`	Specifies the new full chip SDC constraint files for the ILM flow to associate with this constraint mode.
`-name` *modeName*	Specifies the name of the existing constraint mode object to update.
`-reset_latency_files`	Cleans up latency files of all the related views. The timing system maintains view-specific latency files to provide `set_clock_latency` assertions for useful-skew modeling and for providing post-CTS balancing of IO timing. When the `update_constraint_mode` is asserted to provide new constraints for a mode, you can decide whether to remove the related constraints in the latency files.
`-sdc_files {file1.sdc file2.sdc ...}`	Specifies the new SDC constraint files to associate with this constraint mode.
`-tcl_vars {{var_name1 value1} {var_name2 value2} {var_name3 value3} ...}`	Specifies a list of tcl variables and values to be used in the constraint mode.

Examples

- The following command groups the SDC files `io.sdc`, `mission1-clks.sdc`, and `mission1-except.sdc` to create a mode object named `missionSetup`:
  ```
  create_constraint_mode -name missionSetup -sdc_files [list io.sdc mission1-clks.sdc mission1-except.sdc]
  ```
- The following command changes the SDC files associated with the constraint mode `missionSetup` to `io.sdc`, `mission3-clks.sdc`, and `mission3-except.sdc`:
  ```
  update_constraint_mode -name missionSetup -sdc_files {io.sdc mission3-clks.sdc mission3-except.sdc}
  ```

Related Commands

update_delay_corner

```
update_delay_corner
[-help]
[-early_estimated_worst_irDrop_factor percent]
[-early_irdrop_data files_or_directories]
[-early_irdrop_file list_of_files]
[-early_library_set libSetName]
[-early_opcond opcondName]
[-early_opcond_library libName]
[-early_rc_corner rcCornerObj]
[-early_temp_file tempName]
[-irdrop_data files_or_directories]
[-irdrop_file list_of_files]
[-late_estimated_worst_irDrop_factor percent]
[-late_irdrop_data files_or_directories]
[-late_irdrop_file list_of_files]
[-late_library_set libSetName]
[-late_opcond opcondName]
[-late_opcond_library libName]
[-late_rc_corner rcCornerObj]
[-late_temp_file tempName]
[-library_set libSetObj]
-name delayCornerObj
[-opcond opcondName]
[-opcond_library libName]
[-pg_net_voltages voltage_pairs]
[-power_domain powerDomainName]
[-rc_corner rcCornerObj]
[-si_enabled {true | false}]
[-supply_set supplySetName]
[-temp_file tempName]
```

Modifies the parameters of an existing delay calculation corner object. You can use the `update_delay_corner` command to add or change attribute values for an existing delay calculation corner object, or for an existing power domain definition.

You can update a delay calculation corner object before the multi-mode multi-corner definition file is loaded into the design, or after. However, after the software processes the file, any change to an existing object when the software is in multi-mode multi-corner mode results in the timing, delay calculation, and RC data being reset.

You also can use the `update_delay_corner` command to add a power domain definition to the

specified delay calculation corner. Instances contained within an MSMV power domain often require a different library or operating condition that used for the default power domain. Power domain definitions within a delay calculation corner object can be used to assign specific libraries and PVT settings per power domain.
Note: Use separate delay calculation corners to define major PVT corner differences. Use the `-early_*` and `-late_*` parameters within a single delay calculation corner to control on-chip-variation.

The `-early_*` and `-late_*` parameters can be specified separately, to update a delay corner object with early or late information. If you only specify one of the `-early_*` or `-late_*` parameters, the software uses the original information pointer in place of the missing early/late parameter.

For example, if you initially created a delay corner object using:

```
create_delay_corner
-library_set libsNominal
...
```

If you specify `update_delay_corner -early_library_set libsEarly`, the software actually uses:

```
update_delay_corner
-early_library_set libsEarly
-late_library_set libsNominal
```

Use this command after creating at least one delay calculation corner (`create_delay_corner`).

Parameters

`-help`	Prints out the command usage.
`-early_estimated_worst_irDrop_factor` *per cent*	Specifies the early voltage derating factor. When this parameter is specified, the software performs delay calculations using the voltage = nomVolt * (1 – value). *Default*: 0.0
`-early_irdrop_data` *files_or_directories*	Specifies the IR drop files or directories to apply when calculating the early arrival times at a single delay corner.

`-early_irdrop_file` *list_of_files*	Specifies the list of IR drop files to apply when calculating early arrival times at a single power domain. This parameter is used primarily when configuring the multi-mode multi-corner environment for on-chip-variation (OCV) analysis. **Note**: This parameter is obsolete and will be removed in a future release. To ensure compatibility with future releases, you should update your scripts.
`-early_library_set` *libSetName*	Specifies the library set to associate with the power domain for calculating early arrival times for this power domain. This parameter is used primarily when configuring the multi-mode multi-corner environment for on-chip-variation (OCV) analysis.
`-early_opcond` *opcondName*	Specifies the operating condition to use for calculating early arrival times for this power domain. This parameter is used primarily when configuring the multi-mode multi-corner environment for on-chip-variation (OCV) analysis. *Default:* Each library in the early library set uses its own default operating condition.
`-early_opcond_library` *libName*	Specifies the internal library name for the library in which the early operating condition is defined. This is *not* the library file name. This parameter is used primarily when configuring the multi-mode multi-corner environment for on-chip-variation (OCV) analysis. *Default:* The software searches the early library set for the specified operating condition (`-early_opcond`), starting with the master library.
`-early_rc_corner` *rcCornerObj*	Specifies the RC corner object to associate with the early corner object.

`-early_temp_file` *tempName*	Specifies the name of the temperature file for temperature aware delay calculation for early corner.
`-irdrop_data` *files_or_directories*	Specifies the IR drop files or directories to apply to both the early and late delay calculation for the specified delay corner object.
`-irdrop_file` *list_of_files*	Specifies the list of IR drop files to apply to both early and late delay calculation for this power domain object. This parameter is used primarily to configure single-corner or Best-Case Worst-Case (BC-WC) analysis modes. **Note**: This parameter is obsolete and will be removed in a future release. To ensure compatibility with future releases, you should update your scripts.
`-late_estimated_worst_irDrop_factor` *percent*	Specifies the late voltage derating factor. When this parameter is specified, the software performs delay calculations using the voltage = nomVolt * (1 – value). *Default*: 0.0
`-late_irdrop_data` *files_or_directories*	Specifies the IR drop files or directories to apply when calculating the late arrival times at a single delay corner.
`-late_irdrop_file` *list_of_files*	Specifies the list of IR drop files to apply when calculating late arrival times at a single power domain. This parameter is used primarily when configuring the multi-mode multi-corner environment for on-chip-variation (OCV) analysis. **Note**: This parameter is obsolete and will be removed in a future release. To ensure compatibility with future releases, you should update your scripts.

`-late_library_set` *libSetName*	Specifies the library set to associate with this delay corner object for calculating late arrival times for this power domain. This parameter is used primarily when configuring the multi-mode multi-corner environment for on-chip-variation (OCV) analysis.
`-late_opcond` *opcondName*	Specifies the operating condition to use for calculating late arrival times for this power domain. This parameter is used primarily when configuring the multi-mode multi-corner environment for on-chip-variation (OCV) analysis. *Default:* Each library in the late library set uses its own default operating condition.
`-late_opcond_library` *libName*	Specifies the internal library name for the library in which the late operating condition is defined. This is *not* the library file name. This parameter is used primarily when configuring the multi-mode multi-corner environment for on-chip-variation (OCV) analysis. *Default:* The software searches the late library set for the specified operating condition (`-late_opcond`), starting with the master library.
`-late_temp_file` *tempName*	Specifies the name of the temperature file for temperature aware delay calculation for late corner.
`-late_rc_corner` *rcCornerObj*	Specifies the RC corner object to associate with the late corner object.
`-library_set` *libSetName*	Specifies the library set to associate with the power domain. All of the cells and macros in the power domain get their timing and power information from these libraries. This parameter is used primarily to configure single-corner or Best-Case Worst-Case (BC-WC) analysis modes.

`-name` *dcCornerObj*	Specifies the delay calculation corner to which to add the power domain definition, or to which to update the delay corner or power domain attribute values.
`-opcond` *OpcondName*	Specifies the operating condition to use for the power domain. This parameter is used primarily to configure single-corner or Best-Case Worst-Case (BC-WC) analysis modes. *Default:* Each library in the library set uses its own default operating condition.
`-opcond_library` *libName*	Specifies the internal library name for the library in which the operating condition is defined. This is *not* the library file name. This parameter is used primarily to configure single-corner or Best-Case Worst-Case (BC-WC) analysis modes. *Default:* The software searches the library set for the specified operating condition (`-opcond`), starting with the master library.
`-pg_net_voltages` *voltage_pairs*	Specifies the power/ground net voltages to be used for both early/late timing analysis.
`-power_domain` *powerDomainName*	Specifies the name of the power domain to add to the delay calculation corner. This name must match the name of a power domain specified in the power domain file. **Note**: This parameter is required for all the designs that use power domains and should be specified for each delay corner in the MMMC file.
`-rc_corner` *rcCornerObj*	Specifies the new RC corner object to associate with this delay corner.

`-si_enabled {true | false}`	Controls signal integrity (SI) analysis. When set to `true`, the analysis of all MMMC views will include SI analysis by default. You can use this parameter to further determine which analysis views receive SI analysis and which do not. When this parameter is set to `false` on a delay corner, the software will disable SI analysis for all the views that reference that corner. By default (or when this parameter is set to `true`), SI analysis is computed for all the views related to that corner - whenever SI is globally enabled. (The global control of signal integrity (SI) analysis is determined by the `setDelayCalMode -SIAware` setting.)
`-supply_set` *supplySetName*	Specifies the name of the supply set to add to the delay calculation corner.
`-temp_file` *tempName*	Specifies the name of the temperature file for temperature aware delay calculation for single corner.

Examples

- The following command creates the delay calculation corner `dc1`:

```
create_delay_corner -name dc1
-library_set libs-2volt
-opcond_library delayvolt_2V
-opcond slow_2V
-rc_corner rc-cworst
```

- The following commands add definitions for the power domains `domain-3V` and `domain-5V` to the `dc1` delay calculation corner:

```
update_delay_corner -name dc1
-power_domain domain-3V
-library_set libs-3volt
-opcond_library delayvolt_3V
-opcond slow_3V
update_delay_corner -name dc1
```

```
-power_domain domain-5V
-library_set libs-5volt
-opcond_library delayvolt_5V
-opcond slow_5V
```

- The following command changes the libraries used by the delay calculation corner `dc1` to those in the library set `IsCOM-2v`, and changes the RC corner associated with `dc1` to `rc-ctyp`:

```
update_delay_corner -name dc1
-library_set IsCOM-2V
-rc_corner rc-ctyp
```

Related Commands

- create_delay_corner
- get_delay_corner

update_io_latency

```
update_io_latency
[-source]
-verbose
```

Provides an automated means of balancing IO and Core clock latencies after the clock network has been added to the design so that pre and post clock tree skew between the clocks is maintained as closely as possible. This results in minimum change of inbound and outbound IO slacks.

This command performs the following actions:

- Measures and calculates ideal average latency for each Core clock.
- Calculates preCTS skew between IO and Core clocks.
- Asserts `set_propagated_clock` on all clock root pins or ports to put clock trees in propagated mode.
- Measures and calculates propagated mode average latency for each Core clock.
- Adjusts `set_clock_latency` on IO clocks network latency to minimize pre to post CTS IO-to-Core clock skew.

In case a single IO clock interacts with multiple Core clocks, the IO clock will be adjusted by the overall average latency of all the related Core clocks combined.

To be effective, this command should only be used after clock trees have been implemented. This allows the command to see both the ideal and propagated state of the clock trees.

Note: The `set_propagated_clock` command should not be issued after the `update_io_latency` command.

Parameters

`-source`	Adjusts the source latency of core clock.
`-verbose`	Provides additional information to the console as adjustments are made to each IO clock.

Related Information

- `set_propagated_clock`

update_library_set

```
update_library_set
[-help]
[-aocv string]
[-library_side_file string]
-name libSetName
[-si string]
[-socv string]
[-timing string]
```

Updates an existing specified library set.

Note: You can edit a library set before (or after) the multi-mode multi-corner view definition file is loaded into the design. However, after the software processes the file, any change to an existing object when the software is in multi-mode multi-corner mode resets the timing, delay calculation, and RC data.

Parameters

`-help`	Prints out the command usage.
`-aocv` *`string`*	Specifies a list of new AOCV libraries to include in the specified library set.
`-library_side_file` *`string`*	Specifies the library side file.
`-name` *`libSetName`*	Specifies the name of an existing library set to be updated. The library set must have been defined using the `create_library_set` command.
`-si` *`string`*	Specifies a list of new cdB libraries and user-defined noise (UDN) models to include in the library set.
`-socv` *`string`*	Specifies a list of new SOCV libraries to be included in the library set.
`-timing` *`string`*	Specifies a list of new timing libraries to include in the specified library set. Note: The ECSM and CCS libraries can be very large and loading them may take significant time. You can convert the ASCII NLDM (Liberty .lib), ECSM, and CCS libraries to a binary version using the write_ldb command. For conversion of libraries to a binary version, refer to `write_ldb`. Instead of the original ASCII libraries, you can specify the following binary libraries in the configuration file: `create_library_set -name libName -timing "AAA.lib BBB.ecsm CCC.ccs"`

Examples

- The following command creates a library set that associates timing libraries and cdB libraries with a nominal voltage of 1 volt with the library name lsCOM-1V:
  ```
  create_library_set -name IsCOM-1V -timing [list stdcell_F_1V.lib ram_F.lib pad.lib]
  ```
  The following command changes the timing libraries associated with the library set lsCOM-1V:
  ```
  update_library_set -name IsCOM-1V -timing [list stdcell_CVF_1V.lib ram_CVF.lib
  pad.lib ]
  ```

Related Commands

- create_library_set
- get_library_set
- all_library_sets

update_rc_corner

```
update_rc_corner
[-T temperatureValue]
[-cap_table newcapTableFile]
-name existingRcCornerName
[-postRoute_res {resFactor1 resFactor2 resFactor3}]
[-postRoute_cap {capFactor1 capFactor2 capFactor3}]
[-postRoute_xcap {xcapFactor1 xcapFactor2 xcapFactor3}]
[-postRoute_clkres {resFactor1 resFactor2 resFactor3}]
[-postRoute_clkcap {capFactor1 capFactor2 capFactor3}]
[-preRoute_clkres resFactor]
[-preRoute_clkcap capFactor]
[-preRoute_res resFactor]
[-preRoute_cap capFactor]
[-qx_tech_file newFileName]
[-via_variation_file viaVariationFile]
```

Adds or changes attribute values for the specified existing RC corner object.

> You can edit an RC corner object before the multi-mode multi-corner definition file is loaded into the design, or after. However, after the software processes the file, any change to an existing object when the software is in multi-mode multi-corner mode results in the timing, delay calculation, and RC data being reset.

You can set different postroute scale factors for the postroute engine variants by specifying them as duplets and triplets. For example,

resFactor1 resFactor2 resFactor3

Where:

- Single value: If you specify one value, the scale factor applies to effort level `low`. Scale factor value of 1 is used for `medium` and `high` by default.
- Duplet: If you specify two values, the first value is used for effort level `low` and the second value is used for `medium`. Scale factor value of `1` is used for `high` by default.
- Triplet: If you specify three values, the first value is used for effort level `low`, the second value is used for `medium`, and the third value is used for `high`.

Parameters

`-cap_table` *newCapTableFile*	Specifies a new capacitance table to use for extraction when using this RC corner.
`-preRoute_cap` *capFactor*	Specifies the capacitance scale factor for RC Extraction in preRoute mode.
`-preRoute_clkcap` *capFactor*	Specifies the scale factor for capacitance of clock nets in preRoute mode. Default: `0` When this parameter is not specified, the value specified with the `-postRoute_cap` parameter is used for preRoute extraction. When specified, this parameter overrides the value specified with the `-postRoute_cap` parameter for clock nets.
`-preRoute_clkres` *resFactor*	Specifies the scale factor for resistance of clock nets in preRoute mode. Default: `0` When this parameter is not specified, the value specified with the `-postRoute_res` parameter is used for preRoute extraction. When specified, this parameter overrides the value specified with the `-postRoute_res` parameter for clock nets.
`-preRoute_res` *resFactor*	Specifies the resistance scale factor for RC Extraction in pre-route mode.
`-postRoute_cap {`*capFactor1capFactor2 capFactor3*`}`	Specifies the capacitance scale factor for RC Extraction in postRoute mode.

`-postRoute_clkcap {`*`capFactor1capFactor2 capFactor3`*`}`	Specifies the scale factor for capacitance of clock nets in the postRoute extraction mode. Default: `0` When this parameter is not specified, the value specified with the `-postRoute_cap` parameter is used for postRoute extraction. When specified, this parameter overrides the value specified with the `-postRoute_cap` parameter.
`-postRoute_clkres {`*`resFactor1 resFactor2 resFactor3`*`}`	Specifies the scale factor for resistance of clock nets in the postRoute extraction mode. Default: `0` When this parameter is not specified, the value specified with the `-postRoute_res` parameter is used for postRoute extraction. When specified, this parameter overrides the value specified with the `-postRoute_res` parameter for clock nets.
`-postRoute_res {`*`resFactor1 resFactor2 resFactor3`*`}`	Specifies the resistance scale factor for RC extraction in postRoute mode.
`-name` *`existingRcCornerName`*	Specifies the name of the existing RC corner object to update.
`-qx_tech_file` *`newFileName`*	Specifies a new Quantus technology (`.tch`) file which is used to perform sign-off RC extraction.
`-T` *`newTempValue`*	Specifies a new temperature, in units of Celsius, to use to derate resistance values.
`-postRoute_xcap {`*`xcapFactor1 xcapFactor2 xcapFactor3`*`}`	Specifies the cross-coupling capacitance scale factor for RC extraction in postRoute mode.

`-via_variation_file` *viaVariationFile*	Specifies a file for modeling via variation. The VIA variation file lists up all the VIA layer names with the corresponding multiplier. Each RC corner can have its own VIA variation file.
	For example:
	`update_rc_corner`
	`-rc_corner rcCornerName1 \`
	`-via_variation_file viaVariationFileName1`
	`update_rc_corner`
	`-rc_corner rcCornerName2 \`
	`-via_variation_file viaVariationFileName2`

Examples

- The following command creates an RC corner called `rc-cbest` that uses the capacitance table `myTech_bc.CapTbl`, and derates the resistance values based on the temperature of 50 Celsius:
  `create_rc_corner -name rc-cbest -cap_table myTech.4_bc.CapTbl -T 50`
- The following command changes the capacitance table used by RC corner `rc-cbest` to `myCap.2_bc.capTbl`, and the temperature by which resistance values are derated to `25` Celsius:
  `update_rc_corner -name rc_cbest -T 25`

Related Information

- `create_rc_corner`
- `all_rc_corners`

write_global_slack_report

```
write_global_slack_report
[-early]
[-late]
[-rise]
[-fall]
[-include_ports]
[-max_slack val]
[-min_slack val]
[-view view_name]
[> | >> file_name]
[pin_port_list]
```

Reports early and late slacks on every instance pin in the design.

This command computes and reports the required time and slack values of the specified pins.

Parameters

`-help`	Prints out the command usage.
`> | >> filename`	Specifies the output file name. When specified with >, writes the report to the specified file name. If the file already exists, the software overwrites it. When specified with >>, writes the report to the specified file name. If the file already exists, the software concatenates the report to the end of the file. **Note:** To write a compressed report, add the .gz extension to the file name.
`-early/-late`	Specifies the mode for which slack is to be reported.
`-fall/-rise`	Specifies the transition for which slack is to be reported.

`-include_ports`	Reports slack information for ports. By default, the slack information is reported for pins only.
`-max_slack` *val*	Reports pins that have early and late slack values less than the specified value. Type: Float
`-min_slack` *val*	Reports pins that have early and late slack values less than the specified value. *Type:* `Float` **Note**: This parameter is obsolete and will be removed in a future release. Cadence recommends that you use the `-max_slack` parameter.
pin_port_list	Specifies the list of pins or ports for which slack information is to be reported.
`-view` *view_name*	Reports slack information for the specified view.

Examples

- The following command reports the early and late slacks on every instance pin in the design:

```
tempus > write_global_slack_report > out.rpt

# Unit: 1ns
# <late_rise> <late_fall> <early_rise> <early_fall> <view_name> <hpin_name>
# ------------------------------------------------------------------------
*              *          *            *            (null)      u2/Q
*              *          *            *            (null)      u8/Q
*              *          *            *            (null)      b11/A
*              *          *            *            (null)      b11/Y
0.823          0.347      0.115        0.501        (null)      u10999/A
0.823          0.347      0.115        0.501        (null)      u10999/Y
# ------------------------------------------------------------------------
```

- The following command reports slack for a pin collection:

```
tempus> set x [get_pins -hier */A]
```

```
0x14 <---- 'x' stores Pointer for pin collection
```

- The following command will generate a global slack report for pin collection as defined in "x":

```
tempus> write_global_slack_report $x

# Unit: 1ns
# <late_rise> <late_fall>  <early_rise>  <early_fall>  <view_name> <hpin_name>
# ------------------------------------------------------------------------
19.622       19.742        0.321         0.106         (null)      seg1/u1/A
19.622       19.742        0.321         0.106         (null)      seg1/u2/A

```

Related Information

- write_global_slack_worst_trigger_path_on_clocks

write_ldb

```
write_ldb
-library string
-outfile string
```

Converts text library to Cadence binary format library called LDB.

You can use LDB to run timing analysis. The ECSM and CCS libraries can be very large and loading them may take significant time. You can convert the ASCII NLDM (Liberty .lib), ECSM, and CCS libraries to LDB by using the `write_ldb` command.

When loading the design, the timing libraries will be read faster because the software reads the binary versions.

Instead of the original ASCII libraries, you can specify LDB in the `create_library_set` command in MMMC configuration file.

Notes:

- The software generated LDB files can be used in Tempus.
- LDB files generated from Tempus can be used as input by other tools - Innovus, Genus, and Voltus.
- LDB files are not forward compatible, that is, the LDB generated from 15.2 version cannot be used with 15.1 or prior versions of the software.
- The software does not support concatenated Liberty library (multiple libraries in the same dotlib file) files during LDB conversion. To use these files, you are required to separate out individual libraries before converting to individual LDB files.

Parameters

`-library string`	Specifies the name of the input library file.
`-outfile string`	Specifies the name of the generated LDB file.

Examples

- The following example illustrates the conversion of libraries to LDB:

  ```
  write_ldb -library A.lib -outfile A.ldb
  ```

Related Information

- check_ldb_version

write_path_descriptions

```
write_path_descriptions
[-help]
var_name
-out_file string
```

Writes out the path description of all the specified timing paths to an ASCII file. The output file contains a set of `report_timing` commands for each timing path in the given path collection. The file also includes a complete description of each timing path captured through timing points along with the clock and edge information.

Parameters

`-help`	Prints out the command usage.
var_name	Specifies the object collection.
`-out_file` *string*	Redirects output to the specified file.

Examples

- The following example command writes out descriptions of late GBA paths to `pathfile1`:

  ```
  write_path_descriptions var1 -out_file file1 > file2
  ```

  The output file `pathfile1` will contain the following information:

  ```
  report_timing -net -path_type full_clock -late -from_rise A -through_rise B -
  through_rise C -to_rise D -view slow_v -clock_from clk1 -edge_from lead -clock_to
  clk2 -edge_to lead
  ```

Writes delays to a Standard Delay Format (SDF) file. The `write_sdf` command can generate both plain-text and GNU zipped (`.gz`) SDF files.

By default, the `write_sdf` command uses the delays already cached by the system and writes only values of the triplets.

Parameters

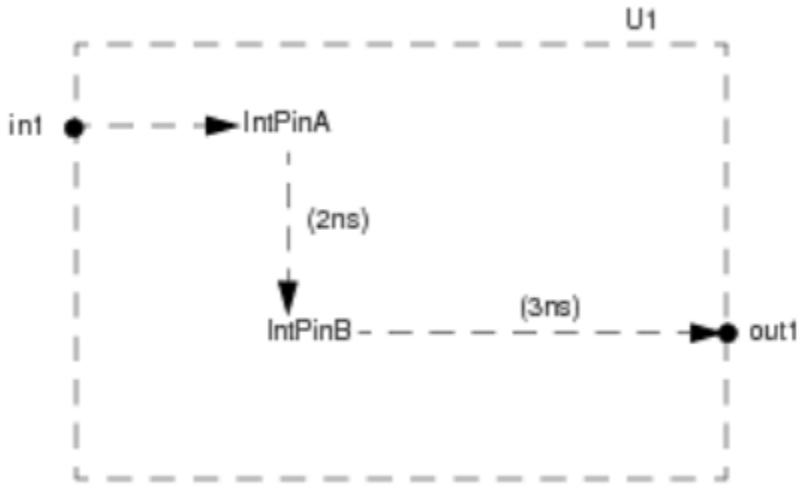
`-help`	Prints out the command usage.
`-abstracted_model`	Saves the gate-level simulation (GLS) SDF file.
`-adjust_setuphold_for_zero_hold_slack`	Adjusts the hold timing check to meet non-negative slack values.
`-base_delay`	Writes out base delay information in the SDF file.
`-celltiming {all | none | nochecks}`	Specifies which cell delays and timing checks to write out. *Default*: `all` • `all` - Writes all cell delays and timing checks to the SDF file. This is the default. • `nochecks` - Disables the writing of timing checks only. • `none` - Prevents cell delays and timing checks from being written into the SDF file.
`-collapse_internal_pins`	
	Collapses arcs across internal pins to a single primary

input to primary output arc.

Use the -collapse_internal_pins parameter when the SDF file being generated is intended for use by an application that does not support the same internal pin structure in its leaf cell libraries (for example, Cadence VXL and NCsim Verilog simulation products). Do *not* use this parameter to generate an SDF file intended for use within the Innovus flow, or by third party tools that utilize the same Liberty timing models.

Default: Arcs between internal pins in a timing model are written to the SDF file as explicit annotations to and from the internal pins.

For example, assume the following arc between internal pins:



The following SDF would be generated by default:

```
(U1/in1 U1/IntPinA (1::1) (1::1))

(U1/IntPinA U1/IntPinB (2::2) (2::2))

(U1/IntPinB U1/out1 (3::3) (3::3))
```

If you specify -collapse_internal_pins, the resulting SDF would show a single arc with the merged delays:

```
(U1/in1 U1/out1 (6::6) (6::6))
```

`-condelse`	Writes `CONDELSE` constructs with the default value when a `COND` construct is written. **Note:** Use this argument with the `-version 3.0` option.
`-delimiter` *char*	Specifies the hierarchy divider character to use in the output file. This option sets the hierarchy divider of only the `write_sdf` command. If omitted, the default hierarchy divider character (`/`) is used as the `write_sdf` default.
`-delta_delay`	Writes out delta delay values to the SDF file.
`-edges {edged | library | noedge | check_edge}`	
	Specifies the edges values. Refer to Table for full qualifications of the possible values for the edges option. *Default*: `edged` • `check_edge` - Keeps edge specifiers on timing check arcs but does not add edge specifiers on delay arcs. • `edged` - Keeps edge specifiers on timing check arcs and delay arcs. • `library` - Assumes that the sdf_edges attributes are specified in the .lib file. The default sdf_edges value of a timing arc is noedge. • `noedge` - Defined in the Table.
`-exclude_cells`	Specifies a list of leaf-cell or hierarchical instances whose timing data will be excluded from the the SDF (Standard Delay Format) file. If you specify a hierarchical instance, the timing data for all leaf-cells below the level of hierarchy will be omitted from the SDF file.
`-exclude_cells_keep_io_nets`	Restricts the filtering to just the annotations which are completely enclosed by the cell. Annotations to or from the cell will be preserved. By default, when the `-exclude_cells` parameter is used, any annotations within the excluded cell and any annotations to or from the excluded cell are filtered from the SDF.

`-exclude_cells_keep_top_level_nets`	Allows you to configure the handling of top-level interconnect annotations to an instance that is excluded from the SDF using the `write_sdf -exclude_cells` parameter. When this parameter is specified, the interconnect arcs which span to the ports of the instance will be included in the SDF. By default, no interconnect arcs to the instance are included. The delay annotated will be the worst-case delays of the top-level nets to/from the first level sink/source pins within the block that traverse a given input/output port of the instance, respectively.
`-exclude_disabled_arcs`	Excludes user set disabled arcs in the Standard Delay Format (SDF) file. If the user sets this option, the disabled arcs set by commands `set_mode`, `set_disable_timing`, and `set_case_analysis` are excluded.
`-exclude_disabled_modes`	Excludes timing arcs that have been disabled due to an active library mode set by the `set_mode` command, from appearing in the SDF file.
`-exclude_whatif_arcs`	Excludes what-if arcs in the SDF file.
`file_name`	Specifies the name of the SDF output file. If omitted, this argument defaults to `stdout`.
`-filter`	Converts all negative interconnect and `IOPATH` delays to zero.
`-ideal_clock_network`	Marks delays of delay arcs, that are on the ideal clock networks, as 0 in the SDF file.

`-interconn {all | none | noport | noinport | nooutport}`	Specifies which interconnect delays to write. *Default*: `all` • `all` - Writes all `INTERCONN` delays into the SDF file. This is the default if the `-interconn` option is not specified. • `none` - No `INTERCONN` delays are written into the SDF file. • `noport` - No top level port `INTERCONN` delays are written into the SDF file. • `nooutport` - Disables only the output port `INTERCONN` delays.
`-map_file {file1 file2 ...}`	Specifies a list of map files. The map files can be used to determine what is written into the SDF files. For example, a map file can provide delay information on internal pins which are not defined in the timing library. Syntax for a map file (for a cell) is as follows: ◦ A template section (the text to output) that reference variables of the form $<number> ◦ A variable definition section that tells the expression to evaluate to obtain the value
`-max_view` *viewName*	Uses the late delay from the specified analysis view to populate the SDF max slot, when in multi-mode multi-corner analysis mode.
`-merge_arcs`	Merges two arcs that are related to the same internal pin and forms one timing arc. For example, consider a cell's `IOPATH` that forms an arc from pin `I` to internal pin `A` and another from pin `A` to output pin `O`. In this case, if you use the `-merge_arcs` option, the software will merge both the arcs related to internal pin `A` and form one timing arc from pin `I` to output pin `O`.

`-min_period_edges {posedge | negedge | both | none}`	Specifies how to write out minimum `PERIOD` checks. Two check arcs are always created for the `min_period` check when you read in a `.lib` file. The following options let you keep or remove the positive edge, the negative edge, both edges, or no edges from the PERIOD statement in the `.sdf` file. • `posedge` - Writes out one positive edge `PERIOD` check. • `negedge` - Writes out one negative edge `PERIOD` check. • `both` - Writes out both the positive edge and the negative edge `PERIOD` checks. This is the default. • `none` - Writes out one `PERIOD` check without any edge specifier.
`-min_view` *viewName*	Uses the early delay from the specified analysis view to populate the SDF `min` slot, when in multi-mode multi-corner analysis mode.
`-no_condition`	Suppresses the COND statements in the SDF file.
`-no_derate`	Writes non-derated delays to the Standard Delay Format (SDF) file. By default, the `set_timing_derate` command writes scaled delays to the SDF file. When the `-no_derate` parameter is specified, the `write_sdf` command removes all the applied derates.
`-no_escape`	Writes out object names without escaping hierarchical dividers. Normally, when writing out a SDF file, the hierarchical divider (`/`) is escaped because it is a special character.
`-no_variation`	Exports the SDF delay and check values without including the variation component, when the selected analysis type is SOCV. By default, the SDF delays and check values will have the mean + N*sigma value.

`-nonegchecks`	Converts all negative timing check values to `0.0`. The `-nonegchecks` parameter has an effect only when the negative checks are legal. In SDF v3.0, the negative checks are only legal in the context of `RECREM` or `SETUPHOLD` checks – they are not legal in case of split checks. In SDC v2.1, the negative values are permitted in `SETUP`, `HOLD`, and `RECOVERY` checks. Therefore, for these checks the `-nonegchecks` parameter is required to convert negative values to zero. The negative checks are legal in the split checks, so the `-nonegchecks` parameter can have an effect. The SDF v2.1, however, does not support `REMOVAL` checks.
`-precision` *non_neg_integer*	Controls the number of digits appearing after the decimal point in the output SDF file. The default precision is the value of the `report_precision`.

`-process`	Specifies one or a combination of the following process names that will appear in the header of the generated SDF file:
	
	• `best`
	• `typical`
	• `worst`
	
	Use the colon delimiter to specify multiple process names. For example:
	
	`-process best:typical:worst`
	
	In the above example, the header of the generated SDF file will contain:
	
	`(PROCESS "best:typical:worst")`

`-resort_values_min_to_max`	Sorts values in the SDF delay triplets into ascending order.

`-recompute_delay_calc`	Instructs the software to recompute any necessary data required for a complete SDF file before exporting. By default, only the existing data that has been computed for STA is exported to the SDF. You must use this parameter to ensure that the SDF file is complete for general use in other applications.
`-recompute_parallel_arcs`	Instructs the software to temporarily recompute delays with separate delay calculation for parallel arcs. The software normally operates in a high performance mode which optimizes the handling of multiple timing arcs between input and output pin pairs. By default, the SDF file generated will contain the same delay information for all of these arcs. To have the SDF recalculated with explicit pin pair data, you should use the option `-recompute_parallel_arcs` to cause delays for each parallel arc to be explicitly calculated. It is recommended to use this option for generating SDF for functional simulation applications. **Note**: When you use the `write_sdf -recompute_parallel_arcs` option timing analysis is performed again. You need to obtain a new delay calculation to generate the SDF, and another delay calculation to put the system back to where it was before `write_sdf` was specified. Since delay calculation is run again, timing analysis will be reset. **Note**: The `-recompute_parallel_arcs` parameter is obsolete. This parameter still works in this release, but to ensure compatibility with future releases update your scripts to use the `-recompute_delay_calc` parameter instead.

`-recrem [merge_always | split | merge_when_paired]`	Determines how `RECOVERY and REMOVAL` timing checks are written. • `merge_always` - Always writes combined `RECREM` checks, even if either a `RECOVERY`, or a `REMOVAL`, check does not exist. For example, if a `RECOVERY` check exists, but a `REMOVAL` check does not, the software writes a combined `RECREM` check in the SDF file as follows: RECREM (*value*) (*value*) () () • `split` - Splits the `RECREM` checks into a `RECOVERY` check and a `REMOVAL` check. • `merge_when_paired` - Writes combined `RECREM` checks only when both a `RECOVERY` and a `REMOVAL` check exist. For example, if both a `RECOVERY` and a `REMOVAL` check exist, the software writes a combined `RECREM` check in the SDF file as follows: RECREM (*value*) (*value*) (*value*) (*value*) However, if a `RECOVERY` check exists, but a `REMOVAL` check does not, the software only writes the `RECOVERY` check in the SDF file: RECOVERY (*value*) (*value*) *Default:* `merge_always` **Note**: The `RECREM` sum should be zero or greater than zero. A negative value will be adjusted to enforce this condition. This is an SDF v3.0 requirement (the software may issue a warning).

`-remashold`	Converts the SDF v2.1 unsupported `REMOVAL` (and the `REMOVAL` portion of the `RECREM` constructs) to `HOLD` checks when used with the `-version 2.1` option. *Default*: Not to write out the unsupported checks. Converts the `REMOVAL` checks to `HOLD` checks when combined with the `-version 3.0` option.The `RECREM` checks are split into a `RECOVERY` check and a `HOLD` check. This option automatically splits the `RECREM` checks. *Default*: To maintain the version 3.0 checks.
`-scale` *float*	Specifies a multiplier to the delay values used in the SDF file. This option does not change the `timescale` setting of the SDF file. The delay values are scaled, but the units are the same. *Default*: `1`

`-setuphold [merge_always | split | merge_when_paired]`	Determines how `SETUP and HOLD` timing checks are written. • `merge_always` - Always writes combined `SETUPHOLD` checks, even if either a `SETUP` or a `HOLD`, check does not exist. For example, if a `SETUP` check exists, but a `HOLD` check does not, the software writes a combined `SETUPHOLD` check in the SDF file as follows: SETUPHOLD (*value*) (*value*) () () • `split` - Splits the `SETUPHOLD` timing checks into separate `SETUP` and `HOLD` checks. • `merge_when_paired` - Writes combined `SETUPHOLD` checks only when both a `SETUP` and a `HOLD` check exist. For example, if both a `SETUP` and a `HOLD` check exist, the software writes a combined `SETUPHOLD` check in the SDF file as follows: SETUPHOLD (*value*) (*value*) (*value*) (*value*) However, if a `SETUP` check exists, but a `HOLD` check does not, the software only writes the `SETUP` check in the SDF file: SETUP (*value*) (*value*) *Default:* `merge_always`
`-splitrecrem`	Splits the `RECREM` checks into a `RECOVERY` check and a `REMOVAL` check. *Default*: To write the combined `RECREM` check. **Note:** Use this option only with the `version 3.0` option.

`-splitsetuphold`	Splits the `SETUPHOLD` timing checks into separate `SETUP` and `HOLD` checks. *Default*: To write the combined `SETUPHOLD` checks. **Note**: In SDC v3.0, the negative values are illegal in `SETUP`, `HOLD`, `RECOVERY`, and `REMOVAL` checks. Therefore, the negative values are converted to zero automatically with the `-splitsetuphold` and `-splitrecrem` parameters.

`-temperature`	Defines the temperature values that will appear in the header of the generated SDF file.
	Use the colon delimiter to specify multiple temperature values. For example:
	
	`-temperature -40.0:25.0:125`
	
	In the above example, the header of the generated SDF file will contain:
	
	`(TEMPERATURE -40.0:25.0:125)`

`-timingcheck {order}`	Sorts the check delays in OCV analysis.

`-target_application { sta | verilog}`	Allows customization of the SDF output for use with STA or Verilog applications. You can select the following options: • sta: You can use the sta option to configure the SDF output for use with static-timing analysis (STA) applications. This includes sign-off timing analysis with products, such as Cadence Tempus, as well as for working with implementation flows that use STA for internal timing analysis. The sta option preserves maximum accuracy and generates SDF output that matches the structure of the Liberty timing libraries. This option is equivalent to the following options: `write_sdf -interconn all`, `-celltiming all`, `-edges edged`, `-setupholdmerge_when_paired`, and `-recrem merge_when_paired`. • verilog: You can use the verilog option to generate SDF output that is compatible with Cadence Verilog-XL or Verilog-NC simulators. This option is equivalent to the following options: `write_sdf -filter -edges check_edge`, `-setuphold merge_when_paired`, `-recremmerge_when_paired`, `-min_period_edges -none`, `-collapse_internal_pins`, and `-recompute_parallel_arcs`. When the `-target_application` option is not specified then by default SDF output is configured for use with STA applications.

`-transform_out_to_out_arcs`	Writes out all output-to-output timing arcs as input-to-output arcs. Input-to-output arc delays are computed by adding the delay from the input pin to one of the output pins plus the delay from that output pin to the other output pin. For instance, in the following figure, the delay between `in` and `out2` would be the sum of `delay1` and `delay2`. `-typ_view` *`viewName`*	Uses the late delay from the specified analysis view to populate the SDF `typ` slot, when in multi-mode multi-corner analysis mode.
`-version {2.1 | 3.0}`	Specifies whether to generate the SDF V2.1 or V3.0. The default SDF version is 3.0. Used in combination with the `-remashold` option.
`-view` *`viewName`*	Uses the early and late delays for the specified analysis view to populate the `min` and `max` SDF triplet slots, when in multi-mode multi-corner analysis mode. The SDF `typ` slot remains empty (*`earlyVal`*`::`*`lateVal`*). In multi-mode multi-corner analysis mode, if you want to use SPEF information when calculating the delays, you must use `spefIn -rc_corner` to import the SPEF files for each RC corner in the design.

`-voltage`	Defines the voltage values that will appear in the header of the generated SDF file.
	Use the colon delimiter to specify multiple voltage values. For example:
	`-voltage 1.980:1.800:1.620`
	In the above example, the header of the generated SDF file will contain:
	`(VOLTAGE 1.980:1.800:1.620)`

Table: **Definition of -edges Option Values**

	edged Value	**library Value**	**noedge Value**
IOPATH from a unate input pin to output pin	No edge specifier	No edge specifier	No edge specifier
IOPATH from a non-unate input pin to output pin	Edge specifier at the input pin	Edge specifier at the input pin when sdf_edges is either "both_edges" or "start_edge"	No edge specifier When merging edged paths, the maximum values are used for MAX and TYP fields; minimum values are used for MIN fields.
IOPATH of a clock/enable pin to data out pin	Edge specifier at the input pin	Edge specifier at the input pin when sdf_edges is either "both_edges" or "start_edge"	No edge specifier
Timing Checks	Edge specifiers match the check arcs specified in the timing library	Overridden by value of the sdf_edges attribute	Only the edge specifiers of the reference pin are written

		For both_edges, the timing checks will contain edge specifier on both starting and ending pins For start_edge, the starting pin (for HOLD type check) or ending pin (for SETUP type check) is edge-specified For end_edge, the ending pin (for HOLD style check) or the starting pin (for SETUP type check) is edge-specified The timing checks are duplicated or combined appropriately. The start_edge and end_edge are interpreted as first and second events, respectively, of the Verilog-XL's $hold() and $setup system tasks	

Examples

- The following command writes out an SDF 2.1 compliant output file named `my.sdf` with 4 digits after the decimal point: `write_sdf -version 2.1 -precision 4 my.sdf`
- The following example SDF files compare the output of `-edges edged` to the output of `-edges noedge`.

  Resultant SDF with `-edges` set to `edged`:

  ```
  (HOLD (posedge D) (posedge CK) (-0.14:-0.14:-0.14)) (HOLD (negedge D) (posedge CK) (-0.06:-0.06:-0.06)) (SETUP (posedge D) (posedge CK) (0.22:0.22:0.22)) (SETUP (negedge D) (posedge CK) (0.41:0.41:0.41))
  ```

  With `-edges` set to `noedge` only the edge specifiers of the clock pin are written.

  ```
  (HOLD D (posedge CK) (-0.14:-0.06:-0.06)) (SETUP D (posedge CK) (0.22:0.41:0.41))
  ```

write_timing_windows

```
write_timing_windows
[-help]
[-pin]
[-power_compatible]
[-view string]
[-ssta_sigma_multiplier float]
[-voltage_threshold string]
output_file
```

Generates a timing window file (TWF). The TWF file mainly contains the earliest and the latest possible arrival times that a signal may arrive on a net or a pin.

The format of a timing window file consists of eight pairs of data as given below:

```
(NET <netname>

minRTW:maxRTW minRt:maxRt minRDr:maxRDr minRSlk:maxRSlk minFTW:maxFTW minFt:maxFt
minFDr:maxFDr minFSlk:maxFSlk)
```

Where:

- `minRTW`: Minimum rise arrival time
- `maxRTW`: Maximum rise arrival time
- `minRt`: Minimum rise transition time
- `maxRt`: Maximum rise transition time
- `minRDr`: Minimum rise source resistance
- `maxRDr`: Maximum rise source resistance
- `minRSlk`: Minimum rise slack time
- `maxRSlk`: Maximum rise slack time
- `minFTW`: Minimum fall timing window
- `maxFTW`: Maximum fall timing window
- `minFt`: Minimum fall transition time
- `maxFt`: Minimum fall transition time
- `minFDr`: Minimum fall source resistance
- `maxFDr`: Maximum fall source resistance

- `minFSlk`: Minimum fall slack time
- `maxFSlk`: Maximum fall slack time

Parameters

`-help`	Prints out command usage.
`output_file`	Writes the TWF file to the specified file name. The *`filename`* parameter must be the last argument in the list. **Note:** To write a compressed file, add the `.gz` extension to the file name.
`-pin`	Generates a TWF for each pin instead of each net. *Default*: Generates a TWF for the crosstalk analysis tool, which contains timing windows on each net.
`-power_compatible`	Generates a timing window file that is suitable for power analysis.
`-ssta_sigma_multiplier` *`float`*	Specifies a sigma multiplier between `0` and `3`. The value that you specify increases the arrival window by that amount and worst slack value is generated. The transition and impedance values are not impacted.
`-view` *`string`*	Generates a TWF for the specified multi-mode multi-corner view only. You must be multi-mode multi-corner analysis mode to use this parameter. If the `-view` parameter is not specified, then by default the first active view will be used to generate timing windows.
`-voltage_threshold` *`string`*	Specifies voltage threshold values for generating a Timing Window File (TWF). All the slews in the TWF file will be scaled with these values. The lower threshold value must be less than the higher threshold value. *Value range:* `0` to `100`

Examples

- The `write_timing_windows -voltage_threshold {20 80}` command outputs the following in the TWF file:

  ```
  (VOLTAGE_THRESHOLD 20 80)
  ```

- When active clocks are set using the `set_active_clocks` command, the `write_timing_windows` command will not display windows for inactive clocks in the output. The example report is shown below:

```

writeAnnotatedTransition

```
writeAnnotatedTransition
[-help]
-file out_file
[-min | -max]
[-writeOutput]
[-direct]
[-noPort]
[-view view_name]
```

Writes the value of transitions on each pin to an output file. You can either set the transitions using the `set_annotated_transition` command or the software computes them internally.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `writeAnnotatedTransition` parameter. For a detailed description of the command and all of its parameters, use the man command: `man writeAnnotatedTransition`.
`-direct`	Refers the ports directly for which the annotated transition will be applied in the output SDC. This option removes the dependency of using the `get_ports` and `get_pins` commands.
`-file out_file`	Specifies the name of the output file.
`-min | -max`	Specifies whether to write out minimum or maximum transition. *Default:* Both minimum and maximum transitions are written out.
`-noPort`	Skips writing the transition values for the primary ports (input and output).

`-view` *`view_name`*	Writes the transitions for the specified analysis view only. You can specify this parameter only when the software is in multi-mode multi-corner timing analysis mode.
`-writeOutput`	Writes the slews for input and output pins, and the output slew for bi-directional pins. If this option is not specified, the software writes the slew for input pins and the input slew of bi-directional pins.

Examples

- The following command generates the output file `tran.rpt`:

  ```
  writeAnnotatedTransition -file tran.rpt
  ```

  The following file is generated:

  ```
  set_annotated_transition -rise -min 0.0278 [get_ports {sig_out4000}]
  set_annotated_transition -fall -min 0.0275 [get_ports {sig_out4000}]
  set_annotated_transition -rise -max 0.0278 [get_ports {sig_out4000}]
  set_annotated_transition -fall -max 0.0275 [get_ports {sig_out4000}]
  set_annotated_transition -rise -min 0.001 [get_pins {buf_in2000/A}]
  set_annotated_transition -fall -min 0.001 [get_pins {buf_in2000/A}]
  set_annotated_transition -rise -max 0.001 [get_pins {buf_in2000/A}]
  set_annotated_transition -fall -max 0.001 [get_pins {buf_in2000/A}]
  set_annotated_transition -rise -min 0.001 [get_pins {buf_in2001/A}]
  set_annotated_transition -fall -min 0.001 [get_pins {buf_in2001/A}]
  set_annotated_transition -rise -max 0.001 [get_pins {buf_in2001/A}]
  set_annotated_transition -fall -max 0.001 [get_pins {buf_in2001/A}]
  set_annotated_transition -rise -min 0.0453 [get_pins {buf_out5000/A}]
  set_annotated_transition -fall -min 0.0418 [get_pins {buf_out5000/A}]
  set_annotated_transition -rise -max 0.0453 [get_pins {buf_out5000/A}]
  set_annotated_transition -fall -max 0.0418 [get_pins {buf_out5000/A}]
  ```

- The following command generates the minimum transitions in the output file, `min_tran.rpt`:

```
writeAnnotatedTransition -min -file min_tran.rpt
```

The following file is generated:

```
set_annotated_transition -rise -min 0.0278 [get_ports {sig_out4000}]
set_annotated_transition -fall -min 0.0275 [get_ports {sig_out4000}]
set_annotated_transition -rise -min 0.001 [get_pins {buf_in2000/A}]
set_annotated_transition -fall -min 0.001 [get_pins {buf_in2000/A}]
set_annotated_transition -rise -min 0.001 [get_pins {buf_in2001/A}]
set_annotated_transition -fall -min 0.001 [get_pins {buf_in2001/A}]
set_annotated_transition -rise -min 0.0453 [get_pins {buf_out5000/A}]
set_annotated_transition -fall -min 0.0418 [get_pins {buf_out5000/A}]
```

- The following command generates the maximum transitions in the output file, `max_tran.rpt`:

  ```
  writeAnnotatedTransition -max -file max_tran.rpt
  ```

  The following file is generated:

  ```
  set_annotated_transition -rise -max 0.0278 [get_ports {sig_out4000}]
  set_annotated_transition -fall -max 0.0275 [get_ports {sig_out4000}]
  set_annotated_transition -rise -max 0.001 [get_pins {buf_in2000/A}]
  set_annotated_transition -fall -max 0.001 [get_pins {buf_in2000/A}]
  set_annotated_transition -rise -max 0.001 [get_pins {buf_in2001/A}]
  set_annotated_transition -fall -max 0.001 [get_pins {buf_in2001/A}]
  set_annotated_transition -rise -max 0.0453 [get_pins {buf_out5000/A}]
  set_annotated_transition -fall -max 0.0418 [get_pins {buf_out5000/A}]
  ```

- get_pins

writeDesignTiming

`writeDesignTiming` *`filename`*

Writes out the timing information of the design.

Use this command when you run the NanoRoute® router in timing-driven mode. The router prioritizes each net to route based on the timing information specified in the output file. Do not edit the file because it is internally generated for the router.

By default, when the router runs with `setNanoRouteMode -route_with_timing_driven true` specified, it automatically generates a timing information file named `timingfile.tif` in the working directory, and uses it for timing-driven routing.

However, you can control the timing information passed to the router by specifying a timing information file with `writeDesignTiming`. If you specify a file with this command, and also specify `setNanoRouteMode -timingEngine` *`filename`*, the router uses the file written out by `writeDesignTiming` to drive routing, instead of the `timingfile.tif` file.

Parameters

`filename`	Specifies the output filename. **Note:** The output file is for internal tool use only. You must not edit the output file.

Related Information

- `setNanoRouteMode`

writeTimingCon

```
writeTimingCon
[-help]
[<filename>]
[-clocks <string>]
[-commands <string>]
[-exclude_annotated {delays | checks | transitions}]
[-pins <string>]
[-view <viewName>]
```

Generates the timing constraints file in Design Compiler format.

Parameters

`-help`	Prints out the command usage.
`-clocks <string>`	Specifies the name of the clocks to be included in the SDC file.
`-commands <string>`	Specifies the name of the commands to be included in the SDC file.
`-exclude_annotated {delays | checks | transitions}`	Disables listing of annotated constraints. • `delays`: Suppresses dumping of `set_annotated_delay` constraints. • `checks`: Suppresses dumping of `set_annotated_check` constraints. • `transitions`: Suppresses dumping of `set_annotated_transition` constraints.
filename	Specifies the name of the constraints file. By default, the constraint file is generated in the current directory. To save to a different directory, you need to specify the complete path.
`-pins <string>`	Specifies the name of the pins to be included in the SDC file.

`-view` *viewname*	Specifies a view name to obtain the desired SDC.

Command Order

Use this command after reading in a timing constraints file.

Examples

- The following command generates constraints file `newc` and saves the generated file in the directory `new`:

  ```
  writeTimingCon new/newc
  ```

- Specifying the following constraints will have new entries in the output constraints file:

  ```
  set_annotated_delay -from u1/A -to u1/Y -cell 2
  set_annotated_check 2 -setup -from f0/CK -to f0/D
  ```

  The output constraint file `constr.pt` will have the following new entries:

  ```
  set_annotated_delay -cell 2 -from [get_pins {u1/A}] -to [get_pins {u1/Y}]
  set_annotated_check -setup -from [get_pins {f0/CK}] -to [get_pins {f0/D}] 2
  ```

- For the following constraints in the design :

  ```
  set_annotated_delay -from u1/A -to u1/Y -cell 2
  set_annotated_transition 2 u1/A
  set_annotated_check 2 -setup -from f0/CK -to f0/D
  ```

  The output constraint file `constr.pt` will have the following entries :

  ```
  set_annotated_transition 2 [get_pins {u1/A}]
  set_annotated_check -setup -from [get_pins {f0/CK}] -to [get_pins {f0/D}] 2
  set_annotated_check -setup -from [get_pins {f0/CK}] -to [get_pins {f0/D}] 2
  ```

checkPartitionSdc

```
checkPartitionSdc
[-help]
{[-chip string -partition_dir string] | [-chip string -module_model_tag string [-add_ons string] [-accumulated] [-overwrite_tag]] | [-
compare_only]}
[-cells string]
[-master_only]
[-no_top]
[-out_dir string]
[-validate_boundary_condition]
```

When you generate the timing budgets for partitions using the `deriveTimingBudget` command, the `checkPartitionSdc` command validates the results. The validation ensures that the timing data of the partitioned block is the same as that of the chip. This saves the ECO iteration for the chips and partitioned blocks, and thereby reduces the overall design cycle time.

Note: This validation is carried out independently by comparing the constraints data and timing data.

The constraints data can be generated from the third-party tools well. To run the checkPartitionSdc command, the constraints data and timing data for the chips and blocks must be available in the Innovus format.

On running this command, some simple constraints are directly validated though the SDC comparison. For some other checks related to pins, the chip and block values are compared. However, for some complex exception constraints, an independent validation is done by checking and comparing the phases reaching at the boundary pins of the chips and the blocks.

The comparison checks the files of the missing, extra, and mismatching constraints in the blocks and the chips. These can help in fixing the partitioned block constraints to get accurate budgets.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `checkPartitionSdc` parameter. For a detaile description of the command and all its parameters, use the man command: `man checkPartitionSdc`
`-accumulated`	Runs comparison for the accumulated budgeting mode.

`-add_ons string`	Specifies the supplement model that can be loaded additionally with an existing model or a design. It can be used with the `-module_model_tag` parameter. This parameter can only be used in the Integrated Hierarchical Database (iHDB) flow. This parameter is useful for the flows where partitioning and timing budgeting are done in parallel, as presented below: `-cells string`	Specifies the list of cell names for which the SDC comparison is to be done. *Default:* `all cells`
`-chip string`	Specifies the TCL file, which loads the chip database before timing budgeting.
`-compare_only`	Compares the dumped data with the previous `checkPartitionSdc` run.
`-master_only`	Dumps and compares constraints for checking only the master partitions for the master-clone designs. In case this parameter not used, the tool dumps and compares constraints taking clones also in consideration.

`-module_model_tag string`	Specifies the module model tag for the cell on which the SDC comparison is to be done.
	For example, the following commands validate the timing budgeting results for the specified module model:
	`set_module_model -default_dir ./DATA2`
	`checkPartitionSdc -chip scripts/chip.tcl -cells $block -module_model_tag init -no_top`
	Note: This parameter is a part of the iHDB flow. Before using this parameter, you must set the default central directory name (`set_module_model -default_dir default_model_data_directory`) where the module models data will be saved/loaded.

`-no_top`	Disables checking of the TOP cell.
`-overwrite_tag`	Regenerates design for the accumulated Budgeting mode.
`-out_dir string`	Specifies the directory, which contains the output in the form of validation comparison reports and log files. *Default*: `./cps`
`-partition_dir string`	Specifies the directory, which contains the partition database.

`-validate_boundary_condition`	Compares the slew values at the chip versus block level. Slew values are generated using the `report_timing` command, and the comparison is done at immediate pins to the block boundary.
	This parameter can be used in the same session in which the default `checkPartitionSdc` check is used. However, it should n run in parallel with the default `checkPartitionSdc` check since writing of setup file may have a conflict.
	The `-validate_boundary_condition` parameter can validate only the boundary conditions for the partition-block constraints generated for `setBudgetingMode -useBoundaryCondition actual` and build the timing graph from the actual netlist. This parameter dumps an output file in the .csv format.
	⚠ The `-validate_boundary_condition` parameter cannot support the `setBudgetingMode -useBoundaryCondition {optimized | template}` values. It also gives an error, if the timing graph is not built.
	Following is a sample output of using the `-validate_boundary_condition` parameter:
	`+---------------------------+-----------+------------+----------+`
	`|  Pin  | Chip Slew | Block Slew | Diff (%) |`
	`+---------------------------+-----------+------------+----------+`
	`| slave_haddr_o[0]  |  0.620 |  0.613 |  1.13 |`
	`| rxdata1[6]  |  0.266 |  0.269 |  1.13 |`
	`| rxdata1[7]  |  0.270 |  0.273 |  1.11 |`
	`| master_hready_o  |  0.364 |  0.368 |  1.09 |`
	`| SPCASCAN_N523  |  0.734 |  0.742 |  1.09 |`
	`| rxdata2[1]  |  0.196 |  0.198 |  1.02 |`
	`| slave_hrdata_i[0]  |  0.098 |  0.097 |  0.11 |`
	`+---------------------------+-----------+------------+----------+`

Examples

- The following command runs validation using the chip database `chip.tcl` and post-partition saved along with post-budgeted database in `ptn` tag:
  ```
  checkPartitionSdc -chip ./chip.tcl -module_model_tag ptn
  ```
- The following command runs validation using the chip database `chip.tcl`, the post-partition database in the `ptn` tag, and post-budgeted database in the `ptn` tag, which are saved in parallel:
  ```
  checkPartitionSdc -chip ./chip.tcl -module_model_tag ptn -add_ons {mmmc}
  ```
- The following command runs validation using the chip database `chip.tcl`, the post-partition database in the `ptn` tag, and post-budgeted database in the `stb` tag:
  ```
  checkPartitionSdc -chip ./chip.tcl -module_model_tag ptn -add_ons {STB/mmmc}
  ```
- The following command runs validation using the chip database `chip.tcl` and the partition database in `./PTNS`:
  ```
  checkPartitionSdc -chip ./chip.tcl -partition_dir ./PTNS
  ```
- The following command runs validation using the chip database `chip.tcl` and the partition database in `./PTNS` for cells P1 and P2:
  ```
  checkPartitionSdc -chip ./chip.tcl -partition_dir ./PTNS -cells {P1 P2}
  ```
- The following command runs validation using the chip database `chip.tcl`, the partition database in `./PTNS`, and the dumping reports and log in `./CHK`:
  ```
  checkPartitionSdc -chip ./chip.tcl -partition_dir ./PTNS -out_dir ./CHK
  ```
- The following command runs validation using the chip database `chip.tcl`, and partition database in `./PTNS`, and only checks the partitions data (no portioned top checking with chip):
  ```
  checkPartitionSdc -chip ./chip.tcl -partition_dir ./PTNS -no_top
  ```

Related Information

Refer to the Timing Budgeting chapter in the *User Guide* document.

deriveTimingBudget

```
  deriveTimingBudget
[-help]
[-parameterized]
[-cycleRatio | -stageBased | -timingCore | -preliminary | -pushDownSDC]
[-allIlmHinsts | -inst instanceName | -ptn partitionName]
[-verbose]
[-views string]
```

Generates timing budgets for partitions for standalone implementation. This command can also generate timing budgets on an instance basis instead of partitions. The generated timing constraint files allow you to do standalone block implementation. In case of partition based budgeting, it also generates timing models that will allow you to do standalone top level implementation. This command also directs summary files into the default budget justification directory.

Note: You must free the timing graph to use multiple `deriveTimingBudget` commands with different options.

Innovus operates in multi-mode multi-corner (MMMC) mode, and generates `viewFiles`automatically for partition implementation and top-level chip assembly. Note that the `deriveTimingBudget` command does not generate a timing graph, if it already exists. Additionally, user will have to provide a timing graph generated without using `deriveTimingBudget` and must set the value of the `setBudgetingMode -virtualOptEngine` parameter same as that of the command used to generate the timing graph.

When the `deriveTimingBudget` command is run, all the public `setBudgetingMode` parameters with their non-default values are displayed before the intended output of the `deriveTimingBudget` command, in an information message. This information message follows the format shown below:

```
This command "deriveTimingBudget" required an extra checkout of license invs_hier. Additional license(s) checked out: 1 'Innovus_Hier_Opt'
license(s)
**INFO: User settings:
setBudgetingMode -abutted true
setBudgetingMode -fixTopLevelPaths all
setBudgetingMode -masterClone merged
setBudgetingMode -noHoldView true
.
.
```

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `deriveTimingBudget` parameter. For a detailed description of the command and all its parameters, use the man command: `man deriveTimingBudget`
`-allIlmHinsts`	Derives timing budgets only for all the ILM-based partitions. When this parameter is used, the software automatically derives the list of ILM instances and budgets for them. **Note:** The `-allIlmHinsts` parameter internally calls `-inst` based budgeting. So, saving budgets is only supported through the `saveTimingBudget` command. Therefore, it is necessary to run `saveTimingBudget` after `deriveTimingBudget -allIlmHinsts`, else `savePartition` will not save the budgeting information of ILM instances.

`-cycleRatio`	Honors the `setCycleBudgetRatio` constraints and enables usage of clock cycle time based budgeting. If no `setCycleBudgetRatio` constraints are applied:
	• The top and block default ratio is 20% and 80% of the clock respectively.
	• The partition for start and end points splits the block ratio in 50% each.
	• Equivalent default constraint is as follows:
	`setCycleBudgetRatio -fromPtn {* .4} -toPtn {* .4}`
	`setCycleBudgetRatio -fromPtn {* .8} -toTop`
	`setCycleBudgetRatio -fromTop -toPtn {* .8}`
	Note: Do not use the `setFixedBudget` command with this parameter.

`-inst` *instanceName…*	
	Performs budgeting for the hierarchical instance(s). This instance could be a black box. You can derive timing budgets for black boxes and other instances in the same run. Specify the `setBudgetingMode -mergeClones` parameter in addition to the `-inst` parameter to obtain worst-case budgets based on worst-case data per-pin for specified instances in a master/clone set. If you specify instances from more than one master/clone set, the tool derives separate worst-case timing budgets for the specified instances in each set. *Default:* If you do not specify this parameter, the software derives budgets for all the partitions.

`-parameterized`	Generates constraints as a function of the clock period. When you set this parameter, the software generates timing constraints, such as `set_input_delay` and `set_output_delay` constraints as a function of the clock period in the top-level and block-level SDCs.
`-preliminary`	Derives timing budgets in the early stages of the design to get a preliminary estimate of the budgets. When you use this parameter, the software uses the net delays and net loads that you specify using the `setBudgetingMode` command. The software does not use virtual optimization for calculating budgets. The software distributes the positive slack equally between source block, destination block, and top-level. For more information, see the 'Deriving Preliminary Budgets in Early Design Phase' section in the Timing Budgeting chapter of the *Innovus User Guide*.
`-ptn` *`partitionName`*	
	Performs budgeting for the specified partition(s). Specify the `setBudgetingMode -mergeClones` parameter in addition to the `-ptn` parameter to obtain worst-case budgets based on worst-case data per-pin for all partitions in the master/clone set containing the partition. You cannot specify `-ptn` if you use `-inst`. *Default:* Performs budgeting on all partitions.
`-pushDownSDC`	Helps timing budgeting in creating only pushdown constraints for block partitions. The constraints applied to only those paths, which are completely inside a partition, are known as pushdown constraints. By considering only the pushdown constraints, this parameter ignores the constraints applied on partition interface paths from full chip SDC. **Note:** In the early design phase, the reg-to-IO reg-to-IO and IO-to-reg paths can be ignored using this parameter. In such a case, the timing constraints for only reg-to-reg paths are generated.
`-stageBased`	Creates a quick stage-based timing graph to be used for timing budgeting. Timing budgeting with the stage-based timing graphs is used in very early stages of the design, before applying optimization for quick budgets. This method is more accurate than the cycle-based timing budgeting. When this parameter is used, any existing timing graph in the design is overwritten by the generated special quick stage-based timing graph. The following example presents the scenarios in which this parameter can be used: **reg2reg path** `-timingCore`	Generates timing constraints for the partition core (internal register-to-register path only). The following are included in the constraints file: • Clock definitions • Core timing constraints such as `set_multicycle_path`, `set_false_path, and set_max_delay`. These constraints are pushed down from the top-level constraints. *Default:* Generates timing budget files for each partition from the imported top-level timing constraint file. **Note:** The software does not generate budgets for the interface ports of the partition. Therefore the `set_input_delay` or `set_output_delay` values are not generated for the partition ports.
`-verbose`	Enables various verbose controls.
`-views` *`string`*	Derives budget for multiple views in parallel for reducing the runtime.

Examples

- For MMMC examples, see the "Timing Budgeting" chapter of the *Innovus User Guide*.
- The following command creates a budget for the black box BBox:

```
deriveTimingBudget -inst BBox
saveTimingBudget -inst BBox
```

[-writeLatencyPerClock]
[-quiet]
```

Displays the following information about a specified budgeting mode parameter in the Innovus log file and in the Innovus console.

- Parameter name
- Current value
- Type (Boolean, string, and so on)
- Whether the current value was set by user

If you do not specify a parameter, the software displays information for all of the budgeting mode parameters.

Parameters

-parameter_names	
	Displays information for the specified parameters. You can specify one or more parameters. See `setBudgetingMode` for descriptions of the budgeting mode parameters you can specify.
`-quiet`	
	Displays the current settings for the specified parameters in Tcl list format only. If you specify `-quiet` without any parameters, the software displays the current settings of all `setBudgetingMode` parameters in Tcl list format.

Examples

- The following command displays the current setting for the `-masterClone` parameter:

  ```
  getBudgetingMode -masterClone
  ```

  The software displays the following information:

  ```
  -masterClone masterOnly # enums={masterOnly merged uniqueViewPerHInst}, default=masterOnly
  masterOnly
  ```

- The following command displays the current setting for the `-abutted` parameter in Tcl list format:

  ```
  getBudgetingMode -abutted -quiet
  ```

  The software displays the following information:

  ```
  false
  ```

- The following command displays the current settings for the `-localLatency` and `-localUncertainty` parameters:

  ```
  getBudgetingMode -localLatency -localUncertainty
  ```

  The software displays the following information:

  ```
  -localLatency false # bool, default=false
  -localUncertainty false # bool, default=false
  {localLatency false} {localUncertainty false}
  ```

justifyBudget

```
justifyBudget
[-help]
{partitionName | instanceName}
{-pins pinList}
[-outfile fileName]
[-summary]
[-view viewName]
```

Queries and verifies the timing budgets generated by the Innovus software. You can also query budgets selectively for some/all partitions or instances.

The `justifyBudget` command honors the `report_timing_format` global, which allows you to customize the timing report according to the specified columns. You must set this global before specifying `justifyBudget` or `deriveTimingBudget -justify` to get the report in the desired format.

Note: In case of combined budgeting, the `justifyBudget` command will justify all the input or output delays attached to the port of a partition.

> The `justifyBudget` command only supports the `-summary` parameter in MMMC mode (the default mode). The report will contain only the headers. To print paths, use `deriveTimingBudget -justify`.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `justifyBudget` parameter. For a detailed description of the command and all its parameters, use the man command: `man justifyBudget`
`-outfile fileName`	
	Specifies the output file name that contains timing budget data for a pin.
`partitionName` | *`instanceName`*	
	Specifies the name of the partition/instance to analyze. When used with `-mergeClones`, the software reports the worst-case data for specified partition/instance pins in the master/clone set containing the partition/instance. The *`instanceName`* can only be specified when the `deriveTimingBudget` command is used with the `-inst` option. In default partition mode, the *`partitionName`* is specified.
`-pins` *`pinList`*	
	Specifies the hierarchical partition pin(s) to be analyzed. You can use `*` to specify all pins.
`-summary`	
	Displays the style summary report containing the header section of the full report to show budget calculation only. Use this parameter after using saveTimingBudget/savePartition.
`-view` *`viewName`*	
	Prints a report for the specified view. If you derived the timing budget in MMMC mode (default), this parameter is required to obtain a report.

Examples

- For examples of budgeting for MMMC designs, see the Timing Budgeting chapter of the *Innovus User Guide*.
- The following command generates the timing budget data for the pin input of partition/instance `partition1` and prints a report for view `SETUP_VIEW1`:
  ```
  justifyBudget partition1 -pins input -view SETUP_VIEW1
  ```
- The following command generates the timing budget data for all pins of the partition/instance `partition1` and prints a report for viewing `HOLD_VIEW1` in the file `justifyData`:
  ```
  justifyBudget partition1 -pins * -outfile justifydata -view HOLD_VIEW1
  ```

justifyException

```
 justifyException
{-pins pinList}
[-outfile fileName]
{partitionName | instanceName}
-view viewName
[-help]
```

Provides a debugging or justification mechanism of exceptions on ports. This command is used to debug exception constraints and justify all exceptions on pins specified by `-pins`. To justify exceptions, you must set the `-justify` parameter of the `setBudgetingMode` command to `true` to save the justify exception data during the `deriveTimingBudget` process.

Parameters

`-help`	Outputs the command usage.
*`partitionName	instanceName`*	
	Specifies the name of the partition or instance to analyze. The *`instanceName`* can only be specified when the `deriveTimingBudget` command is used with the `-inst` option. In default partition mode, the *`partitionName`* is specified.
`-outfile` *`fileName`*	
	Specifies the output file name that contains the justify exception data for the instances or partitions specified by *`instanceName`* or *`partitionName`*. If you do not specify an output file using the `-outfile` parameter, the exception data will be displayed on the screen.
`-pins` *`pinList`*	
	Specifies the hierarchical partition pins to be analyzed. You can use * to specify all pins.
`-view` *`viewName`*	
	Prints a report for the specified view.

Examples

- The following command justifies exception for the pins `input` of partition/instance `partition1` and prints a report for view `SETUP_VIEW1`:
  ```
  justifyException partition1 -pins input -view SETUP_VIEW1
  ```
- The following command justifies exception for all pins of the partition/instance `partition1` and prints a report for view `HOLD_VIEW1` in the file `justfyData`:
  ```
  justifyException partition1 -pins * -outfile justifydata -view HOLD_VIEW1
  ```

modifyBudget

```
modifyBudget
{-ptn partitionName | -inst instanceName}
-file fileName
[-setup | -hold]
[-view viewName]
[-help]
```

Modifies budgets after they have been saved using the `saveTimingBudget` command. To modify budgets, you must create an input budget file containing constraints that look like an SDC file. It only supports `set_input_delay` and `set_output_delay` constraints. The clock names in these constraints are same as the ones in the generated budget file. You can provide a bus name instead of a pin name to apply the same budget to all pins of the bus.

To use `modifyBudget`, you must specify the following command before `deriveTimingBudget`:

```
setBudgetingMode -reportOrModifyBudget true
```

Parameters

`-help`	Prints a brief description that includes the type and default information for each `modifyBudget` parameter. For a detailed description of the command and all its parameters, use the man command: `man modifyBudget`
`-file fileName`	Specifies the name of the input budget file containing manual budgets.
`-hold`	Specifies to modify the hold information.
`-inst instanceName`	Specifies the name of the hierarchical instance for which manual budgets are to be applied.
`-ptn partitionName`	Specifies the name of the partition for which manual budgets are to be applied.
`-setup`	Specifies to modify the setup information.
`-view viewName`	Modifies the budget for the specified view. If you derived the timing budget in MMMC mode (default), this parameter is required to modify the budget.

Example

The following command modifies the budget data for the instance inst1:

```
modifyBudget -inst inst1 -file mod_inst
```

Related Information

The "Modifying Budgets" section in the Timing Budgeting chapter of the *User Guide* document.

resetModifiedBudget

```
resetModifiedBudget
{-ptn partitionName | -inst instanceName}
-pin pinName
[-setup | -hold]
[-view viewName]
[-help]
```

Resets the budget that was modified using the `modifyBudget` command. `resetModifiedBudget` allows you to revert to the original generated budget if the modified budget is not yielding the correct timing for a block, or rectify an incorrectly modified budget.

Parameters

`-pin` *pinName*	Specifies the name of the pin for which manual budgets are to be reset. You can use `*` to specify all pins.
`-hold`	Specifies to reset the hold information.
`-inst` *instanceName*	Specifies the name of the hierarchical instance for which manual budgets are to be reset.
`-help`	Outputs the command usage.
`-ptn` *partitionName*	Specifies the name of the partition for which manual budgets are to be reset.
`-setup`	Specifies to reset the setup information.
`-view` *viewName*	Resets the budget for the specified view.

Example

- The following command resets the modified budget data for the instance `inst1`:

  ```
  resetModifiedBudget -inst inst1
  ```

Related Information

The "Modifying Budgets" section in the Timing Budgeting chapter of the *User Guide* document.

saveTimingBudget

```
saveTimingBudget
[-help]
[-dir dirName]
[{instList}]
[-inst string | -ptn string]
[-module_model_tag string]
```

Saves the previously derived timing budgets to a specified directory. The main outputs of this command are the block constraints and the timing model. In the MMMC mode, the `saveTimingBudget` outputs the block and top `viewdefinition.tcl` as well.

Use this command after deriving the time budgets using the `deriveTimingBudget` command.

Note: The software will not write PG information while using the `saveTimingBudget` command. To get accurate PG information in the `partition-block .lib`, run the following commands in sequence:

```
partition
savePartition
```

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `saveTimingBudget` parameter. For a detailed description of the command and all its parameters, use the man command: `man saveTimingBudget`
instList	Saves the budget files for instances. You use this parameter with the `deriveTimingBudget -inst` command.
`-dir` *dirName*	
	Specifies the relative directory name where the derived timing budget files will be saved. These files are saved in a sub-directory named `cellName_timingViewName.sdc.gz` at the `dirName/cellName/cellName_timingViewName.sdc.gz` location through the relative directory path. If you do not specify this parameter, the timing budget files are saved in the current directory. For example, if you run the following command, a directory named `STB` will be saved at the current path: `deriveTimingBudget -dir STB`
`-inst` *instList* | `-ptn` *ptnList*	
	Saves the budget file for partitions or instances for which you have generated timing budgets. You do not need to specify `-ptn` or `-inst` if you have previously specified `deriveTimingBudget -ilm`. The `-ptn` parameter saves the budget files for partitions. You use this parameter with the `deriveTimingBudget -ptn` command. The `-inst` parameter saves the budget files for instances. You use this parameter with the `deriveTimingBudget -inst` command. *Default:* The tool saves budgets for all instances and partitions specified by `deriveTimingBudget`.
`-module_model_tag` *string*	
	Creates a new `mmmc` directory and saves the view definitions, libs, and constraints therein. The created `mmmc` directory will be located as follows: *shdb_root*`/`*block_name*`/`*tag_name*`/mmmc` For example: • The `saveTimingBudget -module_model_tag ABCD` command will save view definition, libs, and constraints within the `shdb_root/block_name/ABCD/mmmc` directory. • The default behavior of the `savePartition -module_model_tag ABCD` command is not impacted, and the view definition, libs, and constraints are saved in the `.enc.dat` file within the `shdb_root/block_name/ABCD/pnr` directory. • The `saveTimingBudget -module_model_tag ABCD` and `savePartition -module_model_tag ABCD` commands are completely independent (those will not affect the functioning of each other).

Examples

The following examples are based on a scenario, where a design with the `ptn1` partition has two instances, `L1` as the master, and `L1_clone` as the clone:

- The following set of commands saves the timing budget files for partition in the `STB/ptn1` directory. It saves the timing budget information for both the

partition and top. Also, since it uses the `masterOnly` mode, the budgets will be based on the master timing only:

```
deriveTimingBudget -ptn ptn1
saveTimingBudget -dir STB
```

- The following set of commands saves timing budget files only for the `L1_clone` instance in the `STB/ptn1` directory. Since it uses the `merged` mode, the timing budgeting information will be based on the worst case data from both the instances. In this case, any of the master or clone instances, or both, can be specified while running `saveTimingBudget`. The best approach is to not specify either of those, and let the `saveTimingBudget` command save the information generated by the `deriveTimingBudget` command:

  ```
  setBudgetingMode -masterClone merged
  deriveTimingBudget -inst {L1 L1_clone}
  saveTimingBudget -dir STB -inst {L1_clone}
  ```

- The following set of commands saves the timing budget files for the `L1` instance in the `STB/ptn1` directory. It saves the timing budget information for only the partition instance:

  ```
  deriveTimingBudget -inst L1 (or L1_clone)
  saveTimingBudget -dir STB
  ```

- The following set of commands saves the timing budget files for the `L1` instance in the `STB/ptn1.L1` directory, and for the `L1_clone` instance in the `STB/ptn1.L1_clone` directory. It saves the timing budget information only for the partition instances:

  ```
  deriveTimingBudget -inst {L1 L1_clone}
  saveTimingBudget -dir STB
  ```

- The following set of commands saves the timing budget files only for the `L1_clone` instance in the `STB/ptn1.L1_clone` directory:

  ```
  deriveTimingBudget -inst {L1 L1_clone}
  saveTimingBudget -dir STB -inst {L1_clone}
  ```

[-writeFPForHold {true|false}]
[-writeLatencyPerClock {true|false}]
```

Sets the timing budgeting mode. This command governs the way budgets are derived and saved. All parameters relevant to saving or deriving can be specified with this command.

Parameters

`-help`

Outputs a brief description that includes the type and default information for each `setBudgetingMode` parameter. For a detailed description of the command and all its parameters, use the man command:

```
man setBudgetingMode
```

`-abutted {true | false}`

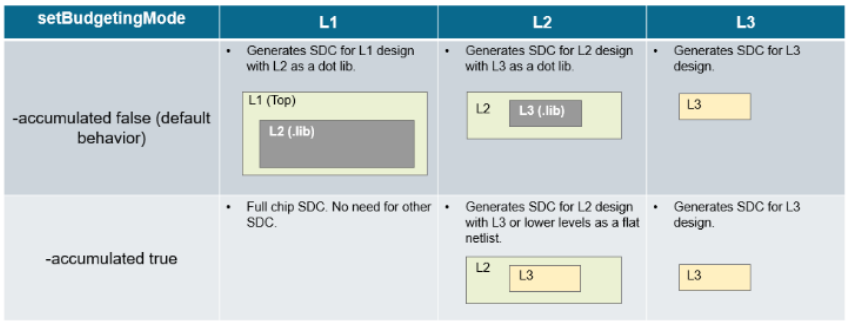
Specifies that the software abuts the partitions when allocating budgets from positive slack paths. With this parameter, the software assumes that all partitions are abutted and therefore the software does not allocate extra delay at the top-level.

Default: `false`

Note: The software automatically handles the abutted partitions (both partial and full) even when you do not specify this parameter.

`-accumulated {true | false}`

Generates SDC for lower-level hierarchy child partition in the .lib and flat forms (`L3` as shown in the example below). The following example also presents the matrix to understand the behavior of the `-accumulated` parameter at different levels of hierarchy:



With the help of the `-accumulated` parameter, SDC supports generation of constraints in the specified child partition through a Tcl variable-enabled conditional loop, as shown below:

```
if {$budget_use_accumulated != 1}{
#Constraints considering child partition in the .lib form
} else {
#Constraints considering child partition in the flat form
}
```

Note:

1. A single `viewDefinition.tcl` or SDC file can support both the .lib or flat flows. This is because there are conditional loops in the `viewDefinition.tcl` and SDC files.
2. Conditional loops are controlled by a Tcl variable named `budget_use_accumulated`. The default value of this Tcl variable is `0`, which specified that constraints will be processed considering the child partition in the .lib form. You need to run `set budget_use_accumulated 1` before loading the design for processing the constraints considering the child partition in the flat form.
3. This parameter does not impact the output of the `viewDefinition.tcl` and SDC files for the bottom-most partitions.

Default: `false`

`-boundaryConditionTemplatePath` *`directory_path`*

Specifies the directory path containing the model files to be used for generating template-based boundary condition through the `-useBoundaryCondition template` parameter. Hence, the `-boundaryConditionTemplatePath` parameter allows you to specify your own template file for generating boundary conditions.

The directory path specified with this parameter should have boundary model files for each view with the file name format as `view_name.model`. If the model files are missing for any view, an error is prompted. If a view is both `setup` and `hold`, the same model will be used.

Default: `""`

`-bufferDelayAdjustment` *value*	
	Specifies the delay for virtual buffer adjustment. If you specify `0`, there will be no adjustment. If this parameter is specified without a value, timing budgeting performs regular virtual buffering. *Default*: `0`
`-bufferDelayLibCell` *libname/cellname*	
	Specifies the buffer that should be used for virtual buffer adjustment. This is applicable in cases of regular virtual buffering, which can be overridden by the `-bufferDelayAdjustment` parameter.
`-bufferDelaySelectionEffort {low|high}`	
	Controls the virtual buffer selection effort for calculating the buffer delay adjustment. The two effort levels are: • `low`: use buffer selection algorithm based on drive strength • `high`: use buffer selection algorithm based on actual one buffer delay *Default*: `low`
`-ccd {true|false}`	
	Generates scripts for verification of time budgeting top and block constraints against pre-budget chip constraints using the Conformal Constraint Designer software. Default: `false`
`-constantModel {true|false}`	
	Specifies the type of timing model created. The `-constantModel` parameter specifies that constant timing models are created. *Default*: `true`
`-distributeMMMC {true|false}`	
	Controls the distribution of MMMC views for budgeting. The distribution could be on the same machine or different machines on a farm/lsf. *Default*: `false`
`-dontWriteWireLoad {true|false}`	
	Writes out the `set_load` command with the `-wire_load` information for the output pins in the generated SDC file, if the design is routed. *Default*: `false`
`-driveCell {true|false}`	
	Writes out the boundary drive information for input pins in the generated SDC file, using the `set_driving_cell` constraint. If not specified, the `set_drive` constraint is written. This is used to model transition on input port based on load attached to the drive cell. *Default*: `false`
`-fixTopLevelPaths {none | all | negativeOnly | positiveOnly}`	
	Fixes the top-level timing budget and proportions the remaining timing budget only for the partitions based on the specified value. Use one of the following parameter values: • `none`: Fixes the default proportionate budgeting. • `all`: Fixes budgeting only for the partitions. • `negativeOnly`: Fixes budgeting only for the partitions with negative slack paths. • `positiveOnly`: Fixes budgeting only for the partitions with positive slack paths. *Default*: `none`
`-handleComplexSDC {true|false}`	

	Specifies to use Common Timing Engine's `write_sdc` for correct push down in case of nested/complex SDC constraints. It can be used when there are regular expressions in SDC constraints. *Default:* `false`
`-honorPortBoundaryCondition {true|false}`	
	When set to `true`, `deriveTimingBudget` pushes down the boundary conditions from the chip IO ports to the block IO ports. This parameter works only in the cases where the block IO ports are directly connected to the chip IO ports (when there is no logic in between the chip and block, and there is no dependency on the abutted condition). When this parameter is set to its default value, `true`, following is the behavior for those partition ports, which are directly connected to the top level ports: • For the actual and optimized boundary condition mode, if the boundary conditions are specified in the chip SDC, they are written as is. Else, nothing is written. • For the template boundary condition mode, if the boundary conditions are specified in the chip SDC, they are written as is. Else, the existing template-based method is used for them. ⚠ If you turn off this parameter, there will be no change in the behavior of any partition port, whether or not it is directly connected. *Default:* `true`
`-honorPortDelays {true|false}`	
	When this parameter is set to `true`, `deriveTimingBudget` replicates the chip IO SID/SOD values to block IO, if these two are directly connected and abut each other. *Default:* `true`
`-honorReportTimingFormat {true|false}`	
	Honors the global variable set through `set_globalreport_timing_format` by the user in the justification reports, which are generated through the `deriveTimingBudget -justify` parameter. This parameter keeps justification reports and columns of `report_timing` in the same format as set by the user. **Note:** This parameter may impact the turnaround time of the `create_timing_budget -justify` parameter. *Default:* `false`
`-ignoreDontTouch {true|false}`	
	Specifies the handling of don't touch (fixed) objects . The parameter allows you to modify these objects also. Default: `false`
`-includeLatency {true|false}`	
	Specifies whether the clock latency is included in the `set_input_delay` and `set_output_delay` constraints. **Note:** The clock latency is always included if the design has propagated clock(s) irrespective of this parameter. `set_input_delay` and `set_output_delay` change and are based on actual arrival times. *Default*: true
`-inputLoad {true|false}`	
	Specifies whether the `set_load` constraints have to be written for input pins in the generated SDC file. With this option, load constraint on ports is specified. *Default*: `false`
`-includeWireLoadsInLib {true|false}`	
	Specifies to include the wire loads in library model pin capacitance to handle high interface net loads. It provides extra information in *.lib* file for more accurate modelling. *Default*: `false`

`-inputTransition {true|false}`	
	Writes out input transition time in the budgeting output files for input pins in the generated SDC file, using the `set_input_transition` constraint. If not specified, the `set_drive` constraint is written. You must enter the transition value directly. *Default*: `false`
`-justify {delay|exception|lib_arc|boundary_condition|all}`	
	Controls the type of justification and also decides whether or not to generate the justification reports. You may use one or more of the following values with this parameter: • `delay`: Budget justification files for all the partition IO ports are generated. • `exception`: Budget justification files for all the partition IO ports are generated with exception data. • `lib_arc`: Justification files for libs are generated. • `boundary_condition`: Justification files for the boundary conditions used in the constraint files are generated. • `all`: All the justification files are generated. **Note:** When this parameter is used without any value, no justification files are generated. Only the summary is generated. *Default*: `""`
`-justifyBudgetDir` *`directory_name`*	
	Directs output of budget justification to the specified directory and dumps the summary files. *Default:* `budget justify`
`-keepPinListsForBlockPorts {true|false}`	
	Specifies to preserve all fan-in and fan-out pin lists for block ports. The default value is `true`. When set to `true`, the runtime will be the fastest but involves high memory usage. The value of `false` means that the peak memory consumed will decrease but with an increase in runtime. You can use this parameter to control memory consumption and runtime for budgeting processes. It does not affect other functions when specified. Default:`true`
`-latencyOnClocks {true|false}`	
	Writes the `set_clock_latency` constraint on the clocks instead of ports in the generated SDC files. Use this parameter when you have multiple clocks on the same port. *Default:* Writes the `set_clock_latency` constraint on the ports. *Default*: `false`
`-localLatency {true|false}`	
	Adjusts the `set_clock_latency` constraint information that you specify using the `setPtnUserCnsFile` command to the constraints file generated after budgeting. When you specify this parameter, the software checks whether the `set_clock_latency` constraint specifies a clock or a port. If the constraint specifies a clock and the clock exists in the partition, then the constraint is added to the constraints file generated after budgeting. If the clock does not exist in the partition, the software does not write out the constraint. If the constraint specifies a port, the constraint is added to the constraints file generated after budgeting. The source latency is calculated as follows: source latency = top-level source latency + top-level network latency - local network latency *Default*: `false`
`-localUncertainty {true | false}`	

	Adds the `set_clock_uncertainty` constraint information that you specify using the `setPtnUserCnsFile` command to the constraints file generated after budgeting. When you use this parameter, the constraint file generated after budgeting has input and output delays using virtual clocks instead of real clocks in the SDC file. The software uses the virtual clocks to differentiate the clock uncertainty for external paths (paths that are coming from or going to the top-level) and internal paths of the partition.
`-makeNegativeInputDelayZero {true | false}`	
	Specifies to adjust negative set input delay to 0. *Default*: `false`
`-masterClone {masterOnly|merged|uniqueViewPerHInst}`	
	Specifies how the constraints are generated for master and clone designs. Following is the description of the parameter values: • `masterOnly`: Derives budgets only for the master partition/inst. • `merged`: Derives budgets based on the worst case data per pin for the master and all its clones. • `uniqueViewPerHInst`: For partitioned block, creates a corresponding view for each instance of the master and all its clones, where timing constraints are generated considering this instance timing separately. So total number of new views in block `viewDefination.tcl` is equal number of instances multiflied with the number of views. For partitioned TOPs .lib model, the "merged" approach is followed. So that there would be only one .lib per view for every partition. No additional views are created for partitioned TOP. *Default*: `masterOnly`
`-noFalsePathsForUnCstrPorts {true|false}`	
	Specifies not to create false paths for unconstrained ports. *Default*: `false`
`-noHoldView {true|false}`	
	Specifies to derive budgets only for setup views. Dummy files are created for the hold view as budgeting is not done for them. *Default*: `false`
`-noSetupView {true|false}`	
	Specifies to derive budgets only for hold views. Dummy files are created for the setup view as budgeting is not done for them. *Default:* `false`
`-overrideNetCap` *value*	
	Specifies the lump capacitance value. The software uses this value when you use the `-preliminary` parameter in the `deriveTimingBudget` command. *Default:* `100ff`
`-reportOrModifyBudget {true|false}`	
	Specifies to enable the collection of data required to use the `modifyBudget` command. You must specify this parameter before budgeting to run `modifyBudget` later in the flow. If this parameter is not specified, the `modifyBudget` command does not produce any results. *Default:* `false`
`-reset`	Resets parameters to their default values. The `-reset` parameter must be the first parameter specified. If you specify `-reset` by itself, the software resets all `setBudgetingMode` parameters to their default values. If you specify parameters after `-reset`, the software resets only those parameters to their default values. Any values that do not already match the default value and are reset. will be reported.
`-rptNegSlackOnPorts` *value*	
	Reports if partition ports have a slack less than the specified value and saves this information in the .warn file. The slack is calculated based on data arrival time and clock time at data sampling points. The report is saved to the .warn file.
`-snapFdBudgetTo` *value*	

Specifies the minimum delay value (in picoseconds) for the path from partition input port to partition output port. If, during timing analysis, the path segment delay used to generate budgeting constraints for the partition ports falls below the specified threshold value, the delay segment is snapped to the specified value and is considered as a fixed delay during budget allocation for the path.

The `.warn` file does not issue a warning for feedthrough segments. By default, the software distributes a delay equivalent of two medium-sized buffer delays among the feedthrough segments. As a result, it is unlikely that the feedthrough segment delay will fall below a reasonable value.

`-snapInputBudgetTo` *`value`*

Specifies the minimum delay (in picoseconds) for the path from the partition input port to the internal register. If, during timing analysis, the path segment delay falls below the specified threshold value, the delay segment is snapped to the specified value and is considered as a fixed delay during budget allocation for the path.

Note: During timing analysis, the path segment delay could be greater then the specified value; however, after budget allocations, the allocated delay for the partition can still become smaller than the specified threshold value. The software checks the delays allocated to partitions for input and output paths and creates appropriate warning messages in the partition `.warn` file.

`-snapNegativeOnly {true | false}`

Considers only the negative slack paths when used with `-snapInputBudgetTo` and `-snapOutputBudgetTo`.

Default: `false`

`-snapOutputBudgetTo` *`value`*

Specifies the min delay (in picoseconds) for the path from the internal register to the partition output port. If, during timing analysis, the path segment falls below the specified threshold value, then the delay segment is snapped to the specified value and is considered as a fixed delay during budget allocation for the path.

`-stageBasedFanoutDrivingFactor` *`value`*

Specifies the fanout count of the pin, according to which the buffer stages are added in the timing graph. This parameter provides the basis for the software to calculate the number of fanouts and buffer stages to be virtually added for each stage according to the following table:

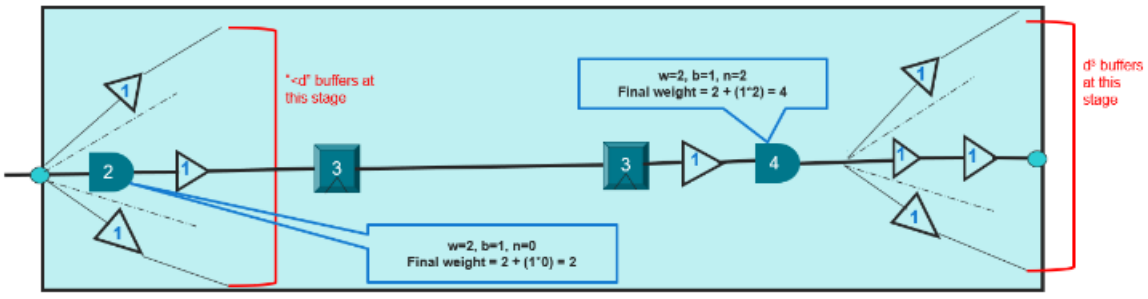
Fanout Range	**Number of Buffer Stafe Added (n):**
1 to d1 to d	0
(d+1) to d2	1
(d2+1) to d3	2
(d3+1) to d4	3
..	..

If the weight of the original cell is w, weight of the buffer is b, and the number of buffer stages is n, then:

Final weight of cell = w + (b*n)

See the example below for understanding the functioning of the `-stageBasedFanoutDrivingFactor` parameter.

```
setBudgetingMode -stageBasedWeight {3 2 1}
```



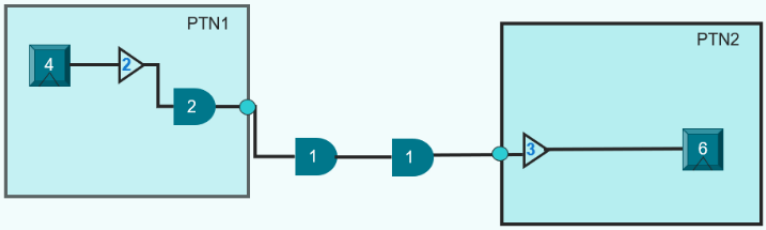
Default: `-1`

`-stageBasedPartitionMultiplier {{HInst1 m1} {HInst2 m2}..}`

Specifies the weight multiplication factor for the partition hinsts. Those hInsts, which are not explicitly mentioned, will have the default weights. If the weights of hinsts have been specified using the `setBudgetingMode -stageBasedWeight` parameter, those are used with their default weights. Else, the default weights (1 for sequential cell, 1 for combinational cell, and 0 for buffer/inverter) are used. In case of nested partitions, if the child partition multiplier is not specified explicitly, then it will have its parent's multiplier. If parent and child partitions have separate multipliers, then they will be honored.

See the example below for understanding the usage of this parameter:

```
setBudgetingMode -stageBasedWeight {2 1 1}
setBudgetingMode -stageBasedPartitionMultiplier {{PTN1 2} {PTN2 3}}
Cycle time = T
Budget for PTN1= 8/19 T
Budget for PTN2= 9/19 T
Budget for top = 2/19 T
```



Default: ""

`-stageBasedWeight {S | C | B}`

Specifies default weights of the sequential, combinational, and buffer/inverter cells for the stage-based timing budgeting. Following are the default weights of these cells:

- Sequential: 1
- Combinational: 1
- Buffer/inverter: 0

Default: `{1 1 0}`

`-topLevel` *`minimumValue`*

Specifies the minimum percentage of total available budget set aside for the top level. This parameter can take any value between 0 - 1.

- `0` - indicates no slack to top (100% to block).
- `1` - maximum value that indicates full slack to top (0 % block)

Default: `-1` (indicates regular slack or reset of the top level)

`-topLevelDelayPerLen` *`value`*

Specifies the top-level estimated delay (in picoseconds) per millimeter length. The software uses this value when you use the `-preliminary` parameter in the `deriveTimingBudget` command.

For more information on the use of the `-topLevelDelayPerLen` parameter, see "Deriving Preliminary Budgets in Early Design Phase" in the Timing Budgeting chapter of the *Innovus User Guide*.

Default: `180ps/mm`

`-topLevelMinDelayPerNet` *`value`*

Specifies the top-level minimum delay-per-net value in picoseconds/millimeter units. The software uses this value when you use the `-preliminary` parameter in the `deriveTimingBudget` command.

For more information on the use of the `-topLevelMinDelayPerNet` parameter, see "Deriving Preliminary Budgets in Early Design Phase" in the "Timing Budgeting" chapter of the *Innovus User Guide*.

Default: `100ps/mm`

`-useBoundaryCondition {optimized|template|actual|empty}`

Specifies the criteria for choosing boundary conditions. Following are the usages of the parameter values:

- `optimized`: The values of boundary conditions are fetched from the engine used to build timing graph. If the engine does not provide any values, than the template is used automatically and a warning is displayed indicating that no optimized boundary conditions are available, and the template is used automatically. For example, `-useBoundaryCondition {optimized}` for `-virtulaOptEngine {proto | none}` will display such a warning.
- `template`: The values of boundary conditions are derived automatically and used through the default template.
  Note: The default templates are saved as `budget_model/`*`view_name`*`.model`.
- `actual`: Uses the actual netlist to build the timing graph.
- `empty`: No boundary condition is dumped.

Default: `template`

`-useRealCellForTimingModel {true|false}`

Use actual gate connected to the partition port to write out the model timing arc, else medium size buffer is used.

Default: `false`

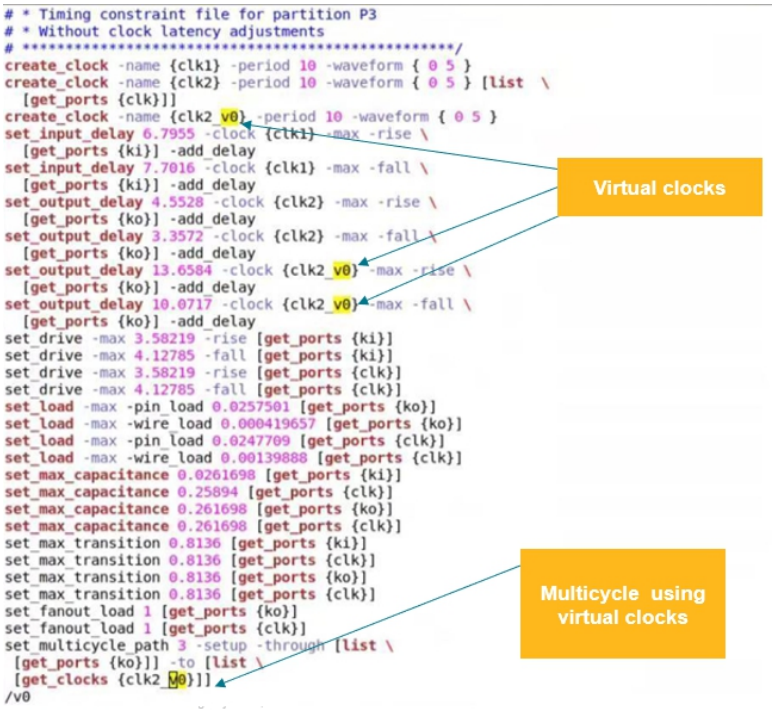
`-virtualClock {true|false}`

When set to `false`, this parameter prevents creation of new virtual clocks during timing budgeting. The software takes the worst path into account and provides the minimum required time amongst all the paths passing through a port. Since there is only a single critical path, no virtual clock is created.

While using this parameter:

- For an endpoint with both single-cycle and multicycle constraints, multicycle constraints are not defined.
- For the cases where both setup and hold views are same, virtual clocks are still created with names appended with `_v0_setuphold`.
- At the partition level, a path which is constrained before budgeting, is not unconstrained after budgeting.
- If a path has both single and multi-cycle constraints, single cycle constraint is retained, and hence, the path is optimized accordingly and timing closure is not affected.

Following is an example of `-virtualClock true`:



Following is an example of `-virtualClock false`:

```
#/*************************************************
# * Timing constraint file for partition P3
# * Without clock latency adjustments
# *************************************************/
create_clock -name {clk1} -period 10 -waveform { 0 5 }
create_clock -name {clk2} -period 10 -waveform { 0 5 } [list  \
  [get_ports {clk}]]
set_input_delay 6.7955 -clock {clk1} -max -rise \
  [get_ports {ki}] -add_delay
set_input_delay 7.7016 -clock {clk1} -max -fall \
  [get_ports {ki}] -add_delay
set_output_delay 4.5528 -clock {clk2} -max -rise \
  [get_ports {ko}] -add_delay
set_output_delay 3.3572 -clock {clk2} -max -fall \
  [get_ports {ko}] -add_delay
set_drive -max 3.58219 -rise [get_ports {ki}]
set_drive -max 4.12785 -fall [get_ports {ki}]
set_drive -max 3.58219 -rise [get_ports {clk}]
set_drive -max 4.12785 -fall [get_ports {clk}]
set_load -max -pin_load 0.0257501 [get_ports {ko}]
set_load -max -wire_load 0.000419657 [get_ports {ko}]
set_load -max -pin_load 0.0247709 [get_ports {clk}]
set_load -max -wire_load 0.00139888 [get_ports {clk}]
set_max_capacitance 0.0261698 [get_ports {ki}]
set_max_capacitance 0.25894 [get_ports {clk}]
set_max_capacitance 0.261698 [get_ports {ko}]
set_max_capacitance 0.261698 [get_ports {clk}]
set_max_transition 0.8136 [get_ports {ki}]
set_max_transition 0.8136 [get_ports {clk}]
set_max_transition 0.8136 [get_ports {ko}]
set_max_transition 0.8136 [get_ports {clk}]
set_fanout_load 1 [get_ports {ko}]
set_fanout_load 1 [get_ports {clk}]
```

No virtual clocks or multicycle defined using them.

Default: `true`

`-virtualOptEngine {none|earlyTimingEngine|proto}`

Specifies the virtual optimization engine to be used. The values of this parameter include:

`none`
Specifies that the timing graph is generated through `report_timing`.

`earlyTimingEngine`
Specifies that the timing graph is generated by `optVirtual -earlyTimingEngine`.

`proto`
Specifies that the timing graph is generated by prototype timing.

Default: `none`

Note: User can use ART (`createActiveLogicView -type timing_budget`) before generating the timing graph to reduce TAT and memory during budgeting flow.

`-writeConstraintsForClkOutputPorts {true|false}`

Specifies to write extra constraints on the output port of block SDC.
When this parameter is specified, the following extra constraints are written out:

- `set_clock_sense` - this constraint is dumped if the clock is used as data going forward after partition
- `create_generated_clock` - this constraint is dumped if the clock is used as clock going forward after partition

If the clock is used as both data and clock going forward, the parameter does not write out these extra constraints.

Default: `false`

`-writeFPForHold {true|false}`

	Writes `false_path -hold` constraints for all I/Os when deriving timing budgets in setup mode.
	For inputs, the `saveTimingBudget` command writes the following constraint:
	`set_false_path -from port -hold`
	For outputs, the `saveTimingBudget` command writes the following constraint:
	`set_false_path -to port -hold`
	Default: `false`

`-writeLatencyPerClock {true|false}`	
	Specifies to write latency per clock instead of per port. When you set this variable to true, `set_clock_latency` is written per clock if multiple clocks enter the partition through the same port. *Default*: `false`

Examples

- The following set of commands load database for timing budgeting:

```
setBudgetingMode -stageBasedWeight {3 2 1}
setBudgetingMode -stageBasedPartitionMultiplier {{PTN1 2} {PTN2 3}}
setBudgetingMode -stageBasedFanoutDrivingFactor 8
deriveTimingBudget -stageBased
```

- The following command sets the input and output budgets to 3000:

```
setBudgetingMode -snapInputBudget 3000 -snapOutputBudget 3000
The resulting message appear in the .warn file when you generate budgets.
/* Start Section: Pin constraint values less than defined threshold time
(setup)*/
Input Threshold Value: 3.000
Output Threshold Value: 3.000
Constraint: set_output_delay 11.524 -clock {CLK2} -max -rise [get_ports {sub1_out1}]
allocates block delay less than input threshold time.
Block delay: 0.476
Constraint: set_output_delay 11.524 -clock {CLK2} -max -fall [get_ports {sub1_out1}]
allocates block delay less than input threshold time.
Block delay: 0.476
/* End Section: Pin constraint values less than defined threshold time (setup)*/
justifyBudget header example:
Budgeted constraint type: set_output_delay(setup rise)
Initial budget available time = 12.000

One Buffer Delay for Adjustment(cell ssiv): 1.000
Fixed Delay for Feedthrough Paths(fixFdThru)= (2 x 1.000) = 2.000
External Segment Fixed Delay From Budget Snap(snapExtFixedDel) = 5.000
Total External Segment Fixed Delay(extFixDel) = 5.000
This Block's Segment Fixed Delay from budget snap(snapIntFixedDel) = 1.000
Total This Block's Segment Fixed Delay(intFixDel) = 1.000
External Segment Extra Delay From Budget Snap (snapExtDelExtra) = 2.000
This Block's Extra Delay From Budget Snap (snapIntDelExtra) = 1.000
Path Extra Delay From Budget Snap (snapExtraDel) = (2.000 + 1.000) = 3.000
Fixed Delay on the Path(pathFixDel) = (5.000 + 1.000 + 1.000 + 2.000) = 9.000
Fixed Delay Adjustment(fixDel)= 9.000
Clock Skew(clkSkew): 0.000
Adjustment for budget available time= -(pathFixDel + fixFdThru - clkSkew + snapExtraDel)
= -(6.000 + 2.000 - 0.000 + 3.000)
= -11.000
Available budget after adjustments(AvailTime)= (12.000 - 11.000) = 1.000

External Segment Delay(extSegDel): 8.000
This Block's Segment Delay(segDel): 0.000
Total delay(totDel): 8.000 + 0.000 = 8.000
Virtual Clock Adjustment(virClk): 0.000
Budgeted constraint = AvailTime * extSegDel / totDel + fixDel + virClk + startClkLat
Budgeted constraint = 1.000 * 8.000 / 8.000 + 9.000 + 0.000 + 0.000 = 10.000
```

setCycleBudgetRatio

```
setCycleBudgetRatio
[-help]
{[[[{-fromTop | -fromPtn {hinst ratio}} {-toTop | -toPtn {hinst ratio}}] ] [-clock string]] | [-reset ]}
```

Sets the budgeting constraint based on the clock cycle, which ensures that budgeting is done in minimum time and memory by deriving partition block delays from the total clock cycle time. This command supports:

- Different top-level ratios based on critical partition to partition connections
- Different ratios between the partitions with different sources and sinks
- Clock-based segment control

Note: This command (cycle-based budget) does not support nested partition.

Parameters

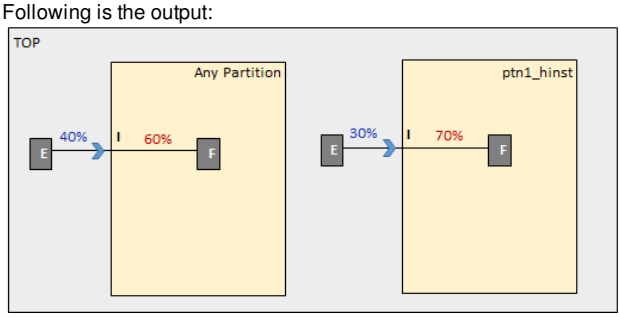
`-help`	Outputs a brief description that includes the type and default information for each `setCycleBudgetRatio` parameter. For a detailed description of the command and all its parameters, use the man command: `man setCycleBudgetRatio`
`-clock string`	Presents the clock name for which the ratio is to be applied. If specified, the cycle time ratio is applied to the paths only from the specific clock. If not specified, all clocks path are impacted with same percentage of cycle time.
`-fromPtn {hinst ratio}`	Specifies that the start of a timing path segment is inside the mentioned hierarchical instance, which should get the mentioned cycle ratio for budgeting.
`-fromTop`	Specifies that the start of a timing path segment is at the top level.
`-reset`	Resets all the previously declared ratio budgets/contraints.
`-toPtn {hinst ratio}`	Specifies that the end of a timing path segment is inside the mentioned hierarchical instance, which should get the mentioned cycle ratio for budgeting.
`-toTop`	Specifies that the end of a timing path segment is at the top level.

Examples

- The following commands present an example of the TOP to PTN path:

  ```
  setCycleBudgetRatio -fromTop -toPtn {* 0.6}
  setCycleBudgetRatio -fromTop -toPtn {ptn1_hinst 0.7}
  ```

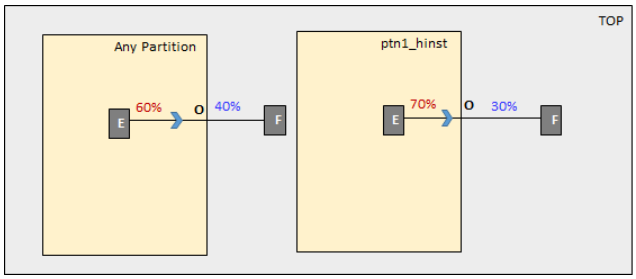
  Note: * matches with any partition hinst. However, it does not matches with TOP.
  Following is the output:

- The following commands present an example of the PTN to TOP path:

  ```
  setCycleBudgetRatio -fromPtn {* 0.6} -toTop
  setCycleBudgetRatio -fromPtn {ptn1_hinst 0.7} -toTop
  ```

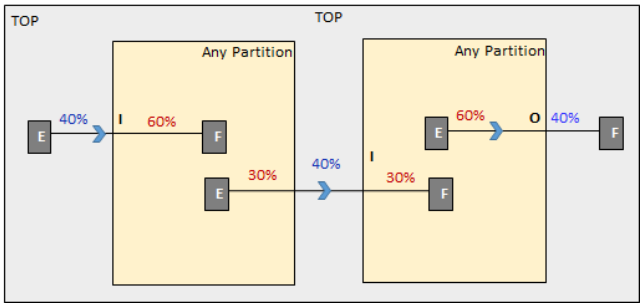
  Note: * matches with any partition hinst. However, it does not matches with TOP.
  Following is the output:



- The following commands present an example of reserving TOP percentage:

```
setCycleBudgetRatio -fromPtn {* 0.6} -toTop
setCycleBudgetRatio -fromTop -toPtn {* 0.6}
setCycleBudgetRatio -fromPtn {* 0.3} -toPtn {* 0.3}
```

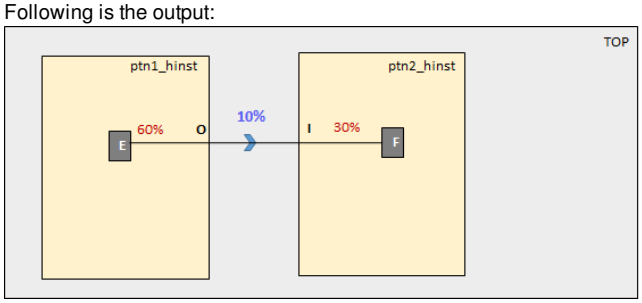
Note: * matches with any partition hinst. However, it does not matches with TOP.
Following is the output:



- The following command presents an example of the PTN to PTN path:

```
setCycleBudgetRatio -fromPtn {ptn1_hinst 0.6} -toPtn {ptn2_hinst 0.3}
```

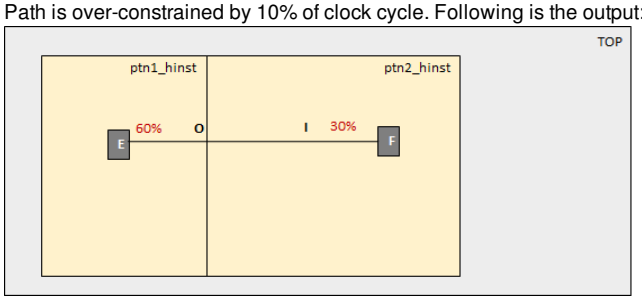
Following is the output:



- The following command presents an example of the PTN to PTN Abutted path:

```
setCycleBudgetRatio -fromPtn {ptn1_hinst 0.6} -toPtn {ptn2_hinst 0.3}
```

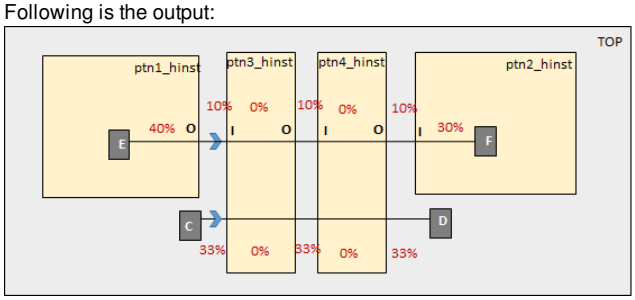
Path is over-constrained by 10% of clock cycle. Following is the output:



- The following command presents an example of how the top level budget is split into top and FT segments of the paths:

```
setCycleBudgetRatio -fromPtn {ptn1_hinst 0.4} -toPtn {ptn2_hinst 0.3}
```

Note: FT segment is over-constrined and given 0% budget.
Following is the output:



- Following are two examples of actual delay-based cycle ratio:
  Example 1:
  Suppose `PhaseShift = 10ns`
  `setCycleBudgetRatio -fromPtn {P1 0.4} -toPtn {P3 0.4}`
  `setFixedBudget -through {P2} -slack 0 ;#` implies that the budget of `P2` is “as is”
  Then,
  `P2` budget = `1ns` (assuming that the actual delay through `P2` is `1ns`)
  `AvailableTime = 10ns - 1ns = 9ns`
  `P1 budget = 0.4 * AvailableTime = 0.4 * 9ns = 3.6ns`
  `P3 budget = 0.4 * AvailableTime = 0.4 * 9ns = 3.6ns`
  `TOP budget = 9ns - 3.6ns - 3.6ns = 1.8ns`
  So each of the two TOP segments get `0.9ns`.
  Following is the output:

  Example 2:
  Suppose `PhaseShift = 10ns`
  `setCycleBudgetRatio -fromPtn {P1 0.5} -toPtn {P3 0.5}`
  `setFixedBudget -through {P2} -slack 0 ;#` implies budget of `P2` is “as is”
  Then,
  `P2 budget = 1ns` (assuming that the actual delay through `P2` is `1ns`)
  `AvailableTime = 10ns - 1ns = 9ns`
  `P1 budget = 0.5 * AvailableTime = 0.5 * 9ns = 4.5ns`
  `P3 budget = 0.5 * AvailableTime = 0.5 * 9ns = 4.5ns`
  `TOP budget = 9ns - 4.5ns - 4.5ns = 0ns`
  So each of the two TOP segments get `0ns`.
  Following is the output:

setFixedBudget

```
  setFixedBudget
[-help]
{[{[{-from {list_of_pins} | -fromFlopsOf {hinst}} {-to {list_of_pins} | -toFlopsOf {hinst}}] | [-through {list_of_hinst}]} {-slack | -delay
} [-add ] <value>] | [-reset ]}
```

This command fixes the budget for a particular path segment between partitions and start/end points and helps in reducing the distribution budget delay in the path segments.

Note: Do not use this command with cycle-based timing budgeting.

This command is valid only for the following segments:

- Chip In -> Partition In
- Start Point -> Partition In
- Partition In -> Partition Out
- Partition In -> End Point (FF D Pin) inside same partition
- Start Point (FF Q Pin) inside same partition -> Partition Out
- Partition Out -> Chip Out
- Partition Out -> End Point

Parameters

`-add`	Adds the slack/delay to previous value (Boolean, Optional)
`-help`	Prints out the command usage
`<value>`	Presents delay or slack values (Float)
`-delay`	Specifies the delay value (Boolean, Optional)
`-from {list_of_pins}`	Presents the 'from pins' to be analyzed (String)
`-fromFlopsOf {hinst}`	Specifies the from hierarchical inst for which start pins to be analyzed (String)
`-reset`	Resets all previously declared fixed budgets (Boolean, Optional)
`-slack`	Specifies the slack value (Boolean, Optional)
`-through {list_of_hinst}`	Specifies the hierarchical instances to be analyzed (String)
`-to {list_of_pins}`	Specifies the 'to pins' to be analyzed (String)
`-toFlopsOf {hinst}`	Specifies the to hierarchical inst for which end pins to be analyzed (String)

Examples

The following command fixes the budget of the hierarchical instance feed-through paths to the existing delay:

```
setFixedBudget -through P5 -slack 0
```

The following command gives a fixed clack of 1 to the paths from port 'in' to hierarchical instance input pin 'p4/in'; budgets will distribute rest of the slack to other segments of the paths:

```
setFixedBudget -from in -to P4/in -slack 1
```

The following command fixes the delay of this segment to 0.5 from the hierarchical instance input pin 'p4/in' to the endpoint 'P4/FF1/D'; budgets will be calculated for the whole path considering the path delay of this segment as 0.5:

```
setFixedBudget -from P4/in -to P4/FF1/D -delay 0.5
```

Related Information

The Timing Budgeting chapter of the *User Guide* document.

setPtnUserCnsFile

```
setPtnUserCnsFile
-fileName name
-ptnName partitionName
[-view]
```

Specifies the constraints file for a specific partition. The software appends the constraint information in this file to the timing constraints generated when you use the `savePartition` or `saveTimingBudget` command. You can specify the following constraints in the constraints file for the partition:

- `set_clock_uncertainty`
- `set_clock_latency` (network latency constraints)

You must specify the `-localLatency` and `-localUncertainty` parameters in the `setBudgetingMode` command before using the `setPtnUserCnsFile` command.

Parameters

`-fileName` *name*	Specifies the name of the file containing constraints specific to a partition.
`-ptnName` *partitionName*	Specifies the name of the existing partition.
`-view`	Specifies a partition-specific constraint file for each MMMC view.

- reset_sense

create_clock

```
create_clock
-period period_value
[-name clock_name]
[-waveform edge_list]
[-add]
[-comment string]
[sources]
```

Creates a clock object and defines its waveform in the current design. If you do not specify any sources, but you specify the `-name` *clock_name* argument, a virtual clock is created. The new clock has an ideal clock latency, and the software does not assume any propagation delay through the clock network.

The clock that you create using the `create_clock` command cannot have multiple pulses per period. You can specify multiple constraints on the same pin using the `-add` parameter.

If one of the sources is already the source of a clock, the source is removed from that clock. If you need to specify multiple clocks on the same source for simultaneous analysis, you must specify the `-add` parameter, to add this clock to the existing clock.

For example, if you specify the following command sequence, the `PH2` clock waveform overwrites the `PH1` waveform.:

```
create_clock -name PH1 ... [get_ports sysclk]

create_clock -name PH2 ... [get_ports sysclk]
```

To have both clocks applied, you must specify the following command sequence:

```
create_clock -name PH1 ... [get_ports sysclk]

create_clock -name PH2 -add ... [get_ports sysclk]
```

You can create a collection of clocks, which is a group of objects referenced by a string identifier using the get_clocks command.

Parameters

`-add`	Specifies multiple clocks on the same source for simultaneous analysis with different clock waveforms. You must specify the `-name` parameter with this parameter.
`-comment` *`string`*	Allows you to insert comments. The comments are read but are ignored with a one-time warning message. They are not used during timing analysis reporting nor are they written out during saving of constraints.
`-name` *`clock_name`*	Specifies the string name of the ideal clock being created. If you do not specify this option, the clock gets the same name as the first clock source that you specify using the `-sources` option. If you do not specify any sources, you must specify the `-name` *`clock_name`* option, which creates a virtual clock not associated with a port or pin.
`-period` *`period_value`*	
	Specifies the value of the ideal clock in library time units.
`sources`	Specifies the list of pins or ports associated with an ideal clock waveform of the clock. If you do not specify this option, you must specify the `-name` *`clock_name`* option, which creates a virtual clock not associated with a port or pin. If you specify a clock on a pin that already has a clock, the new clock replaces the old one.
`-waveform` *`edge_list`*	
	Specifies the rise and fall edge times of the clock waveforms in library time units over an entire clock period. The first value in the edge list is the time at which the first transition on the clock occurs, which is the first rising transition after time zero, and edges are monotonically increasing. The numbers should represent one full clock period. If you do not specify the `-waveform` *`edge_list`* option, a default waveform is assumed, and the leading edge is placed at `0` and the trailing edge is placed at the midpoint of the period, such that a symmetric clock is generated.

Examples

- The following command creates an `ideal_clk1` clock on port `clkA` with a period of `5`, a rise at `0`, and a fall at `2.5`:
  create_clock [get_ports {clkA}] -name ideal_clk1 -period 5 -waveform {0 2.5}

- The following command creates an `ideal_clk2` clock on port `clkB` with a period of `10`, a rise at `1`, and a fall at `9`:
  create_clock [get_ports {clkB}] -name ideal_clk2 -period 10 -waveform {1 9}

create_generated_clock

```
create_generated_clock
[-help]
target_pin_list
[-add]
[-comment string]
[-duty_cycle percent]
[-edge_shift edge_shift_list]
[-invert]
[-master_clock source_clock_name]
[-name <clock_name>]
-source source_pin
{[-multiply_by factor]
[-divide_by factor]
[-edges edge_list]
[-combinational]}
```

Creates a new clock signal from the clock waveform of a given pin in the design, and binds it with the pins or hierarchical pins in the *target_pin_list* argument. Whenever the source clock changes, the derived clock(s) change automatically.

You can generate a new clock waveform using one of the three ways:

- Multiply the frequency of the source clock
- Divide the frequency of the source clock
- Select the edges of the source clock to be mapped to the edges of the new clock

Given below are the SDC semantics to be used when the `create_generated_clock` command is defined:

- The edges are interpreted as alternating rise and falling edges.
- Each edge must be greater than and equal to its previous edge.
- Less than 3 edges are not allowed.
- Legal edge numbers start at “1”, edge 0 is undefined.
- Legal assertion of period 0 will be -edges {1 1 1 }.

If incorrect clock definitions are specified, an error will occur and the clock will not be generated.

When the `create_generated_clock` command is specified without the `-master_clock` parameter, and the software finds multiple clocks reaching the specified source pin, then the regular clocks are picked ahead of the generated clocks. In case if multiple regular clocks are present, the master clock is picked based on alphabetical sorting order of the clock names.

Note: A `create_generated_clock` assertion on a pin overrides any existing `create_generated_clock` assertion if both the constraints have the same source pin. In the following command sequence, the second assertion overrides the first:

```
create_generated_clock -name GCK1 -source CK -divide_by 2 U_FD1/Q
create_generated_clock -name GCK2 -source CK -multiply_by 2 U_FD1/Q
```

To have both assertions applied, you must specify the `-add` parameter. For example:

```
create_generated_clock -name GCK1 -source CK -divide_by 2 U_FD1/Q
create_generated_clock -name GCK2 -add -master_clock CLK -source CK -multiply_by 2 U_FD1/Q
```

Parameters

`-help`	Prints out the command usage.
`-add`	Models multiple generated clocks on the same source when multiple clocks must fan into the source pin. Ideally, one generated clock must be specified for each clock that fans into the master pin. Specify this parameter with the `-name` and `-master_clock` parameters. You can use the `-add` parameter to specify a different clock name for each generated clock, when used with the `-master_clock` option. Subsequently, you can use this clock name for setting other constraints, such as, `set_false_path` or `set_input_delay`.
`-combinational`	Restricts the path search for latency to only paths which do not cross sequential devices, or the source pins of other generated clocks. When you specify `-combinational`, if there are both sequential and combinational latency paths, the software only considers the combinational paths for the generated clock. If there are no combinational latency paths for the generated clock, the generated clock does not inherit latency from its parent clock hierarchy. By default, when calculating the latency of a generated clock, the software searches for the longest (and shortest) paths from the parent waveform to the generated clock point. All paths are considered, including those which traverse sequential elements such as flip-flops, registers, and latches. The default behavior is intended for cases where there is a cascade of generated clocks, and some of the clocks are not explicitly defined. The `-combinational` option can be used in conjunction with the `-multiply_by`, `-divide_by`, or `-edges` options.
`-comment` *string*	Allows you to insert comments. The comments are read but are ignored with a one-time warning message. They are not used during timing analysis reporting nor are they written out during saving of constraints.
`-divide_by` *integer*	Determines the frequency of the new clock by dividing the frequency of the source clock by *dfactor*. For example, if *dfactor=5*, the new frequency is 1/5 of the source frequency, and the new clock period is 5 times the source clock period.
`-duty_cycle` *percent*	Sets the duty cycle (high pulse width or clock period). The number (*percent*) is between `0` and `100`. For example, if *percent=50*, the high pulse width of the new clock waveform is the same as its low pulse width. **Note:** The `-duty_cycle` option can only be used with the `-multiply_by` option, otherwise it will be ignored with a warning.
`-edges` *edge_list*	Selects a list of edges from the source clock that form the edges of the derived clock. See the frequency division example below.
`-edge_shift` *edge_shift_list*	Specifies the amount of shift for each edge in the *edge_list* option. The amount of shift will be in library time units.
`-invert`	Inverts the source clock. Use with the `-source` option and the `-multiply_by` or `-divide_by` options.

`-master_clock` *`source_clock_name`*	Generates a target clock from the specified clock name. If you specify the `-master_clock` option and multiple signals arrive at the source pin, the clock specified by this option is used to generate the target clock. Use the `-add` parameter along with`-master_clock` parameter to add a clock to the existing clock when you want to specify multiple clocks on the same source for simultaneous analysis.
`-multiply_by` *`integer`*	Determines the frequency of the new clock by multiplying the frequency of the source clock by *`mfactor`*. For example, if *`mfactor=4`*, the new frequency is 4 times the source frequency, and the new clock period is 1/4 of the source clock period.
`-name` *`clock_name`*	Specifies the name for the generated clock. *Default*: The system creates a name for you. Always specify a name for the generated clock. Some commands issue an error if you use the system-generated name.
`-source` *`source_pin`*	Specifies the name of the source pin from which the generated clock is to be derived - with respect to the master clock containing the master clock as well as the generated clock definition.
`target_pin_list`	Specifies the list of pins where the generated clock assertion is applied. The clock signal propagating downstream from each of these pins becomes associated with the generated clock.

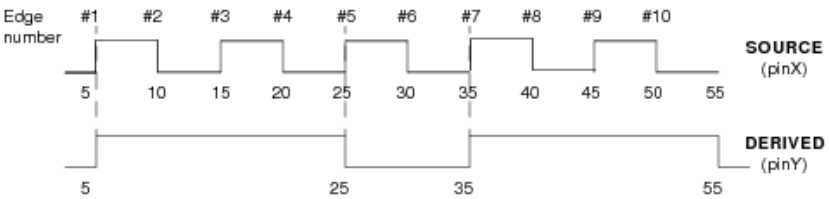
Examples

- The following command generates the derived clock waveform, as shown in the figure below:
  ```
  create_generated_clock -name mult_3 -source pinX -multiply_by 3 -duty_cycle 50 pinY
  ```

Figure: **Derived Clock (Frequency Multiplication)**

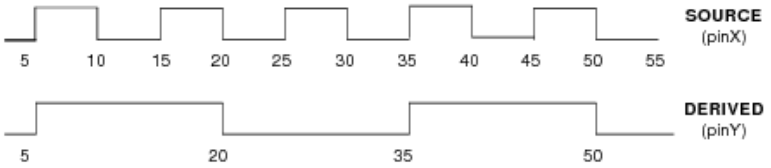
- The following command shows one way to create a divide-by-3 clock by using edge numbers of the source waveform to specify the new waveform, as shown in the figure below:
  ```
  create_generated_clock -name genclk -source pinX -edges {1 5 7} pinY
  ```

Figure: **Derived Clock (Frequency Division)**



- The following command uses the `-divide_by` option to get the same clock period; the difference is in the duty cycle: create_generated_clock -name div_3 -source pinX -divide_by 3 pinY
  With the `-edges` option, the above example creates a clock with a duty cycle of 67 percent (20/30). However, using the `-divide_by 3` option preserves the 50 percent duty cycle of the source clock as shown in the figure below:

Figure: **Derived Clock (Frequency Division, 50 Percent Duty-cycle)**



- Using the following commands, when there is more than 1 source clock, the tool creates the generated clock based on the source clock specified with the `-master` option: create_clock -name c1 -period 10 [get_ports {ck}] -add create_clock -name c2 -period 10 [get_ports {ck}] -add create_generated_clock -name newclk -source ck -divide_by 2 -master_clock c1 reg/Q -add
  Using the `report_clocks` command, the output waveform of the `newclk` clock is a divide-by-2 of the `c1` clock and is reported as shown in the example below.

Example: **report_clocks after using the -master option**

```
> create_clock -name CK1 -period 20 [get_ports {CLK1} ] -add
> create_clock -name CK2 -period 10 [get_ports {CLK1} ] -add
> create_generated_clock -name GCLK -source CLK1 -divide_by 2 u8/Q -add -master_clock CK2

> report_clocks

```

Related Information

- create_clock
- get_clocks
- report_clocks

current_design

```
current_design
[-help]
[design_name]
```

Sets the specified design to be the current design.

Parameters

`-help`	Prints out the command usage.
design_name	Specifies the name of the top design.

Related Commands

- set_max_transition
- set_min_capacitance
- set_min_transition

current_instance

```
current_instance
[hierarchical_instance]
```

Sets the instance given by *hierarchical_instance* to be the current instance. Design objects referenced by subsequent commands can be found relative to this instance. All searches for design objects are started in this instance. If design objects are referenced hierarchically, *hierarchical_instance* is used as the root (top) of the hierarchy.

Parameters

hierarchical_instance	Specifies the name of the instance to become the current instance. If *hierarchical_instance* is not given, the current instance is set to the top instance of the hierarchy.

Examples

- The following command sets the current instance to MAC/MULTI, sets a constant on a register pin inside the hierarchical instance and then later sets the current instance back to top:

```
current_instance MAC/MULT1
set_case_analysis 0 [get_pins {reg6/SE}]
...
current_instance
```

Related Commands

- set_case_analysis

get_sdc_mode

```
get_sdc_mode
[-help]
```

Determines the constraint mode that is being currently read.

This command can be used inside SDC constraint files which are shared across multiple constraint modes to conditionalize how the constraints are interpreted for specific modes.

group_path

```
group_path
[-help]
[-comment string]
-name path_group_name
[[-from from_list]
 [-to to_list]
 [-through through_list]]
```

Groups paths in a design, and identifies them with a path group name. You can use the path group names for reporting.

You cannot use `group_path` statements in the SDC file when the software is in MMMC mode. In this case a warning is issued. However, the software supports the group_path command in MMMC mode as a command outside of the SDC file. The path groups are considered to be global in nature and apply to all the views, and are not supported on MMMC mode-specific basis. The path groups are persistent through a saveDesign to restoreDesign sequence. They are saved in the `<saveDir>/mmmc/pathgroup.sdc` file of a MMMC save directory.

Note that if a path can be included in multiple path groups, it will only be included in the path group with the most specific definition (`-from ... -through ... -to ...` is more specific than `-from ... -to ...` is more specific than `-from ...`).

Parameters

`-help`	Prints out the command usage.
`-comment` *string*	Allows you to insert comments. The comments are read but are ignored with a one-time warning message. They are not used during timing analysis reporting nor are they written out during saving of constraints.
`-from` *from_list*	Specifies a list of pins, instances, or clocks that are the start of the paths. When you specify a clock object, all paths that are triggered by the clock are included in the path group.
`-name` *path_group_name*	Specifies the name of the path group. If the path_group_name already exists, the specified paths are added to the existing path group.
`-through` *through_list*	Specifies the pins or instances where the paths go through. When you specify multiple through list, the paths that go through the objects in the specified order are added to the path group.
`-to` *to_list*	Specifies a list of pins, instances, or clocks where the path ends. You must specify valid endpoints in the *to_list* or else the software ignores the constraint. When you specify a clock object, all paths that are checked by the clock are included in the path group. If you specify an instance name in the *to_list*, all the data input pins of the instance are added to the path group.

Examples

- The following example groups paths that start from specific pins and end at the D pin of any instances whose name start with the string ff. The example also reports the specified path groups:

  ```
  group_path -name path1 -from {ff1/CLK ff2/CLK} -to {ff*/D}
  report_timing -path_group path1
  ```

- The following command groups paths that go through specific points.

  ```
  group_path -name path2 -through an1/Z -through an2/Z -through an3/Z
  ```

Related Commands

- report_timing
- get_path_groups
- reset_path_group
- report_path_groups

reset_annotated_check

```
reset_annotated_check
[-clock [rise | fall]]
[-cond sdf_condtion]
[-setup | -recovery]
[-hold | -removal]
[-nochange_high | -nochange_low]
[-rise] [-fall]
{[[-from from_pins][-to to_pins]] | -all}
[object_list]
```

Removes annotated timing check values that you had set by using the `set_annotated_check` command or by SDF annotation.

Note: The `reset_annotated_check` command does not reset the timing check values set by SDF annotations.

Parameters

`-all`	Resets all annotated timing check values in the design.
`-clock [rise | fall]`	Specifies the direction of the related pin of the check to reset. *Default:* Resets checks against both edges of the clock
`-cond` *`sdf_condtion`*	Resets all annotated timing check values for which a condition is specified.
`-fall`	Restricts the reset to only affect the falling edge of the constrained pins. *Default:* Checks on both rising and falling signals are reset
`-from` *`from_pins`*	Specifies the beginning instance pin of the timing arcs for which the annotated check is reset. This is usually the reference (for example, clock pin) of the constraint. The selected timing arcs are those that have their source pins specified using this option and the sink pins specified using the `-to` option. If this option is not specified, only timing arcs whose sink pins are specified using the `-to` option are selected. You cannot use this parameter with *`object_list`* parameter.
`-hold | -removal`	Resets annotations on the hold or removal check type.
`-nochange_high | -nochange_low`	Resets the annotations on the specified timing check type.
`object_list`	Resets the annotated checks on specified list or collection of cell instances.
`-rise`	Restricts the reset to only affect the rising edge of the constrained pins. *Default:* Checks on both rising and falling signals are reset
`-setup | -recovery`	Resets annotations on the setup or recovery check type.
`-to` *`to_pins`*	Specifies the terminating instance pin of the timing arcs for which the annotated check is reset. This is usually the constrained pin (data pin) of the check. The selected timing arcs are those that have their sink pins specified using this option and the source pins specified using the `-from` option. If this option is not specified, only timing arcs whose source pins are specified using the `-from` option are selected. You cannot use this parameter with *`object_list`* parameter.

Examples

- The following command resets all the timing check annotations in the design:
  ```
  reset_annotated_check -all
  ```
- The following command resets all timing check annotations on a particular cell:
  ```
  reset_annotated_check [get_cells BLK/BR1]
  ```

- The following command resets specific checks on a specific instance:
  ```
  reset_annotated_check -setup -hold [get_cells BLK/BR2]
  ```
- The following command resets checks on a specific timing check arc:
  reset_annotated_check -from BLK/BR1/CK -to BLK/BR1/D

Related Commands

- set_annotated_check

reset_annotated_delay

```
reset_annotated_delay
{[-all] | [[-from from_pins] [-to to_pins]] | [object_list]}
```

Resets annotated delay assertions that have been previously specified using the `set_annotated_delay` command. When you reset an annotated delay, the system uses the delays which are calculated from the original libs for the arc.

Parameters

`-all`	Resets all annotated delay assertions in the design.
`-from` *from_pins*	Specifies timing arcs for which the delay is reset. The selected timing arcs are those that have their source pins specified using this option and the sink pins specified using the `-to` option. If this option is not specified, only timing arcs whose sink pins are specified using the `-to` option are selected.
object_list	Resets the annotated delays on specified list or collection of cell instances.
`-to` *to_pins*	Specifies timing arcs for which the delay is reset. The selected timing arcs are those that have their sink pins specified using this option and the source pins specified using the `-from` option. If this option is not specified, only timing arcs whose source pins are specified using the `-from` option are selected.

Examples

- The following command resets all the annotated delay assertions in the design:
  ```
  reset_annotated_delay -all
  ```
- The following command resets all the `set_annotated_delay` assertions applied on pins (either `from` or `to`) of instance `f0`:
  ```
  reset_annotated_delay f0
  ```
- The following command resets the `set_annotated_delay` assertions with the `from` and `to` pin pair combination:
  ```
  reset_annotated_delay -from u1/Y -to u2/A
  ```

Related Information

- `set_annotated_delay`

reset_annotated_transition

```
reset_annotated_transition
{-all | port_or_pin_list}
```

Resets annotated transitions previously asserted by the `set_annotated_transition` command.

Parameters

`-all`	Resets all annotated transitions in the design.
`port_or_pin_list`	Specifies a list of specific pins or primary ports to reset the transition.

Examples

- The following commands reset the `set_annotated_transition` constraint on an internal pin `pad/Y0`.
  ```
  reset_annotated_transition pad/Y0
  ```

  or

  ```
  reset_annotated_transition [get_pins {pad/Y0}]
  ```

  You can also specify a collection as the pin argument. For example:

  ```
  reset_annotated_transition [get_pins pad/*]
  ```
- The following commands reset the `set_annotated_transition` constraint set on a port `in`:
  ```
  reset_annotated_transition in
  ```

  or

  ```
  reset_annotated_transition [get_ports {in}]
  ```

  Any `set_input_transition` constraint applied on the same port is not removed. This is applicable only for input ports, as `set_input_transition` cannot be applied on output ports.
- The following command resets all the `set_annotated_transition` constraints:
  ```
  reset_annotated_transition -all
  ```

Related Information

- set_annotated_transition

reset_aocv_stage_weight

```
reset_aocv_stage_weight
port_list
[-early]
[-late]
```

Resets the existing stage weight values set for the specified ports.

Parameters

`-early`	Resets weight for early paths.
`-late`	Resets weight for late paths.
port_list	Specifies a list or collection of input, output, and bidi ports for which stage weight values are to be reset.

Examples

- The following example resets the stage weight values of ports `clock1` and `out0`:

  ```
  reset_aocv_stage_weight [get_ports {clock1 out0}]
  ```

Related Information

- `set_aocv_stage_weight`

reset_case_analysis

```
reset_case_analysis
list_of_ports_or_pins
```

Removes the assertions set by the `set_case_analysis` command.

Parameters

list_of_ports_or_pins	Specifies the list of ports or pins for which the assertions are to be removed.

Examples

- The following commands sets the assertion to 0 and then resets them:

```
set_case_analysis 0 CM1/S0
get_property [get_pins CM1/S0] constant_value

# Returns a value of 0

reset_case_analysis [get_pins CM1/S0]
get_property [get_pins CM1/S0] constant_value

# Returns a value of NA
```

Related Commands

- set_case_analysis

reset_clock

```
reset_clock
{-all | clock_list}
```

Removes previously created clock assertions.

Parameters

`-all`	Removes all clocks in the design.
clock_list	Specifies the list of clocks for which the clock assertion is removed.

Examples

- The following commands reset a list of clocks and all clocks, and display the results using the `report_clocks` command:

```
report_clocks

# Generates the following report:

------------------------------------------------------------
Clock Descriptions
------------------------------------------------------------

reset_clock_gating_check

```
reset_clock_gating_check
[-setup]
[-hold]
[-rise]
[-fall]
[-high | -low]
[object_list]
```

Resets the specified setup and hold values for clock gating checks to the default values.

Parameters

`-high	-low`	Resets the non-controlling value (high or low) of the clock.
`-hold`	Resets clock gating hold values.
`-rise	-fall`	Resets the specified setup (or hold) value to the rising (or falling) signals on the specified pins.
`-setup`	Resets clock gating setup values.
object_list	Specifies a list of clocks, instances, or pins for which clock gating checks are to be reset to default values. If the *object_list* parameter is not specified, the clock gating check is reset on the current design.

Related Information

- set_clock_gating_check

reset_clock_groups

```
reset_clock_groups
[-help]
{-physically_exclusive | -logically_exclusive | -asynchronous}
{-name name_list | -all}
```

Resets clock groups that have been set using the `set_clock_groups` command.

Parameters

`-help`	Prints out the command usage.
`-all`	Removes all physically exclusive, logically exclusive, or asynchronous clock groups in the design. Removes all the physically exclusive, logically exclusive, or asynchronous clock groups in the design. This parameter should be used with one of the parameters: `-logically_exclusive`, `-physically_exclusive`, or `-asynchronous` at one time, and should not be used with the `-name` parameter.
`-asynchronous`	Specifies the asynchronous clock groups to be removed. This parameter must be used with either `-all` or `-name` parameter.
`-logically_exclusive`	Specifies the logically exclusive clock groups to be removed. This parameter must be used with either `-all` or `-name` parameter.
`-name name_list`	Specifies the previously defined names of clock groups to be removed. This parameter should be used with one of the parameters: `-logically_exclusive`, `-physically_exclusive`, or `-asynchronous` at one time.
`-physically_exclusive`	Specifies all the physically exclusive clock groups to be removed. This parameter must be used with either `-all` or `-name` parameter.

Examples

- The following command resets all physically exclusive clock groups in the design:
  ```
  reset_clock_groups -physically_exclusive -all
  ```
- The following command resets physically exclusive clock group `CLKGRP0`:
  ```
  reset_clock_groups -physically_exclusive -name CLKGRP0
  ```

Related Commands

- set_clock_groups

reset_clock_latency

```
reset_clock_latency
[-source]
[-clock clock_list]
pin_or_clock_list
```

Resets assertions made by previous set_clock_latency commands.

Parameters

`-clock clock_list`	Specifies the list of clocks with which associated `set_clock_latency` constraints, at the pin level, are to be removed. **Note:** This parameter cannot be used with clocks specified using the *`pin_or_clock_list`* parameter.
`pin_or_clock_list`	Specifies a list of pins, ports, or clock objects for which the assertions are to be removed.
-source	Removes the source latency.

Examples

- The following commands show the use of the `reset_clock_latency` command to remove a leaf-level `set_clock_latency` assertion, after the clock tree has been put into propagated mode:

  ```
  set_clock_latency 3.141 [get_pins BLK/BR2/CK]
  report_timing -to BLK/BR2/D -path_type full_clock
  ```

  The following report is generated:

  ```
  Path 1: MET Setup Check with Pin BLK/BR2/CK
  Endpoint: BLK/BR2/D (v) checked with leading edge of 'WAVE'
  Beginpoint: BLK/BR1/Q (v) triggered by leading edge of 'WAVE'
  Other End Arrival Time 3.141 <---
  - Setup 0.191
  + Phase Shift 10.000
  = Required Time 12.950
  - Arrival Time 0.249
  = Slack Time 12.701
  ...

  set_propagated_clock [get_ports tclk]
  ```

```
report_timing -path_type full_clock -net -to BLK/BR2/D
```

The following report is generated:

```
Path 1: MET Setup Check with Pin BLK/BR2/CK
Endpoint: BLK/BR2/D (v) checked with leading edge of 'WAVE'
Beginpoint: BLK/BR1/Q (v) triggered by leading edge of 'WAVE'
Other End Arrival Time 3.141 <--------
- Setup 0.191
+ Phase Shift 10.000
= Required Time 12.950
- Arrival Time 0.594
= Slack Time 12.356
...
```

In this example, setting the root of the clock tree to propagated mode is not sufficient to override the `set_clock_latency` assertion at the clock endpoint. You must use the `reset_clock_latency` command to remove the assertion, so that the register sees propagated clock timing.

```
reset_clock_latency [get_pins BLK/BR2/CK]
report_timing -path_type full_clock -net -to BLK/BR2/D
```

The following report is generated:

```
Path 1: MET Setup Check with Pin BLK/BR2/CK
Endpoint: BLK/BR2/D (v) checked with leading edge of 'WAVE'
Beginpoint: BLK/BR1/Q (v) triggered by leading edge of 'WAVE'
Other End Arrival Time 0.345 <--------
- Setup 0.186
+ Phase Shift 10.000
= Required Time 10.159
- Arrival Time 0.588
= Slack Time 9.571
```

- The following commands show that `reset_clock_latency` is only effective when it is applied on the same object for which you had set the assertion using the `set_clock_latency` command:
  Latency here is specified on a pin object:

  ```
  set_clock_latency 3.141 [get_pins BLK/BR2/CK]
  report_timing -path_type full -net -to BLK/BR2/D
  ```

  The following report is generated:

  ```
  Path 1: MET Setup Check with Pin BLK/BR2/CK
  Endpoint: BLK/BR2/D (v) checked with leading edge of 'WAVE'
  Beginpoint: BLK/BR1/Q (v) triggered by leading edge of 'WAVE'
  Other End Arrival Time 3.141 <-
  - Setup 0.191
  + Phase Shift 10.000
  = Required Time 12.950
  ```

```
- Arrival Time 0.249
= Slack Time 12.701
```

Resetting of the latency is done on a clock object and has no effect on downstream latencies specified on pin objects.
In this example, a `reset_clock_latency` on the clock waveform that is driving BLK/BR2/CK will have no effect.

```
reset_clock_latency [get_clocks WAVE]
report_timing -path_type full -net -to BLK/BR2/D
```

The following report is generated:

```
Path 1: MET Setup Check with Pin BLK/BR2/CK
Endpoint: BLK/BR2/D (v) checked with leading edge of 'WAVE'
Beginpoint: BLK/BR1/Q (v) triggered by leading edge of 'WAVE'
Other End Arrival Time 3.141 <-
- Setup 0.191
+ Phase Shift 10.000
= Required Time 12.950
- Arrival Time 0.249
= Slack Time 12.701
```

Related Information

- set_clock_latency

reset_clock_sense

```
reset_clock_sense
[-all]
| [[-clocks clock_list] pin_or_port_list]]
```

Resets clock sense constraint(s) specified using the `set_clock_sense` command.

Parameters

`-all`	Resets all the specified `clock_sense` constraints.
`-clocks` *clock_list*	Specifies the list of clocks for which the clock sense constraints are to be removed. The clocks must have previously been defined using the `set_clock_sense -clock` parameter.
pin_or_port_list	Specifies the list or collection of cell output pins for which the clock sense constraints will be removed.

Examples

- The following command resets all the previously defined `clock_sense` constraints from a design:

  ```
  reset_clock_sense -all
  ```

Related Information

- `set_clock_sense`

reset_clock_transition

```
reset_clock_transition
clock_list
```

Removes the clock transition assertions you had set on the specified list of clock waveforms.

Parameters

clock_list	Specifies a list of clock waveforms for which the clock transition assertions are removed. The *clock_list* variable can be a Tcl list or collection of clock waveforms.

Examples

- The following commands set the clock transition assertions, and resets them and displays the results using the `report_timing` command:

```
set_clock_transition 0.123 [get_clocks WAVE]
report_timing -net -to BLK/BR2/D

# Generates the following report

Related Information

- set_clock_transition

reset_clock_tree_latency

```
reset_clock_tree_latency
 [object_list]
```

Resets all network clock latency set using the set_clock_latency command in the fanout of the specified clock or pins and ports. The `reset_clock_tree_latency` command resets the latency until the root pins of clocks and generated clocks. Use this command after building clock tree and setting the clock network from the root to propagated mode using the `set_propagated_clock` *`clockRootPinOrPort`* command.

Note: You can use the reset_clock_tree_latency command only on command line and command script. You cannot specify it in an SDC file.

Parameters

`object_list`	Specifies list of objects - pins, ports, or clocks for which latency will be reset.

Related Information

- `set_clock_latency`
- `set_propagated_clock`

reset_clock_uncertainty

```
reset_clock_uncertainty
[-setup]
[-hold]
[-half_cycle_jitter | -full_cycle_jitter]
{  {-from | -rise_from | -fall_from} clksig_from_list
   {-to | -rise_to | -fall_to} clksig_to_list
 | pin_or_clock_list
}
```

Removes the assertions that were made by previous `set_clock_uncertainty` commands.

Parameters

`{-from | -rise_from | -fall_from} clksig_from_list`	
	Removes the assertions for uncertainty value for the specified list of launching clocks. **Note:** You must specify one of these parameters with one of the `-to`, `-rise_to`, or `-fall_to` parameters. You cannot use these parameters when pins are specified.
	`-fall_from`: Removes the uncertainty value only from the falling edge of the launching clocks.
	`-from`: Removes the uncertainty value from both the rising and falling edges of the launching clocks.
	`-rise_from`: Removes the uncertainty value only from the rising edge of the launching clocks.
`-half_cycle_jitter | -full_cycle_jitter`	Removes or resets the clock source jitter assertion(s) of the specified type.
pin_or_clock_list	Removes the target uncertainty assertions from the specified list of clocks or pins. The uncertainty value is removed from the registers clocked by the target waveform, or register pins in the fanout of the specified pin. You can specify a list of clock names, or clock root pin or port names relative to the current module. You also can specify a collection of clocks, or clock root pins or ports. **Note:** You cannot use this parameter when any of the `-from` and `-to` parameter pairs are specified.
`-setup/-hold`	Specifies whether the clock uncertainty is removed for setup or hold checks. *Default*: Removes clock uncertainty for both setup and hold check.

`{-to | -rise_to | -fall_to}` *clksig_to_list*	
	Removes the uncertainty value from the specified list of capture clocks. **Note:** You must specify one of these parameters with one of the `-from`, `-rise_from`, or `-fall_from` parameters. You cannot use these parameters when pins are specified.
	`-fall_to`: Removes the uncertainty value only from the falling edge of the capture clocks.
	`-rise_to`: Removes the uncertainty value only from the rising edge of the capture clocks.
	`-to`: Removes the uncertainty value from both the rising and falling edges of the capture clocks.

Examples

The following commands sets and resets the clock uncertainty assertions and displays the results using the `report_timing` command:

- `set_clock_uncertainty 0.345 -from [get_clocks VCLK] -to [get_clocks WAVE]report_timing -net -from tin`

  ```
  # Generates the following report:
  Path 1: MET Setup Check with Pin TR1/BR1/CK
  Endpoint: TR1/BR1/D (v) checked with leading edge of 'WAVE'
  Beginpoint: tin (v) triggered by trailing edge of 'VCLK'
  Other End Arrival Time 0.000
  - Setup 0.192
  + Phase Shift 10.000
  - Uncertainty 0.345 <---
  = Required Time 9.463
  - Arrival Time 5.877
  = Slack Time 3.586
  ```

- `reset_clock_uncertainty -from [get_clocks VCLK] -to [get_clocks WAVE]report_timing -net -from tin`

  ```
  # Generates the following report:
  Path 1: MET Setup Check with Pin TR1/BR1/CK
  Endpoint: TR1/BR1/D (v) checked with leading edge of 'WAVE'
  Beginpoint: tin (v) triggered by trailing edge of 'VCLK'
  Other End Arrival Time 0.000
  - Setup 0.192
  + Phase Shift 10.000
  = Required Time 9.808
  - Arrival Time 5.877
  ```

```
= Slack Time 3.931
```

Related Information

- set_clock_uncertainty

reset_data_check

```
reset_data_check
{-from | -rise_from | -fall_from} pin_or_port_list
{-to | -rise_to | -fall_to} pin_or_port_list
[-setup]
[-hold]
[-clock clock_object]
```

Removes specified data-to-data checks that you have specified using the set_data_check command.

Parameters

`-clock` *clock_object*	Removes the data check with a related (`-from`) pin event that is triggered by the specified clock. Use this parameter only if the original `set_data_check` constraint also used the `-clock` parameter to specify an explicit clock relationship.
`-from` |`-rise_from` | `-fall_from` *pin_or_port_list*	Specifies the related pins of the data-to-data checks to be removed. The *pin_or_port_list* list can contain either object IDs or hierarchical names relative to the current module. Leaf design cells (instances) can also be specified. Use only one `-from`, `-rise_from`, or `-fall_from` parameter per command. By default, the `-from` parameter removes checks for both the rising and the falling edges. Using `-rise_from` parameter removes checks at the rising edge of the signal on the from pins. Using `-fall_from` parameter removes checks at the falling edge of the signal on the from pins.
`-setup/-hold`	Specifies whether the data check to be removed is for setup or hold check. If you do not specify either `-setup` or `-hold` option, both setup and hold checks are removed.
`-to` | `-rise_to` | `-fall_to` *pin_or_port_list*	Specifies the constrained pins of data-to-data checks to be removed. The *pin_or_port_list* list can contain either object IDs or hierarchical names relative to the current module. Leaf design cells (instances) can also be specified. Use only one `-to`, `-rise_to`, or `-fall_to` parameter per command. By default, the `-to` parameters removes both the rising and the falling edges. Using `-rise_to` parameter removes the rising edge of the signal on the to pins. Using `-fall_to` parameter removes the falling edge of the signal on the to pins.

Examples

- The following commands set and reset the data checks from `port30` to `port28`:

```
set_data_check 0.345 -rise_from port30 -to port28
report_timing -rise_from port30 -to port28
```

The following report is displayed:

```
Path 1: VIOLATED Data To Data Setup Check with Pin port30
Endpoint: port28 (v) checked with leading edge of 'PH1'
Beginpoint: U2/Q (v) triggered by leading edge of 'PH1'
Other End Arrival Time 0.465
- Data Check Setup 0.345
+ Phase Shift 0.000
= Required Time 0.120
- Arrival Time 0.309
= Slack Time -0.189
```

```
reset_data_check -rise_from port30 -to port28
report_timing -rise_from port30 -to port28
```

The following information is displayed:

```
No constrained timing paths with given description found.
Paths may be unconstrained (try '-unconstrained' option) or may not exist.
```

Related Commands

- `set_data_check`
- `report_timing`

reset_disable_clock_gating_check

```
reset_disable_clock_gating_check
object_list
```

Enables clock gating checks for the specified instances or pins.

Parameters

object_list	Specifies the list of disabled pins or instances that are to be enabled.

Related Information

- set_disable_clock_gating_check

reset_disable_timing

```
reset_disable_timing
[-help]
[-from pin_name -to pin_name]
object_list
```

Restores timing arcs that were disabled using the `set_disable_timing` command.

Parameters

`-help`	Prints out the command usage.
`-from pin_name -to pin_name`	Specifies the arc(s) that are to be restored. Specify the `-from` and `-to` options together. You can specify the `-from` and `-to` parameters when the *`object_list`* contains instance or library cell objects. Do not specify the `-from` and `-to` parameters when the *`object_list`* includes instance pin or library cell pin objects. The `-from` and `-to` options are optional. If not specified, all cell arcs found in the instance or library cell objects are restored.
`object_list`	Specifies the instance, instance pin, library arc, library cell, or library cell pin objects. If the *`object_list`* includes instance pin or library cell pin objects, all cell arcs attached to the specified pin objects are restored. If the *`object_list`* contains instance or library cell objects, and the `-from` and `-to` parameters are not specified, all arcs found in the specified instance or library cell objects are restored.

Examples

- The following commands set and reset the timing arcs and display the resulting reports:

```
set_disable_timing -from A -to Y [get_cells b1]
report_inactive_arcs

------------------------------------------------------------------------
```

Related Information

- set_disable_timing
- report_inactive_arcs

reset_drive

```
reset_drive port_list
```

Resets the drive previously asserted with the `set_drive` command on input ports. The `reset_drive` command removes assertions for all rise/fall, minimum/maximum combinations for which the assertion exists.

Parameters

port_list	Specifies a list of input or bidirectional ports for which the drive resistance is reset.

Related Information

- `set_drive`

reset_driving_cell

```
reset_driving_cell
[-rise]
[-fall]
[-min]
[-max]
port_list
```

Resets the driving cell assertions applied with the `set_driving_cell` command for the given rise/fall, minimum/maximum combination on ports.

If `-rise`, `-fall`, `-min`, or `-max` parameters are not specified, the `reset_driving_cell` command resets the assertion for all rise/fall, minimum/maximum combinations for which the assertion exists.

Parameters

`-rise`	Specifies the rising drive assertions.
`-fall`	Specifies the falling drive assertions.
`-min`	Specifies the early drive assertion.
`-max`	Specifies the late drive assertion.
`port_list`	Specifies a list of ports for which the driving cell assertions are reset.

Related Information

- `set_driving_cell`

reset_generated_clock

```
reset_generated_clock
[-help]
{-all | clock_list}
```

Removes generated clock assertions previously created using the `create_generated_clock` command.

To use the `reset_generated_clock` command you must specify the `set_interactive_constraint_modes` constraints for the applicable modes. You can also include these commands in the SDC constraint file - applicable only for the views that include that SDC.

Note: The generated clocks may originate from the library files dotlib - you can use `reset_generated_clock` from the command line, or add it to all the SDC files in use.

Parameters

`-help`	Prints out the command usage.
`-all`	Removes all the generated clocks in the design.
`clock_list`	Specifies the list of clocks (in collection format) for which the generated clock assertions are to be removed.

Examples

Here are some examples.

- The following command removes the generated clock assertions on all the generated clocks `RC/Q`:

  ```
  report_clocks

  # The following report is displayed:

reset_ideal_latency

```
reset_ideal_latency
[-min]
[-max]
[-rise]
[-fall]
object_list
```

Resets the ideal latency constraints, specified using the `set_ideal_latency` command, on instance pins or ports.

Parameters

`-fall`	Resets the ideal latency for the falling edge.
`-max`	Resets the ideal latency for the maximum corner.
`-min`	Resets the ideal latency for the minimum corner.
`object_list`	Resets a list of objects - instance pins, ports, or nets.
`-rise`	Resets the ideal latency for the rising edge.

Related Information

set_ideal_latency

reset_ideal_network

```
reset_ideal_network
object_list
```

Resets the ideal network constraints, specified using the `set_ideal_network` command, on pins, ports, or nets.

Note: The `reset_ideal_network` command is not view/mode-based - it applies to all the active views.

Parameters

object_list	Resets a list of objects - instance pins, ports, or nets.

Related Information

set_ideal_network

reset_ideal_transition

```
reset_ideal_transition
[-min]
[-max]
[-rise]
[-fall]
object_list
```

Resets the ideal transition constraint, specified using the `set_ideal_transition` command, on instance pins or ports.

Parameters

`-fall`	Resets the ideal transition for the falling edge.
`-max`	Resets the ideal transition for the maximum corner.
`-min`	Resets the ideal transition for the minimum corner.
`object_list`	Resets a list of objects - instance pins, ports, or nets.
`-rise`	Resets the ideal transition for the rising edge.

Related Information

set_ideal_transition

reset_input_delay

```
reset_input_delay
[-help]
[-clock clk_name]
[-clock_fall]
[-rise] [-fall]
[-max] [-min]
[-level_sensitive]
pin_or_port_list
```

Resets previously specified input delay assertions.

Parameters

`-help`	Prints out the command usage.
`-clock` *`clock_name`*	Specifies the name of the clock. *Default*: The asynchronous (`@`) clock. If you specify multiple clocks, an error occurs and the constraint is ignored. When you specify the `-clock` parameter, the constraints specified for a pin with matching `-clock` parameter are reset. If you do not specify the `-clock` parameter, all the constraints applied on the specified pin, with or without the `-clock` parameter specification, are reset.
`-clock_fall`	Removes the assertions for the delay that is relative to the falling edge of the clock. You must specify the `-clock` parameter with this parameter. *Default*: Removes the delay assertions relative to the falling edge.
`-fall`	Resets the input delay for the falling edge at the input port. If both the `-rise` and `-fall` options are not specified, then the input delay is reset on both the edges.
`-level_sensitive`	Resets input delay that is launched by a positive level sensitive latch. When you specify the `-level_sensitive` parameter, the command resets all the `set_input_delay` constraints specified with the `-level_sensitive` parameter. If `-level_sensitive` parameter is not specified, the constraints specified for the same pin, with or without the `-level_sensitive` parameter, are reset. **Note:** You must specify the `-clock` parameter with this parameter.
`-max`	Removes the delay assertions that refer to the setup analysis. If you do not specify the `-max` parameter, the input delay assertions for both setup and hold analysis are removed.
`-min`	Removes the delay assertions that refer to the hold analysis. If you do not specify the `-min` parameter, the input delay assertions for both setup and hold analysis are removed.
`pin_or_port_list`	Specifies a single or multiple pins or ports for which the input delay is reset. To specify multiple pins, enclose the list with curly braces (`{}`) and separate the pin information with white space.
`-rise`	Resets the input delay for the rising edge at the input port. If both `-rise` and `-fall` options are omitted, the input delay is reset on both the edges.

Related Information

- `set_input_delay`

reset_load

```
reset_load
object_list
```

Resets the existing `set_load` assertions specified on nets or ports.

Parameters

object_list	Specifies a list of nets or ports in the top cell for which assertions are reset.

Related Information

set_load

reset_max_capacitance

```
reset_max_capacitance
object_list
```

Resets maximum capacitance limit specified (using the the `set_max_capacitance` command) on the objects in the object list. The valid objects in the object list are primary ports, clocks, and current design.

Parameters

object_list	Specifies the list of ports, modules, and/or clock waveforms for which assertions are reset.

Related Information

set_max_capacitance

reset_max_fanout

```
reset_max_fanout
object_list
```

Resets maximum fanout limit specified (using the `set_max_fanout` command) on the objects in the object list. The valid objects in the object list are input and bidirectional ports and current design.

Parameters

object_list	Specifies the list of ports or modules for which assertions are reset.

Related Information

set_max_fanout

reset_max_time_borrow

```
reset_max_time_borrow
object_list
```

Resets the specified maximum time borrow limit of the specified objects.

Parameters

object_list	Specifies the list of pins, instances, or clocks for which the time borrow limit is reset.

Related Information

set_max_time_borrow

reset_max_transition

```
reset_max_transition
object_list
```

Resets the maximum slew (transition) limit specified using the `set_max_transition` command (from the SDC or the Tempus command line) on the objects in the given object list. The valid objects in the object list are primary ports, clocks, and current design.

The maximum transition limit that is set by the user overrides the dotlib value so that sharper slews are implemented on the timing sensitive nets, such as clocks. A violation due to the `set_max_transition` setting does not impact the timing accuracy.

Note: For command-line usage of this command, you need to use `set_interactive_constraint_modes`, for example, `set_interactive_constraint_modes [all_constraint_modes -active]`

Parameters

object_list	Specifies the list (or collection) of ports, modules, and/or clock waveforms for which assertions are to be reset. For example, `reset_max_transition [get_ports *]`

Related Information

- `set_max_transition`

reset_min_capacitance

```
reset_min_capacitance
object_list
```

Resets minimum capacitance limit specified (using the the `set_min_capacitance` command) on objects in the object list. The valid objects in the object list are primary ports, clocks, and the current design.

Parameters

object_list	Specifies the list of ports, modules, and/or clock waveforms for which assertions are reset.

Related Information

set_min_capacitance

reset_min_fanout

```
reset_min_fanout
object_list
```

Resets minimum fanout limit specified (using the `set_min_fanout` command) on the objects in the object list. The valid objects in the object list are input and bidirectional ports and the current design.

Parameters

object_list	Specifies the list of ports or modules for which assertions are reset.

Related Information

- `set_min_fanout`

reset_min_pulse_width

```
reset_min_pulse_width
[-help]
object_list
[-high]
[-low]
[-waveform_aware_type {absolute | source_width_ratio | all}]
```

Resets minimum pulse width constraint on the specified input ports of the top cell and the specified modules.

Parameters

`-help`	Prints out the command usage.
`-low`	Resets the minimum pulse width checks that are applied to low signal levels only.
`-high`	Resets the minimum pulse width checks that are applied to high signal levels only.
`object_list`	Specifies a list of pins or clock waveforms for which the minimum pulse width is to be reset. If a clock waveform is specified, all the pins driven by the clock are affected.
`-waveform_aware_type {absolute | source_width_ratio | all}`	Resets the regular and waveform-aware pulse width assertions.

Related Information

- `set_min_pulse_width`

reset_min_transition

```
reset_min_transition
object_list
```

Resets minimum slew (transition) limit specified (using the `set_min_transition` command) on the objects in the object list. The valid objects in the object list are primary ports, clocks, and current design.

Parameters

object_list	Specifies the list of ports, modules, and/or clock waveforms for which assertions are reset.

Related Information

- `set_min_transition`

reset_mode

```
reset_mode
[-type cell]
list_of_modes
object_list
```

Resets the Liberty timing library modes for a specified instance.

Library modes are set using the set_mode command. By default, all library modes in the timing library are active. If you specify one or more library modes using the `set_mode` command, only the timing arcs consistent with the specified mode(s) are active for the instance. All other library modes become inactive. When you reset the library mode for the instance, all library modes become active again.

Parameters

object_list	Specifies the instances to which to reset the library modes.
list_of_modes	Specifies the name of the library modes to reset.
-type cell	Resets the library mode at the instance level. **Note:** Setting the library mode at the instance level is the only form of `set_mode` that is currently supported. This parameter exists to support constraints coming from external sources.

Examples

- The following command specifies that only the timing arcs consistent with the `test_A` library mode are active for instances of b1:
  The test_A library mode is made inactive.

  ```
  set_mode test_mode [get_cells BUF]
  ```

  The following command reports the status of all library modes associated with BUF 'b1' . It shows that test_A is active and test_B is inactive.

  ```
  > report_mode b1
  ------------------------------
  Mode Group test_mode of b1
  ------------------------------
  Mode     Status    Condition
  Name
  ------------------------------
  test_B   Inactive  !(Y)
  test_A   ACTIVE    Y
  ------------------------------
  ```

  The following command resets the library mode for instances of b1 :

  ```
  reset_mode test_A b1
  ```

  If you generate a report of the library mode status for b1, it shows that both modes are now active:

  ```
  > report_mode b1
  ------------------------------
  Mode Group test_mode of b1
  ------------------------------
  Mode    Status   Condition
  Name
  ------------------------------
  test_B  ACTIVE    !(Y)
  test_A  ACTIVE    Y
  ------------------------------
  ```

Related Commands

- set_mode
- report_mode

reset_output_delay

```
reset_output_delay
[-help]
port_or_pin_list
[-clock clock_name]
[-clock_fall]
[-fall]
[-level_sensitive]
[-max]
[-min]
[-rise]
```

Resets previously specified output delay assertions.

Parameters

`-help`	Prints out the command usage.
`-clock` *`clock_name`*	Specifies the name of the clock. *Default*: The asynchronous (`@`) clock. If you specify multiple clocks, an error occurs and the constraint is ignored. When you specify the `-clock` parameter, the constraints specified for a pin with matching `-clock` parameter are reset. If you do not specify the `-clock` parameter, all the constraints applied on the specified pin, with or without the `-clock` parameter specification, are reset.
`-clock_fall`	Removes the assertions for the delay that is relative to the falling edge of the clock. You must specify the -clock parameter with this parameter. *Default:* Removes the delay assertions relative to the rising edge.
`-fall`	Resets the output delay for the falling edge at the output port. If both `-rise` and `-fall` options are omitted, the output delay is reset on both the edges.
`-level_sensitive`	Resets output delay that is launched by a positive level sensitive latch. When you specify the `-level_sensitive` parameter, the command resets all the `set_output_delay` constraints specified with the `-level_sensitive` parameter. If `-level_sensitive` parameter is not specified, the constraints specified for the same pin, with or without the `-level_sensitive` parameter, are reset. **Note:** You must specify the `-clock` parameter with this parameter.
`-max`	Removes the delay assertions that refer to the setup analysis. If you do not specify the `-max` parameter, the output delay assertions for both setup and hold analysis are removed.
`-min`	Removes the delay assertions that refer to the hold analysis. If you do not specify the `-min` parameter, the output delay assertions for both setup and hold analysis are removed.
`pin_or_port_list`	Specifies a single or multiple pins or ports for which the output delay is reset. To specify multiple pins, enclose the list with curly braces (`{}`) and separate the pin information with white space.
`-rise`	Resets the output delay for the rising edge at the output port. If both `-rise` and `-fall` options are omitted, the output delay is reset on both the edges.

Examples

- The following example sets the output delays for the output port Z. The output signal is required at Z at 2 units before the rising edge of clock Clk1, and at 2.5 units before falling edge of clock Clk2:

```
set_output_delay 2 Z -clock Clk1
set_output_delay 2.5 Z -clock Clk2 -clock_fall -add_delay
```

- The following command will reset the output delay for the rising edge of clock Clk2:

```
reset_output_delay Z -clock Clk2

report_timing -to_rise Z -clock_to Clk2

- The following command resets the output delay for clock Clk2 with respect to the falling edge:

  ```
  reset_output_delay Z -clock Clk2 -clock_fall
  ```

- The following command will reset all the output delays with respect to all the edges for both the clocks - Clk1 and Clk2:

  ```
  reset_output_delay Z
  ```

Related Commands

- set_output_delay

reset_path_exception

```
reset_path_exception
[-exact]
[-type {false_path | multicycle | path_delay}]
[-rise]
[-fall]
[{-from | -rise_from | -fall_from} from_list]
[{-through | -rise_through | -fall_through} through_list]
[{-to | -rise_to | -fall_to} to_list]
[-setup | -hold]
[-all]
```

Removes any previously set path exceptions (or path exception of the specified type) for the given paths. To remove all path exceptions, use the `-all` option with the `reset_path_exception` command.

Parameters

`-all`	Removes all path exceptions. This option cannot be used with the `-from`, `-through and -to` options.
`-exact`	Forces exact matching of the constraints. When this parameter is specified, the reset settings (-from/-through/-to) match with the original constrained path settings.
`-fall`	Applies the assertion at the falling edge of the signal on the path endpoints.
`{-from | -rise_from | -fall_from} from_list`	Specifies pins at the start of the path exceptions that are to be reset.
`-rise`	Applies the assertion at the rising edge of the signal on the path endpoints.
`{-through | -rise_through | -fall_through} through_list`	Specifies the pins that the path to be reset goes through.
`{-to | -rise_to | -fall_to} to_list`	Specifies pins at the end of the path exceptions that are to be reset.
`-setup | -hold`	Resets only the setup (or hold) paths. The `-setup`/`-hold` parameters should be used to reset maximum or minimum delay that is set using the `set_max_delay` and `set_min_delay` commands. *Default*: Both `-setup` and `-hold` are reset.
`-type {false_path | multicycle | path_delay}`	Removes only path exceptions of the specified type. *Default*: All path exception assertions are reset.

Examples

- In the example below the rising path from R1 to R2 has three different path exceptions asserted on it - they are listed in priority from lowest to highest. As shown in the reports below, the false path is the highest precedence and so no path is reported.

```
set_multicycle_path -from R1/CK -rise_to R2/D 2
set_max_delay 3 -from R1/CK -rise_to R2/D
set_false_path -from R1/CK -rise_to R2/D

report_timing -from R1/CK -rise_to R2/D
```

The following information is displayed:

```
No constrained timing paths with given description found.
Paths may be unconstrained (try '-unconstrained' option) or may not exist.

report_path_exceptions
```

The following report is displayed:

```
---------------------------------------
From      To         Early        Late
---------------------------------------
R1/CK     ^ R2/D    false        false
---------------------------------------
```

To report ignored path exceptions, you can use the following command:

```
report_path_exception -ignored

-------------------------------------------
From     To       Early      Late
-------------------------------------------
R1/CK   ^ R2/D               delay 3 ignored
R1/CK   ^ R2/D    add 0 ignored
R1/CK   ^ R2/D               add 1 ignored
-------------------------------------------
```

- In this example, the false path exception is removed from the path. This causes the max path delay assertion to become active - as it is the next highest precedence.

```
reset_path_exception -from R1/CK -rise_to R2/D -type false_path

report_path_exceptions
-------------------------------------
From      To       Early     Late
-------------------------------------
R1/CK    ^ R2/D             delay 3
R1/CK    ^ R2/D    add 0
-------------------------------------

report_timing -from R1/CK -rise_to R2/D

-------------------------------------------------------------------
```

- Consider the following `set_false_path` constraint:

```
set_false_path -from {u1/Y u2/Y} -to {u3/Y}
```

When you specify `reset_path_exception -from {u1/Y}` command without the `-exact` parameter, the command outputs the following:

```
set_false_path -from {u2/Y} -to {u3/Y}
```

The command `reset_path_exception -from {u1/Y} -exact` outputs the following:

```
set_false_path -from {u1/Y u2/Y} -to {u3/Y}
```

In this case (when `-exact` parameter is used), the path exception is not reset because differential matching is not allowed.

Related Information

- `set_false_path`
- `report_timing`

reset_path_group

```
reset_path_group
[-name group_name]
[-all]
```

Removes the specified path groups or completely removes all the groups.

Parameters

`-all`	Removes all path groups.
`-name group_name`	Removes the named group completely.

Example

- The following command removes the group named GRPA:
  ```
  reset_path_group -name GRPA
  ```

Related Information

- `group_path`

reset_pll_timing

```
reset_pll_timing
[-help]
inst_name
-output_clock
clock name or ID
-output_pin output pin name
```

Resets the delay offset settings applied to a PLL (phase locked loop) output clock.

Parameters

`-help`	Prints out the command usage.
inst_name	Specifies the name of the instance on which reference pins, feedback pins, or output pins will be searched.
`-output_clock <`*clock name or ID*`>`	Specifies the name of the PLL output clock.
`-output_pin <`*output pin name*`>`	Specifies the name of the PLL output pin.

Related Commands

- set_pll_timing

reset_propagated_clock

```
reset_propagated_clock
pin_clock_list
```

Removes the propagated clock assertion for the specified clock waveforms or pins.

The ideal or propagated status of clock endpoints in the fanout of the specified pin/clock list is determined by the remaining clock latency propagated clock assertions in the clock network.

When new analysis views are used, the new corners do not have the source latency updated as per the clock propagation (`update_io_latency`) settings, so a reset and re-calculation is required.

Note: You must specify `set_interactive_constraint_modes` constraint prior to running the `reset_propagated_clock` command.

Parameters

`-help`	Prints out the command usage.
`pin_clock_list`	Specifies a list of pins or clocks for which you want to reset the clock propagation mode to ideal mode. The *`pin_clock_list`* parameter can be a collection, however, no hierarchical pins are allowed in the list.

Examples

- The following command sets the `CLK1` clock waveform to `propagated` mode:

  ```
  set_propagated_clock CLK1
  ```

- The following command resets the `CLK1` clock waveform back to `ideal` mode:

  ```
  reset_propagated_clock CLK1
  ```

- The following commands set the `CLK1` clock to `propagated` mode and then reports them:

  ```
  set_propagated_clock [get_clocks CLK1]
  report_clocks
  ```

  The following report is displayed:

  ```

reset_property

```
reset_property
[-object_type {object_type}]
{object_list}
property_name
```

Resets user-defined properties on objects set using the `set_property` command.

Parameters

object_list	Specifies a list of objects for which the property is to be reset.
-object_type {*object_type*}	Specifies the type of object on which the property is to be reset.
property_name	Specifies the name of the property for which the user-defined property is to be reset.

Examples

- The following command resets user-defined property `slk` from pins `C1/A`:

  ```
  reset_property [get_pins C1/A] slk
  ```

Related Information

- get_property
- report_property
- define_property
- set_property

reset_pulse_clock_max_transition

```
reset_pulse_clock_max_transition
object_list
[-transitive_fanout]
[-rise]
[-fall]
```

Resets the maximum pulse clock transition constraint specified (using the `set_pulse_clock_max_transition` command) on the pulse generator cells, pulse generator library cells, clocks, and/or current design.

Parameters

`-fall`	Resets transition limit value for falling transition.
`object_list`	Specifies a list of objects - pulse generator cells, pulse generator library cells, clocks, or current design - for which the transition value is to be reset.
`-rise`	Resets transition limit value for rising transition.
`-transitive_fanout`	Specifies the transition limit value for transitive fanout.

Related Information

- `set_pulse_clock_max_transition`

reset_pulse_clock_max_width

```
reset_pulse_clock_max_width
object_list
[-transitive_fanout]
```

Resets the maximum pulse clock width constraint specified (using the `set_pulse_clock_max_width` command) on the pulse generator cells, pulse generator library cells, clocks, and/or current design.

Parameters

object_list	Specifies a list of objects - pulse generator cells, pulse generator library cells, clocks, or current design - for which the maximum pulse clock width is to be reset.
[-transitive_fanout]	Specifies the pulse width value for transitive fanout.

Related Information

- `set_pulse_clock_max_width`

reset_pulse_clock_min_transition

```
reset_pulse_clock_min_transition
object_list
[-transitive_fanout]
[-rise]
[-fall]
```

Resets the minimum pulse clock transition constraint specified (using the `set_pulse_clock_min_transition` command) on the pulse generator cells, pulse generator library cells, clocks, and/or current design.

Parameters

`-fall`	Resets transition limit value for falling transition.
object_list	Specifies a list of objects - pulse generator cells, pulse generator library cells, clocks, or current design - for which the minimum pulse clock transition value is to be reset.
`-rise`	Resets transition limit value for rising transition.
`-transitive_fanout`	Specifies the transition limit value for transitive fanout.

Related Information

- `set_pulse_clock_min_transition`

reset_pulse_clock_min_width

```
reset_pulse_clock_min_width
object_list
[-transitive_fanout]
```

Resets the minimum pulse clock width constraint specified (using the `set_pulse_clock_min_width` command) on the pulse generator cells, pulse generator library cells, clocks, and/or current design.

Parameters

object_list	Specifies a list of objects - pulse generator cells, pulse generator library cells, clocks, or current design - for which the minimum pulse clock width is to be reset.
[-transitive_fanout]	Specifies the pulse width value for transitive fanout.

Related Information

- `set_pulse_clock_min_width`

reset_resistance

```
reset_resistance
net_list
```

Resets the existing `set_resistance` assertions specified on nets.

Parameters

net_list	Specifies a list of nets for which the wire resistance is reset.

Related Information

- `set_resistance`

set_active_clocks

```
set_active_clocks
[-help]
```
active_clock_list | *all_clocks*

Defines a list of active clocks in the design.

When the `set_active_clocks` command is specified, only the specified clocks are made active while others remain inactive. Any clock created after using the `set_active_clocks` command is active by default. The following commands are impacted:

- `report_clocks` command output displays a new column showing active or inactive clocks in the design.
- `get_clocks` command will report all clocks including inactive clocks.
- `write_timing_windows` command will not display windows for inactive clocks in the output report.
- `get_property` command allows you to query on active clocks using the `is_clock_active` property.

Parameters

`-help`	Prints out the command usage.
active_clock_list | *all_clocks*	Specifies a list of active clocks.

Examples

- The following command makes the specified clocks active while others remain inactive (only `Iclk1` is active, while `Iclk2` is inactive):

```
set_active_clocks Iclk1
```

Related Information

- `report_clocks`
- `get_clocks`
- `get_property`

set_annotated_check

```
set_annotated_check
[-help]
check_value
[-clock clock_check]
[-cond sdf_condtion]
[-fall]
-from from_pins
[-incremental]
[-max]
[-min]
[-rise]
-to to_pins
{-setup | -hold | -recovery | -removal | -nochange_high | -nochange_low}
```

Annotates the setup, hold, recovery, or removal timing check value between two or more pins of a cell in the current design.

Parameters

`-help`	Prints out the command usage.
check_value	Specifies the timing check value.
`-clock` *clock_check*	Specifies clock rising or falling. Default: Sets checks for both clock rise and fall. Use the *clock_check* argument to specify rise or fall.
`-cond` *sdf_condition*	Specifies the condition only if the library has a condition attached to the specified timing check arc. The *sdf_expression* must match the syntax of the condition specified in the library.
`-fall`	Specifies the data fall transition for the timing check. Default: Sets both `-rise` and `-fall`.
`-from` *from_pins*	Specifies start points of the timing arcs for which checks are annotated. Use the *from_pins* argument to specify a list of leaf cell clock pins.
`-incremental`	Set incremental checks.
`-max`	Specifies the maximum timing check for both data rise and data fall transitions. Use this option only if the design uses minimum and maximum (`min-max`) operating conditions.

`-min`	Specifies the minimum timing check for both data rise and data fall transitions. Use this option only if the design uses minimum and maximum (`min-max`) operating conditions.
`-rise`	Specifies the data rise transition for the timing check. Default: Sets both rise and fall.
`-setup | -hold | -recovery | -removal | -nochange_high | -nochange_low`	Specifies the timing check type. Make sure there is a corresponding timing arc between the *`from_pins`* and the *`to_pins`* arguments.
`-to` *`to_pins`*	Specifies endpoints of the timing arcs for which checks are annotated. Use the *`to_pins`* argument to specify a list of leaf cell clock pins.

Examples

- The following commands annotates a `nochange check` between data low and clock low. The nochange margin before the clock is `1.3` and the nochange margin after the clock is `2.4`:

```
set_annotated_check -nochange_low 1.3 -clock fall -fall -from {I1/CP} -to {I1/EN}
set_annotated_check -nochange_low 2.4 -clock fall -rise -from {I1/CP} -to {I1/EN}
```

- The following command annotates a 2.0 setup time between the CP clock pin and the A data pin of the <*instance_name*> instance:

```
set_annotated_check -setup 2.0 -from <instance_name>/CP -to <instance_name>/A
```

Related Commands

- reset_annotated_check
- set_annotated_delay

set_annotated_delay

```
set_annotated_delay
[-help]
delay_value
[-cond expression]
[-delta_only]
[-fall]
[-increment]
[-max]
[-min]
[-rise]
{-net | -cell }
{[-from from_pins] [-to to_pins]}
```

Annotates delay to timing arcs. If you specify the `set_annotated_delay` command without any parameters, the delay value specified is assumed to include both the base delay and any delta (cross-talk) delay.

Parameters

`-help`	Prints out the command usage.
`-cond` *`expression`*	Specifies the sdf condition of the selected timing arcs. *Default*: The delay applies to all the timing arcs selected using the `-from` and the `-to` options. The expression is ignored for net arcs. **Note:** You cannot specify the `-cond` parameter with `-net`. If specified, an error is displayed.
`delay_value`	Specifies the delay value to be annotated to the selected timing arcs.
`-delta_only`	Populates the incremental delay slot with the delay value, so that you can differentiate between the base net delay and a delay offset that is due to cross talk. The software reports the incremental (or delta) delay value separately in the timing report using `report_timing -format incr_delay`, and maintains the separate value for CPPR calculations. If the base delay was previously calculated or annotated from the SDF, the `-delta_only` parameter adds the specified delay to the existing base delay. **Note:** This parameter only can be used with the `-net` parameter; you cannot specify it with the `-cell` parameter.
`-from` *`from_pins`*	Specifies timing arcs to which the delay applies. The selected timing arcs are those that have their source pins specified using this option and the sink pins specified using the `-to` option. If this option is not specified, only timing arcs whose sink pins are specified using the `-to` option are selected. **Note:** You cannot specify hierarchical pins. If specified, an error message is displayed.
`-increment`	Increments the specified delay value on top of the existing base delay value.
`-min | -max`	Specifies the annotated delay for a particular operating corner. You can apply the `-min` parameter to the minimum operating corner and the `-max` parameter to the maximum operating corner.
`-net | -cell`	Specifies whether the delay should be annotated to cell arcs or net arcs.
`-rise/-fall`	Specifies the transition to which the delay applies. For cell arc, this is the output transition. *Default*: The delay applies to both transitions.
`-to` *`to_pins`*	Specifies timing arcs to which the delay applies. The selected timing arcs are those that have their sink pins specified using this option and the source pins specified using the `-from` option. If this option is not specified, only timing arcs whose source pins are specified using the `-from` option are selected. **Note:** You cannot specify hierarchical pins. If specified, an error message is displayed.

Examples

- The following example shows the usage of `-cell` and `-net` options:

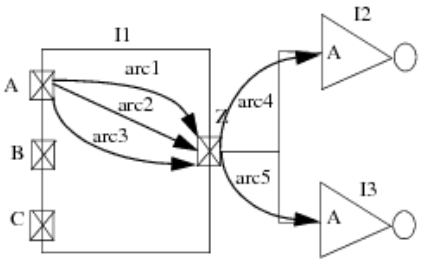
  Example Figure to Show How to Use the -cell and -net Options

  
  - Use the `-cell` option to select the cell arc `carc2` only:
    set_annotated_delay 3.0 -cell -from {I1/IO}
  - Use the `-net` arc option to select net arcs `narc1` and `narc2` only:
    set_annotated_delay 3.0 -net -from {I1/IO}

- This TLF description is used for the following examples:

```
CELL (NAND3 . . . . // arc 1
Path( A => Z 10 01 DELAY(ioDelayRiseModel0) SLEW(SlopeRiseModel0) ) Path( A => Z 01 10
DELAY(ioDelayFallModel0) SLEW(SlopeFallModel0) ) // arc2 Path( A => Z 10 01 COND(B & C) SDF_COND(B
& C) DELAY(ioDelayRiseModel1) SLEW(SlopeRiseModel1) ) Path( A => Z 01 10 COND(B & C) SDF_COND(B &
C) DELAY(ioDelayFallModel1) SLEW(SlopeFallModel1) ) arc3 Path( A => Z 10 01 COND(~B | ~C)
SDF_COND(!B | !C) DELAY(ioDelayRiseModel2) SLEW(SlopeRiseModel2) ) Path( A => Z 01 10 COND(~B | ~C)
SDF_COND(!B | !C) DELAY(ioDelayFallModel2) SLEW(SlopeFallModel2) ) . . . }
```

  Example Figure to Show How to Use the -from and -to Options

- The following command annotates a delay of `3.0` to arcs `arc1`, `arc2`, and `arc3` for the rise and fall transition at the pin I1/Z, for the two corners `{min typ max}`: `set_annotated_delay 3.0 -from A -to Z -cell`
- The following command annotates a delay of 2.5 to net arc `arc4` for both the rising and the falling transition and for the two corners `{min typ max}`: `set_annotated_delay 2.5 -from I1/Z -to I2/A -net`
- The following command annotates a delay of 1.5 to `arc2` for the rising transition and the min corner:
  `set_annotated_delay 1.5 -from I1/A -to I1/Z -rise -min -cond "B & C" -cell`
- The following commands annotate a delay of 3.0 to `arc1` and `arc2`, and a delay of 2.4 to the `arc3`:

```
set_annotated_delay 3.0 -from I1/A -to I1/Z -cell set_annotated_delay 2.4 -from I1/A -to I1/Z -cond {!B | !C} -cell
```

- The following commands first annotate a delay of 3.0 to `arc1`, `arc2` and `arc3`, then overwrite the value set by the first `set_annotated_delay` command: `set_annotated_delay 2.4 -from I1/A -to I1/Z -cond {!B | !C} -cell set_annotated_delay 3.0 -from I1/A -to I1/Z -cell`

Related Commands

- `reset_annotated_delay`

set_annotated_transition

```
set_annotated_transition
[-rise | -fall]
[-min | -max]
slew_value
pin_list
```

Sets the transition time to be annotated on specified ports or pins in the current design. The transition time that you specify using this command overrides the transition time calculated internally within the software. You can use this command to set the transition time of internal cell instance pins.

Parameters

`-min | -max`	Specifies whether the transition value is set for minimum or maximum transition time. *Default:* Transition value is set for both transition times.
pin_list	Specifies a list of pins or ports to be annotated with the transition time that you specify using the *slew_value* parameter.
`-rise | -fall`	Specifies whether the transition value is set for rising or falling transition time. *Default*: Transition value is set for both transitions.
slew_value	Specifies the transition time to be annotated to the selected pins or ports.

Examples

- The following command annotates a transition time value of 0.6 on port A:
  `set_annotated_transition 0.6 [get_ports A]`
- The following command annotates a transition time value of 0.7 on pin I2/A: `set_annotated_transition 0.7 [get_pins I2/A]`
- The following command annotates a transition value of 0.7 on pin I2/A for rising transition time:
  `set_annotated_transition -rise 0.7 [get_pins I2/A]`
- The following command annotates a transition value of 0.7 on pin I2/A for rising transition time and minimum pvt corner: `set_annotated_transition -rise -min 0.7 [get_pins I2/A]`

Related Commands

- set_input_transition

set_aocv_interface_path_offset

```
set_aocv_interface_path_offset
derateOffsetVal
[lib_cells]
[-view view_name]
[-delay_corner dc_corner_name]
[-cell]
[-net]
-power_domain power_domain_name_list
```

You can perform path-based inter power domain (IPD) timing analysis by specifying derate offset value for an entire power domain(s) and specific library cell(s) on paths crossing multiple power domains. This feature is supported for path-based analysis (PBA) mode only.

The `set_aocv_interface_path_offset` command allows you to specify the derate offset value for path segments crossing multiple power domains. The software adds the derate offset value to the AOCV derate value if the combined (AOCV + IPD offset) derate number causes pessimistic PBA timing slack value.

Parameters

`-cell`	It is a boolean option. When the -cell option is specified, intent is to apply “derate offset” only for that cell objects. In absence of these options, derate offset value will be applied to both cell and net type of objects
`-delay_corner dc_corner_name`	Specifies a list of delay corners.
derateOffsetVal	Specifies value of derate offset.
lib_cells	Specifies a list of library cells for a specific interface.
`-net`	It is a boolean option. When the -net option is specified, intent is to apply “derate offset” only for that net objects. In absence of these options, derate offset value will be applied to both cell and net type of objects
`-power_domain power_domain_name_list`	Specifies a list of power domains.
`-view view_name`	Specifies a list of views.

Examples

- The following example specifies the offset derate value of `-0.6` for the power domain `{PD3 PD4}`:
  set_aocv_interface_path_offset -0.6 -power_domain {PD3 PD4} -delay_corner V1_PM1_dc

set_aocv_stage_weight

```
set_aocv_stage_weight
stage_weight
port_list
[-early]
[-late]
[-input]
[-output]
```

While performing advanced on-chip variation (AOCV) analysis of a block in standalone mode, the command allows you to specify the stage weight seen at the port(s) when it is modeled as part of the top level design. The applied stage weights affect the internal weight count of the block for the IO paths. The stage weights can be applied only on ports.

You can view stage weights in the `report_timing` output under the `Stage Weighting` column.

The `set_aocv_stage_weight` command can be used in multi-mode multi-corner mode. The command can be used as part of SDC file.

Parameters

`-early`	Specifies weight for early paths.
`-input`	Specifies input weight for the ports.
`-late`	Specifies weight for late paths.
`-output`	Specifies output weight for port.
`port_list`	Specifies a list or collection of input, output, and bidi ports.
`stage_weight`	Specifies value of stage weight.

Examples

- The following example specifies the stage weight value as `25.5` for port `out0`:

  ```
  set_aocv_stage_weight 25.5 out0
  ```

Related Information

- `reset_aocv_stage_weight`

set_case_analysis

```
set_case_analysis
[-help]
{0 | 1 | zero | one | rising | falling | rise | fall | non_switching}
list_of_ports_or_pins
```

Sets constant or transitional values to a list of pins or ports for use by the timing engine. The specified constants or transitional values are valid only during timing analysis and do not alter the netlist. If there is a conflict between the specified `set_case_analysis` value and the logical value from the netlist, the value from the `set_case_analysis` is used in timing analysis.

Parameters

`0 | 1 | zero | one`	Specifies a logic value of `0` or `1`, which is propagated through combinational logic to disable or enable parts of logic.
`non_switching`	Marks the nets that are in a constant, non-transitioning state. This marking can be used when nets are considered static without the additional impact of logic state injection into the analysis, e.g., when modes are merged into a single constraint mode. The `report_cell_instance_timing` and `report_case_analysis` command reports show non-switching as constant values.
`rising | falling | rise | fall`	Specifies a valid transition value to be considered by the timing engine. For example, if a rising value is specified at a certain pin or port, only the rising signal transition from the pin or port is considered for timing analysis and the opposite transition type (falling) is ignored.
`list_of_ports_or_pins`	Specifies a list of ports or pins on which to apply the constant or transitional value. Specify multiple pins by enclosing them with curly braces `{}`and separating the pin names with white space. The *`list_of_ports_or_pins`* argument can be a collection.

Examples

- The following command sets the value of pin i4/A to `1` for use by the timing engine:
  ```
  set_case_analysis 1 i4/A
  ```
- The following example shows that the pins P1/P2/B and P1/P3/CI are considered only for a rising transition. The falling transition on these pins is ignored:
  ```
  set_case_analysis rising {P1/P2/B P1/P3/CI}
  ```

set_clock_exclusivity

```
set_clock_exclusivity
[-help]
[-exclude_opposite_polarity]
[-exclude_related_input_pins]
[-exclude_same_polarity]
[-group clock_list]
pin_name
```

Controls filtering of mutually-exclusive clocks at strategic points in the design, e.g., the output of clock multiplexers.

Parameters

`-help`	Prints out the command usage.
`-exclude_opposite_polarity`	Isolates positive and negative phases of the clocks in the same group. By default, the positive and negative phases of the clocks in the same group that arrive at a strategic point will not be isolated from each other.
`-exclude_related_input_pins`	Allows comparison of clocks going through the same input pins of the specified gate.
`-exclude_same_polarity`	Allows comparison of clocks going through the same launch or capture paths.
`-group` *clock_list*	Defines a set of clocks that are exclusive to the clocks defined in all other groups.
pin_name	Specifies the name of the pin.

Examples

- The following command will cause downstream analysis from the mux to isolate interactions between the groups:
  ```
  set_clock_exclusivity -group {CLK1 CLK2} -group {CLK3 CLK4} U1/Y
  ```

  This assertion will cause downstream analysis from pin `U1/Y` to isolate interactions between the groups. The groups `{CLK1 CLK2}` and `{CLK3 CLK4}` are allowed, but all other combinations are considered logically exclusive.

Related Commands

- `reset_clock_gating_check`
- `create_clock`

set_clock_gating_check

```
set_clock_gating_check
[-help]
[object_list]
[-fall]
[-hold hold_value]
[-rise]
[-setup setup_value]
[-high | -low]
```

Specifies or overrides the default setup and hold values for clock gating checks.

Parameters

`-help`	Prints out the command usage.
`-high | -low`	Specifies that the non-controlling value of the clock is high or low. Timing analysis performs the check on the non-controlling value of the clock. By default, the software determines the non-controlling value of the clock using information from the gate's logic. For example, for OR gates the non-controlling value is low. For complex gates, such as XOR and MUX, the clock is never controlling and it does not perform checks unless you specify either the `-high` option or the `-low` option. The specified value takes precedence over the default values. This option can only be used with pins or instances. **Note**: The clock pin value is controlling if it causes the gate output to be a constant (`0` or `1`).
`-hold hold_value`	Specifies the hold value. The default is `0.0`.
`object_list`	Specifies a list of clocks, instances, or pins. If a clock is specified, the check applies to all the clock gating gates driven by this clock. If an instance is specified, the check applies to all input pins of the instance. If the *`object_list`* argument is not specified, the clock gating check is applied to the current design. **Note**: The SDC `set_clock_gating_check` asserts checks on ICG (Integrated Clock Gated) cell only if it is applied on either the cell itself or pins. It does not assert checks on ICG cells if `set_clock_gating_check` is applied on a design or clock object.
`-rise | -fall`	Applies the specified setup (or hold) value to the rising (or falling) signals on the specified pins. If the clock is specified or the *`object_list`* variable is not specified, the value applies to rising or falling, setup or hold. If neither option is specified, the default is both rising and falling.
`-setup setup_value`	Specifies the setup value. The default is `0.0`.

Note: The clock gating constraint is not propagated along the clock tree.

The setup check is performed with respect to the edge of the clock signal that changes the state of the clock pin from controlling to non-controlling. For example, for AND and NAND gates, the setup check is performed with respect to the rising edge of the clock input. For OR and NOR gates, the setup check is performed with respect to falling edge of the clock input.

The hold check is performed with respect to the edge of the clock signal that changes the state of the clock pin from non-controlling to controlling. For example, for AND and NAND gates, the hold check is performed with respect to the falling edge of the clock input. For OR and NOR gates, the hold check is performed with respect to rising edge of the clock input.

If the gate logic in unknown, setup and hold checks are performed with respect to both the rising edge and the falling edge of the clock signal and the timing analyzer uses the worst case values.

Priority Rules for Determining Setup or Hold Values

Timing analysis uses the following priority rules to determine the setup (or hold) value to use for a particular clock gating check:

1. Use the clock gating check assertion on the data pin if it exists
2. Otherwise, use the clock gating check assertion on the clock pin if it exists
3. Otherwise, use the clock gating check assertion on the clock waveform for the clock pin if it exists
4. Otherwise, use the global clock gating check assertion if it exists
5. If no clock gating check assertion is present, use the default setup (or hold) value of `0.0`.

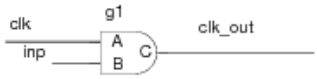
These rules are demonstrated in the examples below.

Note: This command has no effect on a clock gating check defined as a non-sequential setup or hold check in the library and reported as `ClockGatingSetup` or `ClockGatingHold`.

Examples

- The following example shows the priority rules for multiple clock gating check constraints for the gated clock shown in figure below.

Figure: **Gated Clock**



Example: **Tcl Script for set_clock_gating_check**

```
create_clock -name CLK1 -period 12 -waveform {0 6} clk
...
# clock-gating timing check assertions:
# On ideal clock waveform
set_clock_gating_check -setup 0.44 [get_clocks {CLK1}]
# On clock pin
```

```
set_clock_gating_check -hold 0.11 [get_pins {g1/A}]
# On data pin
set_clock_gating_check -setup 0.66 -rise [get_pins {g1/B}]
set_clock_gating_check -hold 0.22 -fall [get_clocks {g1/B}]
```

Given the previous constraints, the following timing margins are used for slack calculation:

- `SETUP g1/B rise: 0.66` -- from assertion on data pin `g1/B` (rule 1)
- `SETUP g1/B fall: 0.44` -- from assertion on ideal clock `CLK1` (rule 3)
- `HOLD g1/B rise: 0.11` -- from assertion on clock pin `g1/A` (rule 2)
- `HOLD g1/B fall: 0.22` -- from assertion on data pin `g1/B` (rule 1)

- `reset_clock_gating_check`

set_clock_groups

```
set_clock_groups
[-name name_list]
[-comment string]
[-logically_exclusive] | [-physically_exclusive] | [[-asynchronous]
   [-allow_paths]]
[-group clock_list]
```

Defines clock groups with specified clock definitions. The software assigns all clocks that are defined after you use the set_clock_groups command to a default clock group. The software does not apply clock groupings on a master clock to the generated child clocks.

If there is an overlap in the clock group specification, the software uses the following precedence to resolve the behavior:

1. Physically exclusive
2. Asynchronous
3. Logically exclusive

The software drops any explicit false path assertions between clocks that you have set as either physically or logically exclusive or asynchronous using the set_clock_groups command.

An alternative to setting the clocks as physically or logically exclusive using the `set_clock_groups` command is to use the multi-mode mechanism. Generally in an implementation flow, sequential setting of active clocks cannot be used. For concurrent analysis of different modes, you can use an multi-mode based approach to drive IPO instead of using the `set_clock_groups` command.

For more information on multi-mode multi-corner analysis, see *Importing and Exporting Designs* chapter in the *Innovus User Guide*.

Parameters

`-allow_paths`	Allows paths between asynchronous clock groups to be traced in timing analysis. These paths are blocked by default. When you use this option, the software still considers the paths to be asynchronous for signal integrity considerations. Signal integrity analysis does not support the `-allow_paths` parameter. Use the `-allow_paths` parameter with the `-asynchronous` parameter.
`-asynchronous`	Defines clock group with asynchronous clocks. Asynchronous clocks have no specified phase relationship. The software considers asynchronous nets to have infinite timing window overlap for signal integrity considerations and considers these as false paths for timing analysis. Use the `-allow_paths` parameter to trace these paths in timing analysis.
`-comment string`	Allows you to insert comments. The comments are read but are ignored with a one-time warning message. They are not used during timing analysis reporting nor are they written out during saving of constraints.

`-group` *clock_list*	Defines a set of clocks that are exclusive or asynchronous to the clocks defined in all other groups. If you define only one group, then all clocks not in the group implicitly belong to a default clock group. The software automatically adds any new clocks that you define after the `set_clock_groups` command to this default clock group.
`-logically_exclusive`	Defines clock group with clocks that do not have any functional paths between them, but coexist in the design at the same time. The software considers aggressor interactions between these clocks for signal integrity considerations, but considers these as false paths for timing analysis. **Note:** The `-logically_exclusive` parameter does not have any impact on SI analysis. For example, clocks selected via a clock mux select.
`-name` *name_list*	Specifies the names of the clock groups to be added.
`-physically_exclusive`	Defines clock group with clocks that cannot exist in the design at the same time. The software does not consider aggressor interactions between clock groups that are physically exclusive for signal integrity considerations. From the perspective of SI analysis, all attackers that are physically exclusive with the victim net are ignored for both glitch and noise-on-delay analysis. Attacker nets that belong to physically exclusive groups cannot attack together. In this case, all sets of attackers belonging to all the physically exclusive groups are evaluated and the set of nets that has the highest impact on SI analysis is chosen. For timing analysis, the software considers these clock groups as false paths. Example: multiple clocks defined on the same source pin

Examples

- The following commands assert two different clocks on the same clock root port, and uses set_clock_group to isolate them from each other:

```
create_clock -name SYSCLK -period 10 [get_ports sclk]

create_clock -name SCANCLK -period 100 -add [get_ports sclk]

set_clock_groups -name PHY_EX_SCLK -physically_exclusive

-group {SYSCLK} -group {SCANCLK}
```

- The following command declares a single bus clock to be asynchronous to all of the other on board clocks in the design (which remain in the default clock group):

```
set_clock_groups -name ASYNCH_BUS -asynchronous -group {BUSCLK}
```

- The following example shows that the clock group {clkA clkB} is asynchronous only to clock group {clkC clkD}:

```
set_clock_groups -asynchronous -group {clkA clkB} -group {clkC clkD}
```

If an extra clock clkE is defined in the design, then timing check will be allowed in between the first group to clkE

and second
group to clkE.

- In the following example since only one clock group is specified with the command `set_clock_groups`command, so the specified clock group is considered to be asynchronous to all the other clocks in the design:

```
set_clock_groups -asynchronous -group {clkA clkB}

set_clock_groups -asynchronous -group {clkC clkD}
```

Related Information

- `create_clock`
- `reset_clock_groups`

set_clock_latency

```
set_clock_latency
[-source [-early | -late]]
[-rise]
[-fall]
[-jitter jitter_val]
[-clock clock_list ]
[-min]
[-max]
[-clock_gate]
latency
pin_or_clock_list
```

Specifies ideal internal clock latency and external clock arrival delay.

Clock latency has two components:

- Source latency:
  - Specified using the `-source` parameter and is the delay from the external clock generator to the clock port of the design.
  - Applied when the clock is either ideal or propagated.
  - `set_clock_latency` set on a clock port has higher precedence than `set_clock_latency` set on a clock waveform.
  - Specified on clock waveforms with both the `set_input_delay` command and the `set_output_delay` command.
- Network latency (clock tree delay):
  - Default latency type and is the delay from the clock port to the register.
  - Applied only when the clock is ideal. When the clock is propagated, this delay is replaced by the actual clock tree delays.
  - Specified on a clock waveform or a clock port is ignored if the clock is propagated.
  - `set_clock_latency` set on a timing pin has higher precedence than `set_clock_latency` set on a waveform.
  - If there are multiple `set_clock_latency` and `set_propagated_clock` assertions between the clock waveform, clock root and clock endpoint, the closest assertion to the clock endpoint takes precedence.
  - Specified on internal circuit pins or hierarchical ports and used in the fanout cone of the network latency pin, when a clock is ideal.

Use the `set_clock_latency` command in two ways:

- To specify clock latency for a clock waveform:
  - Use the following syntax for source latency associated with a clock signal:
    `set_clock_latency [-source] [-early | -late] [-min ][-max] latency pin_or_clock_list`
  - Use the following syntax for network latency associated with a clock signal:

```
set_clock_latency [-min] [-max] latency pin_or_clock_list
```

You cannot specify the `-late` and `-early` parameters for network latency.

Specifying latency on a port or pin overrides any previous latency specified on the port pin or waveform. The *pin_or_clock_list* argument is the list of the clock waveform names as specified by the create_clock command.

- To specify clock latency on clock pins:
  - Use the following syntax for source delay on a clock port:
    ```
    set_clock_latency -source [-early | -late] [-rise] [-fall]
    insertion_delay pin_or_clock_list
    ```
  - Use the following syntax for network delay on a clock pin:
    ```
    set_clock_latency [-min] [- max] [-rise] [-fall]
    insertion_delay -pin pin_or_clock_list
    ```

When a clock is ideal, the last specification along a path is used. This is useful when you want to intentionally skew the clock tree and model the physical hierarchical clock tree.

Parameters

`-clock` *clock_list*	Associates clock latency constraints, placed at the pin level, with a specific clock. This makes it possible to specify a different latency per clock. **Note:** You cannot use the `-clock` parameter with clock waveform objects.
`-clock_gate`	Allows setting the local clock latency value on pin or port objects. This setting overwrites the existing latency value of clock gating cells and is used when performing timing checks against the specified pins or ports.
`-early | -late`	Specifies clock arrival time with respect to the early or the late time of the clock signal. In setup analysis, launch path is the late path and capture path is the early path. In hold analysis, launch path is the early path and the capture path is the late path. If neither parameter is specified, the default is both early and late. Use these parameters only with the `-source` parameter. You cannot use these parameters with network latency. Specify the clock latency at the given operating corner. **Note:** The `-min` and `-max` parameters refer to the operating corner and the `-early` and `-late` parameters refer to the clock arrival time at the source. Use the `-early` and `-late` parameters with the `-source` parameter to specify the four different clock latencies.
`-jitter` *jitter_val*	Specifies the portion of source clock latency value that can have cycle-to-cycle variation. When calculating CPPR adjustment this portion is removed from CPPR adjustment for different clock edge checks (e.g., setup), but it remains as part of cppr adjustment for same clock edge checks (e.g., hold).

latency	Specifies the value of the latency, in library units, as a floating point.
pin_or_clock_list	Specifies a list of clock waveform names or a list of pins to associate with the clock latency. The pin can be a port or an instance pin. Setting source latency on a pin is ignored.
-max	Specifies the clock latency for a particular operating corner. Apply the -max parameter to the maximum operating corner.
-min	Specifies the clock latency for a particular operating corner. Apply the -min parameter to the minimum operating corner.
-rise/ -fall	Specifies the -rise or -fall parameter to the waveform at register clock pins for ideal latency and to the waveform at the source for source latency. Ideal network latency does not change polarity when crossing negative unate arcs.
-source	Specifies a source latency. If you do not specify the -source parameter, network latency is applied.

Examples

- The following set of commands enable you to create a clock using the create_clock command and apply latency to the created clock using the set_clock_latency command:

```
create_clock CLK2 -period 20 [get_ports {clkA clkB clkD}]

set_clock_latency -source 2 {clkB clkD} # Define port settings
set_clock_latency -rise 5 {clkB clkD} # Define port settings
set_clock_latency -early -late -source CLK1 # Define waveform settings
set_clock_latency 3 -early -late -source CLK1 # Define waveform settings
```

set_clock_sense

```
set_clock_sense
[-help]
pin_or_port_list
[-clocks clock_list]
{-positive | -negative | -stop_propagation | -logical_stop_propagation | -stop type_list}
```

Selects which phase of the clock to filter at the specified point.

Parameters

`-help`	Prints out the command usage.
`-clocks clock_list`	Specifies a list of clocks passing through a specified point to which the constraint applies. When this parameter is not specified, the filtering of clock phase will be applicable to all the clocks passing through that specified point. This parameter must be used with a specified pin name and one of the parameters : `-positive`, `-negative`, `-stop_propagation`, `-logical_stop_propagation`, or `-stop`.
`-logical_stop_propagation`	Stops the propagation of specified clocks passing through the specified pins.
`-negative`	Specifies that positive phase filtered clocks pass through pins in the *pin_list*.
pin_or_port_list	Specifies the list or collection of cell output pins. The unateness specified by the set_clock_sense command is applied to clocks propagating through the specified point.
`-positive`	Specifies that negative phase filtered clocks pass through pins in the *pin_list*.
`-stop_propagation`	Stops the propagation of specified clocks and clock source data paths passing through the specified pins.

`-stop` *`type_list`*	Applies clock sense to object types specified in the *`type_list`*. The type list options are - `all`, `clock`, `data`, `clock_source_data`, `default_data`. These are explained below: • `all`: Stops all phases from propagating. This is equivalent to specifying both the `clock` and `data` options. • `clock`: Stops clock phases launched by clock(s) specified in the *`clock_list`* from propagating, and is equivalent to existing `-logical_stop_propagation`. • `data`: Stops all data phases launched by clock(s) specified in *`clock_list`*, starting from the pins/ports specified in *`pin_or_port_list`*. The objects in the *`pin_or_port_list`* can be selected anywhere in the design - clock/data network. • `clock_source_data`: Stops only clock source data phases from propagating. The combination of `clock_source_data` and `clock` is equivalent to the existing `-stop_propagation` option. • `default_data`: Stops only default data phases (representing constrained paths) from propagation. This option cannot be specified along with the *`-clock clock_list`*. The `-stop` parameter extends the capability of the `set_clocks_sense` command to selectively block data timing phases. This parameter provides a more generalized use model for selecting among all types of paths that should be filtered. The `-stop` parameter is mutually exclusive with the `-positive`, `-negative`, `-stop_propagation`, and `-logical_stop_propagation` options.

Examples

- The following command stops the propagation of clock CLK1 through the pin CLKBUF1/Z:
  ```
  set_clock_sense -logical_stop_propagation -clocks CLK1 CLKBUF1/Z
  ```
- The following command allows the positive phase clock CLK1 to pass through CLKBUF1/Z and filters out the negative phase clock CLK1:
  ```
  set_clock_sense -positive -clocks CLK1 CLKBUF1/Z
  ```
- The following command stops clock phases starting from pin1:
  ```
  set_clock_sense pin1 -stop {clock}
  ```
  or
  ```
  set_clock_sense pin1 -logical_stop_propagation
  ```
- The following command stops data phases based only on CK1 and CK2 starting from pin1:
  ```
  set_clock_sense pin1 -stop {data} -clocks {CK1 CK2}
  ```
- The following command stops only the clock source data phases starting from pin1:
  ```
  set_clock_sense pin1 -stop {clock_source_data}
  ```
- The following command stops the clock and clock source data phases:
  ```
  set_clock_sense pin1 -stop {clock clock_source_data}
  ```
  or
  ```
  set_clock_sense pin1 -stop_propagation
  ```

Related Information

- reset_clock_sense

set_clock_transition

```
set_clock_transition
[-rise]
[-fall]
[-min]
[-max]
[-min |-max]
slew_time
clock_list
```

Specifies the slew time of register clock pins. This is useful for pre-layout static timing analysis before clock tree synthesis (CTS) is performed since net delays can be inaccurate with large fanout nets.

Use this command only with ideal clocks. In propagated mode, the software calculates slew times on register clock pins.

Parameters

clock_list	Specifies a list of clocks only with ideal mode in the design, which affects the slew times on all register clock pins in the transitive fanout of the specified clocks. Specified `set_clock_transition` values on register clock pins in the fanout of a clock with propagated latency are ignored.
`-rise | -fall`	Specifies the rising or falling edge of the register clock pins on which the slew time is asserted.
`-min | -max`	Specifies the clock slew time for minimum or maximum process corner slew time.
slew_time	Specifies the slew time (transition time) of the clock pins.

Example

- The following commands specify a `2.0` rise slew time and a `1.0` fall slew time for register clock pins clocked by `CLKA`: set_clock_transition -rise 2.0 [get_clocks CLKA] set_clock_transition -fall 1.0 [get_clocks CLKA]

set_clock_uncertainty

```
set_clock_uncertainty
uncertainty_value
[-setup]
[-hold]
[-half_cycle_jitter | -full_cycle_jitter]
[-rise | -fall]
{  {-from | -rise_from | -fall_from} clksig_from_list
   {-to | -rise_to | -fall_to} clksig_to_list
 | pin_or_clock_list
}
```

Specifies the clock uncertainty (skew) on the clock network.

If you set multiple constraints with the `set_clock_uncertainty` command, the constraints set with the `-from*` *`clksig_from_list`*/`-to*` *`clksig_from_list`* parameters take precedence over simple constraints set on clock objects.

Clock uncertainty set on pins takes highest precedence and overrides clock based uncertainty.

The `set_clock_uncertainty` command can also support clock uncertainty for period, pulse width, skew, and separation checks. To enable this feature, you need to set `timing_enable_uncertainty_for_clock_checks` global variable to `true`. By default, the global is set to `false`.

Parameters

`uncertainty_value`	Specifies the uncertainty value.
`-from | -rise_from | -fall_from` *`clksig_from_list`*	Applies the uncertainty value to the specified list of launching clocks. **Note:** You must specify one of these parameters with one of the `-to`, `-rise_to`, or `-fall_to` parameters. You cannot use these parameters when *`pin_or_clock_list`* is specified.
	`-fall_from`: Applies the uncertainty value only to the falling edge of the launching clocks.
	`-from`: Applies the uncertainty value to both the rising and falling edges of the launching clocks.
	`-rise_from`: Applies the uncertainty value only to the rising edge of the launching clocks.
`-half_cycle_jitter` *`value`* `| -full_cycle_jitter` *`value`*	Specifies the clock source jitter for half-cycle and for full-cycle paths. These parameters can accept different values, that can be specified in the same constraint. **Note**: These parameters can be used on clocks only. You cannot use them when any of the `-from` and `-to` parameter pairs are specified.

pin_or_clock_list	Specifies a list of clocks or pins for target uncertainty. The uncertainty value is applied to the registers clocked by the target waveform, or register pins in the fanout of the specified pin. You can specify a list of clock names, or clock root pin or port names relative to the current module. You also can specify a collection of clocks, or clock root pins or ports. **Note:** You cannot use this parameter when any of the `-from` and `-to` parameter pairs are specified.
`-rise | -fall`	Specifies the rising or falling edge at the capture clock pin on which the uncertainty is applied. *Default*: Applies uncertainty on both edges **Note:** You must use these parameters with the `-to` and `-from` parameters.
`-setup/-hold`	Specifies whether the clock uncertainty applies to setup or hold checks. *Default*: Applies to both setup and hold check
`-to | -rise_to | -fall_to` *clksig_to_list*	Applies the uncertainty value to the specified list of capture clocks. **Note:** You must specify one of these parameters with one of the `-from`, `-rise_from`, or `-fall_from` parameters. You cannot use these parameters if *pin_or_clock_list* is specified.
	`-fall_to`: Applies the uncertainty value only to the falling edge of the capture clocks.
	`-rise_to`: Applies the uncertainty value only to the rising edge of the capture clocks.
	`-to`: Applies the uncertainty value to both the rising and falling edges of the capture clocks.

Examples

- The following command gives all paths starting from registers clocked by `clk1` to registers clocked by the rising edge of `clk2` a hold uncertainty of `2.0`:

  ```
  set_clock_uncertainty 2.0 -from clk1 -to clk2 -rise -hold
  ```

  In case of multiple constraints, the actual uncertainty applied by the software depends on which constraint matches the specific path in question.

- The following command sets an uncertainty on the `clk_in` clock root pin that is applied to all the register pins in the fanout of `clk_in`:

  ```
  set_clock_uncertainty 1.2 clk_in
  ```

- The following command specifies an inter-clock uncertainty of `0.2` between clock waveforms `clk1` and `clk2`:

  ```
  set_clock_uncertainty 0.2 -from clk1 -to clk2
  ```

- The following command specifies a target uncertainty of `0.5` for all registers clocked by the clock waveform

`ideal_clk1`:

```
set_clock_uncertainty 0.5 ideal_clk1
```

Related Information

set_data_check

```
set_data_check
[-help]
<check_value>
[-clock <clock_object>]
[-hold]
[-setup]
{-from <pin_or_port_list> | -rise_from <pin_or_port_list> | -fall_from <pin_or_port_list>}
{-to <pin_or_port_list> | -rise_to <pin_or_port_list> | -fall_to <pin_or_port_list>}
```

Sets data-to-data checks using the specified values of setup and hold time. Data-to data checks are non-sequential checks that are designed to constrain a data signal with respect to another data signal.

In a normal sequential check, a data signal is constrained with respect to a clock signal. In these cases single-cycle timing is used - allowing one full clock cycle for the data transfer. In a non-sequential data-to-data check, there is no clock reference. Therefore, zero-cycle timing rules are used. You can use the `set_multicycle_path` constraint to adjust the cycle accounting rules.

Parameters

`-clock` *clock_object*	Specifies the name of the clock that triggers the data event for the related (`-from`) pin. In the case where there are multiple data events triggered by different clock phases arriving at the `-from` pin, the `-clock` parameter allows you to specify which data event should be used for the "related pin" side of the timing check.
{`-from` <*pin_or_port_list*> | `-rise_from` <*pin_or_port_list*> | `-fall_from` <*pin_or_port_list*>}	Specifies the pins or ports that are set as related pins for data-to-data checks. The *pin_or_port_list* argument can contain either object IDs or hierarchical names relative to the current module. Use only one `-from`, `-rise_from`, or `-fall_from` parameter per command. By default, the `-from` parameter checks both the rising and the falling edges. Using `-rise_from` parameter checks at the rising edge of the signal on the from pins. Using `-fall_from` parameter checks at the falling edge of the signal on the from pins. **Note:** You cannot use the `-from` parameter to specify multiple objects.
`-setup` | `-hold`	Specifies whether the data check value is for setup or hold check. If you do not specify either `-setup` or `-hold` option, the value applies to both setup and hold.
{`-to` <*pin_or_port_list*> | `-rise_to` <*pin_or_port_list*> | `-fall_to` <*pin_or_port_list*>}	Specifies the pins or ports that are set as constrained pins for data-to-data checks. The *pin_or_port_list* argument can contain either object IDs or hierarchical names relative to the current module. Use only one `-to`, `-rise_to`, or `-fall_to` parameter per command. By default, the `-to` parameter constrains both the rising and the falling edges. Using `-rise_to` parameter constrains the rising edge of the signal on the to pins. Using `-fall_to` parameter constrains the falling edge of the signal on the to pins.
check_value	Specifies the value of the setup or hold time for the check.

Examples

- The following example demonstrates how the `set_data_check` command can be used to constrain signals: Consider two control signals, say XE and SE, going to a macro block. Both of these are derived from the same state machine, and hence launched from the same clock domain. You want XE to reach the macro earlier than SE. The `set_data_check` constraint can meet this design intent, by applying data checks on non-sequential signals, without setting path specific limits using the following command:

  ```
  set_data_check -from [get_pins {sub/SE}] -to [get_pins {sub/XE}] -setup 0.5
  ```

  The `set_data_check` command establishes data-to-data checks using similar ideas of setup and hold time as in sequential checks, with the `-from` parameter denoting the reference signal (the clock in a traditional setup/hold timing check), and the `-to` parameter indicating the signal being constrained.

Related Commands

- `reset_data_check`

set_disable_clock_gating_check

```
set_disable_clock_gating_check
object_list
```

Disables clock gating checks for the specified instances or pins.

The `set_disable_clock_gating_check` command has a character limit for the details that are logged into the SDC file (the `writeTimingCon` command output). This helps to prevent SDC file errors.

Parameters

object_list	Specifies the list of pins or instances that are to be disabled.

Examples

- The following command disables clock gating checks for the specified instance:
  ```
  set_disable_clock_gating_check [get_cells clockgate1]
  ```

Related Commands

- `reset_disable_clock_gating_check`

set_disable_timing

```
set_disable_timing
[-from pin_name -to pin_name]
object_list
```

Disables timing propagation through the specified arcs, or a collection of instance-specific arcs that are created using the `get_arcs` command.

Parameters

`-from pin_name -to pin_name`	Specifies the arc that is to be disabled. Specify the `-from` and `-to` options together. You can specify the `-from` and `-to` parameters when the *`object_list`* contains instance or library cell objects. Do not specify the `-from` and `-to` parameters when the *`object_list`* includes instance pin or library cell pin objects. The `-from` and `-to` options are optional. If not specified, all cell arcs found in the instance or library cell objects are disabled.
`object_list`	Specifies the instance, instance pin, library cell, library cell pin objects, collection of library arcs, or collection of timing arcs. If the *`object_list`* includes instance pin or library cell pin objects, all cell arcs attached to the specified pin objects are disabled. If the *`object_list`* contains instance or library cell objects, and the `-from` and `-to` parameters are not specified, all arcs found in the specified instance or library cell objects are disabled.

Examples

- The following command disables the arcs that lead to the output pins of the `i1`, `i2`, and `i3` instances. Note that timing checks at the inputs of `i1`, `i2`, and `i3` are still active. `set_disable_timing [get_cells {i1 i2 i3}]`
- The following command disables the arc from pin `B` to pin `Z` in the `i1` and `i2` instances, and the arc from pin `A` to pin `Z` in the `i3` instance: `set_disable_timing -from B -to Z [get_cells {i1 i2}]`
  `set_disable_timing -from A -to Z [get_cells {i3}]`
- The following example disables timing check arcs from pin `CLK` to pin `D` of the `ff1` instance: `set_disable_timing -from CLK -to D [get_cells ff1]`
- The following example disables the outgoing cell arcs from instance input pin `i1/B`: `set_disable_timing [get_pins i1/B]`
- The following example disables all arcs found in any instances whose reference cell is `AN2`: `set_disable_timing [get_lib_cells AN2]`

- The following example disables a collection of timing arcs:

```
set arcs [get_lib_arcs -from typical/MX2X1/S0 -to typical/MX2X1/Y]
set_disable_timing [index_collection $arcs 3]
```

- The following example disables arcs created using `filter_collection` on library timing arcs:

```
set arc [filter_collection $arcs {when == "((A)&(!(B)))"}]
set_disable_timing $arc
```

Related Information

- `report_timing`
- `reset_disable_timing`

set_dont_touch

```
set_dont_touch
object_list
[true | false]
```

Prevents the specified object from being modified during optimization. However, the specified object can be moved during optimization.

When the `set_dont_touch` command is set to `true`, the specified nets cannot be buffered or become part of the logic cone restructuring. However, you can resize the instances connected to this net because the `set_dont_touch` attribute does not affect the connected instances.

Parameters

`-help`	Prints out the command usage.
`true | false`	Sets or removes the `set_dont_touch` attribute for the specified *`object_list`*. *Default:* `true`
`object_list`	Specifies the list of instances, nets, library cells, or submodules.

Examples

- The following command prevents the specified instance from being modified:
  ```
  set_dont_touch [get_cells {TWA/FF1}]
  ```
- The following commands can be used to prevent any ECO inside RESULTS_CONV_INST hierarchical instance:
  ```
  set_dont_touch [get_cells RESULTS_CONV_INST/*] true
  set_dont_touch [get_nets RESULTS_CONV_INST/*] true
  ```
- The `set_dont_touch RESULTS_CONV_INST/* true` command will return `[get_cells RESULTS_CONV_INST/*]` only. This is because the software looks into the first match (type of object). If a match is not found, then the successive objects are searched.

Related Commands

- `get_cells`

set_dont_touch_network

```
set_dont_touch_network
[-help]
obj_list
[-no_propagate]
```

Prevents the combinational path connected to the given clocks, pins, or ports from being modified.

Parameters

`-help`	Prints out the command usage.
`object_list`	Specifies the objects - clocks, pins, or ports - to be preserved.
`-no_propagate`	Preserves all the nets driven by the specified pin up to the first leaf-cell input (combinational or sequential). If this parameter is omitted, then preserving stops at the first sequential cell in the network.

Examples

- The following command prevents the combinational path connected to the specified pin from being modified:
  ```
  set_dont_touch_network [get_pins and1/z]
  ```

Related Commands

- `get_pins`

set_dont_use

```
set_dont_use
[-help]
object_list
[true | false]
```

Prevents the specified design, hierarchical module, or library cells from being used during optimization. However, optimization is allowed to size out don't use cells if instances are already there in the initial netlist.

Parameters

object_list	Specifies the list of library cells.
true | false	Sets or removes the set_dont_use attribute for the specified object list. Default: true

Examples

- The following command prevents the specified library cell from being used during optimization:
  ```
  set_dont_use [get_lib_cells {and2}]
  ```

Related Commands

- get_lib_cells

set_drive

```
set_drive
[-rise] [-fall]
[-max] [-min]
resistance_value
port_list
```

Sets the drive resistance on the specified input and/or bidirectional ports of the top cell.

The drive resistance models the cell driving the port. This resistance is used to compute the load dependent delay and the slew at the specified ports. The load-dependent delay is added to the arrival times.

The load-dependent delay and the slew are computed by multiplying the drive resistance by the wire capacitance of the net connected to the port.

Use the report_ports command to view drive resistances asserted on ports.

Parameters

`-fall`	Specifies that the drive resistance is to be used for the falling transition at the specified ports. By default, if neither the `-rise` nor the `-fall` option are specified, the drive resistance applies to both the rising transition and the falling transition.
`-min`	Specifies that the drive resistance is to be used to compute the early path delay. By default, if neither the `-min` option nor the `-max` option is specified, the drive resistance applies to both the early path delay and the late path delay.
`-max`	Specifies that the drive resistance is to be used to compute the late path delay. By default, if neither the `-min` option nor the `-max` option is specified, the drive resistance applies to both the early path delay and the late path delay.
port_list	Specifies a list of input or bidirectional ports on which the drive resistance is set.
resistance_value	Specifies the value of the drive resistance. This value must be greater than or equal to zero. The drive resistance is in units found in the target technology library.
`-rise`	Specifies that the drive resistance is to be used for the rising transitions at the specified ports. By default, if neither the `-rise` option nor the `-fall` option are specified, the drive resistance applies to both the rising transition and the falling transition.

Example

- The following command sets a drive resistance of 2.0 for the early path, the late path, the rising and the falling transitions at the in1 and in2 ports and shows how drive resistances are reported using the report_ports command as shown in the example below:

```
tempus > set_drive 2.0 [get_ports {in1 in2}]
tempus > report_ports -type drive_resistance -pin [get_ports {in1 in2}]
```

  The following report is displayed:

```
-------------------------------------------------------------------
Early Late
-------------------------------------------------------------------
Pin     Dir   Assertion       Clock   Rise   Fall   Rise   Fall
Name                          Name
-------------------------------------------------------------------
in1    IN    drive_resistance *(D)(P) 2.000   2.000  2.000  2.000
in2    IN    drive_resistance *(D)(P) 2.000   2.000  2.000  2.000
-------------------------------------------------------------------
```

Related Commands

- all_inputs
- report_ports
- set_driving_cell
- set_input_transition
- set_load

set_driving_cell

```
set_driving_cell
[-library library_name]
-lib_cell cell_name
[-pin pin_name]
[-from_pin from_pin_name]
[-rise]
[-fall]
[-min]
[-max]
[-multiply_by factor]
[-no_design_rule]
[-input_transition_rise rise_slew_value]
[-input_transition_fall fall_slew_value]
port_list
```

Models the drive capability of an external driver connected to the input port. Use this command only for timing analysis. The command does not affect the electrical properties of the design, which means that the capacitance of the output pin of the driving cell does not add to the total capacitance of the input port.

To model the drive capability of the external driver, the timing analyzer computes an offset to the arrival time of an input, and changes the slew time used to compute the delay for the next cell. The timing analyzer computes the offset by subtracting the zero load delay from the total delay of the cell. The `set_driving_cell` command uses the offset value to identify a cell from the library to drive the specified input port(s).

This command overrides the set_drive command per port or per net, if it is the last command applied. Also, if the `set_driving_cell` command is set for a port, the set_input_transition command is ignored for that port. If you do not define drive using the `set_driving_cell` command, the software uses the default value defined in the configuration file. The default value is `0.1ps`.

Parameters

`-fall`	Annotates only the falling drive assertion. The default is to annotate both rise and fall delays.
`-from_pin` *from_pin_name*	Specifies the name of the input port of the driver cell that has an arc to the output port of the driver cell, which is connected to the input port of the design. This option is required only if there are multiple timing arcs in the driver cell from its input ports to its output ports, and the arcs from those pins have different drive characteristics. If you do not specify the `-from_pin` option, the default is to use the first timing arc found on the library cell.
`-input_transition_fall` *fall_slew_value*	Specifies the slew value for the falling signal at the input of the drive cell.
`-input_transition_rise` *rise_slew_value*	Specifies the slew value for the rising signal at the input of the drive cell.
`-lib_cell` *cell_name*	Specifies the name of the driver cell. This parameter supports wildcard patterns and collections.
`-library` *library_name*	Specifies the name of the library that contains the driving cell.
`-max`	Annotates only the late drive assertion. The default is to annotate both early and late.
`-min`	Annotates only the early drive assertion. The default is to annotate both early and late.
`-multiply_by` *factor*	Specifies a multiplier for the drive.
`-no_design_rule`	Does not allow transfer of design rules from the driving cell to the port. If you do not specify this option, the design rules (such as `max_capacitance`) of the library pin are applied to the port.
`-pin` *pin_name*	Specifies the name of the output port of the driver cell that drives the signal at the input port of the design. This option is required if there are multiple output ports on the driver. If there is only one output port on the driver cell, then using this option is not necessary.
port_list	Specifies the list of ports driven by the driver cell.
`-rise`	Specifies only the rising drive assertion is annotated.The default is to annotate both rise and fall delays.

Examples

The following command sets 'AND' cell (arc B -> Y) as the driving cell for the input port IN1:

```
set_driving_cell -lib_cell AND -from_pin B -pin Y IN1
```

Related Information

- all_inputs
- report_ports
- set_drive
- set_input_transition

set_false_path

```
set_false_path
[-hold | -setup]
[-rise]
[-fall]
{[{-from | -rise_from | -fall_from} from_list]
[{-through | -rise_through | -fall_through} through_list]
[{-to | -rise_to | -fall_to} to_list]}
```

Identifies false paths in a design, and breaks or disables specific instance timing arcs in a design.

To break combinational loops, use the set_disable_timing command instead of the `set_false_path` command.

The `set_false_path` command differs from the `set_disable_timing` command as follows:

- `set_false_path` command selectively disables the arrival time information depending on the precedence rules.
- `set_false_path` command does not affect constant values.
- `set_disable_timing` command physically snips a timing arc such that neither arrival times nor constant values propagate through it.
- `set_disable_timing` command is applied in all cases to valid timing arcs.

The `set_false_path -from fpin` command disables all timing paths whose source pin is an `fpin`. Similarly, the `set_false_path -to tpin` command disables all timing paths whose sink pin is a `tpin`. Using the `set_false_path -from fpin -to tpin` command disables all timing paths whose source is `fpin` and sink is `tpin`.

Specify a group of pins by enclosing the group with curly braces (`{}`) within one `set_false_path` command.

To set a false path for any path beginning at `p1` or `p2` and terminating at `t1` or `t2`, group the pins as follows:

```
set_false_path -from {p1 p2} -to {t1 t2}
```

Note: This method of pin grouping reduces the number of exceptions. Having large numbers of exceptions adversely impacts the run time of the timing analysis commands.

Parameters

`-fall`	Applies the assertion at the falling edge of the signal on the path end points.

`{-from | -rise_from | -fall_from} from_list`	Specifies a list of timing paths start points. The from_list argument can contain either object IDs or hierarchical names relative to the current module. The pins can be on intermediate hierarchical boundaries. The from_list argument can be a collection. The valid start points are: • Input port • Bidirectional port • Clock pin of sequential cell Clock pin of sequential cell is one of the following: • Structural clock pin that is part of latch or flip-flop. • Inferred clock pin in cells like macro cells. A pin is an inferred clock pin if it is associated with one of the following: • Reference end of setup check • Reference end of hold check • Reference end of removal check • Reference end of recovery check • Minimum period check • Minimum pulse width check • Pin associated with set_input_delay Specify one of the following:
	`-from`: Applies the false path constraint to all paths originating from the from_list list. If a clock is specified as the -from object, all primary inputs and registers clocked by that clock are used as start points. By default, the -from option applies the constraint to both the rising and the falling edges.
	`-rise_from`: Applies the false path constraint at the rising edge of the signal on the from pins.
	`-fall_from`: Applies the false path constraint at the falling edge of the signal on the from pins.
`-hold/-setup`	Sets false paths for either setup or hold analysis. Note: If you do not specify -setup or -hold, the software sets false paths for both setup and hold analysis.
`-rise`	Applies the assertion at the rising edge of the signal on the path endpoints.

`{-through | -rise_through | -fall_through} through_list`	Specifies a list of timing paths through points. The through_list argument can contain either object IDs or hierarchical names relative to the current module. The pins can be on intermediate hierarchical boundaries. The through_list argument can be a collection. Specify one of the following:
	`-through`: When you use this parameter without using the -from or -to options, the false path constraint is set for all paths that go through the specified pins. When you use it with both the -from and -to options, any path starting at any pin on the -from list and going through any point on the -through pin list and going to any point on the -to list is affected by the constraint. By default, the -through option applies the constraint to both the rising and the falling edges.
	`-rise_through`: Applies the assertion at the rising edge of the signal on the through pins.
	`-fall_through`: Applies the assertion at the falling edge of the signal on the through pins.
`{-to| -rise_to | -fall_to} to_list`	Specifies a list of timing paths end points. The to_list argument can contain either object IDs or hierarchical names relative to the current module. The pins can be on intermediate hierarchical boundaries. The to_list argument can be a collection. The valid end points are: • Output port • Bidirectional port • Data pin of sequential cell Data pin of sequential cell is one of the following: • Structural data pin that is part of latch or flip-flop. • Inferred data pin in cells like macro cells. A pin is an inferred data pin if it is associated with one of the following: • Signal end of setup check • Signal end of hold check • Signal end of non-sequential setup check • Signal end of non-sequential hold check • Signal end of removal check • Signal end of recovery check • Pin associated with set_external_delay • Data pin of clock gating cell Select from one of the following:

	`-to`: Applies the false path constraint to all paths ending in the -to pin list. If a clock is specified as the -to object, all primary outputs and registers clocked by that clock are used as endpoint. By default, the -to option applies the constraint to both the rising and the falling edges.
	`-rise_to`: Applies the false path constraint at the rising edge of the signal on the to pins.
	`-fall_to`: Applies the false path constraint at the falling edge of the signal on the to pins.

Examples

- The following command disables hold checking from `ff1` to `ff2`:

  ```
  set_false_path -hold -from ff1 -to ff2
  ```

- The following command sets all timing paths from `ff1/CK` to `D` input of `ff2` that pass through `u1/Y` and one or more of `u2/Y` and `u3/Y` as false paths:

  ```
  set_false_path -from ff1/CK -through {u1/Y} -through {u2/Y u3/Y} -to ff2/D
  ```

- The following command sets all timing paths from the rise of `ff1/CK` to `ff2/D` through one or more of `u1/Y` and `u4/Y` as false paths:

  ```
  set_false_path -rise_from ff1/CK -through {u1/Y u4/Y} -to ff2/D
  ```

set_fanout_load

```
set_fanout_load
[-help]
fanout_load
port_list
```

Specifies the fanout load on a set of ports.

The library instance pins can have fanout loads defined in the technology library. The fanout does not have specific units so it is assumed that a fanout as used by the constraints is consistent with the fanout defined in the technology libraries. If a pin or port has no fanout attribute, either from the constraints or from the technology library, then the fanout load will be zero. The fanout load is used only for design rule checking and does not impact the timing results.

Parameters

`-help`	Prints out the command usage.
`fanout_load`	Specifies the fanout load value for the port or ports.
`port_list`	Specifies the list of ports for which the fanout load is applied.

Examples

- The following command sets the fanout load of port `out` to `2`: `set_fanout_load 2 out`
- The following command sets the fanout load of ports `in1` and `in2` to `1`: `set_fanout_load 1 {in1 in2}`
- The following command sets the fanout load of element `3` of port `out` to `12`: `set_fanout_load 12 { out[3] }`
- The following command sets the fanout load of all the ports to `2`: `set_fanout_load 2 [get_ports *]`

set_ideal_latency

```
set_ideal_latency
[-help]
[-min]
[-max]
[-rise]
[-fall]
latency_value
object_list
```

Specifies the ideal latency to use for input or output leaf-cell pins and top-level ports that are part of an ideal network. These set a point delay on the specified object.

Note: You should specify `set_ideal_latency` with the `set_ideal_network` command to view the ideal latency result.

Parameters

`-help`	Prints out the command usage.
`-fall`	Specifies the ideal latency for the falling edge.
`latency_value`	Specifies the ideal latency value.
`-max`	Specifies the ideal latency for the maximum corner.
`-min`	Specifies the ideal latency for the minimum corner.
`object_list`	Specifies a list of objects - instance pins or ports.
`-rise`	Specifies the ideal latency for the rising edge.

Examples

- The following command adds an ideal latency of 1.5ns to the input pin A of cell FE_OFC413_scan_se:
  `set_ideal_latency 1.5 FE_OFC413_scan_se/A`

  Please note that the above command will only be valid if the pin is part of an ideal network.

  Now, this ideal latency value can be observed in the output of the following `report_timing` command:
  `report_timing -though FE_OFC413_scan_se/A`

```

- report_timing
- set_ideal_network

set_ideal_network

```
set_ideal_network
object_list
[-no_propagate]
```

Identifies driver pins or ports as sources of an ideal network. By default, all pins and nets in the transitive fanout of the specified port or driver pin are marked as ideal. Ideal network marking normally propagates through combinational cells and stops at sequential cells.

Note: This command is not view/mode-based - it applies to all the active views.

The `set_ideal_network` command sets 0 slew for bi-directional pins. This ensures that unnecessary DRV violations do not occur.

Parameters

`-no_propagate`	Prevents propagation through transitive fanout.
`object_list`	Specifies a list of objects - instance pins, ports, or nets.

Examples

- The following command marks the fanout of the input port scan_se as an ideal network:

```
> set_ideal_network scan_se
```

  This can be observed in the output of below mentioned report_timing command where the whole fanout of 'scan_se' is considered as ideal :

```
> report_timing -from scan_se
```

```

Related Commands

- reset_ideal_network

set_ideal_transition

```
set_ideal_transition
[-min]
[-max]
[-rise]
[-fall]
transition_time
object_list
```

Specifies the ideal transition to use for input or output leaf-cell pins and top-level ports that are part of an ideal network. These set a point delay on the specified object.

Note: You should specify `set_ideal_transition` with `set_ideal_network` to view ideal transition result.

Parameters

`-fall`	Specifies the ideal transition for the falling edge.
`-max`	Specifies the ideal transition for the maximum corner.
`-min`	Specifies the ideal transition for the minimum corner.
`object_list`	Specifies a list of objects - instance pins or ports.
`-rise`	Specifies the ideal transition for the rising edge.
`transition_time`	Specifies the ideal transition time.

Examples

- The following command specifies the ideal transition of 0.5ns on pin scan_se:

```
> set_ideal_transition 0.5 scan_se
```

  Please note that this ideal transition would only be applicable if the pin is part of an ideal network, otherwise this value would be ignored.
  This transition will be propagated through the ideal network as shown in the output of the following `report_timing` command:

```
> report_timing -from scan_se
```

```

Related Information

- `reset_ideal_transition`

- set_ideal_network

set_input_delay

```
set_input_delay
[-clock clock_name]
[-clock_fall]
[-rise] [-fall]
[-max] [-min]
[-add_delay]
[-network_latency_included]
[-source_latency_included]
[-reference_pin pin_name]
[-level_sensitive]
delay_value
port_or_pin_list
```

Defines the arrival time relative to a clock edge on input ports or internal input pins. This input path delay models the delay from an external register to an input port of the module.

If the input delay is not specified on an input port, it is assumed to be zero.

Parameters

`-add_delay`	Adds delay information to the existing input delay. The additional delay information can be for multiple paths relative to different clocks or clock edges leading to an input port or internal input pins. If you do not use the `-add_delay` option, the software uses the last `set_input_delay` related to a pin when there are multiple `set_input_delay` statements for the same pin.
`-clock` *clock_name*	Specifies that the delay is relative to the rising edge of the given clock. If you do not specify the `-clock` parameter, the delay is relative to time zero. To specify a delay relative to the falling edge of the clock, use the -clock_fall option with the -clock option. When you specify multiple clocks, an error occurs and the constraint is ignored.
`-clock_fall`	Specifies that the delay is relative to the falling edge of the clock. You must specify the -clock parameter with this parameter. *Default:* Delay is relative to the rising edge. You cannot specify the `-clock_fall` parameter without the `-clock` parameter.
delay_value	Specifies the value for the path delay.
`-fall`	Specifies that the input delay refers to the falling edge of the signal at specified ports or pins. If you do not specify the `-fall` option, the input delay applies to both the edges.

`-level_sensitive`	Models input delay that is launched by a positive level sensitive latch. Use the `-clock` parameter to model a positive level sensitive latch, or the `-clock_fall` parameter to model a negative level sensitive latch. You cannot specify the `-level_sensitive` parameter without the `-clock` parameter.
`-max`	Specifies that the delay refers to the setup analysis. If you do not specify the `-max` parameter, the input delay applies to both setup and hold analysis. **Note**: If for a specific clock the maximum delay is less than the minimum delay, then during analysis the software makes the maximum delay equal to the minimum delay.
`-min`	Specifies that the delay refers to the hold analysis. If you do not specify the `-min` parameter, the input delay applies to both setup and hold analysis.
`-network_latency_included`	Specifies that the clock network latency should not be added to the input delay value. If you do not specify this option, the clock network latency of the related clock is added to the input delay value. This parameter has no effect if the specified clock is in propagated mode.
port_or_pin_list	Specifies a list of input port or pin names. The port_or_pin_list argument can be a collection.
`-reference_pin` *pin_name*	Adds source and network latency of the specified reference pin to the input delay value in propagated mode. A reference pin is a leaf pin in the fanout cone of the clock source of the clock that you specify using the `-clock` parameter. You cannot use the `-reference_pin` parameter to specify multiple pins. If specified, the command issues a warning and accepts the first pin. You cannot use the `-reference_pin` parameter with the `-network_latency_included` or `-source_latency_included` parameters. You cannot use the `-reference_pin` parameter to specify hierarchical pins.
`-rise`	Specifies that input delay refers to the rising edge of the signal at the specified ports or pins. If you do not specify the `-rise` option, the input delay applies to the both edges.
`-source_latency_included`	Specifies that the clock source latency should not be added to the input delay value. With different delay values for `-rise/-fall` and `-min/-max`, only the last specified combination of `-network_latency_included` and `-source_latency_included` parameters is honored. The specified combination can be one of the following: a) Either `-network_latency_included` or `-source_latency_included` b) Both of these c) None of these

Examples

- The following command sets an input delay of 1.0 for all inputs in the current design relative to the rising edge of the `CLK1` clock:

  ```
  set_input_delay -clock CLK1 1.0 [all_inputs]
  ```

- The following command sets an input delay of 2.0 for the input `IN1` port relative to the falling edge of the `CLK1` clock: `set_input_delay -clock CLK1 2.0 -clock_fall { IN1 }`
- The following example shows an input `IN1` port that is constrained by both the rising edge and the falling edge of the same `CLK1` clock. The `-add_delay` option prevents the second `set_input_delay` statement from overwriting the first `set_input_delay`:

  ```
  set_input_delay -clock CLK1 1.0 { IN1 }
  set_input_delay -clock CLK1 -clock_fall -add_delay 2.0 { IN1 }
  ```

- When multiple `-min` and `-max` values are specified relative to the same clock using the `-add_delay` option at the same port or pin, the worst case value for each case is used. For the `-min` case the smallest value is retained, and for the `-max` case the largest value is retained. For example, the input delay value of 1.0 is stored for the shortest path and the value of 4.0 is stored for the longest path in the following example:

  ```
  set_input_delay -min -clock CLK1 1.0 { IN1 }

  set_input_delay -min -clock CLK1 2.0 -add_delay { IN1 }

  set_input_delay -max -clock CLK1 3.0 -add_delay { IN1 }

  set_input_delay -max -clock CLK1 4.0 -add_delay { IN1 }
  ```

- `set_output_delay`

set_input_transition

```
set_input_transition
[-help]
[-min]
[-max]
[-rise]
[-fall]
transition_time
port_list
```

Specifies the slew time for a port on the top level module. This command is useful only in specifying a hard ramp signal as if the port were driven by a very powerful driver. The command does not change the arrival time of an input, but changes the slew time used to compute the delay of the cell on the sink of a net. If you do not define transition using the `set_input_transition` command, the software uses the default input port transition defined in the configuration file. The default value is `0.1ps`. You can also set the `delaycal_input_transition_delay global variable` to override the default value.

The `set_input_transition` command specification for clock signals does not impact setup/hold timing calculations.

Note: The `set_input_transition` command does not support internal pins. For specifying transition on internal pins use the `Set_annotated_transition` command.

Note: The most recent command settings (of `set_driving_cell`, `set_input_transition`, or `set_drive`) that are applied to a port will be considered - the software will override the previous commands.

Parameters

`-help`	Prints out the command usage.
`-fall | -rise`	Specifies that the slew time should be applied to the rising edge or the falling edge of the signal (data or clock). If neither time is specified, the default is to use both.
`-min | -max`	Indicates whether the slew times are with respect to the early (hold) or the late (setup) time checks of the data signal. If neither option is specified, the default is to use both.
`port_list`	Specifies the list of ports for which the slew time is specified. **Note:** You cannot use the `set_input_transition` command to specify transition on output ports. **Note:** When you use both `set_input_transition` and `set_annotated_transition` commands for specifying transition on input ports, the worst value is used as the transition value.
`transition_time`	Specifies the transition time.

Examples

- The following command specifies the slew time of `0.5` on port `input3`.

  ```
  set_input_transition 0.5 input3
  ```

- The following command specifies the input falling slew of 0.6ns on the port input1 for minimum delay type:

  ```
  set_input_transition -min -fall 0.6 input1
  ```

Related Commands

- set_clock_transition

set_load

```
set_load
[-max] [-min]
[-pin_load]
[-wire_load]
[-subtract_pin_load]
capacitance_value
object_list
```

Sets the specified capacitance on the defined ports (or nets) of the top cell.

The specified capacitance overrides the capacitance from the wire load models and SPEF.

You can use the `report_ports` command to view capacitance of asserted ports. The pin load appears in the report as `port_cap` in the assertion column and the wire load appears as `port_wire_cap` in the assertion column.

In the timing report (generated using the `report_timing` command), the load value for ports is displayed as a sum of the `set_load` value on a port and the existing wire capacitance obtained from the SPEF file, and pin capacitance obtained from the library files.

Parameters

capacitance_value	Specifies the value for the capacitance. The capacitance is in units from the target technology library.
-min	Specifies the minimum capacitance. The minimum capacitance is used to compute best-case delays in BcWc analysis mode and early path delays in OCV analysis mode.
-max	Specifies the maximum capacitance. The maximum capacitance is used to compute worst-case delays in BcWc analysis mode and late path delays in OCV mode. It is also used to check the maximum capacitance design rule.
object_list	Specifies a list of ports or nets in the top cell.
-pin_load	Specifies the external pin capacitance for a port. You can use this parameter for ports only. For ports, the asserted capacitance is either the external pin capacitance when the `-pin_load` parameter is specified, or the external wire capacitance when the `-wire_load` parameter is specified, or the total external capacitance when neither option is specified.

`-subtract_pin_load`	This parameter can be used only if nets are specified in the object list. When this parameter is specified, the total net capacitance value will be the same as set by the `set_load` *capacitance_value object_list* command. When this parameter is not specified, the asserted load value will only change the wire capacitance value from the SPEF. The total net capacitance value will be the `set_load` capacitance value plus the pin capacitance from the library file.
`-wire_load`	Interprets the specified capacitance as the external wire capacitance of the port. Use this option only for ports. Use this option with the *`port_net_list`* argument if the list contains only ports.

Examples

- The following command sets an external minimum pin capacitance of 1.5 units on the `in1 in2` ports: `set_load 1.5 -min -pin_load [get_ports {in1 in2}]`
- The following command sets an external minimum wire capacitance of 1.2 units on the `in1 in2` ports: `set_load 1.2 -min -wire_load [get_ports {in1 in2}]`
- The following command sets an external maximum pin capacitance of 2.6 units on the `in1 in2` ports: `set_load 2.6 -max -pin_load [get_ports {in1 in2}]`
- The following command sets an external maximum wire capacitance of 3.0 units on the `in1 in2` ports: `set_load 3.0 -max -wire_load [get_ports {in1 in2}]`
- The following command reports the capacitances set on the ports, as shown in example below:
  `report_ports -pin [get_ports {in1}]`

```

set_logic_one

```
set_logic_one
-help
ports_pins
```

Sets ports or pins to logic 1 in the design.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `set_logic_one` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_logic_one`.
`ports_pins`	Specifies the list of the ports or pins that are to be set to logic 1.

Examples

- The following command sets the specified port to logic 1:
  ```
  set_logic_one [get_ports {din[1]}]
  ```

Related Commands

- `get_ports`

set_logic_zero

```
set_logic_zero
-help
ports_pins
```

Sets ports or pins to logic 0 in the design.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `set_logic_zero` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_logic_zero`.
`ports_pins`	Specifies the list of the ports or pins that are to be set to logic 0.

Examples

- The following command sets the specified port to logic 0:
  ```
  set_logic_zero [get_ports {din[0]}]
  ```

Related Commands

- `get_ports`

set_max_capacitance

```
set_max_capacitance
[-help]
capacitance_limit
object_list
[-clock_path]
[-data_path]
[-fall]
[-override]
[-rise]
```

Sets the maximum capacitance limit on the specified instance pin, ports of the top cell, the specified designs, and/or clock waveforms. The pins of cell instances of timing libraries will have their own maximum constraint. The software will pick the more aggressive value of the two.

When set on a port, the total capacitance of the net connected to that port must be less than or equal to the specified limit. Maximum capacitance limits also come from library objects, which is the default maximum capacitance limit of libraries and the maximum capacitance limit on library cell pins. Pins in the design inherit the limits from libraries.

Note: The limit set on the top cell applies to its ports. Thus, if maximum capacitance limits are set on the top cell and its ports, the most constraining limit will apply to the ports.

When limits are set on a clock waveform, you can use `-clock_path`, `-data_path`, `-rise`, and `-fall` parameters to provide more specifications.

The `set_max_capacitance` constraint on clock objects will be honored only by the `report_constraint` command for DRV violations. The constraint will not be used in optimizations.

Parameters

`-help`	Prints out the command usage.
`-clock_path`	Applies the max capacitance constraint only to pins in the clock network of the clocks defined in the object list.
`-data_path`	Applies the max capacitance constraint only to data path pins, where the path is launched by the clocks defined in the object list.
`-fall`	Applies the max capacitance constraint only to falling capacitance.
`-rise`	Applies the max capacitance constraint only to rising capacitance.
`capacitance_limit`	Specifies the value for the minimum capacitance limit. The limit must be greater than or equal to zero. The limit is in capacitance units from the target technology library.
`object_list`	Specifies a list of objects - ports, instance pins, library cell pins, designs, and/or clock waveforms.

`-override`	Overrides the maximum capacitance limit from other sources, such as, library or constraints. This parameter can be used to force a specific constraint value for a specified list of instance pins/port/library cell pins - this overrides the maximum/minimum values set prior to this setting. To enable this feature, make the following setting: `set timing_constraint_enable_drv_limit_override true`

Examples

- The following example sets a maximum capacitance limit of `1.2` units on all the ports of the top cell and a maximum capacitance limit of `0.5` units on the port named `d_out`:

```
set_max_capacitance 1.2 [get_ports *]
set_max_capacitance 0.5 d_out
```

- The following example uses the `report_ports` command to show the maximum capacitance limit set on ports, as shown in the example below:

```
set_max_capacitance 0.9 [get_ports *] report_ports -type port_cap_limit -pin [get_ports *]
```

Example: **Maximum Capacitance Limit Set on Ports Report**

```
> report_ports -type port_cap_limit -pin [get_ports *]

----------------------------------------
Pin     Dir  Assertion       Value
Name
----------------------------------------
CLK2    IN   port_cap_limit  ( : 0.900 )
CLK1    IN   port_cap_limit  ( : 0.900 )
in2     IN   port_cap_limit  ( : 0.900 )
in1     IN   port_cap_limit  ( : 0.900 )
out2    OUT  port_cap_limit  ( : 0.900 )
out1    OUT  port_cap_limit  ( : 0.900 )
----------------------------------------
```

Related Commands

- `get_ports`
- `report_ports`
- `set_max_transition`
- `set_max_fanout`
- `report_constraint`

set_max_delay

```
set_max_delay
value
[-combinational_from_to | -ignore_clock_latency]
[{-from |-rise_from | -fall_from} from_list]
[{-through | -rise_through | -fall_through} through_list]
[{-to | -rise_to | -fall_to} to_list]
[-comment string]
[-rise]
[-fall]
```

Specifies a maximum delay for a timing path. The `set_max_delay` command takes precedence over other path exceptions specified for the same path, except for the `set_false_path` command.

Use either the `-from`, `-to`, or `-through` option with the `set_max_delay` command to identify the paths. Specifying both the `-from` and `-to` options identifies a path with specific starting and ending points.

When you specify a sequential cell name for starting point of the timing path, the valid path starts from the clk pin. This means the latency and delay from clk to output Q is also included in the delay. For path segmentation, you can specify the path to start from Q output of the register by adding /Q after the cell name. In this case, path from clk to Q is not considered in the calculation.

Use only one `-from`, `-rise_from`, or `-fall_from`, `-to`, `-rise_to`, or `-fall_to` parameter per command. You can use multiple `-through` parameters in the same command.

Parameters

`-combinational_from_to`	Defines a path defined by -from/to pins as combinational. When this parameter is used, the path between the -`from`/-`to` pins is treated as purely combinational, that is, both the source/capture clock latencies are excluded from slack computation. The presence of -`from`/`-to` pins is required for this option to take effect; the -`from`/`-to` pins can be sequential or combinational start/end pins. The `-combinational_from_to` parameter will be deprecated in a future release. This parameter will continue to work in the current release, but for compatibility with future releases you should migrate your scripts to use the `-ignore_clock_latency` parameter. You can use the following global variables to match the semantics between the `-ignore_clock_latency` and `-combinational_from_to` parameters: • `timing_constraint_path_delay_exclude_check_delay_from_ignore_clock_latency` • `timing_constraint_path_delay_exclude_io_delay_from_ignore_clock_latency`
`-comment string`	Allows you to insert comments. The comments are read but are ignored with a one-time warning message. They are not used during timing analysis reporting nor are they written out during saving of constraints.

`-fall`	Apply the assertion at the falling edge of the signal on the path endpoints.
`-from |-rise_from |-fall_from` *from_list*	Specifies a list of timing paths start points. The *from_list* argument can contain either object IDs or hierarchical names relative to the current module or clock names. The pins can be on intermediate hierarchical boundaries. The *from_list* argument can be a collection. The valid start points are: • Input port • Bidirectional port • Clock pin of sequential cell Clock pin of sequential cell is one of the following: • Structural clock pin that is part of latch or flip-flop. • Inferred clock pin in cells like macro cells. A pin is an inferred clock pin if it is associated with one of the following: • Reference end of setup check • Reference end of hold check • Reference end of removal check • Reference end of recovery check • Minimum period check • Minimum pulse width check • Pin associated with `set_input_delay` Specify one of the following:
	`-from`: Applies the maximum delay constraint to all paths originating from the *from_list* list. If a clock is specified as the `-from` object, all primary inputs and registers clocked by that clock are used as start points. By default, the `-from` option applies the constraint to both the rising and the falling edges.
	`-rise_from`: Applies the maximum delay constraint at the rising edge of the signal on the from pins.
	`-fall_from`: Applies the maximum delay constraint at the falling edge of the signal on the from pins.

`-ignore_clock_latency`	When this parameter is specified, the software does not count the launch/capture clock latency delays into the timing path delay. The `-ignore_clock_latency` parameter is an industry-standard construct introduced in SDC 2.1 to control the handling of clock-related timing with respect to the `set_max_delay`/`set_min_delay` constraints.
`-rise`	Applies the assertion at the rising edge of the signal on the path endpoints.
`-through | -rise_through | -fall_through` *`through_list`*	Specifies a list of timing paths through points. The *`through_list`* argument can contain either object IDs or hierarchical names relative to the current module or clock names. The pins can be on intermediate hierarchical boundaries. The *`through_list`* argument can be a collection. Specify one of the following:
	`-through`: When you use this parameter without using the `-from` or `-to` options, all paths that go through the specified pins have the specified delay. When you use it with both the `-from` and `-to` options, any path starting at any pin on the `-from` list *and* going through any point on the `-through` pin list *and* going to any point on the `-to` list is affected by the constraint. By default, the `-through` option applies the constraint to both the rising and the falling edges.
	`-rise_through`: Applies the assertion at the rising edge of the signal on the through pins.
	`-fall_through`: Applies the assertion at the falling edge of the signal on the through pins.

`-to| -rise_to | -fall_to` *to_list*	Specifies a list of timing paths end points. The *to_list* argument can contain either object IDs or hierarchical names relative to the current module or clock names. The pins can be on intermediate hierarchical boundaries. The *to_list* argument can be a collection. The valid end points are: • Output port • Bidirectional port • Data pin of sequential cell Data pin of sequential cell is one of the following: • Structural data pin that is part of latch or flip-flop. • Inferred data pin in cells like macro cells. A pin is an inferred data pin if it is associated with one of the following: • Signal end of setup check • Signal end of hold check • Signal end of non-sequential setup check • Signal end of non-sequential hold check • Signal end of removal check • Signal end of recovery check • Pin associated with `set_external_delay` • Data pin of clock gating cell Select from one of the following:
	`-to`: Applies the maximum delay constraint to all paths ending in the `-to` pin list. If a clock is specified as the `-to` object, all primary outputs and registers clocked by that clock are used as endpoint. By default, the `-to` option applies the constraint to both the rising and the falling edges.
	`-rise_to`: Applies the maximum delay constraint at the rising edge of the signal on the to pins.
	`-fall_to`: Applies the maximum delay constraint at the falling edge of the signal on the to pins.
value	Specifies the maximum delay value.

Example

- The following command specifies that all paths from `in1` to `out1` must have delays less than `10` units:

```
set_max_delay 10 -from in1 -to out1
```

set_max_fanout

```
set_max_fanout
[-help]
fanout_limit
object_list
[-override]
```

Sets the maximum fanout load limit constraint on the specified instance pin, ports of the top cell, the specified designs, and/or clock waveforms. The pins of cell instances of timing libraries will have their own maximum constraint. The software will pick the more aggressive value of the two.

When set on a port, the fanout load of the net connected to the port must be less than or equal to the specified limit value to meet the constraint. The fanout load of a net is the sum of the fanout loads of the pins driven by the net. When set on a module, the limit applies to all the nets of that module. Libraries and library cell pins may also have the maximum fanout load limit. In this case the most constraining limit is applied to the nets.

Use the `report_ports -type fanout_load_limit` command to view the maximum fanout load limits set on ports of the top cell.

Fanout load limit can be asserted on input ports, output pins, bidirectional pins, or ports and library pins. You cannot apply the constraint on input pins and output ports.

Parameters

`-help`	Prints out the command usage.
`fanout_limit`	Specifies the value of the maximum fanout load limit constraint. This is a float number and it must be greater than or equal to zero.
`object_list`	Specifies a list of objects - input ports, instance output pins, designs, or library cell output pins.
`-override`	Overrides the maximum fanout limit from other sources, such as, library or constraints. This parameter can be used to force a specific constraint value for a specified list of instance pins/port/library cell pins - this overrides the maximum/minimum values set prior to this setting. To enable this feature, make the following setting: `set timing_constraint_enable_drv_limit_override true`

Examples

- The following example sets a maximum fanout load limit of `5.0` units on all the ports of the top cell:
  ```
  set_max_fanout 5.0 [get_ports *]
  ```
- The following example shows a report of the maximum fanout load limit set on ports using the `report_ports` command, as shown in the example below:
  ```
  set_max_fanout 5.0 [get_ports *] report_ports -type fanout_load_limit -pin [get_ports *]
  ```

Example: Maximum Fanout Load Limit Set On Ports Report

```
> report_ports -type fanout_load_limit -pin [get_ports *]
-----------------------------------------
Pin    Dir  Assertion        Value
Name
-----------------------------------------
CLK2   IN  fanout_load_limit 5.000
CLK1   IN  fanout_load_limit 5.000
in2    IN  fanout_load_limit 5.000
in1    IN  fanout_load_limit 5.000
-----------------------------------------
```

set_max_time_borrow

```
set_max_time_borrow
[-help]
borrow_value
object_list
[-interface]
```

Specifies the maximum time that can be borrowed by one stage from the next logic stage following a latch to meet timing constraints. Time borrowing is sometimes called cycle stealing. Time borrowing is performed automatically when performing timing analysis.

Use the `set_max_time_borrow` assertion on pins or waveforms. If the assertion is placed on a clock waveform, all latches triggered by this clock signal get the specified maximum time borrow limit. If both the clock waveform arriving at the clock pin of a latch and the clock pin itself have time borrow limit constraints, the maximum borrow limit on the latch is decided by the assertion on the latch clock pin.

Parameters

`-help`	Prints out the command usage.
borrow_value	Specifies the maximum amount of time that can be borrowed. The minimum value allowed is `0`, which disables time borrowing. The maximum allowed is equal to the pulse width minus the setup time: Max = pulse width - setup
`-interface`	Specifies the IO paths for which the maximum time will be borrowed.
object_list	Specifies the list of instance pins, instances, or clocks on which the borrow value is applied. The *object*`_list` argument can be a collection.

Examples

```
set_max_time_borrow 2 [get_cells {i1, i2, i3}]

set_max_time_borrow 1.7 I4/g

set_max_time_borrow 2.5 [get_clocks CLK1]
```

Related Information

- `get_clocks`

set_max_transition

```
set_max_transition
[-help]
transition_limit
object_list
[-clock_path]
[-data_path]
[-fall]
[-override]
[-rise]
```

Sets the maximum slew time limit (transition) on the specified instance pin, ports of the top cell, and/or clock waveforms.

The pins of cell instances of timing libraries will have their own maximum constraint. The software will pick the more aggressive value of the two.

When set on a port, the slew time at the port must be less than or equal to the specified limit. Maximum transition limits on pins can come from library objects, which are the default maximum transition of the libraries or maximum transition on library cell pins. In this case, the most constraining limit, which is the smallest, will apply on pins and ports.

Use the `report_ports -type slew_limit` command to view the maximum transition limits set on ports of the top cell.

When limits are set on a clock waveform, you can use `-clock_path`, `-data_path`, `-rise`, and `-fall` parameters to provide more specifications.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `set_max_transition` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_max_transition`.
`-clock_path`	Applies the max transition constraint only to pins in the clock network of the clocks defined in the object list.
`-data_path`	Applies the max transition constraint only to data path pins, where the path is launched by the clocks defined in the object list.
`-fall`	Applies the max transition constraint only to falling transitions.
`object_list`	Specifies the list of objects - ports, instance pins, library cell pins, clock waveforms, or current design.
`-override`	Overrides the maximum transition limit from other sources, such as, library or constraints. This parameter can be used to force a specific constraint value for a specified list of instance pins/port/library cell pins - this overrides the maximum/minimum values set prior to this setting. To enable this feature, make the following setting: `set timing_constraint_enable_drv_limit_override true`
`-rise`	Applies the max transition constraint only to rising transitions.
`transition_limit`	Specifies the value of the maximum slew time limit (maximum transition), which must be greater than or equal to zero. The maximum slew time limit is in time units in the current session.

Examples

- The following command sets a maximum transition limit of `0.9` units on all the ports of the top cell:
  ```
  set_max_transition 0.9 [get_ports *]
  ```
- The following example shows a report of the maximum transition limit set on ports using the `report_ports` command, as shown in the example below:
  ```
  set_max_transition 0.9 [get_ports *]
  report_ports -type slew_limit -pin [get_ports *]
  ```

Example: Maximum Transition Limit Set on Ports Report

Pin Name	Dir	Assertion	Value
in1	IN	slew_limit	(: 0.9000)
in2	IN	slew_limit	(: 0.9000)
out1	OUT	slew_limit	(: 0.9000)

out2	OUT	slew_limit	(: 0.9000)
out3	OUT	slew_limit	(: 0.9000)
out4	OUT	slew_limit	(: 0.9000)

- The following command sets the maximum transition limit of 0.001 units on pins in the `all_clocks` collection:
  ```
  set_max_transition 0.001 -clock_path [all_clocks]
  ```
- The following command sets the transitions to the specified value for your entire design:
  ```
  set_max_transition value [current_design]
  ```
- The following command impacts report_contraint output as shown below:
  ```
  set_max_transition 0.01 TDP_COE_INST/TDP_COE_GL_INST/p82
  ```
  The following command shows output as shown below:
  ```
  report_constraint -all_violators -drv_violation_type max_transition

  ###############################################################
  # format : frame 0 : split 0

  Check type : max_transition

  ------------------------------------------------------------------------------
  Pin Name                          Required Actual  Slack    View
  ------------------------------------------------------------------------------
  TDP_COE_INST/TDP_COE_GL_INST/p82  0.010    1.138   -1.128   func_slow_RCMAX
  ------------------------------------------------------------------------------
  ```

Related Commands

- get_ports
- report_ports
- set_max_capacitance
- report_constraint

set_min_capacitance

```
set_min_capacitance
[-help]
capacitance_limit
object_list
[-clock_path]
[-data_path]
[-fall]
[-override]
[-rise]
```

Sets the minimum capacitance limit on the specified ports of the top timing module and/or clock waveforms.

When set on a port, the total capacitance of the net connected to that port must be greater than or equal to the specified limit. When set on a module, the limit applies to all the nets of that module. The total capacitance of each net of the module must be greater than or equal the specified limit. The minimum capacitance limit also comes from library objects, which is the default minimum capacitance limit of libraries and minimum capacitance limit on library cell pins. Pins in the design inherit the limits from libraries. When limits are set on a module and the limit is inherited from libraries, the most constraining limit, which is the largest limit, is used.

Note: The limit set on the top timing module applies to its ports. Thus, if minimum capacitance limits are set on the top timing module and its ports, the most constraining limit will apply to the ports.

Use the `report_ports -type port_cap_limit` command to view the minimum capacitance limits set on ports.

When limits are set on a clock waveform, you can use `-clock_path`, `-data_path`, `-rise`, and `-fall` parameters to provide more specifications.

The `set_min_capacitance` constraint on clock objects will be honored only by the `report_constraint` command for DRV violations. The constraint will not be used in optimizations.

Note: This command syntax is applicable only when the flow-compatible mode is on.

Parameters

`-help`	Prints out the command usage.
`-clock_path`	Specifies all pins that are in the network of the specific clocks in the object list.
`-data_path`	Specifies all pins that are in the data paths launched by the specific clocks in the object list.
`-fall`	Specifies falling capacitance.
`-rise`	Specifies rising capacitance for all selected pins.
`capacitance_limit`	Specifies the value for the minimum capacitance limit. The limit must be greater than or equal to zero. The limit is in capacitance units from the target technology library.
`object_list`	Specifies the list of objects - ports, instance pins, library cell pins, modules, and/or clock waveforms.
`-override`	Overrides the minimum capacitance limit from other sources, such as, library or constraints. This parameter can be used to force a specific constraint value for a specified list of instance pins/port/library cell pins - this overrides the maximum/minimum values set prior to this setting. To enable this feature, make the following setting: `set timing_constraint_enable_drv_limit_override true`

Examples

- The following example sets a minimum capacitance limit of `0.02` units on all the ports of the top timing module and a minimum capacitance limit of `0.05` units on the top timing module:

  ```
  set_min_capacitance 0.02 [get_ports *]
  set_min_capacitance 0.05 [current_design]
  ```

  The limit used for ports is `0.05`, which is the most restrictive limit set on the top timing module (`0.05`) and the limit set on ports (`0.02`).

- The following example uses the `report_port` command to show the minimum capacitance limit set on ports:

  ```
  set_min_capacitance 0.02 [get_ports *]
  report_ports -type port_cap_limit -pin [get_ports *]
  ```

- The following command sets the minimum capacitance limit of `0.001` units on pins in the `all_clocks` collection:

  ```
  set_min_capacitance 0.001 -data_path [all_clocks]
  ```

  Example: Minimum Capacitance Limit Set on Ports Report

  ```
  report_ports -type port_cap_limit -pin [get_ports *]
  ------------------------------------------------------
  ```

```
Pin       Dir    Assertion         Value
Name
-----------------------------------------------------
CLK2      IN     port_cap_limit    ( 0.020 : 0.900 )
CLK1      IN     port_cap_limit    ( 0.020 : 0.900 )
in2       IN     port_cap_limit    ( 0.020 : 0.900 )
in1       IN     port_cap_limit    ( 0.020 : 0.900 )
out2      OUT    port_cap_limit    ( 0.020 : 0.900 )
out1      OUT    port_cap_limit    ( 0.020 : 0.900 )
-----------------------------------------------------
```

Related commands

- report_ports
- set_max_capacitance
- set_max_transition
- set_min_transition
- report_constraint

set_min_delay

```
set_min_delay
value
[-combinational_from_to | -ignore_clock_latency]
[{-from |-rise_from | -fall_from} from_list]
[{-through | -rise_through | -fall_through} through_list]
[{-to | -rise_to | -fall_to} to_list]
[-rise]
[-fall]
[-comment string]
```

Specifies a minimum delay for a timing path. The `set_min_delay` command takes precedence over other path exceptions specified for the same path, except for `set_false_path` command specifications.

Use either the `-from`, `-to`, or `-through` option with the `set_min_delay` command to identify the paths. Specifying both the `-from` and `-to` options identifies a path with specific starting and ending points. If a clock is specified as the `-to` object, all primary outputs and registers clocked by that clock are used as an endpoint.

When you specify a sequential cell name for starting point of the timing path, the valid path starts from the clk pin. This means the latency and delay from clk to output Q is also included in the delay. For path segmentation, you can specify the path to start from Q output of the register by adding /Q after the cell name. In this case, path from clk to Q is not considered in the calculation. For example, in the following set of commands, the valid path starts from different points:

```
set_min_delay 0.66 -from TR1/BR1 -to BLK/BR1/D

set_min_delay 0.66 -from TR1/BR1/Q -to BLK/BR1/D
```

For the first command, the valid path starts from clk, and for the second command the valid path starts from the Q output. In the second case, the path from clk to Q is not considered. For an example of the results generated for paths with and without path segmentation, see the Examples section below.

Use only one `-from`, `-rise_from`, or `-fall_from`, `-to`, `-rise_to`, or `-fall_to` parameter per command. You can use multiple `-through` parameters in the same command.

Parameters

`-combinational_from_to`	Defines a path defined by -from/to pins as combinational. When this parameter is used, the path between the -`from`/-`to` pins is treated as purely combinational, that is, both the source/capture clock latencies are excluded from slack computation. The presence of -`from`/`-to` pins is required for this option to take effect; the -`from`/`-to` pins can be sequential or combinational start/end pins. The `-combinational_from_to` parameter will be deprecated in a future release. This parameter will continue to work in the current release, but for compatibility with future releases you should migrate your scripts to use the `-ignore_clock_latency` parameter. You can use the following global variables to match the semantics between the `-ignore_clock_latency` and `-combinational_from_to` parameters: • `timing_constraint_path_delay_exclude_check_delay_from_ignore_clock_latency` • `timing_constraint_path_delay_exclude_io_delay_from_ignore_clock_latency`
`-comment` *`string`*	Allows you to insert comments. The comments are read but are ignored with a one-time warning message. They are not used during timing analysis reporting nor are they written out during saving of constraints.
`-fall`	Applies the assertion at the falling edge of the signal on the path endpoints.

`-from |-rise_from	-fall_from` *`from_list`*	Specifies a list of timing paths start points. The *`from_list`* argument can contain either object IDs or hierarchical names relative to the current module or clock names. The *`from_list`* argument can be a collection. The valid start points are: • Input port • Bidirectional port • Clock pin of sequential cell Clock pin of sequential cell is one of the following: • Structural clock pin that is part of latch or flip-flop. • Inferred clock pin in cells like macro cells. A pin is an inferred clock pin if it is associated with one of the following: • Reference end of setup check • Reference end of hold check • Reference end of removal check • Reference end of recovery check • Minimum period check • Minimum pulse width check • Pin associated with set_input_delay Specify one of the following:
	`-from`: Applies the minimum delay constraint to all paths originating from the *`from_list`* list. If a clock is specified as the `-from` object, all primary inputs and registers clocked by that clock are used as start points. By default, the `-from` option applies the constraints to both the rising and the falling edges.
	`-rise_from`: Applies the minimum delay constraint at the rising edge of the signal on the from pins.
	`-fall_from`: Applies the minimum delay constraint at the falling edge of the signal on the from pins.
`-ignore_clock_latency`	When this parameter is specified, the software does not count the launch/capture clock latency delays into the timing path delay. The `-ignore_clock_latency` parameter is an industry-standard construct introduced in SDC 2.1 to control the handling of clock-related timing with respect to the `set_max_delay`/`set_min_delay` constraints.

`-rise`	Applies the assertion at the rising edge of the signal on the path endpoints.
`-through | -rise_through | -fall_through` *through_list*	Specifies a list of timing paths through points. The *through_list* argument can contain either object IDs or hierarchical names relative to the current module or clock names. The pins can be on intermediate hierarchical boundaries. The *through_list* argument can be a collection. Specify one of the following:
