	• `cts`: Checks related to clock tree definition such as constraint targets and route types. This is run before cts but after creating the clock tree spec. This check cannot run with pre-cts Innovus DB (just after place_opt_design). You need to set CCOpt option (target skew, target trans, etc) and also need to load the CCOpt spec file.
	• `route`: Checks related to routing such as congestion, placement, and pin access issues. The `-type` route cannot be run with pre-placed DB. This check is run before routing. It is useful to run check_drc ahead of time so the design markers are up to date.
	• `signoff`: Checks related to the signoff activities including extraction and ECOs. This check is run before TSO. To use this types, you need to set the Tempus path, else the tool will give an error.
	• `all`: Checks related to all categories.
	Note: `-type` or `-no_check` is required (except when using `-help` argument)

`-no_check`	Do not run any checks, echo the error messages associated with the checks that would be run for the specified `-type`. Run `check_design -no_check` to see the list of checks. `-type` or `-no_check` is required (except when using `-help` argument)

`-out_file` *fileName*	Specifies the output report file. Contents dumped to this file are in the Tcl format. Sourcing this file will create a TCL dictionary of the violations found by check_design.

Examples

- The following example shows the usage of the `-out_file` option:

```
> check_design -type "place cts route" -out_file checks.tcl

*** Summary of all messages that are not suppressed in this session:

checkDesign

```
checkDesign
[-help]
{ -all
   [-danglingNet [highlight]] | [[-io]
   [-netlist [-danglingNet [highlight]]]
   [-physicalLibrary]
   [-timingLibrary]
   [-powerGround]
   [-tieHiLo]
   [-floorplan]
   [-place]
   [-spef][-assigns]] }
[[-noText] [-outdir directoryName] [-browser]]
| [-noHtml [-outfile fileName]]
```

Checks for missing or inconsistent library and design data at any stage of the design and writes the results to a text and HTML report. This eliminates the need to perform these checks manually. By default, the HTML report is saved as *design_name*`.main.htm` whereas the text version of the report is saved as *design_name*`.main.htm.ascii`.

The Innovus Implementation System (Innovus) software checks the following data:

- I/Os
- Netlist
- Physical library
- Timing library
- Power and ground pins
- Tie-high and tie-low pins
- Floorplan
- Placement

Cadence recommends that you check libraries and data as follows:

- Perform I/O checking at any time. I/O problems might not impede any tool, but they might add to design problems.
- Perform netlist checking at any time after the design has been loaded.
- Perform physical library checking before floorplanning.
- Perform timing library checking before any timing-related operation (for example, timing driven placement or routing, timing optimization, clock-tree synthesis, and static timing analysis)
- Perform power/ground checking before routing and extraction, and verifying geometry and connectivity.
- Perform tie-high and tie-low checking before routing and extraction.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `checkDesign` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man checkDesign`.
`-all`	Performs all checks.
`-assigns`	Reports all assign statements in the netlist, including assigns to 1'b0/1'b1.
`-browser`	Opens a browser and displays the HTML version of the report. **Note:** This option cannot be used with `-noHtml`.
`-danglingNet [highlight]`	Checks the design for nets that have no instance or top-level terminals, and outputs their names into the report file. The `-danglingNet` parameter can be used only if the `-netlist` or `-all` parameter is specified. If you specify `highlight`, the software also highlights the "dangling" nets in the main window, after the `checkDesign` command finishes.

`-floorplan`	Checks the floorplan, generates error or warning messages, and reports the following information: • Off-grid horizontal and vertical tracks • Instances not snapped to row site • Unplaced I/O pins • Off Grid Power/Ground Pre-routes • Instances not on the manufacturing grid • Preroutes not on the manufacturing grid (error) • Regular preroutes not on tracks
`-io`	Checks I/O pads, generates warning messages, and reports the following information: • Unplaced I/O cells • Floating pins that belongs to I/O pads (warning) • I/O pins connected to non-I/O instances (directly connected to core cells) • Unplaced I/O pins • Floating I/O pins
`-netlist`	Checks the netlist, generates error or warning messages, and reports the following information: • Output pins tied to power/ground nets (for example, `BUFX1 U1 (.A(net1),.Y1(1'b0))`) • Input pins floating (warning) • Multiple driver nets (warning)
`-noHtml`	Generates only a text version of the report. *Default:* The report is generated in both HTML and text format.
`-noText`	Generates only an HTML version of the report. *Default:* The report is generated in both HTML and text format.
`-outdir` *directoryName*	Specifies the directory in which the HTML and text reports are saved. If `-noText` is specified, saves only the HTML version of the report to the specified directory. **Note:** The `-outdir` parameter cannot be used with `-noHtml`.
`-outfile` *fileName*	Writes the text version of the report to the specified file. **Note:** You can specify this option only if you specify `-noHtml`. *Default:* If you specify `-noHtml` but do not specify `-outfile`, the software writes the text version of the report to a file named *design_name*`.main.htm.ascii`.
`-physicalLibrary`	Checks the physical libraries and reports whether all cells have LEF views. The software generates error messages for the following conditions: • Cells not defined in LEF • Cells with missing dimensions • Pins with missing direction • Cells pins with missing geometry • Cell dimensions are not an integer multiple of the core site dimensions • A macro does not have fully covered obstruction • Fixed mask block have some pins not colored
`-place`	Checks the placement, generates error or warning messages, and reports the following information: • Number of instances with placement violations • Instances placed outside of the core area • Instances overlapping other instances • Instances overlapping placement blockages

`-powerGround`	Checks power and ground connections, generates warning messages, and reports the following information: • Power terminals connected to ground net • Ground terminals connected to power net • Floating power and ground terminals • Power and ground terminals connected to non-power and ground nets.
`-spef`	Checks spef.
`-tieHiLo`	Reports unconnected tie-high or tie-low terminals and tieHi/Lo pins and P/G pins connected to different nets. The system generates a warning message.
`-timingLibrary`	Checks whether the cells used in the design have been defined in the timing library. This option does not check for the presence of timing arcs. All physical cells are excluded from this check.

Examples

- The following command checks the design and generates a text version of the report called `checkDesign.ascii`:

  ```
  checkDesign -all -noHtml -outfile checkDesign.ascii
  ```

  The following is a sample of the resulting text report:

```

  - Preparing for Placement

checkUnique

```
checkUnique
[-help]
[-verbose]
```

Checks the uniqueness of the netlist. Certain features, such as clock tree synthesis and IPO, require a module (a non-leaf cell) to be instantiated only once. If the netlist is unique, the result is `1`; otherwise, the result is `0`.

You can use the `checkUnique` command after importing a design.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `checkUnique` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man checkUnique`.
`-verbose`	Displays the names of modules instantiated more than once.

Example

The following command checks the uniqueness of the netlist and displays the names of any modules instantiate more than once:

```
innovus 4> checkUnique -verbose
```

The sample output is as shown below:

```
Non-leaf cell A instantiated 2 times.
0
```

createTrack

```
createTrack
[-help]
-dir direction
-layer layerNameList
-num numOfTrack
-start coordinate
-step step
```

Creates non-uniformed, customized tracks in selected design area. Typically, the routing grid is generated when the floorplan is initialized. The first track is located at an offset from the placement grid set by the OFFSET value for the layer in the LEF file. The track spacing is the PITCH value for the layer defined in LEF.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `createTrack` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man createTrack`.
`-dir direction`	Specifies track direction as a string.
`-start coordinate`	Specifies the starting coordinate to create the track. The unit for the coordinates is user unit (micron).
`-num numOfTrack`	Specifies the number of tracks to create for the grid. You cannot specify `0 numtracks`.
`-step step`	Specifies the spacing between the tracks.
`-layer layerNameList`	Specifies the routing layer used for the tracks. You can specify more than one layer.

defComp

```
defComp
[-help]
fileName
[-bump]
[-defAsGolden]
[-ignoreLayerFrom layer]
[-ignoreLayerTo layer]
[-ignoreLogicChange]
[-metalShapeDiff]
[-placeBlockage]
[-reportFile reportFile]
[-row]
[-snetPin]
[-unit units_value]
[-ignoreCellPlace lef_macro_classes_list
          [-checkCellPrefix prefix_list]]
```

Compares a DEF file with the physical design data in the Innovus database and reports any differences. You can use the `defComp` command after importing a design.

For example, after you perform an Engineering Change Order (ECO) and make changes to a DEF file, you can use the `defComp` command to compare the new file to the information stored in the Innovus database. Use the following command to compare physical design data:

```
defComp defFile -reportFile fileName
```

The default filename is `defPhyDiff.rpt`

The report file includes the following information:

- `VERSION` statement
  ```
  VERSION num
  ```
- `UNITS` statement
  ```
  UNITS num
  ```
- `ADDINST` statement
  ```
  ADDINST instName cellName x y orientation
  ```
  Note: The report provides the connectivity of added instances in the `NETS` section described below.
- `DELINST` statement
  ```
  DELINST instName cellName x y orientation
  ```
- `CHANGECELL` statement
  ```
  CHANGECELL instName newCellName oldCellName
  ```
  The master cell of the instance *instName* is changed from *oldCellName* to *newCellName*. The coordinate, orientation, and connectivity of the instance are not changed. If a master cell is changed along with any of the coordinates, orientation, or connectivity of the instance, Innovus considers this change as a deletion and addition of the instance. Rather than including a `CHANGECELL` statement, the file contains one pair of `DELINST` and `ADDINST` statements.
- `MOVEINST` statement
  ```
  MOVEINST instName [COORD oldX oldY newX newY] [ORIENT oldOrientation newOrientation]
  ```
  The statement contains the `COORD` phrase if the instance *instName* has moved, and the `ORIENT` phrase if the instance has changed orientation.
- `ADDNET` statement
  ```
  ADDNET netName
  ```
- `DELNET` statement
  ```
  DELNET netName
  ```
- `ADDPIN` statement
  ```
  ADDPIN netName instName pinName
  ```
- `DELPIN` statement
  ```
  DELPIN netName instName pinName
  ```
- `CHANGEROUTE` and `ENDCHANGEROUTE` statements
  ```
  CHANGEROUTE netName
  ```

```
ENDCHANGEROUTE
```

These statements mark the beginning and end of the CHANGEROUTE section that contains changes on the routing segment on net *netName*. The wire change statements are included between the CHANGEROUTE and ENDCHANGEROUTE statements.

- POWERROUTE and ENDPOWERROUTE statements

  ```
  POWERROUTE netName
  ENDPOWERROUTE
  ```

  These two statements mark the beginning and the end of the POWERROUTE section that contains the power routing differences between two DEF files. The wire change statements are included between the POWERROUTE and ENDPOWERROUTE statements.

- CHANGEAREA statement

  ```
  CHANGEAREA llx lly urx ury
  ```

  The bounding-box of any added or deleted wire shapes (regular, patch-wire, or special-wires including wire extensions) or vias (bbox across all layers) is merged into the CHANGEAREA box. For added/deleted instances, the bounding box of the placement overlap area (LEF SIZE) is used. That means any PIN or OBS shape that sticks outside the placement overlap area are not included in the bbox. COVER cells with no placement area use the bounding box of all the PIN and OBS shapes in the cell.

- Wire change statements
  The ADDWIRE, DELWIRE, ADDVIA, and DELVIA statements appear between the CHANGEROUTE and ENDCHANGEROUTE statements, orPOWERROUTE and ENDPOWERROUTE statements.

- ADDWIRE statement

  ```
  ADDWIRE layerName width x1 y1 x2 y2
  ```

- DELWIRE statement

  ```
  DELWIRE layerName width x1 y1 x2 y2
  ```

- ADDVIA statement

  ```
  ADDVIA [botLayerName bx1 by1 bx2 by2] topLayerName tx1 ty1 tx2 ty2
  ```

  Note: For turnvias, Innovus reports *topLayerName* only.

- DELVIA statement

  ```
  DELVIA [botLayerName bx1 by1 bx2 by2] topLayerName tx1 ty1 tx2 ty2
  ```

  Note: For turnvias, Innovus reports *topLayerName* only.

- ADDOBS statement

  ```
  ADDOBS layerName x1 y1 x2 y2
  ```

- DELOBS statement

  ```
  DELOBS layerName x1 y1 x2 y2
  ```

Parameters

`-help`	Prints a brief description that includes the type and default information for each `defComp` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man defComp`.
`-bump`	Checks only bump-related objects, such as bump and areaio instance in the COMPONENTS section, bump assignment, and special routing in the SPECIALNETS section.The information reported includes: • Added, moved, and deleted bumps • Added, changed, and deleted routing • Added, changed, and deleted net assignments **Note:** When this option is specified, `defComp` suppresses checks on default objects, such as standard cells and blocks, and only checks bump-related objects.
`-checkCellPrefix` *prefix_list*	Checks instances whose instance name begins with the specified prefix. You can use this parameter only if you also specify the `-ignoreCellPlace` parameter. If you specify more than one prefix, you must enclose the list in braces, for example, `{CORE PAD}`. Default: All LEF `MACRO` classes specified by the `-ignoreCellPlace` parameter are ignored.
`-defAsGolden`	Treats the DEF file as the golden file when comparing the DEF file to the data in the database. By default, the software compares the DEF to the data in the database and reports the differences relative to the database. For example, `ADDINST` in the report file means the instance is not in the database, but in the DEF file. When you specify `-defAsGolden`, the software reports the differences relative to the DEF file. Therefore, if the instance is not in the database, but is in the DEF file, `DELINST` is written in the report file.
fileName	Specifies the name of the DEF file you want to compare with the physical design data in the database.
`-ignoreCellPlace` *lef_macro_classes_list*	Ignores the specified cell classes, for example `{CORE PAD}`.
`-ignoreLayerFrom` *layer*	Ignores the specified metal or cut layer, and all metal and cut layers above. You can specify this parameter with the `-ignoreLayerTo` parameter to select a layer range. You must specify metal layers as `Metal1`, `Metal2`, `Metal3`, and so on, and cut layers as `V1`, `V2`, `V3`, and so on. *Default:* All layers are compared.
`-ignoreLayerTo` *layer*	Ignores the specified metal or cut layer, and all metal and cut layers below. You can specify this parameter with the `-ignoreLayerFrom` parameter to select a layer range. You must specify metal layers as `Metal1`, `Metal2`, `Metal3`, and so on, and cut layers as `V1`, `V2`, `V3`, and so on. *Default:* All layers are compared.
`-ignoreLogicChange`	Ignores logic changes when comparing a DEF file with the physical design data in the Innovus database.
`-metalShapeDiff`	Without the option, the command will report the same routing segment or via with one pair of line as difference - one with "ADDWIRE/ADDVIA" and one with "DELWIRE/DELVIA" - in the report file if it is on a different net or if its routing type has changed from special to regular or vice versa between db and def file. With the option, the command will not report such difference in report file.
`-placeBlockage`	Compares placement blockage and block halo equivalence.
`-reportFile` *fileName*	Specifies the name of the report containing the results of the comparison. *Default:* `defPhyDiff.rpt`
`-row`	Compares row and site equivalence, name, location, and orientation.
`-snetPin`	Reports any pins that have changed between the NETS and SPECIALNETS sections.
`-unit` *units_value*	Uses the specified `UNITS` value (typically, the `UNITS` value in the DEF file) to scale all distance values in the report file. *Default:* Uses the current database unit (DBU) value in the database, derived from the LEF information, to scale distance values.

Example

- The following command compares data in the `myDEF` file with that in the database, and writes the results to `myResultsFile.rpt`:
  ```
  defComp myDEF -reportFile myResultsFile.rpt
  ```
- The following command checks rows, placement blockages, and block halos in `myDEF`. This example checks all instances except class `CORE` and `PAD`; however, it checks `CORE` and `PAD` cells whose instance name prefix is `PRE`. This example also checks all wires and vias except for those on and between layers `Metal2` and `Metal6`, and writes the comparison results to `myResultsFile.def`.
  ```
  defComp -row -placeBlockage -ignoreCellPlace {CORE PAD} -checkCellPrefix PRE -ignoreLayerFrom Metal2 -ignoreLayerTo Metal6 -reportFile
  myResultsFile.def myDEF
  ```
- The following report is generated by the command `defComp -def a.def -reportFile defCompArea.out`:
  ```

defIn

```
defIn
[-help]
fileName
[-add_blockage]
[-allWarning]
[-components]
[-deleteBump]
[-deleteSpecialRoute]
[-ignore_drcfill]
[-ignore_pg_connectivity]
[-nets]
[-preserveShape]
[-removeHalfWireExtensionOnPin]
[-specialnets]
[-specialRouteUserClass user_class_name]
[-verilog_from_def_netlist_flow]
[-incremental_routing]
```

Loads the specified DEF file. `defIn` can be used at any step after importing a design. The typical usage is:

- Load a DEF file containing the floorplan saved by Innovus or other tool.
- Load a DEF file containing the scan chain information so that placement can do scan chain reorder.
- Load a DEF file containing the cell's placement and routing saved by Innovus or other tool.

Note: `defIn` ignores the shielding segment with self reference.

ⓘ When you load a DEF file, you must be at the same level in the hierarchy where the DEF file was saved.

The Innovus software loads the DEF file information into the database in several ways, depending on the object:

- Tracks, gcells, rows, die area
  The software deletes all of the existing objects in the database and reads in the new information.

  Note: The `defIn` command can read a rectilinear die area, but converts it to a rectangular die area with blockages at the cut off area.
- Blockages, fills, special nets
  The software compares the physical data (such as shape and layer) to the existing data in the database. If it finds the same data in the database, it ignores the data in the DEF file. If the data does not already exist, the software adds it to the database. For special nets, the software merges wire segments in the DEF file with any existing ones in the database that overlap and have the same attributes, such as layer, width, shape, and direction. The software does not delete any existing data.

  Note: As a lot of spacing rules in advanced nodes no longer just rely on wire width, `DESIGNRULEWIDTH` is not allowed for 20nm and below nodes.
- Nondefault rules, vias
  The software adds the objects to the database if they do not already exist there. If a nondefault rules definition with the same name already exists, the software ignores the one in the DEF file. If a via definition with the same name already exists, and the via is a fixed via, the software ignores the one in the DEF file. If a generated via definition with the same name already exists, the geometries are read, but the name might be changed. The software does not delete any existing objects of these types.

  The DEF reader checks the NDR rule only if its name is "DEFAULT" and checks whether all definition of the "DEFAULT" NDR match the LEF default rule. If the NDR rule name is not DEFAULT, the tool will give the following warning message:

  ```
  WARN: The definition of "s%" are different between the NDR Rule "DEFAULT" in DEF file and the implicit default rule in LEF File.
  ```

  Also, DEF reader will not create a "DEFAULT" NDR in DB, and give following warning message:

  ```
  WARN: Innovus does not allow user to specify an NDR rule named as "DEFAULT", ignore it when reading the DEF file and use LEF rule to replace it.
  ```
- Nets
  For each net in the DEF file, the software removes the existing regular routing (not special routing), then adds the routing from the DEF file for this net. If the net has a shielding segment with self reference, `defIn` will ignore the check. For example:

  ```
  SPECIALNETS 1 ;
  - VDD + SHIELD VDD ( 0 0 ) ( 0 100 ) ...
  ```

If the shielded net is not self referenced, `defIn` will check the shielding segment. For example:

```
SPECIALNETS 1 ;
- VDD + SHIELD net1 ( 0 0 ) ( 0 100 ) ...

NETS 1 ;
-nets + SHIELDNET VDD ...
```

- Pins
  For each pin in the DEF file, the software removes the existing physical information for the pin, then adds the physical information from the DEF file for this pin. If a pin does not already exist, and it is a power or ground pin, the software adds it to the database. If the pin is not a power or ground pin, the software generates an error message.
- Groups, regions
  If a group name in the DEF file matches an existing hierarchical instance name in the database, the region's boundary constraint is attached to the hierarchical instance, overriding any existing boundary constraint. The software checks whether the group members belong to the hierarchical instance, and generates a warning message if any do not belong. If a group name does not match any hierarchical instance name, the software creates the instance group with an attached region boundary constraint, if one exists. Regions that are not used by groups in the same DEF file are ignored. The software does not remove existing groups.

  Note: You can import DEF files containing wildcards (`*`) in the `GROUPS` statement. The `defIn` command does not support multiple groups per region.
- Components
  You cannot add new logical cells. You can add new physical cells, such as:
  - Cells with `CLASS PAD`
  - Cells with `CLASS COVER` and no signal pin
  - Instance with `+ SOURCE DIST`

You can use the `defIn` command after importing a design.

You can use the `defIn -verilog_from_def_netlist_flow` command only after using the `loadDefFile` command.

Note: Do not attempt to use the `defIn -verilog_from_def_netlist_flow` command in any other Tcl scripts.

> ***After loading the DEF netlist using the `defIn -verilog_from_def_netlist_flow` command, you can perform floorplanning, non-timing driven placement and routing, wire editing, and verification. You cannot use the DEF netlist flow for parasitic extraction, delay calculation, and timing-driven placement and routing effectively because the DEF names do not properly match the Verilog names used in timing constraints and timing analysis.***

Parameters

`-help`	Prints a brief description that includes the type and default information for each `defIn` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man defIn`
`-add_blockage`	Converts undefined instances (except COVER cells) into blockages.
`-allWarning`	Lists all warning messages issued when you load the DEF file. *Default:* Limits the number of warning messages to the first 1,000.
`-components`	Reads the `COMPONENTS` section of the DEF file and ignores other sections, except when the `-nets` or `-specialnets` parameters are specified.
`-deleteBump`	Deletes all bumps in the database before reading the DEF file.
`-deleteSpecialRoute`	Deletes all special routes in the database before reading the DEF file. This includes the RDL routing as well as the power and ground special routes in the design.
`-ignore_drcfill`	Ignores the special routing with DRCFILL shape attribute.
`-ignore_pg_connectivity`	Ignores the pg connectivity in the SPECIALNETS and NETS sections.
`fileName`	Specifies the name of the DEF file to load.
`-incremental_routing`	Prevents deletion of the whole routing of the signal net, and just adds the new wires and vias.
`-nets`	Reads the `NETS` section of the DEF file and ignores other sections, except when the `-components` or `-specialnets` parameters are specified.
`-preserveShape`	Prevents creation of symbolic center-line connected routing data and preserves the routing data as-is. The option will override the global environment variable `defInShapeBasedDefFile`.
`-removeHalfWireExtensionOnPin`	Truncates the half-width extension back to zero extension for all wire end points that overlap a pin. This is useful for DEF files created by `defOut -addHalfWireExtensionOnPin`, which forces all `NETS` section routing to use the default half-width wire extension. **Note:** Using this parameter can cause DRC violations.
`-specialRouteUserClass` *`user_class_name`*	
	Sets the specified user-class name on all the special routes read in from the DEF file.
`-specialnets`	Reads the `SPECIALNETS` and `VIAS` sections of the DEF file and ignores other sections, except when the `-components` or `-nets` parameters are specified.
`-verilog_from_def_netlist_flow`	Reconciles the names in the DEF and Verilog files generated by the `loadDefFile` command. This procedure is required if you want to retrieve any information that matches the original DEF file.

Example

- The following command loads the `TOPCHIP` DEF placement file:
  ```
  defIn TOPCHIP.def
  ```
- The following command loads the power grid from a DEF file:
  ```
  defIn -specialnets TOPCHIP.def
  ```

```

Writes the specified information to a DEF file. By default, the `defOut` command writes floorplan, and all placed and unplaced standard cell information to the DEF file.

The `defOut` command does not support multiple groups per region. The `defOut` command supports rectilinear die area.

By default, the `defOut` command does not write out any `NONDEFAULTRULE` or `VIA` defined in the LEF file. To write out a LEF via, set the `defOutLefVia` global environment variable to `1`. To write out a nondefault rule, set the `defOutLefNDR` global environment variable to `1`.

You can use the `defOut` command after importing a design.

Note: You can select the DEF version for your output file by setting the `lefDefOutVersion` global environment variable to the version number. For example, to set the version number to 5.6, type the following command:

```
set lefDefOutVersion 5.6
```

Parameters

`-help`	Prints a brief description that includes the type and default information for each `defOut` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man defOut`.
`-addHalfWireExtensionOnPin`	
	Typically, signal routing in the `NETS` section uses the default half-width wire extensions everywhere except for zero extensions on pins. This parameter forces the zero-extension on pins to the default half-width extension, and makes the DEF compatible for older tools that do not support DEF zero wire extensions. **Note:** Using this parameter can cause DRC violations.
`-allLayers`	By default, only wires and vias on routing layers are written to the DEF. This option will write out wires, vias, and shapes on non-routing layers to the SPECIALNETS section. This includes the LEF MASTERSLICE layers, IMPLANT layers, and ROUTING or CUT layers with sub-types MIMCAP or PASSIVATION. These shapes might have been added with add_shape, or imported from DEF or OA directly.

`-bumpAsPin`	Writes bump cells as top-level pins in the `PINS` section. If a PORT in a block has a PASSIVATION layer, the tool treats it as an embedded bump. `defOut -bumpAsPin` outputs all the layer information for embedded bumps in the PIN section as for normal bumps. Use the `-bumpAsPin` parameter to generate a DEF file for use with Quantus gate-level extraction. A DEF file generated with this parameter cannot be read back into the Innovus software.
`-cut_pg_rail`	Cuts the pg rails.
`-cutRow`	Cuts rows against placement obstructions, block halos, or power domain fence minimum gaps. *Default:* Placement blockages are written to the DEF file.
`-earlyGlobalRoute`	Writes information about the wires generated by Early Global Router to the `NETS` section of the DEF file. This option implies the `-routing` parameter; therefore, if you specify this parameter, you do not need to specify `-routing`.
`fileName`	Specifies the DEF output file. If you add `.gz` as a suffix, the `defOut` command will automatically compress the generated file.
`-flatten_via_pillar`	Some advanced nodes that use SADP (self-aligned double patterning) use via-pillars. A via-pillar is a single via definition with two or more disjoint metal-shapes on the bottom (or top) routing layer of the via. This option will flatten the via pillar into several separate "normal" vias (e.g. a via with only a single metal shape on the top and bottom via layers). The multiple normal vias will be geometrically equivalent to the single via pillar. This can be useful for external tools that do not support a via pillar. **Note:** DEF created with this option should not be read back into Innovus. It should only be used for external tools that do not support via-pillars properly.
`-floorplan`	Writes the floorplan data to the DEF file. This information includes rows, chip size, `CLASS PAD` instances, `CLASS BLOCK` instances, and all placed standard cells.
`-ioRow`	Generates I/O rows based on I/O pad placement, and writes the I/O row information to the DEF file.
`-netlist`	Writes the netlist (that is, the routing connectivity information) to the DEF file. This option is typically used after the design has been placed. **Note:** Use `-netlist` with `-unplaced` if the design has not been placed.
`-noCoreCells`	Excludes core cell information from the DEF file to reduce the data size for import into APD.
`-noPrintWildCard`	Suppresses the use of the wildcard format to represent special net connectivity.
`-noSpecialNet`	Excludes special vias from the DEF file.
`-noStdCells`	Excludes placed and unplaced standard cell information from the DEF file. **Note:** • If you specify this parameter with the `-floorplan` or `-unplaced` parameters, it overrides their setting. • Fixed and cover instances are considered as pre-placed floorplan objects. This option does not apply to them.
`-noTracks`	Excludes output track and gcell statements to the DEF file.
`-no_virtual_trim`	Excludes the trim metal shapes on a virtual trim metal layer.
`-outputMaskLayers` *`listOfLayers`*	
	Specifies the output MASK data on the specified layers only. The valid values for this option are "metal", "cut", or a list of layers separated by a space character in a form of either a single layer or a range of layers. For example, `-outputMaskLayers {Metal1:Metal3 Via23}` You can also specify none as a value. When none is specified, `defOut` does not give any MASK data on any layer in the output.
`-routing`	Writes the routing information to the `NETS` section of the DEF file. If the `-routing` option is not specified, both power and signal vias are not written to the DEF file. **Note:** The `-routing` parameter implies the `-netlist` parameter; therefore, if you specify this parameter, you do not need to specify `-netlist`.

`-routing_to_specialnet`	Writes all regular NETS routing to the SPECIALNETS section instead. It converts all regular routing wires and vias that are normally written to the NETS section, to SPECIALNETS routing as RECT or VIA statements. This is intended to be read by analysis tools (such as RC extraction tools) that do not understand all the NETS routing properly. Some tools do not understand some newer DEF syntax, or how to interpret wrong-way routes that are wider than the default routing-rule for some advanced nodes due to WIDTH, WIDTHTABLE or SPANLENGTHTABLE rules with WRONGDIRECTION values. **Note**: Specialnet routing cannot be modified by the signal router. So, it should not be read back for any flows that will require optimization or future incremental or ECO routing. This option cannot be used with the `-earlyGlobalRoute` option.
`-scanChain`	Writes scan chain information to the DEF file. This option is mandatory to ensure that START/STOP instances of scan chain are preserved during timing/power closure when reloading the DEF in another session.
`-selected`	Writes out information for selected as follows: • If an instance or net is selected, writes only the DEF header and COMPONENT section for instances you have selected in the Innovus main window. If you specify the `-routing` parameter along with this parameter, the `defOut` command writes selected nets with their special routing and regular routing to the NETS section of the DEF file. • If a net is not selected but individual segments or vias are selected, writes only the selected vias to the DEF file. All LEF vias are excluded by default. If the `defOutLefVia` global variable is set to `1`, `defOut -selected` includes selected LEF vias when writing out selected vias. If the `-noSpecialNet` option is specified, special vias on the selected net will not be written out. • If a bump is selected, writes bump pin connection to the `SPECIALNETS` section of the DEF file. If a net is selected but bump pins are not individually selected, bump pin connection is not written. • If a blockage is selected in the main window, writes blockage information to the DEF file. • If a group is selected, all the instances in the selected groups are treated as selected and are writtten out.
`-skip_trimmetal_layers`	Specifies not to write trimmetal shapes in the FILLS section.
`-specialRouteUserClass` *user_class*	Specifies the user class for special route.
`-trimmetal_gap_fill`	Writes trimmetal gap fills to a dummy net _TRIMMETAL_FILLS_RESERVED in the SPECIALNETS section.
`-unit` *unit_per_micron*	Defines the units for the DEF file.
`-unplaced`	Writes information about unplaced standard cells to the DEF file.
`-useEEQCellWithLibertyInfo`	
	Specifies to use the EEQ cell with the timing library information as the master cell of a leaf instance.
`-usedVia`	Specifies that only used vias should be written to the DEF file. Unused vias are ignored. All LEF vias are also excluded by default. To include used LEF vias in the DEF file, set the `defOutLefVia` global variable is set to `1` before specifying `defOut -usedVia`. • If the `-routing` option is specified along with `-usedVia`, used signal vias are also written out. • If the `-noSpecialNet` option is specified along with `-usedVia`, used special vias are not written out. • If you specify both `-usedVia` and `-selected`, the `-usedVia` option is ignored and only selected vias are written to the DEF file. The following warning message is issued: `**WARN: (ENCDF-1039): Option -usedVia will be ignored because option -selected is specified. Only selected vias will be output.` • If neither `-selected` nor `-usedVia` is specified and the `defOutLefVia` variable is set to `0` (default), all DEF vias are written out. • If neither `-selected` nor `-usedVia` is specified and the `defOutLefVia` variable is set to `1`, all DEF and LEF vias are written out.
`-verilog_from_def_netlist_flow`	

	Reconciles the names in the DEF and Verilog files generated by the `loadDefFile` command. The `loadDefFile` command generates a flat Verilog file in which all of the special characters are escaped. Use this parameter to convert the escaped names back to the original names in the DEF file.
`-withShield`	By default, `defOut` does not write out the shielding routing on the power/ground net when outputting regular routing of selected nets in NETS section. When `-withShield` is specified, `defOut` writes out those shielding routing (if any) on the power/ground net which is in the SPECIALNETS section. The`-withShield` option must be used with the `-routing` and `-selected` options. **Note:** Multiple nets can be selected. If none of the selected nets have shielding routing, the `-withShield` option has no effect.
`-wrongway_routing_as_specialroute`	
	Writes wrong-way routing in the SPECIALNETS section. This option duplicates any wrong-way routing segments that require extra-width into the SPECIALNETS routing section as a RECT with +SHAPE DRCFILL. This option is intended to be used for tools (such as RC extraction tools) that do not understand how to increase the width of DEF wrong-way NETS routing properly. DEF requires wider widths for some wrong-way routes due to LEF DRC rules using the WIDTH, WIDTHTABLE, or SPANLENGTHTABLE statements along with WRONGDIRECTION values. These types of tools normally understand SPECIALNET RECT statements and can merge the SPECIALNET RECT on top of the NETS wrong-way routing segment and therefore use the correct width. The duplicate SPECIALNETS RECTs are given the +SHAPE DRCFILL keyword in order to make it easy to filter them out for tools that do not need them. When loading back the DEF with these DRCFILL, use `defIn -ignore_drcfill` to ignore these duplicate wrong-way direction segments.

Example

- The following command writes floorplanning data, and information on placed and unplaced standard cells to `TOPCHIP_SP.def`:
  ```
  defOut -floorplan -unplaced TOPCHIP_SP.def
  ```
- The following command also writes floorplanning data, and information on placed and unplaced standard cells:
  ```
  defOut test.def
  ```
- The following command writes floorplan and standard cell information to the DEF file. It does not write out unplaced standard cell information.
  ```
  defOut -floorplan
  ```
- The following command excludes all information on placed and unplaced standard cells from the DEF file:
  ```
  defOut -floorplan -noStdCells
  ```

  The resulting DEF file contains floorplan data only.
- The following command writes the shield wires that are shielding the selected nets to the DEF file:
  ```
  defOut -selected -routing -withShield test.def
  ```
- The following command writes bump cells as top-level pins in the PINS section of the `test.def` file:
  ```
  defOut -bumpAsPin test.def
  ```

  The PINS section in the test.def file is as follows:

```
++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++
PINS 102 ;

defOutBySection

```
defOutBySection
[-help]
filename
[-addHalfWireExtensionOnPin]
[-bumpAsPin]
[-compPlacement]
[-earlyGlobalRoute]
[-fills]
[-groups [-noPrintGroupRegex]]
[-ioRow]
[-netRouting]
[-noComps]
[-noCoreCells]
[-noDieArea]
[-nonDefaultRules]
[-noNets]
[-noPrintWildCard]
[-no_virtual_trim]
[-outputMaskLayers layerNames]
[-pBlockages]
[-pins]
[-rBlockages]
[-rows]
[-scanChains]
[-selected]
[-specialNetRouting]
[-specialNets]
[-specialRouteUserClass user_class_list]
[-specialShape swire_type_list]
[-tracks]
[-unit unit_per_micron]
[-unplaced]
[-usedVia]
[-verilog_from_def_netlist_flow]
[-vias]
```

Writes information to the specified sections in a DEF file. By default, it writes DIEAREA (and associated FE_CORE_BOX* properties), and the netlist part (not the placement or routing part) of the COMPONENTS and NETS sections that must be explicitly suppressed with options below if you don't want them. Other sections or sub-sections are only added based on option settings.

By default, the `defOutBySection` command does not write out any via defined in the LEF file. If the `defOutLefVia` global environment variable is set to `1`, the `defOutBySection` command writes out the via defined in LEF file.

You can use the `defOutBySection` command after importing a design.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `defOutBySection` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man defOutBySection`
`-addHalfWireExtensionOnPin`	
	Forces the zero-extension on pins to the default half-width extension.
`-bumpAsPin`	Writes bump cells as top-level pins in the PINS section. Use this parameter to generate a DEF file for use with Quantus gate-level extraction. **Important**: A DEF file generated with this parameter cannot be read back into the Innovus software.
`-compPlacement`	Writes component placement and orientation information to the `COMPONENTS` section of the DEF file. The output is limited to instances with PLACED/FIXED/COVER status, unless `-unplaced` is also specified.
`-earlyGlobalRoute`	Writes wire information generated by the Early Global Router to the `NETS` section of the DEF file.
filename	Specifies the name of the DEF output file.

`-fills`	Writes metal fill information to the `FILLS` section of the DEF file.
`-groups`	Writes group information to the `GROUPS` section of the DEF file. When you use this parameter, Innovus also writes information about regions.
`-ioRow`	Generates I/O rows based on I/O pad placement and writes the I/O row information to the DEF file.
`-netRouting`	Writes routing data to the `NETS` section of the DEF file.
`-noComps`	Excludes component information from the DEF file.
`-noCoreCells`	Excludes core cell information from the DEF file to reduce the data size for import into APD.
`-noDieArea`	Excludes the DIEAREA and associated FE_CORE_BOX* properties (FE_CORE_BOX_LL_X, FE_CORE_BOX_UR_X, FE_CORE_BOX_LL_Y, FE_CORE_BOX_UR_Y). You can use this option if you do not need some sections, such as SCANCHAINS or NONDEFAULTRULES, to be consistent with the DIEAREA or core-box settings.
`-nonDefaultRules`	Writes non default rules (NDRs) to the NONDEFAULTRULES section of the DEF file. **Note**: The `-nonDefaultRules` parameter works only with `-noNets`. As the NETS section is always dumped by default, so the NONDEFAULTRULE section is also dumped by default. However, if `-noNets` is specified, the NONDEFAULTRULE section will be dumped only if `-nonDefaultRules` is also specified.
`-noNets`	Excludes net information from the DEF file. **Note**: If `-noNets` is specified, the `-netRouting` and `-earlyGlobalRoute` parameters are ignored.
`-noPrintGroupRegex`	Suppresses the use of regular expressions to represent instance names. You must also specify the `-groups` parameter.
`-noPrintWildCard`	Suppresses the use of the wildcard format to represent special net connectivity. If specified, the `-compPlacement` parameter is ignored. **Note**: The `-noPrintWildCard` parameter must be used along with the `-specialNets` parameter to be effective. If you specify `-noPrintWildCard` without `-specialNets`, the software ignores it. *Default:* If you do not specify this parameter, Innovus writes connectivity information in the `SPECIALNETS` section in wildcard format, if possible.
`-no_virtual_trim`	Excludes the trim metal shapes on a virtual trim metal layer.
`-outputMaskLayers` *layerNames*	Outputs MASK data on specified layers only.
`-pins`	Writes pin information to the `PINS` section of the DEF file.
`-pBlockages`	Writes placement blockage information to the `BLOCKAGES` section of the DEF file.
`-rBlockages`	Writes routing blockage information to the `BLOCKAGES` section of the DEF file.
`-rows`	Writes row information to the `ROWS` section of the DEF file.
`-scanChains`	Writes scan chain information to the `SCANCHAINS` section of the DEF file.
`-selected`	Writes out information for selected as follows: • If a net or instance is selected, writes only the DEF header and `COMPONENT` section for instances or nets you have selected in the Innovus main window. If you specify the `-specialNetRouting` parameter along with this parameter, the `defOutBySection` command writes selected nets with their special routing to the NETS section of the DEF file. • If a net is not selected but individual segments or vias are selected, writes only the selected vias to the DEF file. All LEF vias are excluded by default. If the defOutLefVia global variable is set to 1, `defOutBySection -selected` includes selected LEF vias when writing out selected vias. • If a bump is selected, writes bump pin connection to the `SPECIALNETS` section of the DEF file. If a net is selected but bump pins are not individually selected, bump pin connection is not written. • If a blockage is selected in the main window, writes blockage information to the DEF file. • If a group is selected, all the instances in the selected groups are treated as selected and are writtten out.

`-specialNets`	Writes the pin connections for special nets to the `SPECIALNETS` section of the DEF file. When specified along with `-selected`, writes out the pin connections for only selected nets. Does not write routing information.
`-specialNetRouting`	Writes routing information for special nets to the `SPECIALNETS` section of the DEF file, when specified with the `-specialNets` parameter. Use this parameter with `-selected` to write routing information of only selected nets. Use this parameter with `-specialRouteUserClass` to write routing information of only those special routes that have a `user_class` attribute from the specified list.
`-specialRouteUserClass` *`user_class_list`*	
	Writes out only the special routes with a user_class attribute from the specified list.
`-specialShape` *`swire_type_list`*	Writes special routing information with specified shape types. **Note:** Use `defOutBySection -specialShape` after you have used the `setSpecialRouteType` command to mark special wires and vias and set them to a specific shape type.
`-tracks`	Writes routing track information to the `TRACKS` and `GCELLGRID` statements of the DEF file.
`-unit` `unit_per_micron`	Defines the units for the DEF file.
`-unplaced`	Includes UNPLACED instances in the `COMPONENTS` section when combined with the `-compPlacement` option.
`-usedVia`	Specifies that only used vias should be written to the DEF file. Unused vias are ignored. All LEF vias are also excluded by default. To include used LEF vias in the DEF file, set the `defOutLefVias` global variable is set to `1` before specifying `defOutBySection -usedVia`. • If you specify both `-usedVia` and -selected, the `-usedVia` option is ignored and only selected vias are written to the DEF file. The following warning message is issued: **WARN: (ENCDF-1039): Option `-usedVia` will be ignored because option `-selected` is specified. Only selected vias will be output. • If neither `-selected` nor `-usedVia` is specified and the `defOutLefVias` variable is set to `0` (default), all DEF vias are written out. • If neither `-selected` nor `-usedVia` is specified and the `defOutLefVias` variable is set to `1`, all DEF and LEF vias are written out.
`-verilog_from_def_netlist_flow`	
	Reconciles the names in the DEF and Verilog files generated by the loadDefFile command. The loadDefFile command generates a flat Verilog file in which all of the special characters are escaped. Use this parameter to convert the escaped names back to the original names in the DEF file.
`-vias`	Writes via information to the `VIAS` section of the DEF file.

Example

- The following command writes component placement, pin, and special net information to the `test.def` file:

```
defOutBySection -compPlacement -pins -specialNets test.def
```

- In the following set of commands, `setSpecialRouteType` first traces special wires and vias that touch the named bump cells and sets them to `IOWIRE`. `defOutBySection` then writes the special routing with IOWIRE shape type to the `test1.def` file.

```
setSpecialRouteType -bumpCell {bc*} -stopTypeList {IOWIRE} -setType IOWIRE

defOutBySection -specialShape {IOWIRE} test1.def
```

- With only the VDD net selected in the main window, the following command writes the routing information without pin connections for only those special routes in VDD that have the user_class attribute names `attrA` or `attrB`.

```
defOutBySection -specialNetRouting -specialRouteUserClass {attrA attrB} -selected
```

deleteModule

```
deleteModule
moduleName
[-help]
[-cell | -cells ]
```

Deletes a hierarchical instance and it's module and optionally, its cell.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `deleteModule` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man deleteModule`.
`-cell`	Deletes the module of the hierarchical instance. It only works when the specified hierarchical instance is the last one in the design that references this module.
`-cells`	Deletes all submodules that are hierarchically inside the module from which the given hierarchical instance *`moduleName`* is instantiated. If a submodule is multi-referenced and all sibling hierarchical instances instantiated from the submodule are hierarchically inside the *`moduleName`* hierarchical instance, the submodule will be deleted. Otherwise, the multi-referenced submodule will not be deleted.
`moduleName`	Specifies the hierarchical instance to delete.

Examples

- The following command deletes instance RESULTS_CONV_INST:
  ```
  deleteModule DTMF_INST/RESULTS_CONV_INST
  ```
- The following command deletes instance RESULTS_CONV_INST and deletes its cell:
  ```
  deleteModule DTMF_INST/RESULTS_CONV_INST -cell
  ```

deleteTrack

```
deleteTrack
[-help]
[-dir {X|Y}]
[-layer layerNameList]
```

Deletes a set of tracks in the database. Without arguments, it deletes all the tracks in the database.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `deleteTrack` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man deleteTrack`.
`-dir {X | Y}`	Specifies the direction of the track to be deleted. X indicates vertical lines; Y indicates horizontal lines. This is optional.
`-layer layerNameList`	Specifies the routing layer on which the tracks to be deleted. You can specify more than one layer. This is optional.

Examples

- The following command deletes the track between M1 and M2:
  ```
  deleteTrack -layer {M1 M2}
  ```
- The following command deletes the vertical tracks:
  ```
  deleteTrack -dir X
  ```

disconnectDanglingPort

```
disconnectDanglingPort
[-help]
[-keepInput]
[-keepOutput]
[-keepInout]
[-partitionOnly]
```

Disconnects dangling nets from ports in the whole design, from the top level to the bottom level. Use `reportDanglingPort` to report the dangling ports.

You can use the `disconnectDanglingPort` command after importing a design.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `disconnectDanglingPort` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man disconnectDanglingPort`.
`-keepInput`	Keeps the input dangling port connected.
`-keepOutput`	Keeps the output dangling port connected.
`-keepInout`	Keeps the inout dangling port connected.
`-partitionOnly`	Disconnects dangling nets in partitions only. *Default:* Disconnects all dangling nets.

Examples

- The following command disconnects dangling wires in partitions only:
  ```
  disconnectDanglingPort -partitionOnly
  ```

- The following set of commands first reports the dangling ports and then disconnects them:
  ```
  innovus > reportDanglingPort -outfile danglingport.rpt
  ```

  Sample content of the file `danglingport.rpt`:
  ```
  Port sel of module user_DFT_inst_BandA_0
  Port a of module user_DFT_inst_BandA_0
  Port b of module user_DFT_inst_BandA_0
  Port y of module user_DFT_inst_BandA_0

  innovus > disconnectDanglingPort
  Port sel of module user_DFT_inst_BandA_0 is disconnected...
  Port a of module user_DFT_inst_BandA_0 is disconnected...
  Port b of module user_DFT_inst_BandA_0 is disconnected...
  Port y of module user_DFT_inst_BandA_0 is disconnected...
  4 connected dangling ports are disconnected.
  ```

dumpOutVias

```
dumpOutVias
[-help]
[-autogen]
[-file filename]
[-all_via | -signal | -all_rule | -default | -ndr ]
```

Helps in debugging and testing. All the boolean options are default to false. If none is set, the vias are dumped out in LEF format.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `dumpOutVias` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man dumpOutVias`.
`-all_rule`	Dumps out vias from all routing rules. this option is of type boolean.
`-all_via`	Dumps out all vias. This option is of type boolean.
`-autogen`	Dumps out auto-generated vias. This option is of type boolean.
`-default`	Dumps out vias of default routing rule. This option is of type boolean.
`-file filename`	Specifies the output file name. This option is of type string. *Default*: `dump_via.out`
`-ndr`	Dumps out vias of nondefault routing rules. This option is of type boolean.
`-signal`	Dumps out signal vias. This option is of type boolean.

Example

The following command dumps out all signal vias to the default output file, `dump_via.out`:

```
dumpOutVias -signal
```

Here's the sample output:

```
#### Begin signal vias ####
VIA V01  # LEF
  LAYER POLY ; RECT -0.033 -0.033 0.033 0.033 ;

generateLef

```
generateLef
[-help]
outputLefFileName
[-clfFile clfFileName]
[-lefFile lefFileName]
[-lefFileList {technology.lef cell1.lef cell2.lef ...}]
[-noWE]
[-techFile technologyFileName]
```

Uses input data to create an optimized LEF file with generated vias for the NanoRoute® router.

Input data can include the following:

- Original or customized LEF technology files
- Milkyway technology file
- Milkyway CLF file

Note: Include sample vias for each cut layer in the LEF file. You must also include test via rules in the input in order for the output to contain the created vias.

- Scans default vias from input data to determine the following:
  - Minimum overhang
  - Width
  - Spacing
  - End-of-line overhang
- Generates auto-vias for default, power, and other generated explicit vias.
- Retains original naming convention for LEF macro reference. If there is a conflict, utilizes original names.
- Updates technology description with all vias (for example, adds multi-cut vias automatically if a `MINIMUMCUT` statement is provided).

Use the `generateLef` command before routing with the NanoRoute router.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `generateLef` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man generateLef`.
`-clfFile clfFileName`	Specifies a Milkyway CLF input file. You must also specify the `-techFile` parameter when you specify this parameter.
`-lefFile lefFileName`	Specifies a LEF input file.
`-lefFileList {technology.lef cell1.lef cell2.lef …}`	Specifies a list of LEF files to read into the software to use for generating vias with different orientations, extensions, and offsets.  The file can list only one filename per line. The first file listed must be the technology LEF file.
`-noWE`	Generates default vias for no wire extension routing.
`outputLefFileName`	Specifies the new LEF file to output.
`-techFile technologyFileName`	Specifies a Milkyway technology file. You must also specify the `-clfFile` parameter when you specify this parameter.

Examples

- The following command converts an old LEF file to an optimized LEF file for NanoRoute:
  ```
  generateLef -lefFile old.lef new.lef
  ```

- The following command converts a Milkyway technology file to an optimized LEF file for NanoRoute:
  ```
  generateLef -techFile mw.tf mw.lef
  ```
- The following command converts a CLF file to an optimized antenna LEF file for NanoRoute:
  ```
  generateLef -clfFile mw.clf ant.lef
  ```

  - "Running the NanoRoute Router with the Innovus Text Commands"
  - "Using a Design Flow that Includes Astro or Apollo"

generateVias

```
generateVias
-help
[ -ndr_only ]
```

Auto-generates vias required by nanoroute for the default and non-default rules (NDRs). The vias are based on the wire-widths of the routing-rule and are created to meet all the DRC via enclosure rules with variations for good pin-access, variations of double-cut vias for good double-cut via utilization, and min-area vias required for stacked-vias that have no route connected to meet the min-area metal rule.

The command only creates vias in the current Innovus session; they are not saved and restored for usage in a later Innovus session. So this command is normally only used for experimentation, or possibly if you just want temporary extra DFM vias to be used for this one session. If you want to save the vias for usage by nanoroute in later Innovus sessions, use `setGenerateViaMode -auto true`. The command is not set to "on" by default as `setGenerateViaMode` is set to `false` by default.

The command requires correct DRC rules (e.g. enclosure, spacing, minimum-cut, min-area rules, etc), and at least one LEF VIARULE GENERATE statement (or OpenAccess standardViaDef) for every via layer used for routing (as required by OpenAccess). The cut enclosure values in the VIARULE GENERATE statement are not used except for old LEF technology files (LEF version 5.5 and older) that have no enclosure rules (this is not recommended usage, but is kept for backward compatability). The VIARULE cut-spacing values are ignored–only the DRC cut-spacing values are used.

No predefined vias are required (e.g LEF VIA DEFAULT, or NONDEFAULTRULE USEVIA or an OpenAccess validVias list for any routing ConstraintGroup are not needed).

Any predefined vias that do exist, are kept unless `-deleteViaBeforeGenerate` is used (see below). Generated vias are compared to predefined vias and if they are geometrically identical, that specific generated via is not kept so no duplicate vias are created.

Note: NDRs that have the same widths as the default rule will inherit the same vias, including any pre-defined vias.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `generateVias` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man generateVias`.
`-ndr_only`	Specifies vias generation for non-default rules only. When specified, it generates signal routing vias for all NDR (non-default rules) and skips generating via for default rule. It is always used for designs having full set of default rule vias, but not sufficient non-default rule vias. **Example** `generateVias -ndr_only` This generates vias for all NDRs, including the NDRs created by `add_ndr` or `createNdr` commands. You must use `setGenerateViaMode -auto true -ndr_only true` in the Innovus flow.

Example

- `generateVias`
  Will add auto-generated vias to any existing vias for all routing rules.

See also:

- `dumpOutVias` to write out the vias and look at them.
- `setGenerateViaMode` to generate vias persistently for multiple Innovus sessions.

genPinText

```
genPinText
[-format {assura dracula pvs}]
[-help]
[-layerMap fileName]
[-offset {x y}]
{[-nets {nets…}]
[-cells {cells…}]}
pin_text_file
```

Generates a file containing pin text information for nets and cells. You can read this file into Layout Versus Schematic (LVS) tools such as Dracula® and Assura™ for debugging problem areas.

You can use the `genPinText` command after you have finished placing, routing, and verifying your design in Innovus.

Note: Pin label is attached to physical pin shapes. If physical pin shapes do not exist, the pin text is labeled on any one instance pin shape. If both physical pin and instance pin shapes do not exist on the net, no pin text is generated in the output.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `genPinText` parameter. For a detailed description of the command and all of its parameters, use the man command: `man genPinText.`
`-cells {`*cells …*`}`	Specifies the list of leaf-level cells or top cell for which the pin text information is to be generated. The list of cells can be specified within braces or quotes. Additionally, pin text information can be output for all the cells using `"*"`. The `x y` values generated for the pin text are coordinates in user units local to the cell. You should not specify this parameter with the `-nets` parameter if you want to use this file with Dracula; however, you can specify both parameters if you use Assura or a third-party LVS tool.
`-format {assura dracula pvs}`	Specifies the output format.
`-layerMap` *fileName*	Specifies the name of the file that contains the mapping between LEF layers and layers defined in the LVS tool. The layer map file has the following format: `LEF_LAYER_NAME VERIF_LAYER_NAME` If you do not specify this parameter, Innovus assumes that the LEF layer names and LVS layer names are identical.
`-nets {`*nets …*`}`	Lists the name of the nets for which you want to generate pin text. You cannot use a wildcard (`*`) to specify all nets. You must use braces to enclose the list of nets. You should not specify this parameter with the `-cells` parameter if you want to use this file with Dracula; however, you can specify both parameters if you use Assura or a third-party LVS tool.
`-offset {x y}`	Specifies, in microns, the location of the design in the GDSII output file. When the GDSII output file is saved, the design shifts to the specified location.
pin_text_file	Specifies the pin text output file name. For information about the output file format see the Examples section below.

Examples

- The `genPinText` command creates a file containing one line of data for each cell or net you specify. The line has the following format:

  `name X=x Y=y ATTACH=verif_layer_name cell_name`

  The elements are

name	Specifies the net name (from the `-nets` parameter) or pin name (from the `-cell` parameter).
`X=`*x* `Y=`*y*	Specifies the x and y coordinates for the pin text.
`ATTACH=`*verif_layer_name*	Specifies the layer name used in the LVS tool.
cell_name	Specifies the cell name. The default is the top cell name.

- The following command creates a file, `pins.txt`, containing pin text information for `clk1` and `VDD`:

```
getPinText -nets {clk1 VDD} pins.txt
```

The output file would resemble the following:

```
clk1 X=0.0 Y=10.0 ATTACH=metal1 top_cell

VDD X=-10.0 Y=-10.0 ATTACH=metal2 top_cell

VDD X=20.0 Y=20.0 ATTACH=metal3 top_cell
```

- The following command creates a file, `hedtext.txt`, for cells `block1` and `block2`:
  ```
  genPinText -cells {block1 block2} hedtext.txt
  ```

  The output file would resemble the following:

  ```
  pin1b1 X=0.0 Y=0.0 ATTACH=metal1 block1
  pin2b1 X=1.0 Y=1.0 ATTACH=metal2 block1
  ```

  and so on, until all pins for `block1` are listed. Coordinates are local to `block1`.

  ```
  pin1b2 X=0.0 Y=0.0 ATTACH=metal2 block2
  pin2b2 X=1.0 Y=1.0 ATTACH=metal2 block2
  ```

  and so on, for all pins for `block2`.
- The following command creates a file, `pins.txt`, containing pin text information for `clk1`,`clk2`, and `rst` pins of the top cell `myTopCell`:
  ```
  getPinText -nets {clk1 clk2 rst} -cells {myTopCell} pins.txt
  ```

  The output file would resemble the following:

  ```
  clk1 X=204.27 Y=157.64 ATTACH=METAL2 myTopCell
  clk2 X=152.13 Y=0.28 ATTACH=METAL2 myTopCell
  rst X=0.33 Y=167.72 ATTACH=METAL2 myTopCell

get_abstract_mode

```
get_abstract_mode
[-help]
[-abstract_blockage_cut_around_pin]
[-antenna_connectivity]
[-antenna_diffusion_geom]
[-antenna_gate_geom]
[-blockage_detailed_layers]
[-boundary_layers]
[-cell_symmetry]
[-export_lef_version]
[-extract_layers_power]
[-extract_layers_signal]
[-extract_pin_layers_power]
[-extract_pin_layers_signal]
[-input_cell_type]
[-input_gds_layer_map_file]
[-input_lef_tech_file]
[-keep_temp_files]
[-pins_analog_names]
[-pins_clock_names]
[-pins_ground_names]
[-pins_output_names]
[-pins_power_names]
[-pins_text_pin_map]
[-pre_skill]
[-selected_cells]
[-site_name]
[-verbose]
```

Retrieves the current settings of all or specific `set_abstract_mode` parameters. The `set_abstract_mode` command sets options for the `run_abstract` command. For specified `set_abstract_mode` parameters, `get_abstract_mode` displays the following information in the Innovus log file and at the console:

- Parameter name
- Current value
- Type (Boolean, string, and so on)
- Whether the current value was set by user

If you do not specify a parameter, the software displays information for all of the `set_abstract_mode` parameters.

Note: This command is under beta control. Contact your Cadence representative for more information related to this command.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `get_abstract_mode` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man get_abstract_mode`
`parameter_names`	Displays information for the specified parameters. You can specify one or more parameters. See `set_abstract_mode` for descriptions of the parameters you can specify.
`-quiet`	Displays the current settings for the specified parameters in Tcl list format only. If you specify `-quiet` without any parameters, the software displays the current settings of all `set_abstract_mode` parameters in Tcl list format.

Example

The following command returns the cell type that will be selected for translation with abstract:

```
get_abstract_mode -input_cell_type
```

The output is as follows:

```
-input_cell_type std # enums={std io block}, default=std
```

`std`

Related Information

- `set_abstract_mode` command
- `run_abstract` command

getCmdLogFileName

```
getCmdLogFileName [-help]
```

Reports the name of the command log file.

You can use the `getCmdLogFileName` command at any time during an Innovus session.

Parameters

`-help`	Prints a brief description of the `getCmdLogFileName` command usage. For a detailed description of the command and all of its parameters, use the `man` command: `man getCmdLogFileName`.

Example

The following command gives the command log file name:

```
> getCmdLogFileName
innovus.cmd3
```

getDesignMode

```
getDesignMode
[-help]
[-addPhysicalCell]
[-backsideBottomRoutingLayer]
[-backsideTopRoutingLayer]
[-bottomRoutingLayer]
[-compressedPGDB]
[-congEffort]
[-dual_rail_via_pitch]
[-earlyclockFlow]
[-earlyPBAMode]
[-expressRoute]
[-flowEffort]
[-idealHoldFixing]
[-ignore_followpin_vias]
[-merge_trim_shapes]
[-node]
[-optimizationDensityScreenMargin]
[-pessimisticMode]
[-powerEffort]
[-process]
[-slackWeighting]
[-topRoutingLayer]
[-trim_grid_group]
[-quiet]
```

Returns the current settings of the `setDesignMode` command.

Note: The `setDesignMode` command is used to change the process technology dependent default settings globally for each application.

Parameter

`-help`	Outputs a brief description that includes type and default information for each `getDesignMode` parameter. For a detailed description of the command and all of its parameters, use the man command: `man getDesignMode`.
`parameter_names`	Displays information for the specified parameters. See `setDesignMode` for descriptions of the `setDesignMode` parameters you can specify.
`-quiet`	Displays the current settings for the specified parameter in Tcl list format only. If you specify `-quiet` without a parameter, the software displays the current settings of all `setDesignMode` parameters in Tcl list format.

Examples

- The following command displays the current setting of `setDesignMode -process`:

  ```
  getDesignMode -process
  ```

  The software displays the following information:

  ```
  -process 90                # int, default=90, min=3, max=250
  ```

- The following command displays the current setting of `setDesignMode -process` in Tcl list format only:

  ```
  getDesignMode -process -quiet
  ```

  The software displays the following information:

  ```
  90
  ```

Related Information

- setDesignMode

getExportMode

```
getExportMode
[-help]
[-fullPinout]
[-implicitPortMapping]
[-quiet]
```

Retrieves the current settings of all or specific `setExportMode` parameters. The `setExportMode` command controls how the software writes out a Verilog netlist. For specified `setExportMode` parameters, `getExportMode` displays the following information in the Innovus log file and at the console:

- Parameter name
- Current value
- Type (Boolean, string, and so on)
- Whether the current value was set by user

If you do not specify a parameter, `getExportMode` displays information for all of the `setExportMode` parameters.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `getExportMode` parameter. For a detailed description of the command and all of its parameters, use the man command: `man getExportMode`.
`parameter_names`	Displays information for the specified parameters. You can specify one or more parameters. See `setExportMode` for descriptions of the parameters you can specify.
`-quiet`	Displays the current settings for the specified parameters in Tcl list format only. If you specify `-quiet` without any parameters, the software displays the current settings of all `setExportMode` parameters in Tcl list format.

Examples

- The following command displays the current setting of the `-fullPinout` parameter:
  ```
  getExportMode -fullPinout
  ```
  The software displays the following information:
  ```
  -fullPinout true # bool, default=false, user setting

  true
  ```
- The following command displays the current settings for all `setExportMode` parameters:
  ```
  getExportMode
  ```
  The software displays the following information:
  ```
  -fullPinout true # bool, default=false, user setting

  -implicitPortMapping false # bool, default=false

  {fullPinout true} {implicitPortMapping false}
  ```
- The following command displays the current setting of the `-fullPinout` parameter in Tcl list format only:
  ```
  getExportMode -fullPinout -quiet
  ```
  The software displays the following information:
  ```
  true
  ```

- The following command displays the current settings for all `setExportMode` parameters in Tcl list format only:

  ```
  getExportMode -quiet
  ```

  The software displays the following information:

  ```
  {fullPinout true} {implicitPortMapping false}
  ```

Related Information

- `setExportMode`

getGenerateViaMode

```
getGenerateViaMode
[-help]
[-auto]
[-ndr_only {true|false}]
[-quiet]
[-nonDefault]
```

Displays the information about the specified `setGenerateViaMode` parameter in the Innovus log file and in the Innovus console. Displays the following information:

- Option name
- Current value
- Type (Boolean, string, and so on)
- Whether the current value was set by user

If you do not specify a parameter, the software displays information for all of the `setGenerateViaMode` mode parameters.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `getGenerateViaMode` parameter. For a detailed description of the command and all of its parameters, use the man command: man `getGenerateViaMode`.
`-auto`	Enables auto via generation when design is loaded.
`-nonDefault`	Displays the current settings which are not default settings.
`-ndr_only {true|false}`	Generates vias for non default rules only. *Default:* `false`
`-quiet`	Displays the current settings in Tcl list format only.

Example

The following command gives the values of `-auto` and `-ndr_only` parameters that are set using the `setGenerateViaMode`:

```
> getGenerateViaMode
-auto true # bool, default=false, user setting
-ndr_only true # bool, default=false, user setting

{auto true} {ndr_only true}
```

Related Information

getImportMode

```
getImportMode
[-help]
[-keepEmptyModule]
[-minDBUPerMicron]
[-syncReLativePath]
[-treatUndefinedCellAsBbox]
[-quiet]
```

Retrieves the current settings of all or specific `setImportMode` parameters. The `setImportMode` command controls how the software reads in the Verilog netlist and other design files. For specified `setImportMode` parameters, `getImportMode` displays the following information in the Innovus log file and at the console:

- Parameter name
- Current value
- Type (Boolean, string, and so on)
- Whether the current value was set by user

If you do not specify a parameter, the software displays information for all of the `setImportMode` parameters.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `getImportMode` parameter. For a detailed description of the command and all of its parameters, use the man command: `man getImportMode`.
`parameter_names`	Displays information for the specified parameters. You can specify one or more parameters. See `setImportMode` for descriptions of the parameters you can specify.
`-quiet`	Displays the current settings for the specified parameters in Tcl list format only. If you specify `-quiet` without any parameters, the software displays the current settings of all `setImportMode` parameters in Tcl list format.

Examples

- The following command displays the current setting for the `-keepEmptyModule` parameter:
  ```
  getImportMode -keepEmptyModule
  ```
  The software displays the following information:
  ```
  -keepEmptyModule true # bool, default=true

  true
  ```
- The following command displays the current settings for all `setImportMode` parameters:
  ```
  getImportMode
  ```
  The software displays the following information:
  ```
  -minDBUPerMicron 0                # uint, default=0
  -syncRelativePath false           # bool, default=false
  -treatUndefinedCellAsBbox false   # bool, default=false

  {keepEmptyModule true} {minDBUPerMicron 0} {syncRelativePath false} {treatUndefinedCellAsBbox false}
  ```
- The following command displays the current setting for the `-keepEmptyModule` parameter in Tcl list format only:
  ```
  getImportMode -keepEmptyModule -quiet
  ```
  The software displays the following information:

```
true
```

- The following command displays the current settings for all `setImportMode` parameters in Tcl list format only:

  ```
  getImportMode -quiet
  ```

  The software displays the following information:

  ```
  {keepEmptyModule true} {minDBUPerMicron 0} {syncRelativePath false} {treatUndefinedCellAsBbox false}
  ```

getLogFileName

```
getLogFileName [-help] [-fullPath]
```

Reports the name of the log file.

You can use the `getLogFileName` command at any time during an Innovus session.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `getLogFileName` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man getLogFileName`.
`-fullPath`	Reports the complete path to the log file.

Examples

- The following command reports the name of the log file for the current Innovus session:
  ```
  getLogFileName
  ```

  The software reports:

  ```
  innovus.log1003
  ```

- The following command reports the complete path to the log file for the current Innovus session:
  ```
  getLogFileName -fullPath
  ```

  The software reports:

  ```
  /icd/soclinx23/output/linux/07.10-e028_1/ph_46_08h34sec/innovus.log1003
  ```

Related Information

getStreamOutMode

```
getStreamOutMode
[-help]
[-cellInstanceColor]
[-cellMasterColor]
[-cellNameUserPrefix]
[-cellNameUserSuffix]
[-convertRectToPath]
[-labelAllPinShape]
[-merge_trim_shapes]
[-mergeAppend]
[-oasisCompression]
[-oasisLayerName]
[-oasisSCellOffset]
[-pinTextOrientation]
[-reset]
[-removeNets]
[-SEcompatible]
[-SEvianames]e
[-snapToMGrid]
[-specifyViaName]
[-supportPathType4]
[-textSize]
[-uniquifyCellNamesPrefix]
[-version]
[-virtualConnection]
```

Displays the following information about the specified `setStreamOutMode` parameter in the log file and at the console. Displays the following information:

- Parameter name
- Current value
- Type (Boolean, string, and so on)
- Whether the current value was set by user

If you do not specify a parameter, the software displays information for all of the `setStreamOutMode` parameters.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `getStreamOutMode` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man getStreamOutMode`.
`parameter_names`	Displays information for the specified parameters. You can specify one or more parameters. See `setStreamOutMode` for descriptions of the parameters you can specify.
`-quiet`	Displays the current settings for the specified parameters in Tcl list format only. If you specify `-quiet` without any parameters, the software displays the current settings of all `setStreamOutMode` parameters in Tcl list format.

Examples

- The following command displays the current setting of the `-removeNets` parameter:

  ```
  getStreamOutMode -removeNets
  ```

  The software displays the following information:

  ```
  -removeNets {} # string, default=""

  {}
  ```

- The following command displays the current settings for all `setStreamOutMode` parameters:

```
getStreamOutMode
```

The software displays the following information:

```
-removeNets {} # string, default=""

-SEcompatible false # bool, default=false

-SEvianames false # bool, default=false

-snapToMGrid false # bool, default=false

-specifyViaName default # string, default=default

-supportPathType4 true # bool, default=true

-textSize 1 # float, default=1

-uniquifyCellNamesPrefix false # bool, default=false

-version 3 # int, default=3, min=1, max=32767

-virtualConnection true # bool, default=true

{removeNets {}} {SEcompatible false} {SEvianames false} {snapToMGrid false} {sp

ecifyViaName default} {supportPathType4 true} {textSize 1} {uniquifyCellNamesPr

efix false} {version 3} {virtualConnection true}
```

- The following command displays the current setting of the `-removeNets` parameter in Tcl list format only:
  ```
  getStreamOutMode -removeNets -quiet
  ```

  The software displays the following information:

  ```
  {}
  ```
- The following command displays the current settings for all `setStreamOutMode` parameters in Tcl list format only:
  ```
  getStreamOutMode -quiet
  ```

  The software displays the following information:

  ```
  {}
  ```

Related Information

- `setStreamOutMode`
- Importing and Exporting Designs chapter of *Innovus User Guide*.

init_design

```
init_design
[-help]
[-setup setup_view_list -hold hold_view_list]
```

Initializes a design using the Tcl globals. These globals are listed in the Related Globals section. The `init_design` flow replaces the configuration-file-based flow. `init_design` can be called only if design/library information is not already loaded. When calling `init_design`, you need to specify the `-setup` and `-hold` options depending on the following:

- If a view definition file (`view_definition.tcl`) is provided that properly initializes the system with the `set_analysis_view` command, `init_design` does not require `-setup` and `-hold`. However, if you do specify the active views using `-setup` and `-hold` and these conflict with the active view setting in the view definition file, the tool informs you about the conflict and then initializes the system with the active views specified in the `init_design` invocation.

  Note: If the view definition file is provided but it does not properly initialize the system with the `set_analysis_view` command (i.e the system is not in MMMC mode after sourcing the view definition file) and the `-setup` and `-hold` active views were not specified for `init_design`, the tool returns an error.
- If you are not providing a separate view definition file and are coding the MMMC objects inline in the script, the `-setup` and `-hold` options are required in the `init_design` invocation. If the `-setup` and `-hold` options are not specified, you receive the following warning:

  ```
  Active setup and hold analysis views were not provided by the -setup and -hold arguments to init_design. The system requires at least one active setup and hold analysis view to be declared before any timing commands can be run. If you need to run timing commands, you can add the -setup and -hold options to your init_design invocation. You can use the all_analysis_view command to identify the currently available views.
  ```

In Legacy mode, `eval_common_ui {read_mmmc, read_physical, read_netlist, init_design}` will give an error message, because Stylus initialization is not supported in Legacy.

Additionally, the `init_design` command:

- Initializes the default bounding box of square size with 70% utilization
- Creates default rows, the site of row depends on the height of the cell used in the netlist
- Creates track in the box based on the tech LEF

Parameters

`-help`	Prints a brief description that includes the type and default information for each `init_design` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man init_design`
`-hold` *`hold_view_list`*	Specifies the hold analysis view list. The system requires at least one active hold analysis view to be declared before the design can be initialized. You can use the `all_analysis_view` command to identify the currently available views. **Note:** Active hold analysis view should be provided in either the view definition file or by the `-hold` argument to `init_design`.
`-setup` *`setup_view_list`*	Specifies the setup analysis view list. The system requires at least one active setup analysis view to be declared before the design can be initialized. You can use the `all_analysis_view` command to identify the currently available views. **Note:** Active setup view should be provided in either the view definition file or by the `-setup` argument to `init_design`.

Examples

- The following set of commands initialize the design from a Verilog netlist using the top cell you specify (`myTopCell`):

```
set init_verilog ./myVerilog.v

set init_design_settop 1

set init_top_cell myTopCell

set init_design_netlisttype Verilog # optional, since Verilog is the detault

#set other initialization globals as required....

init_design
```

- The following set of commands load the design from a Verilog netlist. The top cell is determined automatically:

```
set init_verilog ./myVerilog.v

set init_design_settop 0

set init_design_netlisttype Verilog # optional, since Verilog is the detault

#set other initialization globals as required....

init_design
```

- The following set of commands initializes the design using the `myDesignLib/myTopCell/myViewName` cellview as the source of connectivity:

```
set init_oa_design_cell myTopCell

set init_oa_design_lib myDesignLib

set init_oa_design_view myViewName

set init_design_netlisttype OA

#set other initialization globals as required....

init_design
```

loadDefFile

```
loadDefFile
[-help]
defFile
[-hier [-stub stubfile | -reflib {listOfRefLibs}]]
```

Reads a DEF file to build the in-memory database in Innovus. You can then continue to use other Innovus commands.

You can use the `loadDefFile` command after running the `loadLefFile` command.

When a list of OpenAccess reference libraries is specified, `loadLefFile` is not required before `loadDefFile`; otherwise, use this command after you load the library information.

> ***After loading the DEF netlist, you can perform floorplanning, non-timing driven placement and routing, wire editing, and verification. You cannot use the DEF netlist flow for parasitic extraction, delay calculation, and timing-driven placement and routing effectively because the DEF names do not properly match the Verilog names used in timing constraints and timing analysis.***

Parameters

`-help`	Prints a brief description that includes the type and default information for each parameter of the `loadDefFile` command. For a detailed description of the command and all of its parameters, use the `man` command: `man loadDefFile`.
`defFile`	Specifies the name of the DEF file to load.
`-reflib` *`listOfRefLibs`*	Specifies a list of OpenAccess reference libraries to load. When specified, the reference libraries are assumed to be correct by construction and `verilogAnnotate` is not run. This reference library is used for `def2oa`. Because the reference libraries are already provided, there is no need to use `loadLefFile` with this option.
`-hier`	Preserves the design hierarchy. When specified, creates a reference library by calling `lef2oa`. It will also create stub (`stub.v`) from pre-loaded LEF files. This stub will be used to run `verilogAnnotate` on reference libraries created by the `lef2oa` command. The reference library created this way is used by `def2oa`.
`-stub` *`stubfile`*	Specifies the name of the stub file to load. This option can be specified only with `-hier`. When specified, the stub file is used in `verilogAnnotate`. Stub is not created internally from LEF files.

Examples

- The following command loads the DEF file `myDef`:
  ```
  loadDefFile myDef
  ```
- The following command preserves the design hierarchy while loading the OpenAccess reference libraries and the DEF file `myDef.def`:
  ```
  loadDefFile -hier -reflib {reflib1 reflib2} mydef.def
  ```

Related Information

- `loadLefFile`
- Importing and Exporting Designs chapter in the *Innovus User Guide*

loadLefFile

```
loadLefFile
[file1 file2 ...]
[-help]
[-areaIo]
[-blackbox]
[-incremental]
```

Imports all the technology and library data that is specified in the LEF files into the Innovus environment. In addition, this command provides the location of the LEF files the routers need to access.

You can use the `loadLefFile` command at any time.

> The `loadLefFile` command checks your LEF file to make sure that layers are defined in the correct order (as described in the *LEF/DEF Language Reference*.) For example, routing layers must be defined alternately with cut layers:

```
LAYER METAL1
TYPE ROUTING
...
END METAL1

LAYER VIA12
TYPE CUT
...
END VIA12

LAYER METAL2
TYPE ROUTING
...
END METAL2
```

If you do not define layers in the correct order (for example, if you define all routing layers before cut layers, the Innovus software displays an error message.

Parameters

`-help`	Prints a brief description that includes the type and default information for each parameter of the `loadLefFile` command. For a detailed description of the command and all of its parameters, use the `man` command: `man loadLefFile`.
`-areaIo`	Treats the pad macro cell as an arealo cell. This option is used for versions of LEF prior to 5.5.
`-blackbox`	Treats the block macro cell as a blackbox. This option is used for versions of LEF prior to 5.5.
`file1 file2 ...`	Specify the names of LEF files to be loaded.
`-incremental`	Appends the antenna data into existing layers and macro cells. This is only used for appending LEF 5.4 antenna data.

Example

The following command imports the LEF file technology data:

```
loadLefFile sample.lef
```

Related Information

- `loadDefFile`
- Importing and Exporting Designs chapter in the *Innovus User Guide*

read_name_mapping

```
read_name_mapping
[-help]
in_file
[-debug]
```

Reads a name mapping file which records the mapping relationship between the original HDL (RTL bit level) names in Genus to the corresponding gate-level netlist names in Genus or Innovus for primary ports or reg/wire variables, and any logical phase inversions generated by Genus.

It can be used for Power Analysis using RTL switching activities and Formal Verification with Conformal LEC to facilitate key point mapping between the RTL names and the Innovus gate-level names. Innovus will not modify the incoming string <RTL_bit_level_name> and will attach this information to the corresponding netlist pin or port objects.

The input syntax of the file is as follows:

```
add mapped point RTL_bit_level_name netlist_inst_q_pin_or_port [-invert]
```

- *RTL_bit_level_name*: It is the hierarchical name of an RTL bit-level object corresponding to primary ports or reg/wire variables using "/" for the hierarchy delimiter
- *netlist_inst_q_pin_or_ports*: It is the hierarchical name of a gate-level instance q-pin or a port
- [-invert]: It indicates a logical phase inversion has been done during optimization for this pin or port

Parameters

-help	Prints a brief description that includes the type and default information for each read_name_mapping parameter. For a detailed description of the command and all of its parameters, use the man command: man read_name_mapping
-debug	Print debug info.
in_file	Name of input name mapping file.

Example

The following example show how different bits are merged into a multi-bit cell, so using simpler names is better.

```
add  mapped  point  IL_reg[1]      CDN_MBIT_reg/Q1      -invert
add  mapped  point  TRNS1_reg[0]   CDN_MBIT_reg/Q2
add  mapped  point  Vflag_reg      CDN_MBIT_reg/Q3
add  mapped  point  Zflag_reg      CDN_MBIT_reg/Q4
```

Example of the name mapping format used by Genus in presence of complex typed-names:

```
add mapped point clk clk //in
add mapped point sel sel //in
add mapped point in1[1] in1[1] //in
add mapped point in1[0] in1[0] //in
add mapped point out1[1] out1[1] //out
add mapped point out1[0] out1[0] //out
add mapped point out3/x[1] out3[x][1] //out
add mapped point out3/x[0] out3[x][0] //out
add mapped point isub/out1/x[1] isub_out1_reg[x][1]/Q
add mapped point isub/out1/x[0] isub_out1_reg[x][0]/Q
add mapped point out1[1] out1_reg[1]/Q
add mapped point out1[0] out1_reg[0]/Q
add mapped point out3/x[1] out3_reg[x][1]/Q
```

```
add mapped point out3/x[0] out3_reg[x][0]/Q
```

- write_lec_files
- write_lec_directory_naming_style
- write_name_mapping

read_stream

```
read_stream
[-help]
-layer_map layer_map_files
{[-pvs_fill ] | [[in_files] [-cells cell_list [-offset {x y}]]]}
```

Reads in-stream files or a layer map and outputs a summary of the cell names read in, and any layer/data types that have data with no map_file entry. The data is automatically scaled during reading to the correct DB units based on the stream units.

- It reads in the metal fill stream data (with top cell name and offset) to overlay on the design. The fill data is displayed to database fill shapes (equivalent to reading DEF FILL data) to allow editing or changing the fill data.
  Reading in fill data is done once per session.
- It reads in-stream cells that have the same names as Innovus cell names to display the stream cell data (for example, overlay or toggle between stream shapes and LEF shapes for the cells).
  If a stream cell name is repeated, it replaces any previous data for that cell.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `read_stream` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man read_stream`.
`-cells cell_list`	Reads only the specified cells from GDS files.
in_files	Lists GDS and OASIS files.
`-layer_map layer_map_files`	Specifies the layer map file to map GDS layer to design layer
`-offset x y`	Specifies, in microns, the offset for the top-level fill cell.
`-pvs_fill`	Specifies to process the PVS FILL data in the read process.

Layer Map File Format

The `-layer_map` file maps stream layer/dtype data to Innovus layer and objects. Stream data does not have net ids, so you can only map stream data for display, or to fill, fill_opc or fill_blockage shapes.

The format for the layer map file is one line for each stream layer and dtype:

```
layer data_type layer_name object_type
```

Where

- *layer* is an stream layer number. It is an integer.
- *data_type* is a stream data_type number. It must be either an integer, or a range (e.g. 0-255).
- *layer_name* is normally must be a LEF (or OA tech) layer name. It can only be a “custom” layer name if the obj_type is “display” (e.g. this data is not on any of the LEF layers, but is useful for display purposes). Any custom layer data will be displayed like data created with add_gui_shape or add_gui_text. The *layer_name* is case-sensitive.
- *object_type* is one of these keywords:
  - `fill`: Equivalent to DEF FILL shapes
  - `fill_opc`: Equivalent to DEF FILL with + OPC shapes
  - `fill_blockage`: Equivalent to DEF BLOCKAGE + FILLS shapes
  - `display`: Is only for display purposes, and cannot be flattened.

  `fill`, `fill_opc`, and `display` can optionally be followed by
  `:mask:mask_num`
  where `mask_num` is the mask number for the shape for a multi-mask layer (equivalent of `DEF + MASK mask_num` for a shape).
  fill_blockage can optionally be followed by
  `:name:blockage_name`
  where *blockage_name* is the name given to all the blockages from this layer/dtype.

  Any text on the same layer/data_type will be mapped to the same DB layer as a text object on that layer. About the TEXT font and size, font 0 could be default (or other font decided by RD). Size could use the original size in GDS and scale it if dbu mismatch to Innovus.

The *object_type* keywords are case insensitive. The tool ignores blank lines or lines beginning with #.
A given layer/dtype combination can only appear once.

Example of Stream map-file for metal fill, via-fill, and fill blockages

```
#Stream map-file for metal fill, via-fill, and fill blockages
#only metal1 has two masks
#layer    dtype     layer_name     obj_type
1         1         metal1         fill:mask:1
1         2         metal1         fill:mask:2
51        1         cut1           fill
2         1         metal2         fill
52        1         cut2           fill
3         1         metal3         fill
…
101       1         metal1         fill_blockage:name:blkg1
101       2         metal1         fill_blockage:name:blkg2
101       3-255     metal1         fill_blockage
```

Example of Stream map-file for cell-data to display on top of LEF cell data

```
#Stream map-file for cell-data to display on top of LEF cell data
#Only routing layers and the cell-outline on custom layer “outline”
#are mapped. It does not show cut layers or layers below metal1.
#layer    dtype     layer_name     obj_type
1         0-255     metal1         display
2         0-255     metal2         display
...
#custom layer “outline” is created if it does not already exist
100       1         outline        display
```

Examples

Parse stream cells with specified layer map display stream cell data on top of LEF cell data. The report output is redirected to read_stream.rpt.

```
>read_stream {stdcells.gds memory.gds} -layer_map gds_layer.map > read_stream.rpt
```

Read in metal-fill data and overlay it on the design. The report will be in the log file.

```
>read_stream fill.gds -cell top_fill -layer_map gds_layer.map
```

Example of output report

```
#Cell names read in:
top_fill
fill_1
fill_2
…
#Layer/dtype data in the stream file with no map-file entry
1    10
4    1, 9
…
```

relink_db_files

```
relink_db_files
[-help]
-db_dir db_directory
-new_lib_dirs {new_lib_directory1 new_lib_directory2 ...}
```

Relinks symbolic links to library files inside a DB directory.

By default, `saveDesign` saves the location of library files as symbolic links under `<db_dir>/libs/...`. When a DB directory is copied to a new network where all the libraries are in a different location, or a new version of the library files are needed, you can use `relink_db_files` to change the symbolic links to new locations .

The `relink_db_files` command will search each `-new_lib_dirs` directory and the sub-directory tree below it for each library file name inside `<db_dir>`, and create a symbolic link to the new location. Only the base file name is used for the search (except for `qrcTechFile`). Therefore, two path names inside the new directory, such as `/timing/fast/std.lib` and `/timing/slow/std.lib`, will have duplicate names of "`std.lib`". The duplicate names are not supported and will cause an error. You can use the `restoreDesign` command to update all the LEF full-path names or use a new MMMC files with all the new .lib full-path names if duplicate file names need to be updated. If there are missing library file names, the tool will show an error.

The `relink_db_files` command supports `.lib`, `.lef`, and `qrcTechFile` library file types.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `relink_db_files` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man relink_db_files`
`-db_dir db_directory`	The current db directory which contains incorrect library symbolic links.
`-new_lib_dirs {new_lib_directory1 new_lib_directory2 ...}`	The new directories to search for library files.

Example

If the current LEF files are all under`/libs/lefs_v1.0/` (or sub-directories) and the current `.lib` and `qrcTechFiles` are all under`/libs/timing_v1.0/` (or sub-directories), you use the following command to update the LEF files to use `/libs/lefs_v2.0/`:

```
>relink_db_files -db_dir my_db -new_lib_dirs {/libs/lefs_v2.0 /libs/timing_v1.0}
```

Note: The command must find every library file. Therefore, you need to list the top of the old timing directory tree along with the top of the new LEF files directory tree.

Related Information

- `saveDesign`
- `restoreDesign`

replaceLefMacro

```
replaceLefMacro
[-macros {listOfMacros}]
lefFile
```

Replaces the current `MACRO` information in the design with the `MACRO` information in the specified LEF file. You can use the `replaceLefMacro` command to change the geometry information of a macro, such as boundary size, pin location, pin layer, and pin size. You cannot use the command to change the number or name of pins for a macro.

The `replaceLefMacro` command only reads and replaces the `MACRO` information from the LEF file; it does not use any other information in the file.

Note: In the following scenarios tool cannot replace the LEF file automatically.

- If you replaced the LEF macro file multiple times. In this case, the tool would not know which file to keep at the end.
- If the old LEF file that contains the original macro contains other MACRO definition. In this case, the old file cannot be removed by the tool. If the old file is not removed, the new file is appended to the list. As mentioned in the above point, the list may have multiple LEF files that contain the same MACRO but with different definition. When reading LEF files with multiple definitions, the tool keeps only the first one. As a result, in the next session the file that you want will not be loaded.

After trying different macro definitions, you need to replace the content of the macro definition manually. You can do this either by overwriting the one in original LEF file, or if the original LEF file contains only that macro, replacing the LEF file in the LEF file list.

Parameters

lefFile	Specifies the LEF file to read.
-macros {*listOfMacros*}	Replaces the information for the specified macros only. *Default:* Replaces the information for all macros in the LEF file.

report_gates

```
report_gates
[-help]
[-hinst hInstName]
[-out_file fileName]
[-sort {name count area leakage_power internal_power total_power switching_power}] [-power | -leakage_power ]
```

Reports the technology library cells that were implemented (and identifies their originating libraries), the area of the cell instances, and the break up of the instances into timing models, sequential cells, integrated clock-gating cells, inverters, buffers, and logic gate cells. Optionally power information can be reported.

The result is based on the cell_area calculated from LIB information. Use set_db use_area_from_lef true (default: false), if you want to get correlation between reports generated with `report_gates` command and `report_qor` or `report_utilization` commands. When a lef is read into Genus, the property "use_area_from_lef" is automatically set to `true`.

Timing models can refer to memory cells, IPs, and so on.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `report_gates` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man report_gates`
`-hinst hInstName`	Specifies the name of the hinst to collect the cell information. Only cells in the specified hinst will be considered.
`-leakage_power`	Provides leakage power statistic only.
`-out_file fileName`	Specifies the file in which report will be saved. If not specified, information is dumped in the log.
`-power`	Provides internal, switching, leakage and total power statistic.
`-sort {name count area leakage_power internal_power total_power switching_power}`	Specifies the sorting criteria to sort content of the tables to generate leakage_power/internal_power value only respected if the option -power is also specified.

Examples

```
>report_gates -sort name -out_file check.rpt
```

```

```

report_sequential

```
report_sequential
[-help]
[-deleted]
[-full]
[-hinst hInst_names]
[-mapped]
[-optimized]
[-out_file <string>]
```

Reports information about sequentials the design. Sequentials are the elements that have a library is_sequential tag. These can be flops, latches, and clock gates.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `report_sequential` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man report_sequential`
`-deleted`	Generates a report with the deleted flops and the reason.
`-full`	Generates a report with the sequential name, whether it was inferred or instantiated, the type of sequential, and the type of reset.
`-hinst hInst_names`	Hinst for the report. By default, the design is reported.
`-mapped`	Generates a report with synthesis requirements modified to map the sequential.
`-optimized`	Generates a report with sequentials optimized to constants or are unloaded, but have not been removed.
`-out_file file_name`	File to dump the report. Default is stdout

Examples

- The following command reports the deleted flops:

```
innovus 1> report_sequential -deleted
Sequential elements: deleted flops
--------------------------------------

  Reason      Instance Name

--------------------------------------

unloaded       foo/bar/q_reg[15]

unloaded       foo/bar/q_reg[31]

unloaded       foo/bar/q_reg[47]

unloaded       foo/bar/q_reg[63]

unloaded       foo/bar/q_reg[79]

constant 0     moo/ff_reg_9
```

- The following command reports the optimized flops:

```
innovus 2> report_sequential -optimized
Sequential elements: optimized flops
-----------------------------------------

  Reason      Instance Name

-----------------------------------------

constant 0     RESULTS_CONV_INST/out_p1_reg[7]

constant 0     TDSP_CORE_INST/EXECUTE_INST/alu_cmd_reg[3]

constant 0     TDSP_CORE_INST/EXECUTE_INST/read_data_reg

constant 0     TDSP_CORE_INST/EXECUTE_INST/read_port_reg
```

restoreDesign

```
restoreDesign
[-help]
[design]
[-dynamic_view analysis_view]
[-hold_views hold_views]
[-leakage_view analysis_view]
[-noBinaryConstraint]
[-noTiming]
[-readGlobals tcl_file_name]
[-setup_views setup_views]
[{{session} | {-cellview lib cell view}} [-mmmcFile fileName] [-lef_files list_of_files]]
[-noTimingGraph]
```

Restores a saved database created by `saveDesign` in a previous session. It auto-detects the database type and loads it. An OpenAccess DB format is restored with `-cellview {<lib> <cell> <view>}` while a native Innovus DB format is read using `<session> <design>` for the DB directory name.

`saveDesign` optionally includes various types of data, including timing-graph data, RC extraction data. So, the state of the DB after `restoreDesign` depends on what was saved, and you may need to repeat RC extraction, timing analysis, etc. if that data was not saved.

If a design is saved with the newer Innovus version and you try to load the design in an older Innovus version, the tool will give an error and stop. The "older Innovus version" refers to the main version, such as 19.1 and 20.1. The second number after decimal does not make any difference. For example, if a design is saved in 20.12 and loaded in 20.11, it will not give any error and will work properly.

For OpenAccess usage, simple digital-only designs generally go back and forth with no special handling. But some types of Virtuoso custom data cannot be represented directly in the Innovus DB and are stored “on the side” by `restoreDesign` and geometrically equivalent data is visible in Innovus. That data is then restored by `saveDesign` when you write back to OA using the correct OA settings.

There are different types of OA methodologies and flows supported that are controlled by `setOaxMode`. You can also look at the Mixed Signal Interoperability Guide for more details on their effects on `saveDesign`/`restoreDesign`.

Note:

- Innovus does not support loading another DB while a design is already in memory.
- You should not modify the contents of a saved DB (*.enc.dat or *.db) at any time. If the contents of the saved DB are modified, restoring such modified DB might cause problems later or lead to DB corruption or crashes.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `restoreDesign` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man restoreDesign`
`-cellview lib cell view`	Specifies the library name, cell name, and view name for reading an OpenAccess DB design.
design	Specifies the top cell of the design saved in the *session* directory. If you specify any arbitrary cell name as the top cell name, the tool will automatically search the top cell name in DB directory.
`-dynamic_view analysis_view`	Specifies the analysis view for the dynamic power analysis.
`-hold_views hold_views`	Specifies the hold views for loading, rather than the hold views active during `saveDesign`.
`-leakage_view analysis_view`	Specifies the analysis view for leakage power analysis.

`-lef_files list_of_files`	Specifies the LEF files name for loading. Use this option if you want to replace the existing LEF files in the design with new LEF files instead. • This option is intended to allow upgrading to new versions of LEF files that are compatible with the old versions. The list of all LEF files used by this design must be given. • If any pin locations or cell boundaries or OBS shapes are changed for used cells, new DRC violations may occur. • If pins are added or removed from used cells, or used cells are removed, fatal errors may occur when loading the netlist. • If the removed pins and cells are unused in the design, warnings or errors may still occur if any library-specific data was stored for those cells or pins during the design flow (for example, dont_touch data) **Example** Existing LEFs used by `saveDesign`: `tech.lef, A.lef` You can change `A.lef` to `A_v2.lef` as given below: `restoreDesign place.enc.dat top -lef_files {tech.lef A_v2.lef}`
`-noBinaryConstraint`	Specifies not to load the binary timing constraint .tcz file even it is saved to disk in the previous session.
`-noTimingGraph`	Skips reading the timing graph even if it was saved to the disk by `saveDesign`.
`-mmmcFile`	Specifies the path name to a Multi-Mode/Multi-Corner (MMMC) configuration file (for example, the same file format used by `init_mmmc_file`) to replace the MMMC file saved by `saveDesign` (and all the corresponding .lib files, .sdc files, *_power_constraints.tcl etc. referenced by the MMMC file). If a new MMMC file is specified using `-mmmcFile`, the RC data saved by the previous session may mismatch with the new MMMC file and cause issues. If `restoreDesign -mmmcFile` is specified, by default, the tool will not load the RC data. You need to re-extract RC after the design is loaded. **Note**: CCOpt configuration will not be restored with `-mmmcFile` specified. You need to re-run `create_ccopt_clock_tree_spec` after `restoreDesign` to create a new CCOpt configuration against the new MMMC configuration.
`-noTiming`	Skips reading the MMMC file, timing libraries, and timing constraints. **Note:** Most designs that use LEF rely on the .lib information to define the bus order for MACROs that have bus bit terminals. Therefore, using the -`noTiming` option can result in the connectivity to bus ports of leaf level instances being reversed. When .lib information is not available, the default is for bus ports to be treated as descending (for example, [7:0]). When using Verilog modules or OpenAccess abstract views to define the bus order, the connectivity will still be correct even when `-noTiming` is specified. Timing libraries cannot be loaded in the same session after a design is read using the `-noTiming` option. You must use `restoreDesign` without the `-noTiming` option in a new session to load the design with timing libraries and constraints. If you save a design after `restoreDesign -noTiming`, it will not save timing information unless you use `saveDesign -addtiming`.
`-readGlobals tcl_file_name`	Specifies the UDM variables to be honored when restoring the design. You need to provide a tcl file stating the pre-defined UDM variable names to be honored.
session	Specifies the directory from which to load the DB files. If the *<session>* name ends with `.tar.gz` it is treated as a gzipped tar file (see `saveDesign -tgz` option) that is extracted into the directory first. So, `restoreDesign test.enc.dat.tar.gz` will create a directory named test with all the DB files inside it.
`-setup_views setup_views`	Specifies the setup views for loading. Rather than the setup views active during `saveDesign`.

Examples

- The following command loads the saved design files from the test.enc.dat directory:
  ```
  restoreDesign test.enc.dat top
  ```
- For physical-only editing, you can do this to speedup `restoreDesign`/`saveDesign` by ignoring the timing during `restoreDesign`, and adding it back during `saveDesign`.
  ```
  restoreDesign test1.enc.dat top -noTiming
  <physical-only editing>
  saveDesign test2.enc.dat -addtiming
  ```
  Then in a new session
  ```
  restoreDesign test2.enc.dat top     #has timing from test1.enc.dat
  ```
  If the logical netlist was modified during editing of test1.enc.dat, then reading test2.enc.dat may have unpredictable timing results.
- The following command reads the "designLib top placed" OpenAccess cellview but replaces the existing MMMC settings in the design with the settings in `new_mmmc.tcl`:
  ```
  restoreDesign -cellview "designLib top placed" -mmmcFile new_mmmc.tcl
  ```
- The following command reads the `placed.enc.dat` design but replaces the saved MMMC settings in the design with the settings in `new_mmmc.tcl`:
  ```
  restoreDesign placed.enc.dat -mmmcFile new_mmmc.tcl
  ```
  Then create a new CCOpt configuration:
  ```
  create_ccopt_clock_tree_spec
  ```

run_abstract

```
run_abstract
[-help]
-gds_files file_list
[-gen_script_only file.il]
[-lib_files file_list]
[-output_lef_file file.lef]
[-run_script_only file.il]
[-verilog_stub_files file_list]
```

Runs abstract to generate LEF from GDSII. The sequence of flow for the `run_abstract` command is as follows:

1. Checks if the executable “abstract” exists in the path. If not, it generates an error.
2. Generates “appropriate” configuration file.
3. Executes abstract with the configuration file.
4. Checks that the “abstract” exits with an exit code of “0”. If not, it generates an error.

The `run_abstract` command is run before loading a design.

The options for the `run_abstract` command are set using the `set_abstract_mode` command.

Note:

1. This command does not fully supports the block LEF abstract. Run 'ABSTRACT' standalone to generate LEF from block GDS.
2. This command is under beta control. Contact your Cadence representative for more information related to this command.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `run_abstract` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man run_abstract`
`-gds_files file_list`	Lists the GDSII files that need to be translated **Note**: It is important that only GDSII files of the same type are listed together. For example, std-cells, IO cells, and block cells should be listed in separate runs.
`-gen_script_only file.il`	Generates the SKILL script that can be given to the abstract tool but does not execute it.
`-lib_files file_list`	Lists liberty (.lib) files. The .lib files can also be used to define pin directions by using the direction from the matching .lib cell and pin names.
`-output_lef_file file.lef`	Outputs the LEF file that will have the LEF macro abstracts but not technology file information.
`-run_script_only file.il`	Does not re-generate the script but just executes it with the specified file.
`-verilog_stub_files file_list`	Can be used to define the pin directions by using the direction from the matching Verilog module and pin names.

saveDesign

```
saveDesign
[-help]
[-addTiming]
[-current_top_cell_only]
[-mmmc2]
[-noFill]
[-no_pvs_fill]
[-skip_file {metric cmd}]
[-no_wait out_file]
{{fileName } | {{{-cellview {libname cellname viewname} | -view viewname} [ -saveRestoreFile file_name] [-oaUsedLibsOnly | -oaLibs ]} }}
[-timingGraph [-noConstraint ]]
[[-user_path [-keep_input_path ]] ]
[-tcon ]
[-rc ]
[-libs ]
[-lib2ldb ]
[-def ]
[-verilog ]
[-tgz ]
```

Saves the complete design database in the native Innovus format if *fileName* is specified, or as an OpenAccess database (OA DB) if `-cellview` or `-view` are specified.

The native Innovus DB format in output directory must be used when you have LEF files for technology and physical library data in your original initialization script (e.g. `init_lef_file <files>`), while the OA DB output must be used if you use OA libraries (e.g. i`nit_oa_ref_lib <libs>` and `init_oa_search_libs <libs>`) during initialization.

There are different types of OA methodologies and flows supported that are controlled by `setOaxMode`. You can also look at the Mixed Signal Interoperability Guide for more details on their effects on `saveDesign`/`restoreDesign`.

You can save a design to the same location from which you restored the design. The new data will overwrite the previous data.

You can use the `saveDesign` command at any time after `init_design`.

By default, external file references used inside the `fileName.dat` directory (e.g. to library files, or SDC files that are not modified) are stored using a portable format that allows you to copy `fileName.dat` anywhere in the same network where the full path names are still valid, and then restore it with `restoreDesign`. This portable format is not supported for OA DBs that require the usage of a cds.lib file to find physical file locations.

Note:

- The `saveDesign` command does not save the state of the `timing_enable_simultaneous_setup_hold_mode` timing global variable. When the global is set to `true`, various physical design functions in the system are disabled. When the design is restored (using the `restoreDesign` command), the physical design commands are required to be active so that the system can be properly initialized.
- The new LEF will not be saved by `saveDesign` in the following scenarios.
  - If you replaced the LEF macro file multiple times. In this case, the tool would not know which file to keep at the end.
  - If the old lef file that contains the original macro contains other MACRO definition. In this case, the old file cannot be removed by the tool. If the old file is not removed, the new file is appended to the list. As mentioned in the above point, the list may have multiple lef files that contain the same MACRO but with different definition. When reading LEF files with multiple definitions, the tool keeps only the first one. As a result, in the next session the file that you want will not be loaded.

  After trying different macro definitions, you need to replace the content of the macro definition manually. You can do this either by overwriting the one in original LEF file, or if the original LEF file contains only that macro, replacing the LEF file in the LEF file list.
- You should not modify the contents of a saved DB (*.enc.dat or *.db) at any time. If the contents of the saved DB are modified, restoring such modified DB might cause problems later or lead to DB corruption or crashes.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `saveDesign` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man saveDesign`.

`-addTiming`	If you use `restoreDesign -noTiming` to restore the DB, the timing data is not loaded. This option allows you to copy the ignored timing data from the original `restoreDesign` location, and add it back during `saveDesign` like this:
	`restoreDesign -noTiming test1.enc.dat top`
	`<physical editing commands ...>`
	`saveDesign -addTiming test2.enc`
	This usage model is intended to allow faster physical-only editing, like DRC fixing, where the netlist is not modified. If you change the netlist, unpredictable results may occur when reading the test2 DB using timing data copied from test1.

`-current_top_cell_only`	Specifies to only write current design module and its submodules in the netlist. By default, all the modules from the input netlist will be saved even if they do not belong to current design.
`-cellview {`*`libname cellname viewname`*`}`	Saves the design in the OpenAccess database format using the specified lib, cell, and view names. The design is saved in the *lib/cell/view* OA directory. **Note**: Usually, the cell name is the same as the design top cell name. If the cell name specified is different from the top cell name, it means that the top module created in OpenAccess would have the new cell name instead of the original name.
`-def`	Saves a DEF file, in addition to the normal DB files in the DB directory. This parameter is not normally used for flat or block flows, and is not used by `restoreDesign`. It can be useful in a hierarchical flow, where you want to use `assembleDesign` to read only the netlist and the DEF files without opening up each design DB and writing out the Verilog and DEF files separately (see `-verilog`).
`fileName`	Specifies the name of the output file with a `restoreDesign` command in it to load the saved DB. The `.dat` extension is appended to the name to create an output directory to save the DB using native Innovus formats. So `saveDesign` test will create a file named `test`, with a command like this in it: `restoreDesign test.dat top` It will also create a directory named `test.dat` with all the DB files in it. You can then use source test to load the saved DB in a future session.
`-keep_input_path`	Saves the path same as the path in the input file.
`-libs`	Normally external file references, such as references to the LEF, .lib, SDC files are saved using a full-path name, symbolic links to the original files inside a libs sub-directory inside the DB directory. This option forces copies of the files, rather than symbolic links, in the libs sub-directory so there are no external file references. This makes the DB directory much larger, but it is suitable for sending to a different network where the library and external data files are not available. An OA DB will still have OA library references using the normal `cds.lib` methodology, but any other external file references will be copied inside the cellview directory. **Note**: Any future sessions that use `restoreDesign` and then `saveDesign` will have references to the files inside this design directory rather than to the original external locations. So, you must keep this DB directory around as long as any other DB references it (or you must use `saveDesign -libs` in the later session to force another local copy of the external files).
`-lib2ldb`	Converts the `.lib` timing libraries referenced in the MMMC file to the `.ldb` format and writes them in a libs sub-directory inside the output design directory. References to the original `.lib` files in the MMMC file are changed to the corresponding `.ldb` files inside the libs sub-directory. This makes the design directory much larger because it has all the timing library data inside it, and is not recommended for normal flows. Normally a user should setup the `.ldb` files in an external library directory and have the MMMC files use them directly to avoid this overhead. Using `.ldb` files will make `restoreDesign` faster when it reads the library data. So, this option is useful for “throw-away” debugging experiments that require repeated sessions at the cost of a one-time conversion, and carrying the library data with the design. See the `write_ldb` command for more information about the usage of .ldb files.
`-mmmc2`	Saves the complete design database in the MMMC2 format.
`-noConstraint`	Saves the timing graph data without the SDC constraints data, and requires the `-timingGraph` option. This is useful to reduce the disk size, and speedup `saveDesign`, `restoreDesign`. But the timing-graph data cannot be loaded by any other release version, and without the SDC files, the timing constraints would be lost if loaded by a different release version. **Note**: You can still load the timing-graph with the current release version, and then use `saveDesign` without the `-noConstraint` option, to regenerate the SDC files from the timing-graph and then use `restoreDesign` with a later release.

`-noFill`	Does not save any metal or via fill shapes inside the DB. This is useful if you did ECO routing, and the fill data is going to be regenerated anyway, so it is not worth saving the current fill data any more. All the fill data that would go to DEF FILLS section (floating fill data), or the DEF SPECIALNETS section with + SHAPE FILLWIRE or FILLWIREOPC will be ignored and not saved.
`-no_pvs_fill`	Does not save the PVS fill data file. In some PVS flows, a stream (GDS) file from PVS is saved inside the Innovus DB directory (see the PVS documentation for more details). During `restoreDesign` this file is not read but can be optionally loaded or used later in the flow. By default, if the PVS fill file exists, `saveDesign` will copy it from the `read_db` location to the new DB directory. If ECO changes to the current design have made the PVS fill file invalid, use this option to stop it from being copied.
`-no_wait` *`out_file`*	Saves the design in a separate process. You can continue executing new commands simultaneously while the design is being saved. This is useful when you want to save intermediate results without waiting for the save to complete. Simultaneous commands that modify the DB will have no effect on the saved design. The memory is shared unless you modify it, so there is little or no increase in the memory usage for small changes, but if you completely changed everything in the DB, you would temporarily have up to double the total memory for both processes to run. Each process may use multiple CPUs up to the limits set by `setMultiCpuUsage -localCpu`. Therefore, if the simultaneous commands use multiple local CPUs, you may temporarily have up to double the max local CPU usage until `saveDesign` is complete. The actual number of CPUs used by `saveDesign` varies with design size and the type of data being saved. So, you would need to experiment with your specific design to find the number of CPUs used, or set the `-localCpu` value temporarily lower to limit it. The output messages or error messages which normally go to stdout/stderr (e.g. the xterm) generated by `saveDesign` will be redirected to *`out_file`*. Any .log or .logv information is ignored and lost. You can check *`out_file`* to see if `saveDesign` completed successfully. If you give the `exit` command, the session will wait for `saveDesign -no_wait` to complete before exiting, while other commands will run simultaneously. This allows flow scripts that run multiple sessions to know any save from the previous session is complete before the next session uses it, without the need to poll or check *`out_file`*. **Example:** The following command saves the design into the `my_design.dat` directory, and any messages are written to `save.1`. `saveDesign my_design -no_wait save.1`
`-oaLibs`	Saves all OA libraries specified in cds.lib under the directory libname/cellname/viewname/libs/oa/. **Note**: This parameter works only in OA designs.
`-oaUsedLibsOnly`	Saves only the libraries listed in the `init_oa_ref_lib`, and `init_oa_search_lib`, which are referenced through the on-demand processing. On specifying this parameter, a new cds.lib file is created with only the specified libraries. The libraries are saved under the directory libname/cellname/viewname/libs/oa/. **Note**: This parameter works only in OA designs.
`-rc`	Saves RC extraction data, including data for incremental extraction. By default, Innovus does not automatically save RC extraction data to save disk space and run-time. The `-rc` parameter does not save RC extraction data if the design is not extracted or if you extract the data using the preRoute extraction engine.
`-saveRestoreFile` *`file_name`*	Specifies the file name that can be sourced to read back the OpenAccess Design. If you add this option, you can save a `*.inn` file and record the `restoreDesign` command. The `*.inn` file can be sourced to restore the OA design.
`-skip_file {metric cmd}`	Removes the specified db files. • If you save a design with the `-skip_file {metric}` option, the tool does not save file db `inn.um.gz` and .metric.gz. • If you save a design with the `-skip_file {cmd}` option, the tool does not save the `inn.cmd.gz` file. • If you save a design with the `-skip_file {metric cmd}` option, all `inn.um.gz`, `.metric.gz`, and `inn.cmd.gz` files cannot be saved.

`-tcon`	By default, if the SDC timing constraints have not been modified, a link to the original external SDC file is kept to reduce the disk size. If the SDC timing constraints were modified, then the SDC files are automatically stored in the DB directory. This option will force all SDC files to be copied locally inside the DB directory, even if they did not change. **Note**: Any future sessions that use `restoreDesign` and then `saveDesign` will have references to SDC files inside this design directory rather than to the original external location. So, you must keep this DB directory around as long as any other DB references it (or you must use `saveDesign` in the later session to force another local copy of the SDC files).
`-tgz`	Saves the design as a gzipped tar file. The `saveDesign` command saves `fileName.dat` and automatically turns on `-libs` and -`sdc` to force all external file references to be copied inside the DB directory (for example, .lib, .lef, .tcz files). Then it tars the directory and gzips it into a single portable Innovus design tar ball, by adding the `.tar.gz` extension to the `fileName.dat` name. The following commands results in a file named `myDesign.enc.dat.tar.gz`: `saveDesign myDesign.enc -tgz`
`-timingGraph`	Saves the timing graph data. When this parameter is specified, the -rc parameter is also automatically enabled. This means that the RC extraction data is also saved along with the timing graph data at the postRoute stage. At the preRoute stage, the RCs are not saved but all information is present to fully time the design without the need to rebuild the timing graph. Commands, such as report_timing and optDesign, that use timing analysis results use the saved timing graph. This can save significant CPU after `restoreDesign`. A user can get the same timing seen previously without waiting for the timing analysis to be repeated. **Note**: This feature is dependent on the build version and tool. Tempus cannot read a timing-graph written by Innovus. You must write and read the timing graph using the same tool and build. You can still load the design with a different tool or build, but the timing-graph is lost and you must repeat the timing analysis. The timing graph data must be fully built (e.g. with report_timing) before calling `saveDesign -timingGraph`.

`-user_path`	By default all external file references (such as. library files) are stored as absolute paths without any symbolic links. So, the DB directory is portable anywhere on the same network. This option stores external file references exactly as you entered it For example, full paths like /x/y or relative paths like ../x/y, ./x/y), and keeps any symbolic links used inside the path names.
	Example:
	Consider that there are two library files `a.lib` and `b.lib` under:
	`/global/project1/libs/mmmc`
	And two lef files c.lef and d.lef under:
	`/global/project1/libs/lef`
	There are two symlinks to the libs:
	`/usa/db1/libs1.0/mmmc/a.lib → /global/project1/libs/mmmc/a.lib`
	`/usa/libs/mmmc/b.lib → /global/project1/libs/mmmc/b.lib`
	And two symlinks to the lefs:
	`/usa/db1/libs1.0/lef/c.lef → /global/project1/libs/lef/c.lef`
	`/usa/libs/lef/d.lef → /global/project1/libs/lef/d.lef`
	Your current work dir is `/usa/db1.1/`. You have an init script like:
	`set init_mmmc_files ./mmmc.tcl`
	`set init_lef_file {/usa/db1/libs1.0/lef/c.lef ../libs/lef/d.lef}`
	`set init_verilog design.v`
	`init_design`
	Where mmmc.tcl has:
	`create_library_set -name test -timing {/usa/db1/libs1.0/mmmc/a.lib ../libs/mmmc/b.lib }`
	Then after saveDesign, **without -user_path**, the libs and lefs will save link to the real files:
	`> saveDesign db1.2`
	The `./mmmc.tcl` file is always stored inside the DB dir, so no external reference is used.

	By default, external file references are resolved to their fullpath name without any symlinks.
	The .lib files inside the mmmc.tcl file will be referenced as: `{/global/project1/libs/mmmc/a.lib /global/project1/libs/mmmc/b.lib}`
	The .lef files will be referenced as: `{/global/project1/libs/lef/c.lef /global/project1/libs/lef/d.lef}`
	This is portable and can be loaded by `restoreDesign` anywhere on the same network.
	`/usa/db1.2/libs1.2/mmmc/a.lib → /global/project1/libs/mmmc/a.lib`
	`/usa/db1.2/libs1.2/mmmc/b.lib → /global/project1/libs/mmmc/b.lib`
	`/usa/db1.2/libs1.2/lef/c.lef → /global/project1/libs/lef/c.lef`
	`/usa/db1.2/libs1.2/lef/d.lef → /global/project1/libs/lef/d.lef`
	
	With -user_path, the libs and lefs keep the symlinks of the current db:
	`> saveDesign db1.2 -user_path`
	The .lib files will be referenced as entered by the user: `{/usa/db1/libs1.0/mmmc/a.lib ../libs/mmmc/b.lib}`
	The .lef files will referenced as entered by the user: `{/usa/db1/libs1.0/lef/c.lef ../libs/lef/d.lef}`
	So `restoreDesign` must be run in the same directory as `saveDesign` was run, or in a directory with the same ./y and /x directory structure.
	`/usa/db1.2/libs1.2/mmmc/a.lib → /usa/db1/libs1.0/mmmc/a.lib`
	`/usa/db1.2/libs1.2/mmmc/b.lib → ../../../libs/mmmc/b.lib`
	`/usa/db1.2/libs1.2/lef/c.lef → /usa/db1/libs1.0/lef/c.lef`
	`/usa/db1.2/libs1.2/lef/d.lef → ../../../libs/lef/d.lef`

`-verilog`	Saves a Verilog file inside the DB directory, in addition to the normal DB files. This parameter is not normally used for flat or block flows, and is not used by `restoreDesign`. It can be used in a hierarchical flow, where you want to use `assembleDesign` to read only the Verilog and the DEF files without opening up each design DB and writing out the Verilog and DEF files separately (see `-def`).

`-view` *viewname*	Specifies the name of the OA view. This view will be saved in the same lib/cell/ directory that you used with `restoreDesign` or with init_design during initialization. This option provides a shortcut to save a view quickly in the same lib/cell structure that you read from.
	Example:
	`restoreDesign -cellview {designLib top layout}`
	`saveDesign -cellview {designLib top place}`
	`saveDesign -view place`
	Both the above `saveDesign` commands are equivalent.

Example

- The following command writes the current design into directory `test.enc.dat`:
  ```
  saveDesign test.enc
  ```

- If you already ran timing analysis, you can save some run time during read like this:
  ```
  report_timing #first time usage, builds timing-graph
  saveDesign test.enc -timingGraph
  ```
  Then in a new session
  ```
  restoreDesign test.enc.dat top
  ```
  report_timing #reports results, without repeating timing analysis

- For physical-only editing, you can do this to speedup restoreDesign/saveDesign by ignoring the timing during `restoreDesign`, and adding it back during `saveDesign`.
  ```
  restoreDesign test1.enc.dat top -no_timing
  <physical-only editing>
  saveDesign test2.enc -addTiming
  ```

  Then in a new session
  ```
  restoreDesign test2.enc.dat top #has timing from test1.enc.dat
  ```
  If the logical netlist was modified during editing of test1.enc.dat, then reading test2.enc.dat may have unpredictable timing results.

```

Writes a netlist file of the design. By default, a logical netlist is saved. The netlist is in hierarchical Verilog format only if the original netlist loaded was hierarchical. The Innovus software saves the netlist from the top level of the hierarchy to the bottom level of the hierarchy if the original netlist is specified from top to bottom. If you run this command after using `loadDefFile`, it bundles bus pins to create busses in Verilog. Saving the netlist is done after running placement with timing driven option, clock tree synthesis, scan group re-order, or IPO.

You can use this command after importing the design.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `saveNetlist` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man saveNetlist`.

`-abstract`	Writes an empty Verilog module with port declarations for the specified module. You can use the -abstract parameter with the following parameters: • `-includePowerGround` • `-excludeTopCellPGPort` • `-derivePGPortDir` • `-exportTopPGNets` • `-module` • `-phys` *Default*: Top module
`-applyMaskShift`	Adds a suffix to the cell name of a leaf instance based on the color assignments of the instance. **Note**: • The netlist must be unique or `-flat` must specified for the option to take effect. • The mask shifted netlist cannot be read back into Innovus, as the cell names with suffix do not actually exist in LEF and timing libraries.
`-cellInstanceColor {true | false}`	Specifies to use the instance-based color.
`-cellMasterColor {true | false}]`	Specifies to use the cell master-based color from the Innovus color engine.
`-derivePGPortDir`	Specifies whether to derive (vs. assume) directions of implicit PG ports in saving a physical netlist.
`-excludeCellDef` *`cellName`*	Excludes the module definition of the specified cells.
`-excludeCellInst` *`cellName`*	Excludes the instances of the specified cells from the netlist. You can exclude logical or physical instances. The *`cellName`* can be a single cell name or a list of cell names separated by a space and surrounded by braces (`{}`) or double quotation marks (`""`). For example: `-excludeCellInst {cell1 cell2}` or `"cell1 cell2"`.
`-excludeIlm`	Excludes the ILM module.
`-excludeLeafCell`	Writes I/O instances, macro or block instances, and standard cell instances to the netlist, but does not include leaf cell definitions in the netlist.
`-excludeTopCellPGPort` *`portName`*	Excludes specified power and ground port(s) from the top cell's module port list. The *`portName`* can be a single port name or a list of port names separated by a space and surrounded by braces (`{}`) or double quotation marks (`""`). For example: `-excludeTopCellPGPort {VSS VDD}` or `"VSS VDD"`.
`-exportTopPGNets`	Specifies to use top-cell PG nets as ports for the top module in a physical netlist created with the `-phys` or `-includePowerGround` option.
`fileName`	Specifies the name of the file where the netlist is written.
`-flat`	Writes a flattened Verilog netlist. *Default:* If you omit this parameter, and if the original netlist loaded was hierarchical, the netlist is written in hierarchical Verilog format.
`-flattenBus`	Writes a flattened-bus Verilog netlist. When this parameter is used, a bus bit, such as "A[0]" is output as "\A[0]". If such conversions conflict with existing object names, `saveNetlist` warns about such conflicts and returns an error: **WARN: (ENCDB-2156): Cannot rename bus-bit %s '%s' in cell '%s' because the name '%s' is already in use on %s in that cell. Change the design to remove the conflicting name or run the command without the `-flattenBus` option. **ERROR: (ENCSYC-1279): Cannot output flatten-bus netlist due to the reported object-name conflicts.

`-followLogicalModuleOrder`	Follows the logical module order. The order of the modules, written without `-includePowerGround`, in a hierarchical logical netlist is different from that, written with the option, in a hierarchical PG netlist. If `-followLogicalModuleOrder` is specified together with `-includePowerGround` (but not `-flat`) the order of the modules in a physical netlist will be the same as that in a logical netlist. **Note**: The same order is for non-leaf modules only.
`-ignoreFixedMask`	Ignores cell fixedMask when maskShift is applied.
`-ilm`	Writes out a netlist with ILM guts. **Note:** This parameter can be specified only in the `flattenIlm` state. If this parameter is specified in the unflatten state, the software returns an error message.
`-includeBumpCell`	Writes bump cell information to the netlist. You can also use `-includeBumpCell` with logical netlist. **Note:** This parameter is effective only when used with either the `-phys` or `-flat` parameters.
`-includePhysicalCell` *cellName*	Includes the physical instances of the specified cells in the netlist. With this parameter, 1'b1/1'b0-style, logical connections are used for tie-off pins. The *cellName* can be a single cell name or a list of cell names separated by a space and surrounded by braces ({}) or double quotes (""), for example, `-includePhysicalCell {cell1 cell2}` or `"cell1 cell2"`. *Default*: If you omit this parameter, no physical cell module definitions will be in the netlist file. **Note:** `-includePhysicalCell` creates a netlist that should not be read back into Innovus.
`-includePowerGround`	By default, PG connections in the original logical Verilog netlist are already written out (unless -flat is given). You can add "physical only" global PG net connections and "physical only" PG nets added by IEEE1801 to the Verilog output with this option. It adds PG nets inside each module and PG ports on each module in order to thread the PG connections to each pin. Some physical tools like LVS prefer to have these explicitly in the hierarchical Verilog.
`-includePhysicalInst`	Activates physical netlisting by including physical instances, such as fillers, in the netlist. With this parameter, GNC-based/physical connections, such as vss, are used for tie-off pins.
`-keepAllBackslash`	Keeps all backslashes in names.
`-lineLength` *characters_per_line*	Specifies the maximum number of characters per line for module port lists and instance port connections. When a line length exceeds the specified value, the software wraps the line at the next opportunity. You must specify a non-negative integer for the value. *Default:* `0` (The software wraps lines at the earliest opportunity.)
`-maskShiftSuffix` *maskShiftSuffix*	Adds a user-specified suffix to the cell name of a leaf instance instead of the tool's default suffix. The default suffix is `_<layer>_<mask>`. For example, BUFX1_M0_1 default suffix means the M0 color flipped from mask 0 to mask 1. The `-maskShiftSuffix` option works only when `-applyMaskShift` is used. **Note**: The netlist must be unique or `-flat` must specified for the option to take effect.
`-module` *moduleName*	Saves the specified module of the netlist.
`-omitFloatingPort`	Omits the unconnected instance ports from the saved netlist.
`-onlyLeafCell`	Writes only leaf cell definitions in the netlist. *Default:* If you do not specify this parameter, the software writes leaf cell definitions, standard cell instances, and macro/block instances in the netlist file.
`-onlyMacro`	Writes only macro or block cell definitions to the netlist. *Default:* If you do not specify this parameter, the software writes leaf cell definitions, standard cell instances, and macro/block instances in the netlist file.
`-onlyStdCell`	Writes only standard cell instances in the netlist. *Default:* If you do not specify this parameter, the software writes leaf cell definitions, standard cell instances, and macro/block instances in the netlist file.

`-phys`	Writes out physical cell instances, and inserts power and ground nets in the netlist. This is used for LVS and for designs with multiple supply voltages. Hierarchical power and ground nets are also supported. **Note:** `-phys` creates a netlist that should not be read back into Innovus.
`-removePowerGround`	Removes PG ports, PG nets, PG pin connections, and replaces PG net connections on signal pins with 1'b1 or 1'b0.
`-replaceTieConnection`	Replaces `1'b1` and `1'b0` constants with undriven nets in the output netlist. Use this parameter if you may want to save a Verilog netlist from Innovus without any `1'b*` constants. **Note:** By default, the `saveNetlist` command writes a Verilog netlist file of the design using `1'b*` constants to represent Assign nets and ports. However, subsequent verification steps that you use outside Innovus might not be able to handle these `1'b*` constants. In such a case, use `-replaceTieConnection`.
`-replaceWorWandWithWire`	Replaces wor/wand with wire statement.
`-replace_inout_with_output_for_pg_ports`	Changes the direction of inout P/G ports to output except for the ones defined by IEEE1801/UPF. Their directions remain unchanged.
`-topCell` *cellName*	Saves the specified module along with its submodules. If you use `saveNetlist -topCell`, tool only saves the top cell in the netlist file, and if you use `saveNetlist` without `-topCell`, the tool saves all modules in the netlist file.
`-topModuleFirst`	Writes out top module first, followed by the rest of the modules. **Note**: This feature is not available for physical netlist writing. As a result, the `-topModuleFirst` option will be ignored if any of the following parameters is also specified: `-phys`, `-includePowerGround`, and `-includePhysicalInst`.
`-useCdsThruForAssign`	Replaces the assign statement with cds_thru, the output netlist will not be able to read back by Innovus. This is only for third party tool.
`-useEEQCellMap {`*masterCell EEQcell1 EEQcell2*`}`	Defines the master cell and the EEQ cells that need to be mapped to the master cell {{masterCell EEQcell1 EEQcell2} ...}
`-useEEQCellWithLibertyInfo`	Specifies to use the EEQ cell with the timing library information as the master cell of a leaf instance.
`-writeConstantForSignalConnection`	Writes constant value for tie pin connection. When this option is specified, tool can assign the tie net name to related signal pin. If this option is not specified, tool assigns the real net name to the signal pin.
`-writeSupply0Supply1`	`-writeSupply0Supply1` must be specified together with `-phys` or `-includePowerGround` to take effect. Its default is off, with which a PG net is written as "supply0/supply1" only if it defined as such in the original Verilog. When on, PG nets are written as "supply0" or "supply1" except for implicit (see IEEE1801) PG nets, which are written as "wire" as needed.

Example

- The following command writes out the netlist in Verilog format of the current state of the design in Innovus to a file `mydesign_cts.v`:

  ```
  saveNetlist mydesign_cts.v
  ```

- The following command saves the netlist with `dtmf_recvr_core` as the top module to the `output.v` file:

  ```
  saveNetlist -topCell dtmf_recvr_core output.v
  ```

- The following command saves the physical netlist of ILM internals to the `output.v` file:

  ```
  saveNetlist -ilm -phys output.v
  ```

  Use this combination of options to pass on power or ground (P/G) information correctly to the netlist in low power ILM flow.

- The following example shows the netlist generated by `saveNetlist -abstract`.

  ```
  module test(in1, in2, out1, out2, clk1, clk2, clk3, se1, se2);
   input [3:0] in1;
   input [7:0] in2;
   input clk1, clk2, clk3, se1, se2;
   output [3:0] out1;
   output [7:0] out2;
  ```

```
endmodule
```

[-verbose {true | false}]
```

Sets options for the `run_abstract` command.

Use the `get_abstract_mode` command to return the current settings for the `set_abstract_mode` command.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `set_abstract_mode` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man set_abstract_mode`
`-reset`	Resets all or specified options to default value. Any values that do not already match the default value and are reset will be reported.
`-abstract_blockage_cut_around_pin` *`layer_list`*	
	Specifies that obstruction should be cut around pin for standard cells. By default, `run_abstract` creates obstructions on pin shapes. • If `-input_cell_type` is `std`, the default value for `-abstract_blockage_cut_around_pin` is the list of all metal and via layer names. This means that abstract will not cover obstruction on pins for standard cells on all metal and via layers if `-abstract_blockage_cut_around_pin` is specified. • If `-input_cell_type` is `block` or `io`, the default value for `-abstract_blockage_cut_around_pin` is the list of all via layer names. This means that abstract will not cover obstruction on pins for blocks and io pads on all via layers if `-abstract_blockage_cut_around_pin` is specified. *Default:* ""
`-antenna_connectivity {`*`layer1 connect_layer layer2`*`}`	
	Specifies the layers for which connectivity is to be extracted. The syntax is `{`*`layer1 connect_layer layer2`*`}`. Example: `set_abstract_mode -antenna_connectivity {{poly V0 M1} {Diff V0 M1}}`. *Default:* ""
`-antenna_diffusion_geom {{`*`layer_name`*`} {`*`logical_expression`*`}}`	
	Specifies the diffusion layer, followed by the expression to remove the gate channel area from the diffusion region. Example: `set_abstract_mode -antenna_diffusion_geom {Diff_real {Diff andnot Poly}` *Default:* ""
`-antenna_gate_geom {{`*`layer_name`*`} {`*`logical_expression`*`}}`	
	Specifies the poly layer that forms a gate along with the layer expression to derive the gate area. This option also triggers the creation of antenna models. Example: `set_abstract_mode -antenna_gate_geom {{Gate} {Poly and Diff}}` *Default:* ""
`-blockage_detailed_layers` *`layer_list`*	Specifies the layers for which a detailed blockage model is to be created. The detailed blockage model generates blockages only at those places on the layer where there are real shapes in the cell. This only applies to the IO and block cells and not to standard cells. *Default*: ""
`-boundary_layers` *`layer_list`*	Specifies the drawn layers to extract the cell boundary. If not specified, abstract uses the prBounbdary object as the boundary size. By default, *`layer_list`* list is empty, and the prBoundary is used. The prBoundary comes from an explicit GDS layer that is used to compute the LEF SIZE (and OVERLAP OBS shapes for rectilinear boundaries). If there is no explicit GDS prBoundary layer, the boundary can be computed from the bounding box of geometries on this list of layers. **Note:** This option will not normally work for core standard cells because they almost always have diffusion and metal shapes extending outside the real prBoundary. These shapes are usually shared with the row above or below for the power rails. This option can be useful for blocks that have no prBoundary and where a little lost area due to worst-case bounding box approximations is acceptable. *Default*: ""

`-cell_symmetry {R0 | X | Y | R90 | X Y | X R90 | Y R90 | X Y R90}`	
	Specifies a property value for cell symmetry. The valid values for the property symmetry are R0, X, Y, R90, X Y, X R90, Y R90, and X Y R90. Example: `set_abstract_mode -cell_symmetry {X Y R90}` *Default:* `{X Y}`
`-export_lef_version {5.3 | 5.4 | 5.5 | 5.6 | 5.7 | 5.8}`	
	Specifies the version of LEF to be exported. The default version is the same as the version of the technology LEF file being imported. *Default*: `5.7`
`-extract_layers_power` *layer_list*	Specifies the layers through which the extractor extracts each power net. This is used to reduce the search space if abstract is taking too much run time for each cell. Usually not applicable to standard cells. For blocks, it is common to only extract the power nets on the top one or two metal layers. *Default*: ""
`-extract_layers_signal` *layer_list*	Specifies the layers through which the extractor extracts each net. This is used to reduce the search space if abstract is taking too much run time for each cell. Usually not applicable to standard cells. *Default*: ""
`-extract_pin_layers_power` *layer_list*	Determines the shapes, which are found by the extractor, to be turned into pins. This argument is valid only if the associated layer, geometry specification and connectivity have been provided in the technology LEF. Usually not applicable to standard cells. *Default*: ""
`-extract_pin_layers_signal` *layer_list*	Determines the shapes, which are found by the extractor, to be turned into pins. This argument is valid only if the associated layer, geometry specification and connectivity have been provided in the technology LEF. Usually not applicable to standard cells. *Default*: ""
`-input_cell_type {std | io | block}`	Selects the cell type being translated with abstract. The tool adjusts its settings on the basis of the selected cell type. *Default*: `std`
`-input_gds_layer_map_file` *file.map*	Specifies the file that maps GDS layer number/data type to LEF layer names in the Virtuoso format. *Default*: ""
`-input_lef_tech_file` *file.lef*	Specifies the technology LEF file. This is used to get all the layer names and their types, such as routing, cut and the layer order for extracting connectivity. *Default*: ""
`-keep_temp_files {true | false}`	Specifies to keep the temporary files/libraries that are created in the process after the `run_abstract` command finishes. *Default:* `false`
`-pins_analog_names` *pattern*	Identifies analog pin names based on label strings in the abstract to set the "USE ANALOG" property of LEF.
`-pins_clock_names` *pattern*	Identifies clock pin names based on label strings in the abstract to set the “USE CLOCK” property of LEF.
`-pins_ground_names` *pattern*	Identifies ground pins based on label strings in the abstract to set the “USE GROUND” property of LEF.
`-pins_output_names` *pattern*	Identifies output pins based on label strings in the GDS to set the direction to OUTPUT property of LEF.
`-pins_power_names` *pattern*	Identifies power pin names based on label strings in the abstract to set the “USE POWER” property of LEF.
`-pins_text_pin_map` *pattern*	Maps text labels to pins on nets. Specify the layer purpose pairs based on which you want the abstract generator to search for geometry of any given layer-purpose pair with a text label.
`-pre_skill` *file.il*	Specifies a skill file that will be executed in abstract before the auto-generated script is executed. Optional.
`-selected_cells` *pattern*	Selects cells to create abstract for using regex style expressions.

`-site_name` *site_names*	Specifies the site to be used for macros. This site is added to all the cells.
`-verbose {true|false}`	Specifies the verbose mode with extra print. *Default:* `false`

Examples

- The following command sets the values for the property symmetry:

```
> set_abstract_mode -cell_symmetry {R0, X, Y, R90}
> get_abstract_mode -cell_symmetry
-cell_symmetry {R0, X, Y, R90} # string, default="", user setting
{R0, X, Y, R90}
```

- The following command sets the version of LEF to be exported:

```
> set_abstract_mode -export_lef_version 5.3
> get_abstract_mode -export_lef_version
-export_lef_version 5.3 # enums={5.3 5.4 5.5 5.6 5.7 5.8}, default=5.7, user setting
5.3
```

Related Information

- `get_abstract_mode` command
- `run_abstract` command

set_cell_power_domain

```
set_cell_power_domain
[-help]
[-reset]
[-file file_name]
```

Defines domains for multi-VDD and multi-VSS cells. When reading an instance ASCII power file to perform power-rail analysis, if there are missing power values associated with ground pins, the software uses the information specified with the `set_cell_power_domain` command to derive domain association and distributes power to each ground net accordingly.

This domain information is stored in a side file that is used by power analysis to calculate power using the correct voltage for each domain. If you are specifying an external instance ASCII power file with pin information, this domain information is used to correctly distribute power to each pin.

Use this command before performing power and rail analysis.

Parameters

`-file file_name`	

	Specifies the name of the file containing the cell names and corresponding power-ground pairs.
	The format of the file is:
	`CELL: <cell name1>`
	`<power1> <gnd1>`
	`<power2> <gnd2>`
	`CELL: <cell name2>`
	`<power1> <gnd1>`
	`...`

`-help`	Outputs a brief description for the `set_cell_power_domain` parameter. For a detailed description of the command, use the `man` command: `man set_cell_power_domain`.
`-reset`	Resets all specified options back to default values.

Examples

- The following command specifies a file `domain_file` for the cell `mycell` having multiple power and ground pins (`VDD` at `1v` and `VDDm` at `0.84v`):
  ```
  set_cell_power_domain -file domain_file
  ```
  The following is a snippet from `domain_file`:
  ```
  CELL: mycell
  VDD_1v  VSS_1v
  VDDm_0.84v  VSSm_0.84v
  ```

[-powerEffort {none | low | high}]
[-process integer]
[-slackWeighting {unityWeighting|viewBasedWeighting}]
[-topRoutingLayer layer]
[-trim_grid_group group_name]
```

Specifies the process technology value. You can use this command to change the process technology dependent default settings globally for each application instead of setting several mode options.

With advanced technologies and new design, manufacturing techniques accurate delay calculation becomes more challenging. The main challenges are:

- Delay and slew interpretation of distorted waveforms.
- Waveforms are affected by:
  - Distributed RC
  - Back-miller current
  - Crosstalk and input noise
  - Different non-linear characteristics of gates
- Ultra low voltage applications

Tempus STA for advanced nodes has several capabilities for signoff timing accuracy at the respective nodes. The `setDesignMode` command automatically enables the node specific signoff STA setting required to meet the signoff STA accuracy challenges at the specific nodes.

Use the `getDesignMode` command to return the current settings for the `setDesignMode` command.

When you specify a process technology value using the `setDesignMode` command, the Innovus software assigns coupling capacitance threshold values to the RC extraction filters automatically. These values determine whether the coupling capacitances of the nets in a design will be lumped to the ground.

Note: In TQuantus extraction, the grounding of coupling capacitances also depends on the capacitance filtering mode set by the `-capFilterMode` parameter of the `setExtractRCMode` command.

The following table lists the coupling capacitance threshold values that are applied based on the specified process node. Note that the table might not be readable when viewed with the Unix man command. Check the `setDesignMode` command description in the *Innovus Text Command Reference* to view the table.

Process Node	Extraction Filters		
	coupling_c_th	relative_c_th	total_c_th
Above 130nm	3.0000	0.03	5.0000
130nm and below	0.4000	1	0.0000
90nm and below	0.2000	1	0.0000

65nm and below	0.1000	1	0.0000
45nm and below	0.1000	1	0.0000

Note: The filtering values set by the Innovus software, which are based on the process node setting, attempt to capture the most significant effect of coupling capacitances on SI analysis, and are strongly recommended. However, you can choose to specify different filtering thresholds using the `-coupling_c_th`, `-relative_c_th`, and `-total_c_th` parameters of the `setExtractRCMode` command.

In addition to the extraction filters, the software selects the extraction engine based on the process node. For 65nm and below process nodes, the software uses the TQuantus extraction engine, which provides scaling factors closer to 1 with better correlation to sign-off extraction. It also provides coupling capacitances to the wires on the layers above and below the victim wire.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `setDesignMode` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setDesignMode`
`-backsideBottomRoutingLayer` *layer*	Specifies the highest backside LEF layer name for global and detail routing. *Default*: `""`
`-backsideTopRoutingLayer` *layer*	Specifies the lowest backside LEF layer name for global and detail routing. *Default*: `""`
`-bottomRoutingLayer` *layer*	Specifies the lowest lef layer name for global and detail routing. For a special partial routing on the first routing layer in certain nodes, the routing enablement of that layer must be a global decision in the entire flow of the design. For example, if M0 or M1 routing is enabled, you need to set `setDesignMode -bottomRoutingLayer M0/1` from the init step. This bottom routing layer setting must not be changed in later stages of the flow. *Default*: `""`
`-compressedPGDB {true|false}`	Specifies whether the compressed PG feature is enabled. When it is set to `true`, `restoreDesign` will automatically compress the PG data while loading the design. You can use "dbGet top.isPGCompressed" to check if PG in the design is compressed. *Default*: `false`
`-congEffort {low|medium|high|auto}`	Specifies the congestion effort level. It controls placement as well the place_opt_design behavior. It is also possible to have other tuning for other steps in the flow. *Default:* `auto` Specify one of the following values: • `auto`: Automatically determines whether the design is congested and performs extra congestion driven effort for highly congested designs. • `high`: Runs more iterations of placement in an effort to achieve better congestion results. This parameter increases the run time. This also does congestion-aware buffering. When `-congEffort` is set to `high`, `optDesign` takes actions to be more congestion friendly and may call more iterations of placement to achieve better congestion results. It will also implicitly set `setPlaceMode -congEffort high` you have not set `setPlaceMode -conEffort`. However, if you have set `setPlaceMode -congEffort`, it will not override your setting. That is, the setting of "`setPlaceMode -congEffort`" will be honored. If you set both `setDesignMode -congEffort` and `setPlaceMode -congEffort`, the `placeDesign` and incremental placement will take your setting of `setPlaceMode -congEffort`. However for the flow, `optDesign` will take whatever tuning you have done for the `-congEffort` level. • `low`: Runs fewer iterations of placement to arrive quickly at a legal placement. This parameter might decrease placement quality. • `medium`: Runs placement on designs at a normal effort level.

`-reset`	Resets parameters to their default values. The `-reset` parameter *must* be the first parameter specified. If you specify `-reset` by itself, the software resets all `setDesignMode` parameters to their default values. Any values that do not already match the default value and are reset will be reported.
`-addPhysicalCell {hier | flat}`	
	Adds support for physical cells such as Add Filler, Add Well Tap, Add End Cap in a hierarchy that exists at the location of each of the newly added cells. *Default:* `hier`
`-dual_rail_via_pitch` *`min_via_pitch min_filler_via_pitch cell_boundary_spacing`*	
	This option is used when two horizontal power-rails on the first and third routing layer are used for standard-cells, and the min-spacing of stacked-vias between the dual-rails is controlled during placement and routing. • *`min_via_pitch`*: It is the minimum center-to-center pitch of the stacked-vias touching any active standard-cell (not a filler cell). • *`min_filler_via_pitch`*: It is the minimum center-to-center pitch of the stacked-vias touching only filler cells. • *`cell_boundary_spacing`*: Specifies how close a PIN or OBS shape must be to the cell boundary to block a stacked-via in the power rail at that point. The placer makes sure that there is room for a stacked-via as required, the global routers estimate the congestion cost before the stacked-vias are created, and the power-router adds them during the followpin routing as required.
`-earlyClockFlow {true|false}`	Enables the early clock flow inside `place_opt_design`. For the early clock flow inside `place_opt_design`, CCOpt creates a clock tree based on the initial clustering and annotates clock latencies for timing optimization. The flow also enables CCOpt ideal mode useful skew during the WNS/TNS fixing step inside `place_opt_design`. CCOpt skewing can be turned off by using `setOptMode -opt_skew_pre_cts false`. *Default*: `false`
`-earlyPBAMode {none | high}`	Specifies that early PBA mode should be used in Innovus during the `route_opt_design` run for delay calculation. This mode adjusts delay calculation settings to align to Tempus or `signoffTimeDesign` Path-Based Analysis (PBA) timing results. Early PBA mode is only supported in `route_opt_design` based optimization. You can enable early PBA mode before launching the `route_opt_design` command. This mode should only be used in Innovus, you must disable early PBA mode in Tempus, `signoffTimeDesign, and signoffOptDesign`. *Default*: `none`
`-expressRoute {true|false}`	Specifies to force routing-stage with the express flow, that is `-flowEffort express`.
`-flowEffort {express|standard|extreme}`	
	Guides the effort of every super-command. • `express`: Configures the flow to give the best turnaround time with good WNS/area correlation as compared to the standard flow. The flow is appropriate for prototyping. • `standard`: Configures the flow to give the best overall combination of quality of results and full-flow turnaround time. This flow is appropriate for the majority of designs. • `extreme`: Configures the flow to give the best quality of results at some cost in turnaround time. This flow is appropriate for designs where timing closure is challenging. *Default:* `standard` **Note:** The individual parameters of `set*Mode` commands have higher priority over the `setDesignMode -flowEffort` parameter.
`-idealHoldFixing {true|false}`	Enables the ideal hold fixing flow. *Default:* `false`

`-ignore_followpin_vias {true|false}`	This option directs the detailed placer, optimization, and signal routing to ignore any sViaInst (special-route vias) with the followpin shape. You can use this option if the two bottom routing layers both have a horizontal routing direction, and you use dual power-rails on those two layers on top of each other for the standard-cell power rails. In this usage, other commands and options will add as many sViaInsts as possible between the power-rails, and remove any sViaInsts that cause spacing violations between the sViaInst cut shapes and any cell or signal routing cut shapes. This gives the placer and router more freedom to get higher density, run faster, but still put as many sViaInsts as possible between the dual power-rails. When set to true, followpin vias are ignored during detailed placement, optimization, and routing. *Default:* `false`
`-merge_trim_shapes {{layers` *`layer_name_list`* `gap` *`gap_value`* `max_merge_num` *`number_of_max_merge`* `masks {`*`mask_num`* `...}} ...}`	
	Specifies the setting for trim shapes merge. • `layers`: You use this t specify the trim layer list which needs to merge trim shapes. • `Gap`: You use this setting when the end to end gap is less the value. • `max_merge_num`: You use this to specify the max trim shapes number that are merged. • `masks`: You use this to specify the trim shapes color that needs to be merged. *Default*: `""`
`-node {N22|N12|N10|N7|N7Plus|N6|N5|N5PlusPlus|N4|N3|N3E|N2|S11|S10|S8|S7|S5|S4|S3|S2|G7|G5|ICF|I7|I5|P1277|P1278|P1280|C12|C7|unspecified}`	
	Sets the design technology node. *Default*: `unspecified`
`-optimizationDensityScreenMargin` *`margin`*	Increases margin on the top of original density screen for optimization. *Default*: `0` *Min*: `0` *Max*: `1`
`-pessimisticMode {true|false}`	Specifies that delay calculation pessimistic mode should be used in Innovus during implementation. This mode adjusts delay calculation settings to maintain a degree of pessimism during implementation to help limit optimistic outliers during external timing signoff. **Note**: The pessimistic mode must not be used in Innovus if Tempus is the final signoff timing engine. *Default:* `false`
`-powerEffort {none|low|high}`	
	Specifies the effort to reduce the dynamic and leakage power. The tradeoff between dynamic and leakage power can also be controlled. • `none`: No power optimization is performed and power is not considered during timing optimization. • `low`: Power is considered during timing optimization and power optimization is performed in all flow stages. • `high`: Additional algorithms are used to minimize power consumption. Turnaround time with this option will be longer than using `low` or `none`. *Default:* `none`

`-process integer`	Specifies the process technology value to set for all the applications. Units in nanometers (nm). The `setDesignMode -node` and `-process options` to assign a tech node (such as N7) and a process number (such as 7) for the design. Innovus tools (placement, routing, etc) then use both the tech node and the process number to differentiate the designs and provide specific functions. It is important for the design to have a correct node and process information for the Innovus tools to work properly. *Type:* Integer *Range:* 2-250 **Note**: The process 2 is under the beta control. Contact your Cadence representative for more information related to this command. *Default:* 90
`-slackWeighting {unityWeighting|viewBasedWeighting}`	
	Specifies slack weighting to be used in the implementation flow. *Default*: `unityWeighting`
`-topRoutingLayer layer`	Specifies the highest lef layer name for global and detail routing. *Default*: `""`
`-trim_grid_group group_name`	Specifies the GROUP name of the set from which the trim metal grid will be used for placement and routing. *Default:* "" If the specified group name does not exist in LEF, the tool will return an ERROR. See the LEF documentation on the TRIMMETALTRACK keyword for more details.

Examples

- The following command sets the specified process technology value to 80:
  ```
  setDesignMode -process 80
  ```
- The following command resets the `-process` parameter to its default value:
  ```
  setDesignMode -reset -process
  ```
- The following command also resets the `-process` parameter to its default value:
  ```
  setDesignMode -reset
  ```
- The following commands forces the super commands to use their extreme-effort settings:
  ```
  setDesignMode -flowEffort extreme
  place_design or optDesign or routeDesign
  ```

setExportMode

```
setExportMode
[-help]
[-reset]
[-fullPinout {true | false}]
[-implicitPortMapping {true | false}]
```

Controls certain aspects of how the software writes out a Verilog netlist.

Use the `getExportMode` command to return the current settings for the `setExportMode` command.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `setExportMode` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setExportMode`.
`-fullPinout {true | false}`	
	Writes out all connected and unconnected pins in the netlist. *Default:* `false`
`-implicitPortMapping {true | false}`	
	Writes out the netlist with implicit port mapping (that is, ordered port connections or position-based port connections) for hierarchical instances. *Default:* `false`
`-reset`	Resets parameters to their default values. The `-reset` parameter *must* be the first parameter specified. If you specify `-reset` by itself, the software resets all `setExportMode` parameters to their default values. If you specify parameters after `-reset`, the software resets only those parameters to their default values. Any values that do not already match the default value and are reset will be reported.

Examples

Assume the following hierarchical module:

```
module

block (out1, out2, out3, A, B, C);

.

.

.

endmodule
```

- The following example shows how the `saveNetlist` command writes out an instance of the module `block` in the netlist by default:
  ```
  block i1(.out2(Y), .A(n1), .B(n2), .C(n3));
  ```

- The following command instructs the `saveNetlist` command to write out all connected and unconnected pins when it saves the netlist:
  ```
  setExportMode -fullPinout true
  ```

  The instance of module `block` is written in the saved netlist as follows:
  ```
  block i1(.out1(), .out2(Y), .out3(), .A(n1), .B(n2), .C(n3));
  ```

- The following command instructs the `saveNetlist` command to write out the netlist with implicit port mapping for hierarchical instances when it saves the netlist:
  ```
  setExportMode -implicitPortMapping true
  ```

The instance of the module `block` is written in the saved netlist as follows:

```
block i1( , Y, , n1, n2, n3);
```

- The following command resets the `-fullPinout` parameter to its default value:

  ```
  setExportMode -reset -fullPinout
  ```

- The following command resets all `setExportMode` parameters to their default values:

  ```
  setExportMode -reset
  ```

Related Information

- `getExportMode`
- `saveNetlist`

setGenerateViaMode

```
setGenerateViaMode
[-help]
[-reset]
[-auto {true|false}]
[-ndr_only {true|false}]
```

Auto-generates vias required by nanoroute for the default and non-default rules (NDRs). The vias are based on the wire-widths of the routing-rule and are created to meet all the DRC via enclosure rules with variations for good pin-access, variations of double-cut vias for good double-cut via utilization, and min-area vias required for stacked-vias that have no route connected to them to meet the min-area metal rule.

This command should be used before init_design, in which case the vias will be created during the initial netlist load. If you change the settings after loading the design, you will need to use saveDesign/restoreDesign to trigger the auto-generation of vias with the new settings. If you want to experiment with different settings inside one Innovus session, use generateVias instead.

The command requires correct DRC rules (e.g. enclosure, spacing, minimum-cut, min-area rules, etc), and at least one LEF VIARULE GENERATE statement (or OpenAccess standardViaDef) for every via layer used for routing. The cut enclosure values in the VIARULE GENERATE statement are not used except for old LEF technology files (LEF version 5.5 and older) that have no enclosure rules (this is not recommended usage, but is kept for backward compatability). The VIARULE cut-spacing values are ignored–only the DRC cut-spacing values are used.

No predefined vias are required (e.g LEF VIA DEFAULT, or NONDEFAULTRULE USEVIA is not necessary, and OpenAccess routing ConstraintGroup (NDR) definitions do not require any validVias list).

If there are predefined vias, the generated vias are compared to the predefined vias and if they are geometrically identical, that specific generated via is not kept so no duplicate vias are created. In that case a combination of pre-defined and auto-generated vias will be used by nanoroute.

The auto-generated vias are created as parameterized vias rather than fixed vias (e.g. VIA using VIARULE rather than RECT statements in DEF, or an OpenAccess standardVia rather than customVia).

Parameters

`-help`	Prints a brief description that includes the type and default information for each `setGenerateViaMode` parameter. For a detailed description of the command and all of its parameters, use the man command: `man setGenerateViaMode`.
`-reset`	Resets all or specified options to default value. Any values that do not already match the default value and are reset will be reported.
`-auto {true|false}`	Enables auto via generation when design is loaded. The option is of type bool. *Default*: false
`-ndr_only {true|false}`	Generates vias for non default rules only. *Default:* `false`

Example

- `setGenerateViaMode -auto true`
  Will add auto-generated vias to any existing vias for all routing rules when the design is loaded.

See also:

- `dumpOutVias` to write out the vias
- `generateVias` to generate vias in the current Innovus session
- Design Implementation Flow chapter of *Innovus User Guide*.

setImportMode

```
setImportMode
[-help]
[-reset]
[-discardFloatingVNets {true|false}]
[-keepEmptyModule {true| false}]
[-minDBUPerMicron DBUPerMicron]
[-syncRelativePath {true | false}]
[-timerMode {true|false}]
```

Controls aspects of how the software reads in the Verilog netlist and other design files.

Use the `getImportMode` command to return the current settings for the `setImportMode` command.

You can use the `setImportMode` command before importing a design.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `setImportMode` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setImportMode`.
`-discardFloatingVNets {true|false}`	
	If `true`, an hnet (Verilog wire statement) that has nothing connected to it, is deleted from the netlist. The default value is `false` in Innovus to allow for netlist repair, but `true` in Tempus to delete non-timed nets and reduce memory. *Default*: `false`
`-keepEmptyModule {true | false}`	
	Keeps empty modules. If set to false, the software converts the empty modules into special leaf cells that do not have a physical library associated with them. If the module is a hard macro, using a value of `true` or `false` produces the identical behavior: the software keeps the module. *Default*: `true` Note: Empty modules can be removed later from the design by using the `deleteEmptyModule` command.
`-minDBUPerMicron` *`DBUPerMicron`*	
	Sets the minimum database units per micron allowed when LEF files initialize the database units. You can specify a value for the minimum database units per micron allowed when LEF files initialize the database units. This option is intended for users with LEF files that have database units that are not fine enough for NanoRoute to run properly - when NanoRoute requires the LEF database units to be finer than the manufacturing grid. If you do not want to modify your LEF file, you can use this option to override the LEF database units value. The default value is 0, which means that the software uses the LEF file units. The software uses the units set in the LEF file, if the LEF units are greater than the minimum database units you specify. Conversely, if the units you specify are greater than the LEF units, the software uses the units you specify. The value you set is saved so the next time you open the design it will have the same database units. *Default:* 0
`-reset`	Resets parameters to their default values. The `-reset` parameter *must* be the first parameter specified. If you specify `-reset` by itself, the software resets all `setImportMode` parameters to their default values. If you specify parameters after `-reset`, the software resets only those parameters to their default values. Any values that do not already match the default value and are reset will be reported.
`-syncRelativePath {true | false}`	
	Synchronizes all relative paths in the top.globals file to the current working directory. Use this parameter if you want to restore the design without first changing your current working directory to the directory saved in the previous design session. *Default*: `false` (You must change your working directory to the directory saved in the previous design session before you restore the design.)
`-timerMode {true|false}`	When set to true, the tool loads only the Verilog and MMMC file (including timing constraint, timing lib, and RC extraction) during `restoreDesign`.

Examples

- The following command synchronizes all relative paths to the current working directory:
  ```
  setImportMode -syncRelativePath true
  ```
- The following command resets the `-syncRelativePath` parameter to its default value:
  ```
  setImportMode -reset -syncRelativePath
  ```
- The following command resets all `setImportMode` parameters to their default values:
  ```
  setImportMode -reset
  ```

setLibraryUnit

```
setLibraryUnit
[-help]
[-cap capUnit]
[-time timeUnit]
```

Sets the time and capacitance unit values for constraints and report generation.

The timing constraints (SDC) files do not contain any unit specification for capacitance and time values. Hence, the units for these values are considered to be same as those specified in the timing libraries. The commands, e.g., `report_timing`, require consistent units to generate reports. If an inconsistency occurs in the timing libraries, the default unit of time (as ns) and capacitance (as pf) is used.

You can use this command when you need to override the library units, or force the setting of units when libraries have different units.

Note: You must set the `setLibraryUnit` command before the design and constraints are read.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `setLibraryUnit` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setLibraryUnit`.
`-cap` *capUnit*	Specifies the capacitance load unit in the timing library. *Default:* `1.0` pf
`-time` *timeUnit*	Specifies the time unit to be used for timing constraints. The valid values are 1ns, 1ps, 10ps, 100ps. *Default:* `1.0` ns

Example

- The following command sets the time unit for the design to `10`ps:
  ```
  setLibraryUnit -time 10ps
  ```

Related Information

- Timing Analysis chapter in the *Innovus User Guide*

setNet

```
setNet
[-help]
{-net netName | -file fileName}
[-setTermSpecial]
-type {regular | special}
```

Marks the specified nets and their related pins as either special nets and pins, or regular nets and pins.

When the Verilog list is first loaded into the design, all LEF pins except those with `USE POWER` and `USE GROUND` are considered "regular pins" by default, and are routed by Trial Route and NanoRoute. You can use this command to mark nets (and their pins) as special prior to routing to keep NanoRoute from attempting to route them. This is useful when you have nets that need to be routed by hand, or with other specialized routers.

If you later decide you want the nets to be routed by NanoRoute, you can use the `setNet` command to set them back to regular.

Note: The `setNet` command has no effect if the net is already routed.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `setNet` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setNet`.
`-file fileName`	Changes all nets (and their related pins) in the specified file to be either special or regular. The file must contain a list of net names, with one net name per line.
`-net netName`	Changes the specified net and its related pins to be either special or regular.
`-setTermSpecial`	Sets the term
`-type {regular | special}`	
	Specifies the type to which to change the net. `regular`: Changes the net and its pins to a regular net, so that NanoRoute will route them. `special`: Changes the net and its pins to a special net to keep NanoRoute from attempting to route them.

Example

The following command sets the net `myAnalogNet` and its related pins as special:

```
setNet -net myAnalogNet -type special -setTermSpecial
```

The NanoRoute router ignores this net when routing.

setStreamOutMode

```
setStreamOutMode
[-help]
[-cellInstanceColor {true|false}]
[-cellMasterColor {true|false}]
[-cellNameUserPrefix {prefix}]
[-cellNameUserSuffix {suffix}]
[-check_map_file {true|false}]
[-ignoreFixedMask {true|false}]
[-labelAllPinShape {true | false}]
[-mergeAppend {true|false}]
[-oasisCompression {true|false}]
[-oasisLayerName {true|false}]
[-oasisSCellOffset {true|false}]
[-pinTextOrientation {default | automatic}]
[-reset]
[-removeNets {list_of_nets}]
[-SEcompatible {true | false}]
[-SEvianames {true | false}]
[-snapToMGrid {true | false}]
[-specifyViaName {default | format_string}]
[-streamConvertRectToPath {true|false}]
[-streamVersion version_number]
[-supportPathType4 {true | false}]
[-textSize value]
[-uniquifyCellNamesPrefix {true | false}]
[-virtualConnection {true | false}]
```

Controls certain aspects of GDSII Stream files generated by the Innovus software.

You can use the `setStreamOutMode` command any time before running the `streamOut` command.

Use the `getStreamOutMode` command to return current settings for the `setStreamOutMode` command.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `setStreamOutMode` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setStreamOutMode`.
`-cellInstanceColor {true|false}`	
	Streams out the instance-based color. The instance mask shift is honored in `streamOut`. When the option is on and the `-merge` option is used, the merged gds files with mask shift suffix must be provided through the `-merge` option. Default: *false*
`-cellMasterColor {true|false}`	
	Streams out the cell-based color from the Innovus color engine. Default: *true*
`-cellNameUserPrefix {prefix}`	
	Adds a prefix to all cell names being written out. Uses the user-specified prefix to avoid potential conflict when integrating different macros, which are potentially two different cells (in two different libraries) with the same name.
`-cellNameUserSuffix {suffix}`	
	Use the user-specified suffix instead of appending color pattern to normal cell names. This applies only to the fixed color shift (flip) pattern (i.e. the single-shift, flip, pattern) applied to the design. *Default:* ""
`-cellNameUserSuffix {suffix}`	

	Use user-specified suffix instead of appending color pattern to normal cell names. This applies only to the fixed color shift (flip) pattern (i.e. the single-shift, flip, pattern) applied to the design. *Default:* ""
`-check_map_file {true|false}`	
	Checks the specified map file. If the objects exist in Innovus and but these objects are not mapped in the map file, the missed objects mapping and missed objects are printed in the log file. Tool checks only the main objects mapping. *Default*: `false`
`-ignoreFixedMask {true|false}`	Ignore macro FIXEDMASK keywords, enable color flip function.
`-labelAllPinShape {true | false}`	
	Labels all pin shapes, whether or not they are physically connected, when set to `true`. *Default*: `false`
`-mergeAppend {true|false}`	
	Merges the object shapes from the Innovus DB and object shapes from the external cell gdsii/oasis files. If the metal layers have multi-pattern shapes, the color information from the Innovus DB is used. For example: • If the instance color is not flipped, the instance object shapes are merged to the object shapes from the same name cell of external gdsii/oasis files. • If the instance color is flipped, the instance object shapes are merged to the object shapes from the same name cell (with mask shift suffix) of external gdsii/oasis files. If there is no color shift cell in the gdsii/oasis files, the same name cell is used from external gdsii/oasis files. *Default*: `false`
`-oasisCompression {true|false}`	
	CBLOCK compression is partial-selective encryption technology uses OASIS CBLOCK records to encrypt arbitrarily encapsulated sets of data records within an OASIS layout file. REPETITION compression supports an 'array' of cell placements, geometries, or text elements, instead of write each the element separate only different in position, this can save duplicate information for an OASIS layout file size. *Default*: `true`
`-oasisLayerName {true|false}`	
	Support LAYERNAME in the OASIS file. *Default*: `false`
`-oasisSCellOffset {true|false}`	Includes cell offset table to declare the byte offset from the beginning of the file (byte 0) to the corresponding CELL record location that appears in the file. *Default*: `false`
`-pinTextOrientation {default | automatic}`	

	Controls the pin text orientation, making it more readable. • `default` implies that the labels are centered in the pin shapes and have `R0` orientation and `LowerLeft` justification. • `automatic` implies that the labels for pin shapes that are abutted to the design boundary are centered on the edge of the pin shape. **streamOut labels (automatic)** `-removeNets {`*`list_of_nets`*`}`	
	Removes the specified nets from the output file. *Default:* `""` (empty string)
`-reset`	Resets parameters to their default values. The `-reset` parameter *must* be the first parameter specified. If you specify `-reset` by itself, the software resets all `setStreamOutMode` parameters to their default values. If you specify parameters after `-reset`, the software resets only those parameters to their default values. Any values that do not already match the default value and are reset will be reported.
`-SEcompatible {true | false}`	
	Output instance only if `FOREIGN` is specified. *Default:* `false`
`-SEvianames {true | false}`	
	Determines the naming convention used for vias declared in the LEF file. *Default:* `false` • Specify `true` to create unique names. • Specify `false` to retain LEF via names.
`-snapToMGrid {true | false}`	
	Specifies whether to snap the nets' wires to the manufacturing grid. *Default:* `false`
`-specifyViaName {default |` *`format_string`*`}`	
	Specifies the naming convention that the `streamOut` command uses for via cells declared in the DEF file. *Default:* `%t_VIA%u` (This default value is used so that the names of the via cells are compatible with versions 4.2 and earlier versions of the Innovus software.) **Note:** When the version of the GDS file is 3 (this is the default version), via names are truncated if they are longer than 32 characters. The software automatically appends a unique identifier to names if there is a name conflict. You can use any of the following characters to specify a format string to generate names that give you information about the cell contents. Separate the characters with underscores (_) to improve readability. You can list them in any order.

	• `%c` Specifies the number of columns. • `%l(lcu)` Specifies the via layers. For the lower layer, use `%l` or `%l(l)`. For the cut layer, use `%l(c)`. For the upper layer, use `%l(u)`. You can specify one, two, or all three layers. You must enclose the `l`, `c`, and `u` in parentheses, as in the following examples: `%l(c)`, `%l(lu)`. • `%n` Specifies the number of cut rows and columns that make up a cut array. • `%r` Specifies the number of cut rows. • `%t` Specifies the top structure name. • `%u` Specifies a unique number for the via. • `%v` Specifies the via name in the DEF file. For more information, see "Vias," in the DEF Syntax chapter of the *LEF/DEF Language Reference*.
`-streamConvertRectToPath {true|false}`	Converts DEF SPECIALNETS path/rectangle and FILLS shapes to GDSII/stream PATH data instead of BOUNDARY data when enabled. Conversion to path data can result in significantly smaller output database when there are many rectangle shapes (example: after metal fill is included). *Default:* `false`
`-streamVersion` *`version_number`*	Specifies the version for a created GDSII Stream file. If you use the `streamOut -merge` parameter, `streamOut` uses the highest version of the merged files, instead of the value specified by the parameter. *Default:* `3` *Minimum*:`1` *Maximum*: `32767`
`-supportPathType4 {true | false}`	
	Converts `PATHTYPE4` to `PATHTYPE0`. If you specify `-supportPathType4 false`, the software converts `PATHTYPE4` paths to `PATHTYPE0` when outputting the path. *Default:* `true`

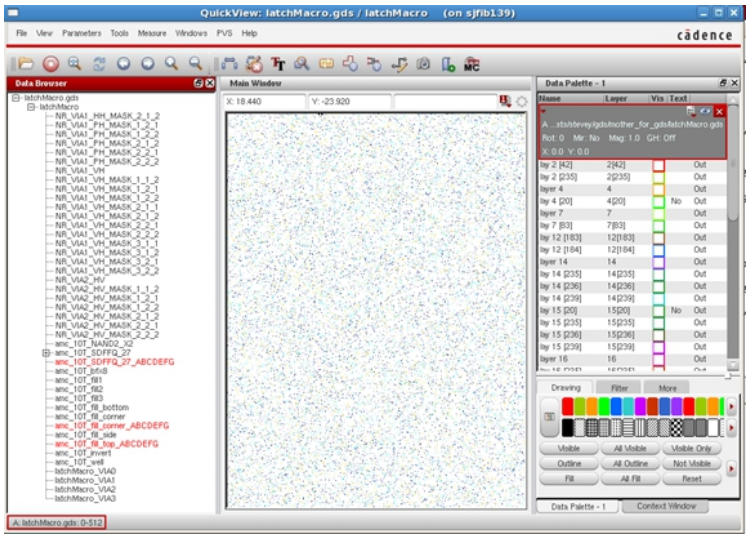
`-textSize` *`value`*	Changes the size of the text used in the text labels in the GDSII Stream file written by the Innovus software.
	Default: `1`
	• To increase the size of the text, specify a positive real number that is greater than 1, as in the following example:
	`setStreamOutMode -textSize 10.0`
	• To decrease the size of the text, specify a positive real number that is less than 1, as in the following example:
	`setStreamOutMode -textSize 0.5`
	Note: The `-textSize` parameter affects the size of only automatically created text. It does not affect text created through `add_gui_text`.

`-uniquifyCellNamesPrefix {true | false}`	
	Adds a prefix, instead of a suffix, to uniquified cell names. The prefix is the source filename. If this parameter is not specified, the software adds a suffix (also the source filename) to uniquified cell names.
`-virtualConnection {true | false}`	

	Specifies whether a colon (`:`) label is appended to pin names for DEF pins with the `.extra`*N* syntax and to LEF pins with multiple ports (if `-outputMacros` is specified for LEF pin ports that have disjoint shapes). *Default:* `true` • Specify `true` to append a colon to pin names. • Specify `false` not to append a colon to pin names. **Note:** For more information, see the DEF Syntax chapter of the *LEF/DEF Language Reference*.

Examples

- The following command retains the via names defined in the LEF file:
  ```
  setStreamOutMode -SEvianames false
  ```
  When you type this command and run the `streamOut` command, the Innovus software does the following:
  - For `block1`, the software creates `VIA12Default`, `VIA12DoubleCut`, and so on.
  - For `block2`, the software creates `VIA12Default`, `VIA12DoubleCut`, and so on.
    If `block1` and `block2` are later merged into a top-level design, name collisions of the via masters occur. This result is acceptable if these are the same vias. However, if the vias are not the same, this command causes errors.
- The following command creates unique via names for vias defined in the LEF file:
  ```
  setStreamOutMode -SEvianames true
  ```
  When you type this command and run `streamOut`, the Innovus software does the following:
  - For `block1`, the software creates `block1_VIA1`, `block1_VIA2`, and so on.
  - For `block2`, the software creates `block2_VIA1`, `block2_VIA2`, and so on.
    If `block1` and `block2` are later merged, there is no risk of name collision between via masters.
- The following command generates names for via cells. The names identify the top structure name (`%v`), lower via layer (`%l(l)`), and DEF via name (`%v`):
  ```
  setStreamOutMode -specifyViaName %t_%v_%l(l)
  ```
- The following command resets the `-SEvianames` parameter to its default value:
  ```
  setStreamOutMode -reset -SEvianames
  ```
- The following command resets all `setStreamOutMode` parameters to their default values:
  ```
  setStreamOutMode -reset
  ```
- The following command specifies “ABCDEFG” as the suffix for the color flipped cells.
  ```
  setStreamOutMode -cellNameUserSuffix ABCDEFG
  ```
  When this command is used, “ABCDEFG” is suffixed for color flipped cells.



Without this command, suffix are automatically added for color flipped cells.

specify_lib

```
specify_lib
[-help] [<in_file <file1[file2] ...>>] [-reset]
```

Specify the name of the timing library file(s) for dynamic power analysis. This command allows you to run the dynamic power analysis flow without reading a dotlib into design database to reduce background memory consumption. You must have an external TWF file to run this flow as the timing engine will not be invoked from within the software. This flow is recommended for large designs where front-end processing of timing libraries is high. Some of the database query commands will not work if `specify_lib` is used.

This command works in conjunction with the `specify_def` and `specify_spef` commands.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `specify_lib` parameter.
in_file <file1[file2] ...	
	List of timing library files.
`-reset`	Resets all specified options back to default values.

Examples

- The following Tcl shows the use model of the `specify_lib` command that works in conjunction with the `specify_def/specify_spef` flow to perform dynamic power analysis:

```
read_lib -lef tech1.lef tech2.lef
specify_lib /../library1.lib /../library2.lib
specify_def adder_routed.def
specify_spef {test.spef }
read_twf test.twf2
read_verilog test2.v
set_top_module test
set_default_switching_activity -comb_clockgate_ratio 1 -period 2.01ns -input_activity 0.2 -icg_ratio 1
set_power_analysis_mode -default_supply 1.1 -method dynamic_vectorless
report_power
```

streamOut

```
streamOut
gdsFileName
[-attachInstanceName attributeNumber]
[-attachNetName attributeNumber]
[-attachNetProp {{prop_name1 attr_num1} {prop_name2 attr_num2........}}]
[-area {x1 y1 x2 y2} [-strict][-enclosed_instances_only]]
[-dieAreaAsBoundary]
[-format {stream oasis}[-outputInstanceName instName] [-outputNetName netName]]
[-help]
[-ignoreSubtype {NETTYPE SHAPE}]
[-libName libraryName]
[-mapFile mapFile]
[-mergeViaCellMapFile cell_list]
[-merge {listOfExternalGDSOASISFiles} [-noTSV tsv_name_list][-uniquifyCellNames]]
[-reportFile file_name]
[-mode {ALL | FILLONLY | NOFILL | NOINSTANCES}]
[-offset x y]
[-outputCriticalNetColorFromFileOnly sideFile]
[-outputMacros]
[-signoff_fill]
[-structureName structureName | -noStructureName]
[-units {100 | 200 | 1000 | 2000 | 10000 | 20000}]
```

Creates a GDSII Stream file of the current database. Writes a summary of errors and warnings to the log file.

You can use the `streamOut` command after the design is placed, but is most commonly used only after the design is routed (which may also include metal fill shapes).

- If you do not specify a map file, the Innovus software creates a generic map file, in GDSII Version 3 format. The generic file shows the mapping that was used, if none was specified. You must customize the file to make it appropriate for your design. You can change the version by using the `setStreamOutMode -version` parameter.
- You must specify all layers to stream out. Layers that are not specified in the map file are not included in the file created by this command.
  Note: A cut layer in the map file (for a via) can have both MASK and SIZE at the same time.
- If you specify the `-merge` parameter and you want to merge files with a version number greater than `3`, the software generates a file with the highest version number from the merged files.
- If you do not specify `-outputMacros`, `LEFPIN` and `LEFOBS` do not apply. If you do specify `-outputMacros` and `LEFPIN` and `LEFOBS` are not specified in the map file for the layers in the LEF macros, the GDSII structures for those macros will be empty.
- If `MAXVOLTAGE` and `MINVOLTAGE` constructs are there in the layermap, `streamOut` will output a max voltage label and a min voltage label, for each net, to the GDSII file.

Note: Pin label is attached to physical pin shapes. If physical pin shapes do not exist, the pin text is labeled on any one instance pin shape. If both physical pin and instance pin shapes do not exist on the net, no pin text is generated in the output.

Parameters

`-attachInstanceName` *attributeNumber*	Specifies the instance name value added to the attribute on SREF of the specified attribute number. The attribute number is an integer and its range is 1-127.
`-attachNetName` *attributeNumber*	Specifies that the net name will be added to the specified attribute number on the regular and special net wire shapes and vias SREF, but not on PIN shapes and pin vias. The attribute number is an integer and its range is 1-127.

`-attachNetProp {{prop_name1 attr_num1} {prop_name2 attr_num2........}}`	Specifies the attribute number on wiring shapes that will be used to store the value of the property associated nets in the design. For this option, you specify a list of property name and its attribute number. **Note:** Multiple property names can be specified. Only wiring shapes associated with nets that contain one or more of the specified property names will have values assigned to their attributes. **Example:** `-attachPropName { {prop1 100} {prop2 101} }` In the above example, the attribute number `100` will be used to store the value of the property `prop1`, and the attribute number `101` will be used to store the value of the property `prop2`. It is a list of lists with a pair of property and its attribute number.
`-area {x1 y1 x2 y2}`	Defines the area of the design to be output. Any shapes or instances enclosed, intersecting, or touching the specified area are output. So the data that is output can extend outside the specified area. By default the entire design is output.
gdsFileName	Specifies the GDSII Stream output file. Include the `.gz` extension to enable file compression (for example, `GDS_file.gds.gz`).
`-dieAreaAsBoundary`	Forces the `streamOut` command to write the die area as a polygon (that is, a boundary). Otherwise, the `streamOut` command writes the die area as a rectangle (that is, a box).
`-enclosed_instances_only`	Specifies to stream out only those instances in which the shapes are fully enclosed by the specified area.
`-format {stream oasis}`	Specifies the tape out file format.
`-help`	Outputs a brief description that includes type and default information for each `streamOut` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man streamOut`.
`-ignoreSubtype {NETTYPE SHAPE}`	Ignores the map file line containing the subtype keyword , and warning message is printed in the log file. For example, in the example below, with `-ignoreSubtype {NETTYPE SHAPE}` the line 61, 62, and 63 of the map file will be ignored. • Line61: M2 SPNET:NETYPE:POWER:MASK:2 32 12 • Line62: M2 SPNET:SHAPE:STRIPE:MASK:2 32 22 • Line63: M2 SPNET: NETYPE:GROUND:SHAPE:STRIPE:MASK:2 32 32 • Line64: M2 SPNET:MASK:2 32 2
`-libName` *libraryName*	Specifies the library to convert to GDSII Stream format. *Default:* `DesignLib`
`-mapFile` *mapFile*	Specifies the file used for layer mapping. This file is required for successful stream out, and is read by the next tool used in the design flow. Important If you do not specify a file with this parameter, the Innovus software will read a `streamOut.map` file if one exists. If a `streamOut.map`file does not exist, the software creates a generic map file that you must customize for your design. For information on the map file format, see "GDSII or OASIS Map File Format" in the Importing and Exporting Designs chapter of the *Innovus User Guide*.

`-merge {`*`listOfExternalGDSOASISFiles`*`}`	Specifies a single file or list of files to merge. Checks all merged files for name collisions, and generates a warning if any names are changed. Uses the following conventions for new names: • Replaces dot separators (`.`) with underscores (_). For example, `test.test_gds.gds` is renamed `test_test_gds_gds`. • Adds unique identifiers. For example, if more than one cell is named `test.test.gds.gds`, they are renamed `test_test_gds_gds_1`, `test_test_gds_gds_2`, and so on. Supports the mixed format of the GDSII and OASIS files. You need to specify the merged files with mixed format using the `-merge` option. The tool will identify the files format, covert them, and merge them to a stream out file. Compressed files are acceptable (include the `.gz` extension to enable file compression). The Innovus software automatically creates blackboxes when merging and writing macro files. It ignores any cells in the merge files that are not used in the design. If you specify more than one file, separate the file names with spaces and enclose the list of file names in braces (`{}`) or double quotation marks (`"`) You can use a wildcard to read all `.gds` files in a specified directory. The usage is as follows: `streamOut -merge` *`GDSIIdir`*`/*.gds` where *`GDSIIdir`* is the name of the directory that contains the `.gds` files. ***Use caution when using wildcards, as they might affect the order in which the software reads merge files.***
`-mergeViaCellMapFile` *`cell_list`*	Specifies the list of cells that need merge via cell from an external file.
`-mode {ALL | FILLONLY | NOFILL | NOINSTANCES}`	

	Identifies the layers to write.
	Specify one of the following:
	• `ALL`--Writes all layer information specified in mapFile as follows:
	  ◦ All instances
	  ◦ All via instances
	  ◦ All generated via cells
	• `FILLONLY`--Writes only fill layers specified in mapFile as follows:
	  ◦ No instances
	  ◦ Only fill via instances
	  ◦ Only generated fill via cells
	• `NOFILL`--Writes only non-fill layers specified in mapFile.
	• `NOINSTANCES`--Writes wiring (including vias) only; does not write out `COMPONENT` instances.

`-noStructureName`	Enables you merge to files without loading an Innovus database when the `-merge` parameter is also specified.
`-noTSV` *`tsv_name_list`*	Specifies a list of TSV via names that should not be written out.
`-offset` *`x y`*	Specifies, in microns, the location of the design in the GDSII output file. When the GDSII output file is saved, the design shifts to the specified location.

`-outputCriticalNetColorFromFileOnly` *`sideFile`*	Specifies the net list and the layer range through a side-file. The streamOut command outputs the object color on the specified layers and nets, Other objects remain gray in GDS.
	Here is an example of a side file:
	`<LAYERMAP>`
	`M5 PIN:MASK:1,NET:MASK:1,SPNET:MASK:1,VIA:MASK:1 35 271`
	`M5 PIN:MASK:2,NET:MASK:2,SPNET:MASK:2,VIA:MASK:2 35 272`
	`M6 PIN:MASK:1,NET:MASK:1,SPNET:MASK:1,VIA:MASK:1 36 271`
	`M6 PIN:MASK:2,NET:MASK:2,SPNET:MASK:2,VIA:MASK:2 36 272`
	`</LAYERMAP>`
	`<NETNAMELIST>`
	`TOP/NET1`
	`TOP/NET2`
	`...`
	`</NETNAMELIST>`

`-outputInstanceName` *`instName`*	Writes the instance name to the oasis file.
`-outputMacros`	Writes LEF abstract information such as LEF pin geometries and obstructions for macros. Writes one text label per port within a LEF macro pin plus one text label per shape for feedthrough pins only if `setStreamOutMode -labelAllPinShape` is not set to `true`. Specify this parameter to create GDSII output that contains the LEF macro structures as well as the design data. You can also use this parameter to debug LEF macro definitions against verification DRC rules. The output contains macro pins and obstructions. **Note:** `LEFPIN` and `LEFOBS` apply only when you specify this parameter. If you specify this parameter and `LEFPIN` and `LEFOBS` are not specified in the map file for the layers in the LEF macros the GDSII structures for those macros will be empty.
`-outputNetName` *`netName`*	Writes the net name to the oasis file.
`-signoff_fill`	Merges the signoff fill data attached to the current DB into the output GDS file and instantiates the signoff top fill cell at 0,0 R0 inside the top design cell. The signoff fill format must be GDS.
`-reportFile file_name`	Outputs cell name changed to the file.
`-strict`	Truncates the object outside the area.
`-structureName` *`structureName`*	
	Specifies the superstructure that consists of all geometries that the map file writes out. *Default:* Current design's top cell name
`-uniquifyCellNames`	Creates unique cell names if there are name collisions when the software merges files. Creates unique cell names if there are name collisions when the Innovus software merges files. ⓘ You must specify the `-merge` parameter if you specify this parameter. When you list the merge files, list the top-level file first, as the software uses the first name in the search path when renaming cells. When a cell name is repeated, the software renames the cell *`cellName_filename`*, where *`filename`* is the name of the merge file in which the cell name appears. The software changes the name of references to that cell in the merge file. The software changes the reference name if the referenced cell is defined in the same file, regardless of whether the cell is defined before or after the reference. If a reference in a merge file refers to a cell definition in a different merge file, then the reference is not changed in the GDSII Stream output file. *Default:* If you do not specify this parameter, the software ignores duplicate cell names.
`-units {100 | 200 | 1000 | 2000 | 10000 | 20000}`	Specifies the resolution for values in the GDSII file. Choose `100`, `200`, `1000`, `2000`, `10000`, or `20000`. *Default:* Units specified in LEF file

Examples

- The following command creates a GDSII Stream file (merging cells from the ios.gds file):

```
streamOut amba_usb.gds -mapFile streamOut.map -libName DesignLib
  -attachInstanceName 12 -merge {ios.gds}
  -attachNetName 15
  -units 2000 -mode ALL
  -dieAreaAsBoundary
```

- The following command creates blackboxes for cells not found in the merge libraries and writes macros only for those cells:

```
streamOut newFile.gds.gz -merge {myFile1 myFile2 myFile3} -outputMacros
```

- The following command merges cells needed in the design from all files in `myDirectory` with the current database:

```
streamOut myFile.gds.gz -merge myDirectory/*.gds
```

  If a merge file contains cells such as `A`, `B`, `C`, `D`, `X`, `Y`, and `Z`, and the design contains only cells `A`, `B`, and `D`, then the Innovus software merges only cells `A`, `B`, and `D`.

- The following example shows a stream out map file. The first column specifies the layer object name, and the second column specifies the layer object type. The third and fourth columns specify the GDS layer and data type to stream those objects, respectively. When the object name is "NAME", it indicates the text label for the object types specified in the second column.

```
==========original streamout.map file=============

trimDesign

```
trimDesign
[-help]
[-coreToBoundary distance]
[-dir output_dir_to_save_trimmed_design]
[-encryptName proc_name_to_encrypt]
[-name trim_design_name]
[-nets list_of_net_names]
[-placeOnly]
[-area {x1 y1 x2 y2} | -polygon list_of_points | -selectedRouteBlk ]
```

Allows you to specify the coordinates of a box to create a small portion of the design as an independent design. This trimmed down version of the design can be then used for investigation and analysis. When you share the trimmed design for investigation of a localized issue, you do not need to share the whole third-party IP information, thereby ensuring confidentiality of the third-party data.

While the trimmed design completely preserves the physical data, it does not preserve the timing and the power domain data. Working on a small portion of the design offers a faster turnaround time and a lesser memory footprint.

Notes:

- The `trimDesign` command retains the attributes and properties of all the standard cells and macros that are completely inside the trim box/area. All hard macros that overlap with the trim box/area are also preserved. It does not include any standard cells or macros that are completely outside the specified trim box/area.
- The `trimDesign` command preserves all overlapping rows, sites, and colors.
- The `trimDesign` command flattens all instances and net names. All instances in the trim box/areal lose their original logic hierarchy and appear ‘flat’ in the trimmed database. Any naming conflicts arising due to flattening are automatically resolved. For example, h1/h2/i1 in the full design will appear as i1 in the trimmed design. Also, h1/h4/i1 may appear as i1_uniquify1, to distinguish it from i1.
  Note: To resolve naming conflicts due to the loss of hierarchy, additional name uniquification is done. A mapping of original nets/instances names vs their trimmed design modified names, is written in a map file for book keeping purpose.
- The `trimDesign` command maintains the design parameters such as instance location/orientation, regular/special wire and its connectivity relative to the original full design.
- The `trimDesign` command retains the attributes and properties of all the nets having some instances inside the trim box/area. It also preserves (pushes down) the nets that are not connected to any instance in the trim box/area, but have some wires overlapping with trim box/area. Nets having all instances and wires outside of trim box/area are discarded.
- The `trimDesign` command creates ports for all wires crossing the boundary of the trimmed design.
- The `trimDesign` command preserves the tracks, attributes and colors of all wires that are completely inside the trim box/area. All wires that overlap with the trim box/area are also preserved. It does not include any wire that is completely outside the specified trim box/area.
- The `trimDesign` command preserves the Power/Ground/Special wires that overlap with the boundary of the trim box by cutting them against the boundary. It creates additional PG ports at cross points these wires.
- The `trimDesign` command discards fences, regions, guides, instance groups, and power domains.
- The `trimDesign` command saves the `.globals` files. The `.globals` file has the .lef list copied from original full design’s .globals file.
- The `checkPlace` command reports all violations that were there on instances in the box in the actual design. However, since hierarchical fences are not brought back, the trimmed design may not have the Region/Fence and Not-of-Fence Violations.
- The `verify_drc` command reports all violations that were there on nets in the box of actual design. However, since only the net wires crossing box boundary are preserved, the trimmed design may have some extra violations.

Parameters

`-help`	Prints a brief description that includes type and default information for each trimDesign parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man trimDesign`
`-area` *box_coordinates*	List of coordinates to represent a box for getting the trimmed design. **Note**: The specified box is snapped to the instance grid. All instances in the box lose their original logic hierarchy and appear flat in the new db. *Data_type*: string, required
`-coreToBoundary` *distance*	Specifies that any instance lying within the distance of coreToBoundary (in microns) to the trim box will be discarded. *Default*: 2 *Data_type*: string, optional
`-` `dir` *output_dir_to_save_trimmed_design*	Specifies the name of the directory in which the data related to the trimmed-design is saved. *Data_type*: string, optional
`-encryptName` *proc_name_to_encrypt*	Specifies that the names of instances and nets in the design will be encrypted when the trimmed design is saved. *Data_type*: string, optional
`-name` *trim_design_name*	Specifies the top-level name of the new trimmed design. *Data_type*: string, optional
`-nets` *list_of_net_names*	Species the nets that are to be completely enclosed by the specified shape by taking union of shape with net-boxes. *Data_type*: string, optional
`-placeOnly`	Specifies that only instances will be pushed. *Data_type*: bool, optional
`-polygon` *list_of_points*	List of coordinates to represent a polygon for getting the trimmed design. *Data_type*: string, optional
`-selectedRouteBlk`	Specifies that the selected routing blockages will be used to infer the box or polygon for getting the trimmed design. *Data_type*: string, optional

Examples

- The following command creates a trimmed design, `trim_db`, with the specified polygon coordinates and save the data in the DB file.

  ```
  trimDesign -dir DB -name trim_db -polygon {{500.0 700.0} {500.0 900.0} {500.0 900.0} {700.0 900.0} {700.0 900.0} {700.0 800.0} {700.0 800.0} {800.0 800.0} {800.0 800.0} {800.0 700.0} {800.0 700.0} {500.0 700.0} }
  ```

- The following command creates a trimmed design, based on the selected routing blockage:
  ```
  trimDesign -dir DB -name trim_db -selectedRouteBlk
  ```

- The following command uses a `get_new_name` procedure to encrypt the names on the instances and nets in the trimmed design `trim_db`:
  ```
  trimDesign -dir DB -name trim_db -area {300.0 200.0 800.0 700.0} -encryptName gen_new_name
  ```

  The following is a structure of the encryption procedure file. You can customize this procedure:

  ```
  proc gen_new_name {name} {
    global n
    if {![info exists n]} {
      set n 0
    }
    set new_name en_name__$n
    incr n
    return $new_name
  }
  ```

write_do_lec

```
write_do_lec
[-help]
output_filename
[-checkpoint lec_checkpoint_file]
[-golden_design filename]
[-log_file filename]
[-no_exit]
[-pre_compare filename]
[-pre_exit filename]
[-pre_read filename]
[-revised_design filename]
[-verbose]
[-write_session lec_session_name]
{-hier | -flat }
> output_filename
```

Writes out the dofile for the Conformal® Logical Equivalence Checker tool.

For formal verification of the Innovus-generated netlists, the `write_do_lec` command generates, within Innovus, the Conformal LEC scripts (such as dofile). These scripts are used for equivalence checking. You can generate a flat or a hierarchical comparison script. The dofile written out by this command contains standard Conformal flow commands and you will need to add the DFT constraints if netlist is scan inserted.

The `write_do_lec` command creates a verification directory, if does not already exist, in which the name mapping information file will be created. The name mapping file will usually contain the mapping information of MBIT flops against its split/single bit candidate. By default, the name of this verification directory is `fv/invs/%s`. You can use `write_lec_directory_naming_style` to change the directory name.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `write_do_lec` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_do_lec`
`output_filename`	Specifies the name for the output file to be written.
`-checkpoint` *`lec_checkpoint_file`*	Specifies the name of the LEC checkpoint file to save at the end.
`-flat`	Creates a flat comparison script.
`-golden_design` *`filename`*	Specifies the user-written netlist file name to use as the golden design.
`-hier`	Creates a hierarchical comparison script.
`-log_file` *`filename`*	Specifies the name of the LEC log file.
`-no_exit`	Skips the exit command at end of dofile.
`-pre_compare` *`filename`*	Specifies an extra dofile to be sourced right before 'compare'.
`-pre_exit` *`filename`*	Specifies an extra dofile to be sourced right before 'exit'.
`-pre_read` *`filename`*	Specifies an extra dofile to be sourced right before reading library/design.
`-revised_design` *`filename`*	Specifies the user-written netlist file name to use as the revised design.
`-verbose`	Specifies whether the generated dofile will report verbosely.
`-write_session` *`lec_session_name`*	Specifies the name of the LEC session to save at the end.
`>` *`output_filename`*	Specifies the name for the output file to be written.

write_lef_abstract

```
write_lef_abstract
[-help]
fileName
[-add_obs_layers layer_list]
[-cutObsMinSpacing]
[-cutObsToExposeRouting distance_in_microns]
[-excludeObsLayers layer_list]
[-excludePinLayers layer_list]
[-design_boundary point_list]
[-extractBlockObs]
[-extractBlockPGPinLayers layer_number_list]
[-extractBlockSignalPinLayers layer_list]
[-extractWellLayerObs well_layer_list [-extractWellObsByRow margin]]
[-ignoreBumpOnPin {all pg signal}]
[-ioPadPin]
[-noCutObs]
[-property]
[-extractWellLayerObs well_layer_list [-mergeConnectedWellOnly ]]
[-obsSpacing {val layers [val2 layers ...]} [-obsSpacingPerLayer]]
[-specifyTopLayer layer_number [-obs_above_top_layer layer+]]
[-stripePin [-selected]]
[-stripePin [-portForEachStripePin]]
[-stripePin [-PGPinLayers layer_number_list]]
[-stripePin [-PGNets net+]]
[ -5.6 | -5.7 | -5.8 ]
```

Generates design abstract (LEF) information for the current routed block-level design. By default, `write_lef_abstract` copies all the current design PG and signal pins to the LEF and creates cut-outs in the obstructions (OBS shapes) around the pins. The output LEF file contains process antenna information, if you run `verify_antenna` before you run the `write_lef_abstract` command.

A routing blockage with a pushdown attribute (e.g. a DEF BLOCKAGE with + PUSHDOWN) is treated as an area of routing reserved for the level above this block. The LEF will have these blockages cut-out of the OBS.

In a bottom-up flow (where the block was not created using the `createPartition` command), you normally create a simple LEF abstract that contains:

- one obstruction (`OBS`) shape per routing layer without cutting around pins
- signal pins located along the block boundary
- add power pins for the top metal layer PG stripes (see `-stripePin and -PgpinLayers` options)
- embedded bump pins shapes are also written out as LEF pin shapes

If the block used four routing layers out of a possible six layers, you would run the following command:

```
write_lef_abstract -noCutObs -stripePin -PGpinLayers 4 -specifyTopLayer 4
```

Parameters

`-help`	Prints a brief description that includes the type and default information for each `write_lef_abstract` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_lef_abstract`
`-5.6 | -5.7 | -5.8 | -6.0`	Specifies the LEF version number. This value overrides any value you set with the `lefDefOutVersion` variable. *Default:* The software uses the current `lefDefOutVersion` value. The default value for `lefDefOutVersion` is `5.8`.
`-add_obs_layers layer_list`	Writes the shapes on on the specified layers as OBS shapes in the LEF. These layers cannot be routing or cut layers.
`-cutObsMinSpacing`	Creates cut outs in the blockages around pins using minimum width to calculate the spacing. This option cannot be used with `-noCutObs`. `-cutObsToExposeRouting` *`distance_in_microns`*	Exposes routing within the specified halo distance to a LEF model.
`-design_boundary` *`point_list`*	Specifies a list of points defining the design boundary polygon for the output LEF (a rectangle would use 4 points). It is used instead of the real design boundary to compute the LEF SIZE, OBS shapes to block routing layers, and OBS shapes on the OVERLAP layer if it is non-rectangular. The LEF will also include any special routes that are outside the design boundary as OBS shapes unless they are converted to PIN shapes based on other options. It does not matter if PIN shapes are inside or outside the design boundary, they are always written out. This is intended for a block that only has bumps and/or top-level RDL routing to the bumps that are outside the "real" block boundary. The real block boundary can be specified with this option to shrink the SIZE and OBS shapes to just include the active area of the block, and let the bumps and RDL routing stick outside. An important limitation is that any instances or regular routing shapes (for example, created by `routeDesign`) outside the design boundary will be ignored. It is assumed that placement and routing blockages are used to prevent this outside the "real" block boundary.
`-excludeObsLayers` *`layer_list`*	Ignores the specified layer when saving OBS in the macro LEF file. You can use this parameter to set the layer as the following format: ◦ One layer: For example, if you specify `-excludeObsLayers {AP}`, the AP layer is not saved to OBS. ◦ Multiple layers: For example, if you specify `-excludeObsLayers {M7 M8}`, M7, M8 layers are not saved to OBS.
`-excludePinLayers` *`layer_list`*	Specifies not to create PIN shapes on the specified layers.
`-extractBlockObs`	Extracts all obstruction (`OBS`) information from the instantiated `CLASS BLOCK`, `CLASS PAD AREAIO`, and `CLASS RING` macros and writes out the obstructions to the output LEF file. `OBS` information is extracted for layers that are not already being completely covered under the normal routing layer range and for cut layers between routing layers that are completely covered.
`-extractBlockPGPinLayers` *`layer_number_list`*	

	Extracts the power and ground pin information from any `CLASS BLOCK`, `RING, PAD,` or `COVER` macros with pins on layers in the specified layer list and writes out the pin information to the LEF file.
	The layer names can be either names in the technology file like metal1, or technology independent names like 1 for the first routing layer, 2 for the second routing layer.
	For example, to create PG pins on layers `metal3` and `metal4`, use:
	`-extractBlockPGPinLayers {metal3 metal4}`
	Or
	`-extractBlockPGPinLayers {3 4}`

`-extractBlockSignalPinLayers` *`layer_list`*	Extract signal pins, connected to design term, from the BLOCK, RING, PAD, COVER macros on these layers.
`-extractWellLayerObs` *`well_layer_list`*	Extracts OBS from instances on the specified well layers. If you have DRC spacing value checks for the well layers in your LEF, you can copy the well layer OBS shapes out to the LEF abstract so the well shapes can be checked at the next level up.
`-extractWellObsByRow` *`margin`*	Extracts OBS from the bounding box of rows plus the margin on the specified well layers. You can create well layer OBS shapes in the LEF abstract for all the standard cell rows, with additional margin in microns. This is useful if the standard-cell LEF abstracts do not have well shapes in them but you want to see well OBS in the abstract. This option requires the `-extractWellLayerObs` option to indicate which layers to create.
`fileName`	Specifies the LEF output file.
`-ioPadPin`	Writes out the IO pads that are connected to the design pins as LEF pin shapes.
`-ignoreBumpOnPin {all pg signal}`	By default, pin shapes of bump cells (e.g. LEF MACRO CLASS BUMP) are written out as LEF pin shapes. This option can be used to suppress those LEF pin shapes depending on the type of net they are connected to.
`-mergeConnectedWellOnly`	Merges connected well shapes only, instead of merging all shapes into one bounding box.
`-noCutObs`	Creates a single obstruction shape for each routing layer, except routing blockages with the pushdown attribute are still cut-out. *Default:* Creates cut-outs in the LEF OBS for signal pins, and power and ground pins. This option cannot be used with `-cutObsMinSpacing`.
`-property`	Writes out all the user-defined design properties.
`-obsSpacing {`*`val layers`* `[`*`val2 layers ...`*`]}`	

	Writes out the LEF58_OBSSPACING property for the MACRO. This overrides the global USEMINSPACING OBS setting and sets the spacing required between routing and the OBS shapes of just this MACRO. This is equivalent to adding a SPACING *`value`* to every OBS RECT on the affected layers in the LEF. Note, it will only affect an OBS RECT that has no existing SPACING *`value`*.
	`val` = 'min' for min-spacing, and *`layers`* = {} for all layers.
	The order of the arguments is the order in the LEF file. In LEF, the last value for a given layer "wins" over previous values for that macro.
	For example, `-obsSpacing {min {} 1.0 {m2 m3} 2.0 {m5}}` would add this to the LEF:
	`PROPERTY LEF58_OBSSPACING "`
	`OBSSPACING MIN ;`
	`OBSSPACING 1.0 LAYER m2 LAYER m3 ;`
	`OBSSPACING 2.0 LAYER m5 ; " ;`
	So, OBS shapes in this MACRO on every layer would use SPACING <min-spacing> for that specific layer, then m2, m3 are changed to use SPACING 1.0, and finally m5 is changed to use SPACING 2.0.

`-obsSpacingPerLayer`	Writes out the spacing for each layer under the layer definition. This parameter does not work without `-obsSpacing`.
	Data_type: bool, optional
	To assign the value to all layers, you should set the layers as "{}". For example, if you specify `write_lef_abstract -obsSpacing {1.0 {}} -obsSpacingPerLayer`, it means the spacing of all layers is 1.0
	`Macro A`
	`  ...`
	`  OBS`
	`  Layer M1 SPACING 1.0 ;`
	`  RECT ...;`
	`  Layer M2 SPACING 1.0 ;`
	`  RECT ...;`
	`  ...;`
	`  END`
	`  ...`
	`END A`
	The following example sets the spacing of all layers as 1.0, except `M2`.
	`write_lef_abstract -obsSpacing {1.0 {} 2.0 {M2}} -obsSpacingPerLayer`
	`Macro A`
	`  ...`
	`  OBS`
	`  Layer M1 SPACING 1.0 ;`
	`  RECT ... ;`
	`  Layer M2 SPACING 2.0 ;`
	`  RECT ... ;`
	`  Layer M3 SPACING 1.0 ;`
	`  RECT ... ;`
	`  ...`
	`  END`
	`  ...`
	`END A`

`-obs_above_top_layer` *layer+*	Writes out OBS shapes rather than one large abstract OBS shape for special-routes on these layers that are not PIN shapes. The layers will have OBSSPACING FULLDRC added to the LEF so the OBS shapes on those layers are treated as 'real' shapes for DRC checking, and not abstract obstructions. This is intended for blocks that have some sparse special-routing above the blocks "normal" top-layer set with the `-specifyTopLayer` option (for example, it might be a few special-routes for clocks that match up with the chip clock distribution but must be visible inside the block). Only special-routes are currently supported.
`-PGNets` *net+*	Writes out PG stripes only on these PG nets. If you specify a net name that does not exist in the design, or the net is not a PG net, tool will give an error and stop.
`-PGpinLayers` *layer_number_list*	

	Writes out power and ground stripes on the specified layer numbers as power and ground pins.
	The layer names can be either names in the technology file like metal1, or technology independent names like 1 for the first routing layer, 2 for the second routing layer.
	For example, to create PG pins on layers metal3 and metal4, use:
	`-PGPinLayers {metal3 metal4}`
	Or
	`-PGPinLayers {3 4}`
	In the example below, the command will write out metal5 and metal6 stripe shapes, and any via5 cut-shapes on the PG nets to the LEF abstract as PIN shapes
	`-PGPinLayers {metal5 via5 metal6}`
	Note: You must specify the `-stripePin` parameter in order to use this parameter.
	Default: The top metal layer

`-portForEachStripePin`	Creates a separate LEF port for each pin shape created by `-stripePin`. This means that `verifyConnectivity` will check that every port is touching a PG routing shape at the next level. This is normally what users want for individual PG stripes on the top-layer of the block - each separate stripe shape should be connected to a top-level route or via somehow. This can help in detecting some missing power-mesh connections before running a complete IR drop analysis.
`-selected`	Writes out only the selected PG stripes as LEF pin shapes.
`-specifyTopLayer` *layer_number*	

	Creates obstructions (OBS shapes) covering the block only for layers up to the specified layer.
	The layer name can be either a name in the technology file like metal1, or a technology independent names like 1 for the first routing layer, 2 for the second routing layer.
	For example, to specify metal4 as the top layer, use:
	`-specifyToplayer metal4`
	Or
	`-specifyTopLayer 4`
	By default, all routing layers in the technology file are fully obstructed with OBS shapes across the entire block (possibly cut around pin shapes). If this block does not use some of the highest routing layers, you should use this option to limit the OBS shapes to below layer.

`-stripePin`	Writes out power and ground stripes on the top metal layer as power and ground pins. You can use this parameter in a bottom-up methodology, when you create abstracts for blocks that you will use at the next higher level of a hierarchical design. Only special-routes created by power-route commands will be output as pin shapes. That means special-routes that have a shape value of ring, stripe, followpin, iowire, corewire, blockwire, padring, and blockring are included. The shape value is the same as. DEF SPECIALNETS + SHAPE value or dbGet sWire .shape value. Special-routes with a shape value of blockagewire, drcfill, fillopc, fillwire, or notype are not output.

Example

Suppose you have a design that was routed on only the first 5 routing layers, even though the technology has higher metal layers.

You would use the following command to include any PG stripes on metal5 as pins in the block LEF to allow connecting to them from above, and to only create OBS for routing layers up to layer 5.

```
write_lef_abstract my.lef -specifyTopLayer 5 -stripePin -PgpinLayers 5
```

If your design also included a block inside that has PG pins on metal5 with no PG stripes in the current design covering them, you can include layer 5 PG pins from the internal blocks using the following command:

```
write_lef_abstract my.lef -specifyTopLayer 5 -stripePin -extractBlockPGPinLayers 5
```

If you also want to include metal4 PG stripes as pins, and metal4 PG pins from the block, you would use the following command:

```
write_lef_abstract my.lef -specifyTopLayer 5 -stripePin -Pgpinlayers {4 5} -extractBlockPGPinLayers {4 5}
```

If you want to include some sparse special-route shapes on metal6, metal7 (for example, for a few manually routed clock nets) , you would use the following command:

```
write_lef_abstract my.lef -specifyTopLayer metal5  -obs_above_top_layer {metal6 metal7}
```

write_name_mapping

```
write_name_mapping
[-help]
[-bbox_pins]
[-hierarchical]
[-map_pins {input output all}]
[-pin_polarity]
[-enable_one_to_one_mapping |-report_power_format]
[-skip_clock_gate]
[-updated_only]
{output_filename | [[-output output_directory] -prefix filename_prefix]}
[-hdl | -initial | [-input_mapping_file mapping_file [-print_deleted][-include_new_iterms ]]]
```

Writes or updates the initial netlist key point names and corresponding current netlist key point names to a file. Mapping file consists of pin mapping information of all changes done during the flow (between comparison points) including polarity changes .

Parameters

`-help`	Prints a brief description that includes the type and default information for each `write_name_mapping` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_name_mapping`
`-bbox_pins`	Prints the pins of bbox in the output mapping file instead of inst names. • Prints bbox input pins if `-map_pins {input}` is specified. • Prints bbox output pins if `-map_pins {output}` is specified. • Prints both input and output pins if `-map_pins {all}` is specified.
`-enable_one_to_one_mapping`	When the value is set as `true`, only one of the clones is printed in the mapping file.
`output_filename`	Specifies the name of the output mapping file.
`-hdl`	Enables the generation of name mapping from current names to the names defined by the 'hdl_name' attribute. This will be used for power analysis.
`-hierarchical`	Specify if write out other post boundary optimizations mapping
`-initial`	Enables the generation of name mapping from current names to names defined by the 'initial_name' attribute. This will be used for verification of initial input netlist (post-synthesis) to any other netlist generated during the Innovus flow. The `write_do_lec` command in Innovus will call `write_name_mapping -initial` so that Conformal LEC do file and name mapping file are generated in one shot. The do file will source the name mapping file to facilitate key point mapping in LEC.
`-include_new_iterms`	When the value is set as `true`, the output mapping file writes the updated iterms as well as the new iterms that exist in Innovus but not in the input mapping file.
`-input_mapping_file` *`mapping_file`*	When provided Tool will read existing mapping file and write out updated mapping file.
`-map_pins {input output all}`	Specify type of pins to write out. *Default*: input
`-output` *`output_directory`*	Specify output directory
`-pin_polarity`	Specify if write out polarity information
`-prefix` *`filename_prefix`*	Used for file name prefix
`-print_deleted`	When `-print_deleted` is specified the mapping file will also print deleted instances.
`-report_power_format`	Specify if write out 1Pass power replay format.
`-skip_clock_gate`	Filters out ICGs that are not in RTL. If you set `-skip_clock_gate` to `true` with `-hdl`, the tool skips the clock gate pins except the pins with hdl_name. If `-skip_clock_gate` is set to `true` and `-hdl` is not specified, the tool skips all clock gate pins.
`-updated_only`	Skips printing the pin that does not have any change/update during optimizations/flow.

cds_lib

`cds_lib` *`string`*

Type: String

Default: NULL

Specifies the library path as derived from `cds.lib` information. The `cds.lib` entries are available from Tcl in `cds_lib vars.cds_lib` is a system-defined, transient (non-persistent) variable. It should be treated as a *read-only* variable.

Related Information

- `init_design`
- `restoreDesign`

check_design_across_hierarchy

```
check_design_across_hierarchy {true | false}
```

Type: `Boolean`

Default: `true`

Checks for undriven/multi-driven/unloaded/constant pins/ports by checking across hierarchical boundaries. By default checks are across hierarchy.

Related Information

- `check_design_report_async_pins`
- `check_design_report_scan_pins`
- `check_design_threshold_fanout`

check_design_report_async_pins

```
check_design_report_async_pins {true | false}
```

Type: `Boolean`

Default: `true`

Checks async pins in a netlist design.

Related Information

- check_design_across_hierarchy
- check_design_report_scan_pins
- check_design_threshold_fanout

check_design_report_scan_pins

```
check_design_report_scan_pins {true | false}
```

Type: `Boolean`

Default: `true`

Checks scan pins in a netlist design.

Related Information

- check_design_across_hierarchy
- check_design_report_async_pins
- check_design_threshold_fanout

check_design_threshold_fanout

```
check_design_threshold_fanout {true | false}
```

Type: `Integer`

Default: `10000`

Checks for upper threshold in a netlist design.

Related Information

- check_design_across_hierarchy
- check_design_report_async_pins
- check_design_report_scan_pins

cvd

`cvd` *`string`*

Type: String

Default: NULL

Specifies the path name to the physical location of the lib/cell/view that was "restored" using `restoreDesign -cellview`. `cvd` is a system-defined, transient (non-persistent) global variable used in the OpenAccess flow. This should be treated as a *read-only* variable.

Related Information

- `restoreDesign`

defHierChar

`defHierChar` *`delimiter`*

Type: String

Default: `/`

Specifies the hierarchy delimiter character for the `defOut` and `defOutBySection` commands. For example, to set / as the delimiter, use the following code:

```
set defHierChar /
```

Note:

- You cannot unset this variable.
- The `defHierChar` is for the `defOut` and `defOutBySection` commands only. It does not change the hierarchy delimiter character of Innovus.

The hierarchy delimiter used appears in the output DEF File as shown below.

```
DIVIDERCHAR "/" ;
```

Related Information

- `defOut`
- `defOutBySection`

defInCheckMaskShifts

```
defInCheckMaskShifts {on | off | bypass}
```

Type: `Enum`

Default: `off`

Checks conflicts between DEF COMPONENT MASKSHIFT and MACRO MASKSHIFT values with the LEF FIXEDMASK and LAYERMASKSHIFT values, respectively, in the technology and MACRO sections. You can set the following values:

- `on`: When the variable is set as on, the the tool will check for the conflict. In case of a conflict, the tool will give an error and stop running.
- `off`: When the variable is set as off, the tool will not check for the conflict.
- `bypass`: When the variable is set as bypass, the tool will give and error message and will continue running.

Related Information

- `restoreDesign`

defInShapeBasedDefFile

```
defInShapeBasedDefFile {0 | 1}
```

Type: Integer

Default: `0`

Specifies that the input file is a shape-based DEF. DEF file generated by shape-based router may contain overlapping routing. By default, `defIn` drops any overlapping wire segment. Set this variable to `1` if you want `defIn` to consider overlapping wire segments.

If the router of a segment of a metal is connected with the two other segments of the same metal, `defInShapeBasedDefFile` will consider this as "overlapping" metals. For example, the metal5 segment of net A is connected with different length of other metal5 segments of net A. This connection will be considered as overlapping metals.

Related Information

- `defIn`

defOutCompressVia

```
defOutCompressVia {0 | 1}
```

Type: Integer

Default: 0

Compresses the via statement in SPECIALNETS section. This variable controls `defOut` to sort vias with two dimension array, so it can use `DO numX BY numY STEP stepX stepY` statement.

The via array information is only preserved in the `defIn` session, but it will not be kept by `saveDesign`/`restoreDesign`.

Related Information

- `defIn`
- `defOut`
- `restoreDesign`
- `saveDesign`

defOutLefNDR

```
defOutLefNDR {0 | 1}
```

Type: Integer

Default: `0`

Controls whether `defOut` writes out LEF non-default rule information in DEF. By default, `defOut` does not write out non-default rules defined in LEF.

Related Information

- `defOut`
- `defOutBySection`

defOutLefVia

```
defOutLefVia {0 | 1}
```

Type: Integer

Default: `0`

Controls whether `defOut` writes out LEF via information in DEF. By default, `defOut` does not write out vias defined in LEF. Set `defOutLefVia` to `1` to write out LEF vias in the DEF file.

Related Information

- `defOut`
- `defOutBySection`

defOutPolygonDieArea

```
defOutPolygonDieArea {0 | 1}
```

Type: Integer

Default: `1`

By default, `defOut` writes out polygon DIEAREA if the design is rectilinear. To write out rectangular DIEAERA along with blockages in cut-out area for a rectilinear design, set this variable to `0`.

Related Information

- `defOut`

defOverlapWireReportFileName

`defOverlapWireReportFileName` *`fileName`*

Type: String

Default: NULL

Reports overlapping wire segments in the specified file. The `defOverlapWireReportFileName` variable can be used along with the `defInShapeBasedDefFile` variable.

Related Information

- `defIn`
- `defInShapeBasedDefFile`

defStreamOutCheckUncolored

```
defStreamOutCheckUncolored {true 1 false 0 metal_only}
```

Type: enum

Default: `false`

`true` above N5 nodes and `metal_only` for N5 and below nodes

Specifies how to check and ignore uncolored shapes on DPT layers during DEF out and stream out.

- `true 1`: `defOut` and `streamOut` will go through all wires/vias/physical pins first. If the related layer has the definition for the "MASK" and "SAMEMASK" rules, tool checks the object if a color should be assigned.
- `false 0`: Ignores to check the uncolored object.
- `metal_only`: Only checks the color on the metal (including wires, physical pins, and top/bottom layer of vias).

Related Information

- `defOut`
- `streamOut`

enc_save_binary_timing_constraints

```
enc_save_binary_timing_constraints {true | false}
```

Type: Boolean

Default: `true`

If set to `true`, `saveDesign` will save timing constraints in binary format. The value of the global should be persistent in subsequent `saveDesign` and `restoreDesign` operations.

Related Information

- `restoreDesign`
- `saveDesign`

enc_save_timing_constraints_always

```
enc_save_timing_constraints_always {true | false}
```

Type: Boolean

Default: `false`

If `true`, `saveDesign` will copy SDC timing constraint files to the output directory rather than keep links to the original external SDC files. This is the equivalent to always using the `-tcon` option whenever `saveDesign` is called.

Related Commands

- `saveDesign`

fp_vertical_row

```
fp_vertical_row {0 | 1}
```

Type: Integer

Default: `0`

Specifies whether the rows in the floorplan are vertical or horizontal. By default, the rows in the floorplan are horizontal. Set this variable to `1` to enable vertical rows.

Example

- The following command sets the rows in the floorplan to vertical.
  ```
  set fp_vertical_row 1
  ```

Related Information

- `init_design`

ignore_max_via_stack_rule

```
ignore_max_via_stack_rule { true | false}
```

Type: Boolean

Default: `false`

The tech lef file contains `MAXVIASTACK` syntax by default. You can use `ignore_max_via_stack_rule` to turn off `MAXVIASTACK` syntax checking. When `ignore_max_via_stack_rule` is set to `true`, the `MAXVIASTACK` rule in the tech lef file is ignored.

init_abstract_view

`init_abstract_view` *`list_of_views`*

Type: String

Default: `abstract`

Specifies the OpenAccess view names that the tool should examine to find the equivalent LEF MACRO information (for example, PINS, OBS, FOREIGN). If this value is null (""), the tool uses `abstract` as the value. The `init_abstract_view` variable replaces the previous `rda_Input(ui_oa_abstractname)` configuration file variable.

The `init_abstract_view` is used in combination with `init_oa_ref_lib` and in the case where a Verilog netlist is read and views from the `init_abstract_view` list are used for on-demand loading for cells that were not processed from the libraries in the `init_oa_ref_lib` list. It is used by the `init_design` command.

Example

- The following command sets ABS1 as the OpenAccess view to be examined for equivalent LEF MACRO information.
  ```
  set init_abstract_view {ABS1}
  ```

Related Information

- `init_design`
- `init_oa_ref_lib`

init_check_output_pin_constant

```
init_check_output_pin_constant  {0 | 1 }
```

Type: Boolean

Default: `1`

Stops the Verilog reader if any output (or inout) signal pins have any 1'b0 or 1'b1 constants that would cause shorts to power/ground.

The default value of this boolean variable is `TRUE` or `1`.

Related Information

- `init_design`
- `setCheckMode`

init_cpf_file

`init_cpf_file` *file_path*

Type: String

Default: NULL

Specifies the path to the Common Power Format (CPF) file.

Related Information

- `init_design`

init_design_netlisttype

```
init_design_netlisttype netlist_source
```

Type: String

Default: `Verilog`

Specifies the source of the design netlist. You can specify either `Verilog` or `OA`. The `init_design_netlisttype` variable replaces the previous `rda_Input(ui_netlisttype)` configuration file variable.

Example

- The following command specifies Verilog as the source of the design netlist.
  ```
  set init_design_netlisttype {Verilog}
  ```

Related Information

- `init_design`

init_design_settop

```
init_design_settop value
```

Type: Integer

Default: `1`

Specifies whether the top cell name is automatically assigned (`0`) or is set by the user (`1`). This global variable replaces the previous `rda_Input(ui_settop)` configuration file variable.

Example

- The following command specifies that the top cell name is assigned automatically.
  ```
  set init_design_settop {0}
  ```

Related Information

- `init_design`

init_design_uniquify

`init_design_uniquify` *value*

Type: Integer

Default: `0`

Specifies whether the top is uniquified. When set to `1` (true), the design is uniquified during the read and flatten process. Optimization is not allowed on a non-unique design. For use in a master/clone partitioning flow, the value should be `0` (false). The `init_design_uniquify` global variable replaces the previous `rda_Input(ui_uniquify_netlist)` configuration file variable.

Example

- The following command specifies that the design should be uniquified automatically after the top cell is flattened.
  ```
  set init_design_uniquify {1}
  ```

Related Information

- `init_design`

init_gnd_net

`init_gnd_net` *`list_of_nets`*

Type: String

Default: NULL

Specifies the list of global ground nets used in the design. This global variable replaces the previous `rda_Input(ui_gndnet)` configuration file variable.

Example

- The following command specifies `VSS` as the ground net used in the design.
  ```
  set init_gnd_net {VSS}
  ```

Related Information

- `init_design`

init_ignore_pgpin_polarity_check

`init_ignore_pgpin_polarity_check`

Type: String

Default: NULL

Space separated list of leaf cell pin names to ignore polarity checking during `globalNetConnect` and CPF operations. Allows USE POWER pin to be connected to a USE GROUND net (or vice versa).

When specified, GNC/CPF are allowed to silently make connections to PG pins that are not of the same polarity as the PG net that they are being connected to. The list of pin names is only checked for the case where a polarity check failed and then can be ignored and connected in spite of the polarity mismatch.

Example

```
set init_ignore_pgpin_polarity_check "bias"
```

Related Information

- `init_design`

init_import_mode

`init_import_mode` *`import_mode_parameters`*

Type: `String`

Default: `NULL`

You can use this global variable to set the options of the `setImportMode` command (import mode parameters). The string with the options of the `setImportMode` command can be passed during the design initialization. This global variable replaces the previous `rda_Input(ui_import_mode)` configuration file variable.

Example

The following command passes the `-discardFloatingVNets true -keepEmptyModule true` options of the `setImportMode` command during initialization:
`set init_import_mode {-discardFloatingVNets true -keepEmptyModule true}`

Note:

- Empty modules and cells without physical cell definitions should not be converted into blackboxes and partitions.
- Empty modules should be retained.

Related Information

- `init_design`
- `setImportMode`

init_io_file

```
init_io_file file_name
```

Type: String

Default: NULL

Specifies the I/O constraint file, including path if the file is not in the current directory. This global variable replaces the previous `rda_Input(ui_io_file)` configuration file variable.

Example

- The following command specifies the `dtmf.io` file in the current directory as the I/O constraint file.

  ```
  set init_io_file {dtmf.io}
  ```

Related Information

- `init_design`

init_layout_view

```
init_layout_view list_of_views
```

Type: String

Default: NULL

Specifies the list of OpenAccess view names to be processed for cell layout viewing (GDSII equivalent). This global variable replaces the previous `rda_Input(ui_oa_layoutname)` configuration file variable.

The `init_layout_view` global is also used in the case where a Verilog netlist is read and views from the `init_layout_view` list are used in the Quick Abstract Inference flow to derive abstract information from layout views for cells that were not processed from the libraries in the `init_oa_ref_lib` list. It is used by the `init_design` command.

Example

- The following command specifies `LAY3` as the layout view to be imported.

  ```
  set init_layout_view {LAY3}
  ```

Related Information

- `init_design`
- `init_oa_ref_lib`

init_lef_check_antenna

```
init_lef_check_antenna {0 | 1}
```

Type: `Boolean`

Default: `1`

If you set `init_lef_check_antenna` to `true`, LEF or OA cells will have process antenna consistency checks done for LEF ANTENNA* data (or OA equivalent data) attached to their pins. Input pins with 0 gate-area, output pins with 0 diff-area, and inout pins with 0 gate-area or 0 diff-area values will generate warnings. If `false`, the tool will not perform consistency checking.

init_lef_check_mask_shifts

```
init_lef_check_mask_shifts {on | off | bypass}
```

Type: `Enum`

Default: `off`

Checks conflicts between the LEF FIXEDMASK and LAYERMASKSHIFT values in the technology and MACRO sections when reading in any LEF files. You can set the following values:

- `on`: When the variable is set as on, the the tool will check for the conflict. In case of a conflict, the tool will give an error and stop running.
- `off`: When the variable is set to off, the tool will not check for the conflict.
- `bypass`: When the variable is set as bypass, the tool will give and error message and will continue running.

Related Information

- `restoreDesign`

init_lef_file

```
init_lef_file list_of_files
```

Type: String

Default: NULL

Specifies the list of LEF files to be imported. This variable cannot be used with `init_oa_ref_lib`. The `init_lef_file` variable replaces the previous `rda_Input(ui_leffile)` configuration file variable.

Example

- The following command specifies `technology.lef` and `stdcell.lef` as the LEF files to be imported.
  ```
  set init_lef_file {technology.lef stdcell.lef}
  ```

Related Information

- `init_design`
- `saveDesign`

init_mmmc_file

```
init_mmmc_file file_name
```

Type: String

Default: NULL

Specifies a Tcl command script that contains the analysis view configurations for multi-mode multi-corner (MMMC) timing analysis and optimization. If this view definition file is not in the current directory, specify the complete path to the file. The `init_mmmc_file` global variable replaces the previous `rda_Input(ui_view_definition_file)` configuration file variable.

Example

- The following command specifies `mmmc.tcl` as the MMMC view definition file.

  ```
  set init_mmmc_file {mmmc.tcl}
  ```

Related Information

- `init_design`

init_mmmc_version

```
init_mmmc_version {1 2}
```

Type: Enum,

Default: `1`

Specifies the version of MMMC to use for a design. It must be set before `init_design`. If you try to change it after init_design, the tool will ignore the change and give a warning.

Related Topic

- `init_design`

init_oa_default_rule

`init_oa_default_rule` *ruleName*

Specifies a constraint group name at the start of Innovus session. The name provided would be used by Innovus for reading the place-and-route technology rules from the constraint group.

If the user specified constraint group is not found, Innovus outputs an error during `init_design`. If no value is specified for `init_default_oa_rule`, Innovus falls back to the default look-up mechanism for `LefDefaultRouteSpec` constraint group used by any place-and-route tool. Follow these guidelines while using this parameter:

- You can set this parameter only at the start of Innovus session .
- You will need to resolve conflicts in a design arising due to the two incompatible constraint groups used in two design runs in two different Innovus sessions.

The specified constraint group must have the following:

- Valid layers
- Valid vias
- Width
- Spacing

Related Information

- `init_design`

init_oa_design_cell

`init_oa_design_cell` *`cellname`*

Type: String

Default: NULL

Specifies the OpenAccess design cell name to be used. It is used by the `init_design` command.

This global variable replaces the previous `rda_Input(ui_oa_designCell)` configuration file variable.

Example

- The following command specifies `myOACell` as the OpenAccess database cell.
  ```
  set init_oa_design_cell {myOACell}
  ```

Related Information

- `init_design`

init_oa_design_lib

`init_oa_design_lib` *`libraryname`*

Type: String

Default: NULL

Specifies the OpenAccess design library name to be used. This global variable replaces the previous `rda_Input(ui_oa_designLib)` configuration file variable.

Example

- The following command specifies `myOALib` as the OpenAccess database library.
  ```
  set init_oa_design_lib {myOALib}
  ```

Related Information

- `init_design`

init_oa_design_view

`init_oa_design_view` *viewname*

Type: String

Default: NULL

Specifies the OpenAccess design view name to be used. This global variable replaces the previous `rda_Input(ui_oa_designView)` configuration file variable.

Example

- The following command specifies `myOAView` as the OpenAccess database view.
  ```
  set init_oa_design_view {myOAView}
  ```

Related Information

- `init_design`

init_oa_foundry_rule

`init_oa_foundry_rule` *`foundry_rule_name`*

Type: String

Default: NULL

Specifies the foundry constraint group to be used in OpenAccess. If your technology library contains multiple `foundry_innovus_XXXX` constraint groups, use the `init_oa_foundry_rule` variable to specify which one of them has to be read in during design initialization. This variable is used by the `init_design` command.

Example

- The following command specifies `foundry_innovus_2` as the foundry constraint group to be used during design initialization:

  ```
  set init_oa_foundry_rule {foundry_innovus_2}
  ```

Related Commands

- `init_design`

init_oa_ref_lib

```
init_oa_ref_lib list_of_OA_libs
```

Type: String

Default: NULL

Specifies the list of OpenAccess reference libraries to import. Each reference library is processed using the abstract view name list (`init_abstract_view`). The first library in the list indicates the library that will be used for the technology information unless `init_oa_design_lib` is specified. All cells from the specified libraries are read. It is important to include the standard cell library in the list to make sure that cells that are not in the current netlist are read and available for optimization. The `init_abstract_view` and `init_layout_view` lists specify which views of the cells are read. Used by the init_design command.

For example, if the reference library is `"lib1 lib2"`, and the abstract view name list is `"abstract abstract2"`, LEF MACRO information is processed for `lib1` with the `abstract` view. Then, for any cells in `lib1` that do not have `abstract` but do have `abstract2`, that view is processed for MACRO information. If a cell has both views, the first one is used. The process then is repeated for `lib2`.

The `init_oa_ref_lib` variable cannot be used with `init_lef_file`. `init_oa_ref_lib` replaces the previous `rda_Input(ui_oa_reflib)` configuration file variable.

Example

- The following command specifies `OAREFLIB1 OAREFLIB2` as the OpenAccess reference libraries.

  ```
  set init_oa_ref_lib {OAREFLIB1 OAREFLIB2}
  ```

Related Information

- `init_abstract_view`
- `init_design`
- `init_layout_view`
- `init_lef_file`
- `init_oa_design_lib`
- `saveDesign`

init_oa_search_lib

`init_oa_search_lib` *`list_of_OA_ref_libs`*

Type: String

Default: `*`

Specifies the list of OpenAccess reference libraries to be searched when cells are used in the Verilog netlist that are not included in the list of cells in the libraries specified in `init_oa_ref_lib` list. By default all libraries in the cds.lib are searched. The `init_abstract_view` and `init_layout_view` lists are used to indicate which view names are looked for during the search. Applies only when `init_verilog` is used to specify the connectivity to be read. Used by the `init_design` command.

Related Information

- `init_abstract_view`
- `init_design`
- `init_layout_view`
- `init_verilog`

init_oa_special_rule

`init_oa_special_rule` *name*

Type: String

Specifies the special rule to be used in OpenAccess to define the via search order for power routing. Typically used to specify a metal stack `LEFSpecialRouteSpec` type constraint group to read from the technology library if the library contains multiple metal stacks. If nothing is specified, then the constraint group with the name `LEFSpecialRouteSpec` is searched in OpenAccess. It is used by the `init_design` command.

Related Information

- `init_design`

init_original_verilog_files

`init_original_verilog_files` *name*

Type: String

Specifies a list of Verilog files to be read during initialization. `init_design` will set it to the list of input files given to it. The original input file names are retained through the flow for reference, and used by `write_do_lec` for the default golden netlist comparison file names.

Related Information

- `init_design`
- `write_do_lec`

init_pwr_net

`init_pwr_net` *`list_of_power_nets`*

Type: String

Default: NULL

Specifies the list of global power nets used in the design. This global variable replaces the previous `rda_Input(ui_pwrnet)` configuration file variable.

Example

- The following command specifies `VDD` as the power net in the design.
  ```
  set init_pwr_net {VDD}
  ```

Related Information

- `init_design`

init_top_cell

```
init_top_cell top_cell_name
```

Type: String

Default: NULL

Specifies the name of the top module. This variable is used only when reading Verilog netlist information. It replaces the previous `rda_Input(ui_topcell)` configuration file variable.

Example

- The following command specifies `TOP` as the top cell in the design.

  ```
  set init_top_cell {TOP}
  ```

Related Information

- `init_design`

init_verilog

`init_verilog` *`list_of_netlist_files`*

Type: String

Default: NULL

Specifies the gate-level Verilog netlist files to be read. This variable replaces the previous `rda_Input(ui_netlist)` configuration file variable.

An encrypted Verilog file is allowed to be specified for `init_verilog`. The file can be created by command `encrypt -verilog`. To be loaded, the encrypted Verilog must have suffix ".vp", like mydesign.vp.

Example

- The following command specifies `z650n3_n2n.enc.dat/z650n3.v` as the gate-level Verilog netlist file.

```
set init_verilog {z650n3_n2n.enc.dat/z650n3.v}
```

Related Information

- `encrypt`
- `init_design`

init_verilog_tolerate_port_mismatch

`init_verilog_tolerate_port_mismatch` *value*

Type: Integer

Default: `0`

Specifies whether new instance ports can be created during Verilog netlist parsing.

By default, this variable is set to 0. If the ports of the cell and its instantiated instance do not match, the Verilog parser stops processing and the tool errors out. If instead, you would like the tool to continue, set the `init_verilog_tolerate_port_mismatch` variable to `1`. When the variable value is set to `1`, the Verilog parser ignores the mismatch and adds the new port to the cell. This is intended to be used during prototyping when it may be alright to lose some connections in 'dirty netlists'. Warnings about mismatches will still be generated.

Set this variable before the Verliog file is read in.

Related Information

- `init_design`

inn_save_lef_ignore_abstracts

```
inn_save_lef_ignore_abstracts {True | False}
```

Type: Boolean

Default: False

Specifies whether to remember a list of unused LEF block macros (CLASS BLOCK or RING) so they are not read back with `restoreDesign`. If you have a large number of LEF blocks (for example, memories) that are not used in this design, this can speedup `restoreDesign` and reduce memory by skipping those LEF cells. Small blocks with less then 10 pins are still read in, because they are sometimes added later in the flow.

Related Information

- `restoreDesign`

lefdefInputCheckColoredShape

```
lefdefInputCheckColoredShape { true | false}
```

Type: Boolean

Default: `false`

Specifies to check and ignore colored shapes on colorless layers while reading the LEF or DEF data. When set to `true`, the tool errors out if a colored shape is on a colorless layer. When set to `false`, the tool gives an error message and ignores the color.

lefDefOutVersion

`lefDefOutVersion` *`version_num`*

Type: String

Default: `5.8`

Specifies LEF/DEF output version. Possible string values are `5.5`, `5.6`, 5.7, 5.8, and 6.0. The default is `5.8`.

Related Commands

- `defOut`
- `defOutBySection`
- `write_lef_abstract`

lefExtend2DCellShapes

```
lefExtend2DCellShapes { {layer extension_amount}… }
```

Type: String

Default: `""`

Specifies a list of layer and a value for creating obs shape for 2D pin/obs shapes. Cells could have 2D objects, which require larger line-end spacing. You can use `lefExtend2DCellShapes` to automatically add **SPACING 0 OBS** for routing during LEF in..

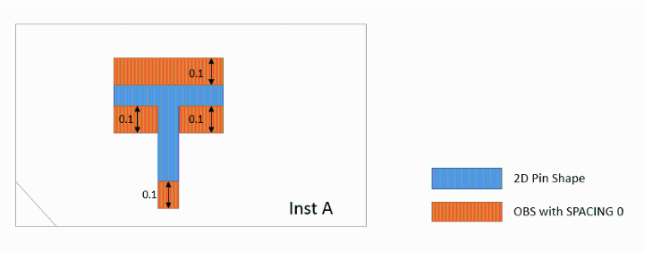
For any 2D shapes, you can extend edges that are perpendicular to the preferred routing direction of the rectilinear shape by specifying the `extension_amount` in `lefExtend2DCellShapes`.

Note: Cells would still require explicit edge constraint to prevent improper cell abutment.

Example

```
set lefExtend2DCellShapes {M1 0.1}
```

The direction of M1 is Vertical.



lefExtendCellObsShapeUnderTrim

```
lefExtendCellObsShapeUnderTrim listOfRoutingLayers
```

Type: String

Default: ""

Specifies a list of routing layers. On each specified *layer* the LEF OBS shapes that are overlapped partially by a shape on the TRIMMETAL layer (that trims the routing layer), will be extended in the preferred routing direction to be fully covered by the trim shape. You can use this global for some advanced node libraries to avoid trim/OBS short violations.

lefIgnoreLayerNames

`lefIgnoreLayerNames` *`layerNames`*

Type: String

Default: `NULL`

Specifies the layer list that needs to be ignored. If you do not specify any layers in this global, the tool load all layers. For example, if you specify `lefIgnoreLayerNames "TSV BSPM0"`, the tool will not load the definition for the TSV layer and BSPM0 layer when loading the tech LEF file. You should use this global to disable the layer list when loading an OA design.

If the disabled layers are used in the Tech LEF for via cell, via rule generation, NDR and property definition, the tool will ignore the definition when loading the Tech LEF file. If the disables layers are used in macro LEF, tool will stop reading the LEF file and give an error. If the disabled layers are used in the definition of the following objects in other design data, the tool will give error to skip this object:

- Wire/Via
- Marco Pin/OBS (Include bump)
- Blockage
- Bus guide
- Track
- Pin guide
- GUI shape/text
- Pin guide

merge_multi_port_to_single_port

```
merge_multi_port_to_single_port {true | false}
```

Type: `Boolean`

Default: `false`

When set to `true`, multiple ports in a LEF PIN are merged into a single port. However, the pin should not have the `MUSTJOINALLPORTS` attribute as it specifies that all of the ports must be connected individually.

readWriteLefCheckUncoloredShapes

`readWriteLefCheckUncoloredShapes {pin_only | on | off}`

Type: `enum`

Default: off

Specifies whether to check for uncolored LEF PIN and OBS shapes on multi-mask routing layers when reading or writing LEF files. If the check is on, LEF read or write commands will error out if there are any uncolored routing layer shapes (cut layers are not checked). If set to `pin_only`, only check LEF PIN shapes and ignore LEF OBS shapes.

- During `write_lef_abstract`, if the tool finds any uncolored physical pin and if `readWriteLefCheckUncoloredShapes` is set to `on`, the tool will print an error message, and will not write out uncolored shapes to the LEF file. However, if `readWriteLefCheckUncoloredShapes` is set to `off`, the tool will not check the uncolored object and dump all physical pins into the macro lef. In this case, the tool does not print any error message.
- When the tool reads the LEF file and finds any uncolored macro pin, and if `readWriteLefCheckUncoloredShapes` is set to `on`, the tool will print an error message and only read colored shapes into the design. However, if `readWriteLefCheckUncoloredShapes` is set to `off`, the tool will not check the uncolored object and will read the definition of all macros into the design. In this case, the tool does not print any error message.

The `readWriteLefCheckUncoloredShapes` global controls the behavior of following commands or flow:

- `write_lef_abstract`
- `restoreDesign` and init design flow
- `replaceLefMacro`

`readWriteLefCheckUncoloredShapes` does not impact `write_lef_library` and read/write oa tech.

Related Information

- `replaceLefMacro`
- `restoreDesign`
- `write_lef_abstract`
- `write_lef_library`

save_cmd_file_limit

`save_cmd_file_limit` *`limit`*

Type: `integer`

Default: `10`

The `saveDesign` command saves the complete .cmd history across multiple sessions. The `save_cmd_file_limit` variable specifies the file length limit (in units of Mb) that is saved in the inn.cmd.gz file inside the save directory. If it is set to 0, the command history is not saved.

Related Information

- `saveDesign`

write_lec_dft_constraints

`write_lec_dft_constraints` *`dictionary`*

Type: `String`

Default: `""`

This variable is a TCL dictionary that holds the LEC DFT pin constraints from the last LEC run by Genus. It is passed forward through the `write_design` command. The `write_do_le`c command will automatically include this constraint in the do file.

Related Information

- `write_do_lec`

write_lec_directory_naming_style

`write_lec_directory_naming_style` *`directory_name`*

Type: `String`

Default: `fv/invs/%s`

Specifies the directory name where the `write_do_lec` command will write verification files when the write_lec_files global is true. The directory will be created if it does not already exist, and will be overwritten if the existing directory has the same name. A `%s` in the string is replaced with the design name. For example, it will overwrite the directory for the same design but not for a different design. A `%d` in the string is replaced with a unique integer to avoid overwriting any existing directory.

Related Information

- `write_do_lec`
- `write_lec_files`

write_lec_files

`write_lec_files {true | false}`

Type: `Boolean`

Default: `true`

Specifies whether the `write_do_lec` command should write intermediate files to the verification directory specified by the `write_lec_directory_naming_style` global. If false, no files are written.

Related Information

- `write_do_lec`
- `write_lec_directory_naming_style`

writeLefAbstractCustomerHeader

`writeLefAbstractCustomerHeader` *`header_information`*

Type: `String`

Default: `""`

Writes LEF abstract files with the customer-specified header information.

15

Integrated Hierarchical Database Commands

- check_module_model
- create_module_model
- define_add_on_module_model
- import_module_model
- pack_module_model_libs
- report_module_model
- restore_module_model
- set_module_model
- update_module_model
- write_module_model_context

check_module_model

```
check_module_model
[-help]
-cell cell_name
[-out_file file_name]
-ref_tag tag_name
[-slack_threshold threshold] [-type {flexIlm ilm pnr}]
```

Checks and validates an ILM model to see if the current reduction ratio will cause any missing constraints at the hinst terminal or any slack difference. The `check_module_model` command compares/checks the target timing result with the reference timing result and generates a summary and detailed report.

Note: If a specified cell has more than one instantiated modules, all hinst terminals are checked and reported.

Usage Model:

- Generate a reference ILM model with the `createInterfaceLogic -keepAll` option and a target ILM model with user-specified settings.
- Restore the top-level design and set/commit target ILM model(s).
- Time the design.
- Call `check_module_model`

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `check_module_model` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man check_module_model`
`-cell cell_name`	Specifies the ILM cell name that will be validated. *Data_type*: string, required
`-out_file file_name`	Specifies the output report file. *Default:* `./check_module_model.rpt` *Data_type*: string, optional
`-ref_tag tag_name`	Specifies the reference tag name of the reference ILM model. *Data_type*: string, required
`-slack_threshold threshold`	Specified the slack threshold for reporting the number of mismatched slacks over the threshold. *Default:* `0.0005` *Data_type*: string, optional
`-type {flexIlm ilm pnr}`	Specifies the type of module model. The model type can be flexllm, ilm, or pnr. *Default*: `ilm` *Data_type*: string, optional

Example

- The following command check the tdsp_core cell and writes the detailed report in the tdsp_check_module_model.rpt file:
  ```
  check_module_model -cell tdsp_core -ref_tag ref_preCts -type ilm  -out_file tdsp_check_module_model.rpt
  ```

Related Information

- commit_module_model
- create_module_model
- report_module_model
- restore_module_model
- savePartition
- set_module_model
- update_module_model
- write_module_model_context
- Hierarchical and Prototyping Flow chapter in the *Innovus User Guide*
  - Integrated Hierarchical Database Flow

create_module_model

```
create_module_model
[-help]
[-allow_port_mismatch]
[-cell string]
[-phys_hier]
[-tag tag_name]
[-type {1801 boundary_model etm extraction_context flexIlm ilm latency lef mmmc pin_assign pnr pnr_shell scan_info spef
timing_context gds}]
```

Creates a module model. It honors the `set_module_model -default_create_options` command settings.

Parameters

`-allow_port_mismatch`	Creates a new updated LEF. It provides an ability to bring in an updated model with mis-matched ports to top-level design. **Note:** This parameter can be specified with the `lef` type (`-type`) of module models. *Data_type*: bool, optional
`-cell string`	Specifies the cell to save. By default, current top cell will be saved. **Note:** For 2D designs, the `-cell` parameter should be used for pnr type of module model only. **Note**: For 3D IC designs, the `-cell` parameter can be used to specify a list of partition names or design name to save for pnr, lef, or pre_pnr types of module models. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `create_module_model` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man create_module_model`
`-phys_hier`	Creates the whole physical hierarchy. *Data_type*: bool, optional
`-tag tag_name`	Specifies tag name of the saved model. **Note:** You cannot use 'latest' as a tag name as it is a reserved keyword for the latest tag. • If a model is created from an Innovus session that is opened by the `update_module_model` command, then the same tag name of the current loaded design will be used if this option is not specified. • This option is required if a block-level design has been opened explicitly. You only need to specify this tag option for one model type. For subsequently created model types, the same tag can be used if it has not been specified. • If the tag information is not available, the `create_module_model` command displays an error message. *Data_type*: string, optional
`-type {1801 boundary_model etm extraction_context flexIlm ilm latency lef mmmc pin_assign pnr pnr_shell scan_info spef timing_context gds}`	

	Specifies the type(s) of module model. The following is the list of the supported model types: • `1801`: UPF for power domain • `boundary_model`: Boundary model for timing analysis • `etm`: Extraction timing model • `extraction_context`: Extraction context model • `flexilm`: Flexible interface logic model • `gds`: Graphical design system model • `ilm`: Interface logic model • `latency`: Clock latency information • `lef`: LEF abstract • `mmmc`: Multi-mode multi-corner definition • `pin_assign`: SPEF file from RC extraction • `pnr`: Innovus DB • `pnr_shell`: Reduced pnr model where only the first level of logics is kept. • `scan_info`: Scan chain information • `spef`: SPEF file from RC extraction • `timing_context`: Timing context model **Note:** Use the `-type 1801` to save UPF associated with an ILM model so that you do not have to keep a track where is the corresponding UPF of an ilm. **Note:** You can specify a list of model types to create multiple types of module models at a time. **Note:** The `pnr_shell` model type is similar to the `flexilm` model but it only has first level of logics. **Note:** The `create_module_model -type spef` honors the `set_module_model -active_rc_corners` command to output SPEF(s) for the specified RC corners. By default, multi corner SPEFs are saved as gzip. The output SPEF(s) are saved at <iHDB_root>/<cell>/<tag>/spef/<topCell>.<cornerName>.spef.gz **Note:** If the `-rc_corner` parameter of the `rcOut` command is not specified, the name of the SPEF output file is <iHDB_root>/<cell>/<tag>/spef/<topCell>.spef.gz **Note:** You can use the `timing_context` or `extraction_context` add on types for creating a timing or extraction context model, respectively, for a specific cell or a master/clone instance. This context model can be loaded additionally with the design later in the flow. Default: `pnr` and `lef` *Data_type*: enum, optional

Example

- The following command creates ilm type of module model that has the postRoute tag.
  ```
  create_module_model -type ilm -tag postRoute
  ```

Related Information

- `check_module_model`
- `commit_module_model`
- `report_module_model`
- `restore_module_model`
- `savePartition`
- `set_module_model`
- `update_module_model`
- `write_module_model_context`
- Hierarchical and Prototyping Flow chapter in the *Innovus User Guide*
  - Integrated Hierarchical Database Flow

define_add_on_module_model

```
define_add_on_module_model
[-help]
[-commit_callback string]
-type string
{[-create_callback string]
[-set_callback string]
[-restore_callback string]
[-write_context_callback string]}
```

Allows you to define the add_on types or supplemental models that can be loaded additionally with an existing model or a design. These user-defined add_on types can be used with the `create_module_model`, `set_module_model`, `restore_module_model`, and `write_module_model_context` commands. You must provide a TCL file containing callback procedures for each applicable Integrated Hierarchical Database (iHDB) flow command that will be run when this command is called.

In the TCL file, the TCL callback procedures must be defined in the following format and must include the specified arguments:

```
proc <callBackTCLProcName> {dir cell tag args} {
…
}
```

Where,

`dir`, `cell`, and `tag` represent values that will be automatically derived by the iHDB capability.
`args` can be set using `set_module_model -default_commit_options {options} -type add_ons_type`

Parameters

`-commit_callback string`	Specifies the user-defined TCL procedure that is executed when the `commit_module_model` command is called with this `add_ons` type. *Data_type*: string, optional
`-create_callback string`	Specifies the user-defined TCL procedure that is executed when the `create_module_model` command is called with this `add_ons` type. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `define_add_on_module_model` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man define_add_on_module_model`
`-restore_callback string`	Specifies the user-defined TCL procedure that is executed when the `restore_module_model` command is called with this `add_ons` type. *Data_type*: string, optional
`-set_callback string`	Specifies the user-defined TCL procedure that is executed when the `set_module_model` command is called with this `add_ons` type. *Data_type*: string, optional
`-type string`	Specifies the newly added add_ons model type name. *Data_type*: string, required
`-write_context_callback string`	Specifies the user-defined TCL procedure that is executed when the `write_module_model_context` command is called with this `add_ons` type. *Data_type*: string, optional

Example

- Following is an example of defining the "attrs" add_ons model type. First this 'attrs' attribute must be defined with the define_add_on_module_model command with its associated callback TCL procedures:

```
source dump_attrs.tcl
set_module_model -default_commit_options {-fe -keepPinGeometry} -type pnr
define_add_on_module_model -type attrs -create_callback ihdb_create_attrs -set_callback ihdb_read_attrs
```

  Where `dump_attrs.tcl` contains:

```
proc ihdb_create_attrs {dir cell tag args} {   ;#This format is fixed

  write_block_attrs $dir/$cell/$tag/attrs/db.attrs

}

proc ihdb_read_attrs {dir cell tag args} {  ;# This format is fixed

  read_block_attrs $dir/$cell/$tag/attrs/db.attrs

}

…
```

- *Block Level*. The following command creates user defined attrs type of module model that has the *merge_attribute* tag.

```
create_module_model -type attrs -tag merge_attribute

create_module_model -tag merge_attribute
```

- *Top-Level*. The following commands configures and commits the *merge_attribute* module model using the `attrs` add-on associated with the `pnr` model type:

```
set_module_model -cell dcm -tag merge_attribute -type pnr -add_ons {attrs}
set_module_model -cell lsu -tag merge_attribute -type pnr -add_ons {attrs}
commit_module_model
```

Related Information

- `check_module_model`
- `commit_module_model`
- `create_module_model`
- `report_module_model`

  - Integrated Hierarchical Database Flow

import_module_model

```
import_module_model
[-help]
-cell string
[-idx_pair string]
-inputs string
-libs [-link_only]
[-rc_corner string]
[-tag string]
-type {lib lef qrc_tech qrc_conf}
```

Imports library files into the iHDB structure.

Parameters

`-cell` *string*	Specifies the cell to import. *Data_type*: string, required
`-help`	Outputs a brief description that includes the type and default information for each `import_module_model` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man import_module_model`
`-idx_pair` *string*	Specifies the idx pair list if the files are copied from the idx database. *Data_type*: string, optional
`-inputs` *string*	Specifies the full path of the input file to be imported. **Note:** The `import_module_model` command supports the import of Quantus™ Extraction Solution input files. *Data_type*: string, required
`-libs`	Specifies whether input file is a library file or not. **Note:** This option should be used for type lef, lib, qrc_tech, or qrc_conf. **Note:** The library files: • *.lib are saved at <iHDB>/<cell>/.libs/mmmc/ • *.lef are saved at <iHDB>/<cell>/.libs/lef/ • qrcTechFile are saved at <iHDB>/<cell>/.libs/mmmc/<rc_corner>/qrcTechFile • qrc.conf are saved at <iHDB>/<cell>/.libs/qx/qrc.conf **Note:** The following GDS related model types can be saved with `-libs` option: • `gds_map` • `stream_libs` • `stream_layermap` *Data_type*: bool, required
`-link_only`	Creates a link or actual hard copy. **Note:** If the `-link_only` parameter is specified, then a link pointing to the current library location is created. If is the `-link_only` parameter is not specified then the actual physical file will be there. *Data_type*: bool, optional
`-rc_corner` *string*	Specifies the list of RC corners. *Data_type*: string, optional
`-tag` *string*	Specifies a tag of a saved file. **Note:** The `-tag` and `-libs` parameters are mutually exclusive. *Data_type*: string, optional
`-type {lib lef qrc_tech qrc_conf}`	
	Specifies the type(s) of module model. The model type can be lib, lef, qrc_tech, or qrc_conf. Default: *Data_type*: string, required

Example

- The following command imports a LEF file:
  ```
  import_module_model -cell tdsp_core -libs -type lef -input_file
  /icd/hierflow2/DATA2/tdsp_core/init/pnr/tdsp_core.enc.dat/libs/lef/*.lef
  ```
- The following command imports streamOut layer map into cell top_die:
  ```
  import_module_model -cell top_die -inputs ./input_data/lvs_data/streamOut.layermap -libs -type steam_layermap
  ```

  This will be saved into <iHDB_root>/top_die/.libs/steam_layermap/steamOut.layermap

pack_module_model_libs

```
pack_module_model_libs
[-help]
[-cell cellName]
[-validate]
```

Packs libraries for the Integrated Hierarchical Database (iHDB) flow designs.

Notes:

- You must specify the default central directory name (`set_module_model -default_dir`), before using this command. In case default central directory is moved to a different location, the libraries can be packed again.
- The packed libraries are saved at *<default_model_data_directory>/<cell>/.libs.*

Parameters

`-cell` *cellName*	Specifies the cell name. All pnr model libraries of all tags under the specified cell will be linked to the packed libraries (*.libs)* saved by the `pack_module_model_libs` command. **Note:** The packed libraries are saved at *<default_model_data_directory>/<cell>/.libs.* *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `pack_module_model_libs` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man pack_module_model_libs`
`-validate`	Compares the checksum before and after packing libraries. It checks whether the libraries before and after packing are the same. **Note:** When the `-validate` parameter is specified, the `pack_module_model_libs` command will output *after_pack_libs.check_sum* and *before_pack_libs.check_sum* under the *.libs* directory for comparison. *Data_type*: bool, optional

Example

- The following command specifies the default central directory name (./DATA) where models data will be saved/loaded and then specifies the cell name. All pnr model libraries of all tags under the specified cell will be linked to the packed libraries (*.libs)* saved by the `pack_module_model_libs` command.

  ```
  set_module_model -default_dir DATA2
  pack_module_model_libs -cell tdsp_core -validate
  ```

  `Output:`
  This command will output the packed libraries at *`DATA2/tdsp_core/.libs`*. It will also create *`after_pack_libs.check_sum`* and *`before_pack_libs.check_sum`* under the *`.libs`* directory for comparison.

report_module_model

```
report_module_model
[-help]
[-active_rc_corners]
[-default_dir]
[-non_committed_hinst]
[-type {flexilm lef ilm pnr pnr_shell}]
```

Reports the module models that are currently loaded/committed at top-level design.

Parameters

`-active_rc_corners`	Reports the active RC corners. *Data_type*: bool, optional
`-default_dir`	Reports the current default module data directory. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `report_module_model` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man report_module_model`
`-non_committed_hinst`	Checks and reports the modules/cells that are available in the default module data directory but are not committed as hierarchical modules (hInst). *Data_type*: bool, optional
`-type {flexilm lef ilm pnr pnr_shell}`	Specifies the type of module model to be reported **Note:** The module models that are not committed are reported with the "init" type and tag. The module models that are committed are reported with the types and tags same as the requested types. *Data_type*: string, optional

Examples

- The following command reports the module models that are currently loaded/committed at top-level design:

```
report_module_model -type lef

Module       Type ReqType Tag     ReqTag    Dir
-------------------------------------------------------------------------------------
ptn_wrapper  lef  lef     preCts  preCts    /icd/demo/v4h/DATA2/ptn_wrapper/latest/lef

default directory : /icd/demo/v4h/DATA2
```

- The following command reports the ilm type of module models:

```
report_module_model -type ilm

Module       Type ReqType Tag         ReqTag      Dir
-----------------------------------------------------------------------------------------------
ptn_wrapper  ilm  ilm     my_postCts  my_postCts  /icd/demo/v4h/DATA2/ptn_wrapper/my_postCts/ilm
tdsp_core    ilm  ilm     my_preCts   my_preCts   /icd/demo/v4h/DATA2/tdsp_core/my_preCts/ilm

default directory : /icd/demo/v4h/DATA2
```

- The following command reports the list of active RC corners:

```
set_module_model -active_rc_corners {rcMin rcMax}
report_module_model -active_rc_corners
```

Related Information

- `check_module_model`
- `commit_module_model`
- `create_module_model`
- `restore_module_model`
- `savePartition`
- `set_module_model`
- `update_module_model`
- `write_module_model_context`
- Hierarchical and Prototyping Flow chapter in the *Innovus User Guide*
  - Integrated Hierarchical Database Flow

restore_module_model

```
restore_module_model
[-help]
[-dynamic_view string]
[-hold_views string]
[-leakage_view string]
[-lef_files string]
[-mmmcFile string]
[-noTiming]
[-noTimingGraph]
[-setup_views string]
[-tag tag_name]
{cell_name | -cell cell_name}
[options]
[-add_ons {1801 mmmc spef eco latency scan_info timing_context extraction_context pin_assign}]
```

Restores a design from a default module model repository. You can use this command only after the default central directory name where the module model data will be saved/loaded has been specified using the `set_module_model -default_dir` command.

The `restore_module_model` command provides you the following flexibilities:

- Ability to provide your own ECO script. The ECO script must be located at <cell>/<tag>/eco/<cell>_eco.tcl.
- Ability to read/restore a design of a specific tag but its ECO file can be loaded from a different tag.

This feature is useful when the ECO changes are done with an old netlist drop and a new netlist drop is saved with a different tag.

For example:

```
restore_module_model -cell tdsp_core -tag my_postcts -add_ons {anotherTag/eco}
```

Supported short-hand `restore_module_model` usage model:

```
restore_module_model <dir>/<cell>/<tag> [-add_ons {add_on_type}]
restore_module_model <cell>/<tag> [-add_ons {add_on_type}] ;# Local directory
restore_module_model <cell> -tag <tag> [-add_ons {add_on_type}] ;# Default root dir
```

Parameters

```
-add_ons {1801 mmmc spef eco latency scan_info timing_context extraction_context
pin_assign}
```

	Specifies the supplement model that can be loaded additionally with an existing model or a design. For example: • The following command restores the ptn_wrapper design that has my_extract_v1 tag and also bring in its extraction_context add_on model: `restore_module_model ptn_wrapper -tag my_extract_v1 -add_ons {extraction_context}` • The following commands show the location from where mmmc data will be loaded during `restore_module_model` according to usage of `-add_ons {mmmc}` ◦ `restore_module_model Ptn1 -tag XYZ` Uses view definition located inside .enc.dat in pnr directory of tag XYZ ◦ `restore_module_model Ptn1 -tag XYZ -add_ons {ABCD/mmmc}` Uses view definition from mmmc directory of tag ABCD ◦ `restore_module_model Ptn1 -tag XYZ -add_ons {mmmc}` Uses view definition from mmmc directory of tag XYZ **Note:** For more information about saving data in separate tags in the mmmc directory, see `saveTimingBudget -module_model_tag` *Data_type*: string, optional
cell_name | -cell *cell_name*	Specifies the module model name. **Note:** This parameter must be specified. *Data_type*: string, required
`-dynamic_view` *string*	Specifies the dynamic view. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `restore_module_model` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man restore_module_model`
`-hold_views` *string*	Specifies the hold views. **Note:** The `-setup_views` and `-hold_views` parameters specify the active analysis views for the loaded design. *Data_type*: string, optional
`-leakage_view` *string*	Specifies the leakage view. *Data_type*: string, optional
`-lef_files` *string*	Specifies the lef file(s). *Data_type*: string, optional
`-mmmcFile` *string*	Specifies the MMMC view file(s) *Data_type*: string, optional
`-noTiming`	Ignores timing libraries and MMMC configuration *Data_type*: bool, optional
`-noTimingGraph`	Specifies not to load timing graph. *Data_type*: bool, optional

options	Specifies the restoreDesign options. *Data_type*: string, optional
-setup_views *string*	Enables you to setup views. **Note:** The -setup_views and -hold_views parameters specify the active analysis views for the loaded design. *Data_type*: string, optional
-tag *tag_name*	Specifies the tag name of the flow. **Note:** If *tag_name* is not specified, 'latest' is used as the default tag value. *Data_type*: string, optional

Example

- The following command restores the dtmf_recvr_core module model that has the start tag.
  ```
  restore_module_model -cell dtmf_recvr_core -tag start
  ```
- The following commands restore the ptn_wrapper design along with its DEF extraction context to do hierarchical extraction:
  ```
  restore_module_model ptn_wrapper -tag my_extract_v1 -add_ons {extraction_context}
  #Load in the detailed LEF abstract of ram_128x16_test
  set_module_model -cell ram_128x16_test -type lef -tag my_extract_v1
  commit_module_model
  earlyGlobalRoute
  setExtractRCMode -engine postRoute
  extractRC
  rcOut -spef with_detailed_def.spef
  ```
-

set_module_model

```
set_module_model
[-help]
[-allow_port_mismatch]
[-dir model_data_directory]
[-hold_views string]
[-phys_hier]
[-setup_views string]
[-tag flow_tag]
[-type {flexilm lef ilm pnr pnr_shell boundary_model }]
[-update]
{[[[[-cell moduleName] [-default_set_options string]] | [-top cell_name [-logical_only ]]]
[-add_ons {1801 etm latency pnr_view scan_info spef timing_context extraction_context}]] |
-default_dir default_model_data_directory |
-default_create_options default_option |
-default_commit_options string |
-active_rc_corners list_of_rc_corners }
```

Sets or configures specific block model(s) to top-level design.

Parameters

`-active_rc_corners list_of_rc_corners`	Specifies the list of RC corners. **Note:** For multi-corners, different applications have different ways to get or specify RC corners for outputting/reading SPEF (Standard Parasitic Exchange Format). In the Integrated Hierarchical Database (iHDB) flow, the `-active_rc_corners` parameter provides a uniform way to use RC corners. **Note:** The `create_module_model -type spef` honors the `set_module_model -active_rc_corners` command to output SPEF(s) for the specified RC corners. By default, multi corner SPEFs are saved as gzip. The output SPEF(s) are saved at <iHDB_root>/<cell>/<tag>/spef/<topCell>.<cornerName>.spef.gz *Data_type*: string, optional
`-add_ons {1801 etm latency pnr_view scan_info spef timing_context extraction_context}`	

	Specifies the supplement model that can be loaded additionally with an existing model or a design. The following is the list of the supported model types: • `1801`: UPF for power domain • `etm`: Extraction timing model • `latency`: Clock latency information • `pnr_view`: Full pnr physical DB • `scan_info`: Scan chain information • `spef`: SPEF file from RC extraction • `timing_context`: Timing context model • `extraction_context`: Extraction context model For example the following command specifies that the etm add on type is associated with the `-type lef` parameter. It uses LEF and timing model ETM (.lib) together at top-level design: `set_module_model -cell tdsp_core -type lef -add_ons {etm}` **Note:** The `1801` add on type can only be specified for `ilm` model type (`-type ilm`). **Note:** The `pnr_view` add on type can only be specified for `ilm` model type (`-type ilm`) where it will load in the full pnr physical DB on top of an ILM model so you can see all cells and routing. This can be used for debugging timing. **Note:** The `spef` add on type honors the `-active_rc_corners` parameter to read in SPEFs (Standard Parasitic Exchange Format) for the specified RC corners. **Note:** The `spef` add on type cannot be used with the `pnr_shell` model type. **Note:** With the `latency` and `scan_info` add on types, the `create_module_model` command can save the latency and scan chain data into iHDB. The `commit_module_model` command can bring back the latency data of an ILM data to the top-level design for pre-CTS stage, and be able to merge block scan chains back to top-level design. *Data_type*: bool, optional
`-allow_port_mismatch`	Allows model I/O ports mismatching from the original database. It replaces the new updated LEF and provides an ability to bring in an updated model with mis-matched ports to top-level design. **Note:** This parameter can be specified with the lef, flexllm, ilm, and pnr type (`-type`) of module models only. *Data_type*: string, optional
`-cell` *moduleName*	Specifies the cell name(s) to be loaded. You can specify a list of cell names. **Note:** The `-cell` parameter accepts wildcards as input. *Data_type*: string, optional

`-default_commit_options` *string*	Specifies the default commit options. These default settings are honored by the `commit_module_model` command.
	Use Model:
	`set_module_model -default_commit_options {`*listOfAssembleDesignOptions*`} -type pnr`
	`set_module_model -default_commit_options {`*listOfSetIlmTypeOptions*`} -type ilm`
	Example:
	`set_module_model -default_commit_options {-fe -keepPinGeometry} -type pnr`
	`set_module_model -default_commit_options {-model si} -type ilm`
	Data_type: string, optional

`-default_create_options` *default_options*	Specifies the default create options for a specific model type. These default settings are honored by the `create_module_model` command. **Note:** You must specify the `-type` parameter with this option. **Note:** While specifying the default create options, ensure that you specify the correct names of the options as per the selected Innovus interface. *Data_type*: string, optional
`-default_dir` *default_model_data_directory*	Specifies the default central directory name where the module models data will be saved/loaded. **Note:** If `set_module_model -default_dir` is not specified, the Innovus system does not set any directory by default. Later on, when you try to run the `restore_module_model` command, it displays an error message that the `-default_dir` parameter is not set. This option MUST be set before loading any Integrated Hierarchical Database (iHDB) design. *Data_type*: string, optional
`-default_set_options` *string*	Sets the default options. *Data_type*: string, optional
`-dir` *model_data_directory*	Specifies the directory where data of the specified cell can be found. **Note:** The `-dir` parameter will override the `-default_dir` setting for this cell. **Note:** The `-dir` parameter cannot be specified if the `-cell` parameter has been specified using wildcards. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `set_module_model` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man set_module_model`
`-hold_views` *string*	Specifies the hold views. **Note:** The `-setup_views` and `-hold_views` parameters allow you to specify the active analysis views for the loaded design. Innovus uses these settings to know which SDC constraints to use. By default, the active views will be based on the viewDefinition.file of pnr model (*.enc.dat). *Data_type*: string, optional
`-logical_only`	Specifies that only the logical data will be read. It controls whether to load DEF and LEF libraries or not. If `-logical_only` is specified, Innovus only loads Verilog/.lib but not DEF/LEF. *Data_type*: bool, optional
`-phys_hier`	Enables you to load the physical hierarchy for viewing purpose. *Data_type*: bool, optional
`-setup_views` *string*	Enables you to setup views. **Note:** The `-setup_views` and `-hold_views` parameters allow you to specify the active analysis views for the loaded design. Innovus uses these settings to know which SDC constraints to use. By default, the active views will be based on the viewDefinition.file of pnr model (*.enc.dat). *Data_type*: string, optional
`-tag` *flow_tag*	Specifies the tag name of the specified cell. It can be design stage/status name such as ‘prects’, ‘cts’, etc…. **Note:** The 'latest' tag will be used if this option is not specified. ‘latest’ can also be specified as tag name for referencing to the latest updated tag. **Note:** For a specific cell, you only need to specify this tag option for one model type. For subsequent model type setting of the same cell, same tag name will be used if it’s not specified. *Data_type*: string, optional

`-top cell_name`	Specifies the top module model. This is a light way to load the top-level Verilog netlist. When specified with `-type pnr`, the tool only loads the Verilog and DEF from the `pnr` model. **Note:** When the `-top` parameter is specified, the default model type (`-type`) is pnr.
`-type {flexilm ilm lef pnr pnr_shell boundary_model}`	Specifies the model type. The model type can be boundary_model, lef, flexllm, ilm, pnr, or pnr_shell. The following is the list of the most frequently used iHDB module model types: • `flexilm`: Flexible interface logic model • `ilm`: Interface logic model • `lef`: LEF abstract • `pnr`: Innovus DB • `pnrshell`: Reduced pnr model where only the first level of logics is kept. • `boundary_model`: Boundary model for timing analysis **Note:** You must specify the `-type` parameter. *Data_type*: enum, optional
`-update`	Specifies that the data of the specified cell will be loaded without doing any checking. *Data_type*: bool, optional

Example

- The following command specifies the default central directory name (./DATA) where models data will be saved/loaded.
  ```
  set_module_model -default_dir ./DATA
  ```
- The following command configures the tdsp_core module model using LEF and timing model ETM (.lib) together at the top-level design:
  ```
  set_module_model -cell tdsp_core -tag my_prects -type lef -add_ons {etm}
  ```
- The following example specifies the default options for type lef:
  ```
  set_module_model -type lef -default_create_options {-specifyTopLayer M10 -stripePin}
  ```

Related Information

update_module_model

```
update_module_model
[-help]
[-cpu number_of_cpus]
[-distribute_job]
[-eco_report]
[-log_dir dir_name]
[-return_tag tag_name]
[-return_type {lef flexIlm ilm pnr}]
[-tag tag_name]
{[-distribute_run | -cell cell_name] [-interactive | -plugin_tcl tcl_commands | -gen_eco_only ]}
```

Invokes an independent session in interactive or batch mode at top-level design. The `update_module_model` command can be called at top-level design.

Note: When an independent session is invoked, the license(s) will be checked-out from the main Innovus session and checked in to the independent session. Once you exit the independent session, the license(s) will return back to main Innovus session.

The `update_module_model` command:

- automatically updates the changes from top to block in an independent session.
- runs the user-provided plug-in commands in batch mode.
- automatically brings back the updated LEF models of the same tag to the top-level once the job is done.

Note: You should run the `create_module_model` command to save different types of models at the end of an independent session.

Parameters

`-cell` *cell_name*	Specifies which cell the command will update changes. *Data_type*: string, optional
`-cpu` *number_of_cpus*	Specifies the number of CPUs that will be used for the independent session. By default it uses the same of number of CPUs as its parent. *Data_type*: int, optional
`-distribute_job`	Enables distributed processing where more than one block design can be run in parallel. *Data_type*: bool, optional
`-distribute_run`	Enables you to execute all the specified `update_module_model` distributed jobs using a Makefile. *Data_type*: bool, optional
`-eco_report`	Specifies the output report file that contains the ECO change information. *Data_type*: bool, optional

`-gen_eco_only`	Generates an eco file that contains general netlist ECO and placement changes. This mode allows you to explicitly review the ECO before applying it to the block DB.  *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `update_module_model` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man update_module_model`
`-interactive`	Invokes independent session in interactive mode. *Data_type*: bool, optional
`-log_dir` *dir_name*	Specifies the log file directory name. *Data_type*: string, optional
`-plugin_tcl` *tcl_commands*	Specifies the TCL commands to be run in a batch independent session. *Data_type*: string, optional
`-return_tag` *tag_name*	Specifies the tag name that will be used to update the specified cell model at the top-level design. *Default*: The default return tag is the tag name of the current loaded block design. *Data_type*: string, optional
`-return_type {flexIlm ilm lef pnr}`	
	Specifies the model type to be brought back to top-level design. The return type can be lef, flexIlm, ilm, or pnr. *Default*: lef *Data_type*: enum, optional
`-tag` *tag_name*	Allows you to explicitly specify the tag name of the cell pnr model that will be loaded. If a tag is not specified, the `update_module_model` command loads the pnr model of the same tag with the currently loaded design (`restore_module_model`). For example, if the currently loaded design has tag *init*, then the `update_module_model` command will load the pnr model of tag *init* for the specified cell. It will display an error if the tag is not available. *Data_type*: string, optional

Example

- The following command opens an independent session in batch mode for the full DB of the cell tdsp_core, tag preCts:

```
update_module_model -cell tdsp_core -return_type ilm -plugin_tcl {
 route_eco
 create_module_model
}
```

Related Information

write_module_model_context

```
write_module_model_context
[-help]
{-cell cellName | -master_clone_inst master_clone_inst}
[-tag tag_name]
[-type {extraction_context timing_context}]
[-type_specific_options type_specific_options]
```

Creates a context model for a specific cell or a master/clone instance. This context model can be loaded additionally with its design later in the flow.

Parameters

`-cell cellName`	Specifies the cell name(s) to be loaded. You can specify a list of cell names. *Data_type*: string, required
`-help`	Outputs a brief description that includes the type and default information for each `write_module_model_context` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_module_model_context`
`-master_clone_inst instance_name`	Specifies the instance name of a master/clone module. Use this option if the instance has clone(s). *Data_type*: string, optional
`-tag tag_name`	Specifies the output tag name. *Default*: latest *Data_type*: string, optional
`-type {extraction_context timing_context}`	Specifies the type of the generated context model. • `extraction_context`: Writes the extraction context information of specified modules/instances. • `timing_context`: Writes the timing context information of specified modules/instances. *Data_type*: enum, optional

`-type_specific_options`	Specifies the options of the type model. • For **`extraction_context`** type of model, the type specific options available are: `{-extension` *`distance`* `| -surrounding_tag` *`name`* `| -ground` *`name`*`}` ○ `-extension` *`distance`* Specifies the block halo distance (in microns) where routing data will be included in an output DEF file. *Default*: 10 ○ `-surrounding_tag` *`name`* Specifies the surrounding object tag name. *Default*: Tag name of the current loaded design. ○ `-ground` *`name`* Specifies the ground net that the surrounding nets will be tied to. • For **`timing_context`** type of model, the type specific options available are: `{-skip_interface_paths	-overwrite	-with_constraints}` ○ `-skip_interface_paths` Specify this option if the module is instantiated many times at the full-chip top design. It preserves the context data impacting only internal reg-reg paths. During analysis with this context data, interface paths will be unconstrained. ○ `-overwrite` Specify this option to overwrite the existing `timing_context` model. It overwrites the existing context data. ○ `-with_constraints` Specify this option to write the SDC file of each of the specified module inside the corresponding sub directories. This option is supported only in SMSC flow and for single instantiated modules. *Data_type*: string, optional

Example

- The following command creates an extraction context model for cell ptn_wrapper with routing data within 50 micron halo distance from ptn_wrapper LEF boundary:

```
restore_module_model dtmf_recvr_core -tag init -noTiming

# Ensure that routing to be cut around specified object should be a LEF
set_module_model -cell ptn_wrapper -type lef -tag my_extract_v1
commit_module_model -mmmc_file design/dtmf_recvr_core.enc.dat/viewDefinition.tcl

earlyGlobalRoute

write_module_model_context -cell ptn_wrapper -tag my_extract_v1 -type_specific_options {-extension 50 -ground vss1 init} -type
extraction_context
```

```

Adds a hierarchical module to the design.

You can use this command after importing a design.

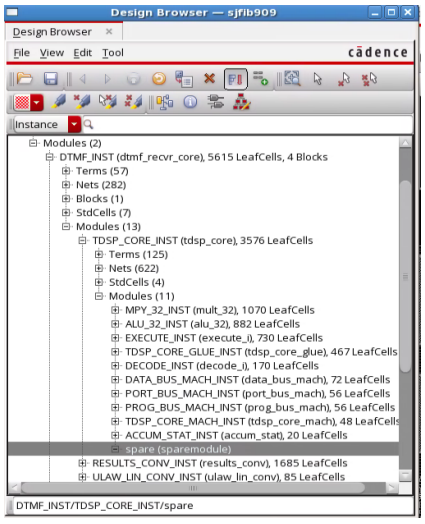
Parameters

`-help`	Outputs a brief description that includes the type and default information for each `addHierInst` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man addHierInst`
`-cell cellName`	Specifies the master of the module. Innovus creates a new, empty master if the cell name is new.
`-hinst hinstName`	Specifies the name of the module instance to add.
`-module moduleName`	Specifies the name of the module instance to add. **Note**: There is no difference between `-module` and `-hinst`. You should use `-module` for backward compatibility. It is recommended to use -hinst.

Examples

- The following command adds a hierarchical instance `DTMF_INST/TDSP_CORE_INST/spare` of module type sparemodule to the design, here DTMF_INST/TDSP_CORE_INST should be an existing hierarchical instance in the design:

  ```
  addHierInst -cell sparemodule -hinst DTMF_INST/TDSP_CORE_INST/spare
  ```



- The following commands create a new module `modA` and hinsts `inst_modA` and `inst_modA_clone` whose master cell is `modA`:

  ```
  addHierInst -cell modA -hinst inst_modA
  ```

```
addHierInst -cell modA -hinst inst_modA_clone
```

The resulting Verilog netlist would have:

```
module modA();

endmodule

modA inst_modA();

modA inst_modA_clone();
```

Related Information

- addModulePort

addInst

```
addInst
[-help]
[-dontSnapToPlacementGrid]
[-moduleBased verilogModule]
[-physical]
-cell cellName
-inst instName
[-loc {x y} [-ori {R0 | R90 | R180 | R270 | MX | MX90 | MY | MY90}]]
[-place_status placementStatus]
```

Adds an instance and places it in the design.

When `-inst` is specified, the instance is bound with the correct cell in the power domain.

When `-inst` and `-loc` are specified, the location also gives a power domain, which is checked against the power domain of the instance. If the power domains are different, a warning is issued.

In a MSV design, a cell specified using the `-cell` parameter should exist in libraries bound to the power domain of the newly added instance.

When `-loc` is specified along with the `-inst` parameter, the power domain given by the location should be consistent with the power domain of the newly added instance.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `addInst` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man addInst`
`-dontSnapToPlacementGrid`	If `-dontSnapToPlacementGrid` is specified, Innovus places the instance at the specified location even if the location is off the placement grid. This parameter is used with `-loc`. *Default*: false
`-moduleBased` *verilogModule*	Adds the new instance to the specified verilog module.
`-physical`	Places a physical instance without updating the netlist.
`-cell` *cellName*	Specifies the master of the instance.
`-inst` *instName*	Specifies the name of the instance to add and place. If the instance name contains special characters, you need to start the part of the instance name, which contains special characters, with a backslash '\' and end it with a space.
`-loc {`*x y*`}`	Specifies the location of the placed instance. *Default:* If you do not specify a location, Innovus places the instance at the design origin.
`-ori {R0 | R90 | R180 | R270 | MX | MX90 | MY | MY90}`	Specifies orientation of the placed instance. *Default:* If you do not specify an orientation, Innovus uses `R0`.
`-place_status` *placementStatus*	Specifies the placement status of the added instance. You can specify the following as the placement status: • `cover`: Specifies that the instance has a location and is a part of a cover macro. It cannot be moved by automatic tools or interactive commands. You must specify the instance's location and its orientation. • `placed`: The status of the added instance is placed. • `fixed`: The status of the added instance is fixed. • `soft_fixed`: The status of the added instance is soft_fixed. It cannot be moved by global placement and can only be moved by the legalization step of detail placement • `unplaced`: The status of the added instance is unplaced. *Default*: `unplaced` **Note:** This option is used along with the `-loc` option. It should not be used along with the `-moduleBased` option.

Examples

- The following command adds buffer instance i1/i2 at location 100, 200:
  ```
  addInst -cell BUF1 -inst i1/i2 -loc 100 200
  ```
- The following command adds buffer instance `insta` to the verilog module `HIER_2`:
  ```
  addInst -moduleBased HIER_2 -cell BUFX2_6 -inst insta
  ```
- The following command adds an instance with base name ant to hierarchy `DTMF_INST/TDSP_CORE_INST/TDSP_CORE_MACH_INST[0].g`:
  ```
  addInst -cell ANTENNA -inst{DTMF_INST/TDSP_CORE_INST/TDSP_CORE_MACH_INST[0].g/ant}
  ```
- The following command adds an instance with base name `TDSP_CORE_INST/TDSP_CORE_MATCH_INST[0].g/ant` to hierarchy `DTMF_INST`:
  ```
  addInst -cell ANTENNA -inst {DTMF_INST/TDSP_CORE_INST\/TDSP_CORE_MATCH_INST[9].g/ant}
  ```

- ecoSwapSpareCell
- loadECO

addModulePort

```
addModulePort
[-help]
moduleName
portName
portDir
[-bus n1:n2]
[-moduleBased]
```

Adds a port or bussed port to a module, specified as a module or a hierarchical instance.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `addModulePort` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man addModulePort`
`-bus n1:n2`	Adds a bussed port to the module. Specify the bus range (the beginning and end of the bus). Use integers to specify the range. If the specified bus already exists, tool will do bus bit resizing. The specified bus bit range must be adjacent to the first or the last bit of the existing bus. Also, it must have the same ascending or descending order as the existing bus.
`-moduleBased`	Specifies if the port is module based.
moduleName	Specifies the name of a hierarchical instance, or a Verilog module if `-moduleBased` is specified, to which you want to add a port. Specify "-" for the top hierarchical instance.
portDir	Specifies the port direction. You can specify the direction as: • `input` • `output` • `bidi`
portName	Specifies the name of the port to be added. The specified *portName* can be a new port name or any of the existing internal net names to which the port will connect in the module. Internal net means net inside the module without connections to any existing port of the module. If the new port name is the same as the existing net name in the module, the net will not connect the port. The new port name will be portName_1. Port Name cannot be the same as any existing port name of the same module. If a bus port is added, the bit port name cannot be the same as any net name in the module.

Examples

- The following command creates an input port `p1` on instance `i1/i2/i3`. The port `p1` must be a new port name in instance `i1/i2/i3`. Instance `i1/i2/i3` contains no nets name p1:
  ```
  addModulePort i1/i2/i3 p1 input
  ```
- The following set of commands adds a hierarchical block and then adds a bussed port to the block.
  ```
  addHierInst -cell i_block -hinst i_block1
  addModulePort i_block1 data output -bus 31:0
  ```
- The following command adds two input bits i1[8] and i1[9] to existing top-level bus port i1[0:7].
  ```
  addModulePort - i1 input -bus 8:9
  ```

Related Information

- `addHierInst`
- `deleteModulePort`

addNet

```
addNet
[-help]
netName
[-bus startID:endID]
[-moduleBased verilogModule]
[-power  | -ground ]
```

Adds a net to the design. The net can be logical or physical.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `addNet` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man addNet`
`-bus` *`startID:endID`*	Specifies the bit range for bus nets. The *`startID`* and *`endID`* indicate the first and last bits on the bus. You must separate the start and end IDs with a colon (:). If the specified bus does not exist, tool will create a bussed Verilog net. If the specified bus already exists, tool will do bus net resizing. The specified bus bit range must be adjacent to the first or last bit of the existing bus. Also, it must have the same ascending or descending order as existing bus. **Note**: PG bus net is not supported
`-ground`	Adds a ground net.
`-moduleBased` *`verilogModule`*	Adds the new net to the specified verilog module. If the module name contains special characters, you need to start the module name with a backslash '\' and end it with a space.
`netName`	Specifies the net to add. If the net name contains special characters, you need to start the part of the net name, which contains special characters, with a backslash '\' and end it with a space. **Note:** You must specify *`netName`* before you specify other parameters. The software issues an error message if you do not specify the *`netName`* first.
`-power`	Adds a power net.

Examples

- The following command adds net `i1/n1`:
  ```
  addNet i1/n1
  ```
- The following command adds one bit i1/n1[6] to existing bus i1/n1[2:5]:
  ```
  addNet i1/n1 -bus 6:6
  ```
- The following command adds three bits i1/n1[-1], i1/n1[0], i1/n1[1] to existing bus i1/n1[2:5]:
  ```
  addNet i1/n1 -bus -1:1
  ```
- The following command adds net with base name ant_net to hierarchy `DTMF_INST/TDSP_CORE_INST/TDSP_CORE_MACH_INST[0].g`:
  ```
  addNet {DTMF_INST/TDSP_CORE_INST/\TDSP_CORE_MACH_INST[0].g /ant_net}
  ```
  Here the "[" and "]" brackets between the backslash and the space are special characters.
- The following command adds net with base name `TDSP_CORE_INST/TDSP_CORE_MATCH_INST[0].g/ant_net` to hierarchy `DTMF_INST`:
  ```
  addNet {DTMF_INST/\TDSP_CORE_INST/TDSP_CORE_MATCH_INST[0].g /ant_net }
  ```
- The following command adds net with base name `ant_net[1]` to `module H[1]`:
  ```
  addNet {\ant_net[1] } -moduleBased {\H[1] }
  ```

Related Information

- deleteNet

attachDiode

```
attachDiode
[-help]
[-prefix prefix]
-diodeCell diodeCellName
-pin instName termName
[-loc x y
[-orient orient]]
```

Adds an antenna diode to a post-routed design. Innovus places the diode as close as possible to the specified pin.

When *instName* is specified, the new instance is bound with the correct cell in the power domain.

When `-loc` is specified, the location also gives a power domain, which is checked against the power domain of the pin. If the power domains are different, a warning is issued.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `attachDiode` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man attachDiode`
`-diodeCell` *diodeCellName*	Specifies the name of the diode cell master
`-loc` *x y*	Specifies the location of the lower left corner of the diode.
`-orient` *orient*	Specifies orientation of the placed diode. To specify this parameter, you must also specify `-loc`.
`-pin` *instName termName*	Specifies the pin associated with the diode.
`-prefix` *prefix*	Specifies the prefix name of the diode cell instances. Innovus appends integers to differentiate the instances.

Example

- The following example adds a diode of type `D1` for `term2` on instance `i2`, at location `500`, `600`:

  ```
  attachDiode -diodeCell D1 -pin i2 term2 -loc 500 600
  ```

attachIOBuffer

```
attachIOBuffer
[-help]
[-baseName baseName]
[-dishonorUpfDomainBoundaryCheckForIsoLsStrategy]
[-excNetFile excNetFileName]
[-excludeClockNet]
[-port]
[-prePlace]
[-selNetFile selNetFileName]
[-skipRefinePlace]
[-suffix suffixName]
{[-in cellNameList] [-out cellNameList]}
[-status {placed fixed softfixed}]
```

Adds buffers/inverters to the I/O pins of a block and places the buffers/inverters near the I/O pins. When a top-level input (output) is connected to a power domain other than the default, the added buffer is matched to the hierarchy of the destination (source) cell and placed inside the power domain.

This command is power-domain aware. To take advantage of this feature when the netlist contains level shifters, load the shifter table before running this command.

Through the `-port` and `-suffix` parameters, you can control the instance and net names created when you use `attachIOBuffer`.

You can use this command after loading a design. Use the `-status fixed` parameter before you run `place_design`.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `attachIOBuffer` paran For a detailed description of the command and all of its parameters, use the `man` command: `man attachIOBuffer`

`-baseName` *baseName*	Specifies the base name of the new nets. For nets with the same base name, you should consider the h and add `1`. For example, if there are several nets with an `abc` base name, ending on `abc98`, then the first same base name is `abc99`. Example: `attachIOBuffer -baseName buf -in BUFX4` Before：  After： `-dishonorUpfDomainBoundaryCheckForIsoLsStrategy`	Dishonors power-domain boundary check for isolation/level-shifter instances.
`-excludeClockNet`	Does not connect the buffer on clock nets. You must trigger the clock net markings prior to running `atta` the `timeDesign` command. To query whether a given clock net is marked, use `dbIsNetClock` *netName*.
`-excNetFile` *excNetFileName*	Specifies the file that contains the names of nets to exclude from the buffer attachment operation.
`-in` *cellNameList*	Specifies the cell name or a list of cell names of the input (`-in`) buffer. If the specified cell is an inverter, `attachIOBuffer` command inserts an inverter pair. **Note:** If the `-in` and `-out` parameters are specified together, both input and output pins will be attached If only `-in` (or `-out`) option is specified, then only input (or output) pins will be attached buffer. If a list of c it will insert the first CPF compliant cell. It is recommended to give non-AO buffers/inverters before AO b the list.

`-out` *cellNameList*	Specifies the cell name or a list of cell names of the output (`-out`) buffer. If the specified cell is an inverte `attachIOBuffer` command inserts an inverter pair. **Note:** If the `-in` and `-out` parameters are specified together, both input and output pins will be attached If only `-in` (or `-out`) option is specified, then only input (or output) pins will be attached buffer. If a list of c it will insert the first CPF compliant cell. It is recommended to give non-AO buffers/inverters before AO b the list.

`-port`	Prepends the port name to the name of the net or instance created. Example: `attachIOBuffer -in BUFX4 -port` Before：  After： 
`-prePlace`	Specifies to legally place the inverter connected to the port and to leave the other inverter unplaced. Example: `attachIOBuffer -in INVX2 -prePlace` `-selNetFile` *selNetFileName*	Specifies the file that contains the names of nets to include in the buffer attachment operation.
`-skipRefinePlace`	Skips legalization of the new buffer/inverter (incremental placement needs to be run later to legalize it).
`-status {placed fixed softfixed}`	Specifies the placement status of the added buffer as placed/fixed/softfixed.
`-suffix` *suffixName*	Appends a string to name of the net or instance created.

Examples

- The following command attaches buffers `bufx4` to the I/O pins. The new nets have a basename of `abc`:
  ```
  attachIOBuffer -baseName abc -in bufx4
  ```
- The following command prepends the port name and appends the `_buf` string to the name of the instance and net created by `attachIOBuffer`:
  ```
  attachIOBuffer -port -suffix "buf"
  ```

Resulting instance name:

```
port1_I_buf
```

Resulting net name:

```
port1_N_buf
```

Related Information

- `place_design`
- `refinePlace`
- `timeDesign`

attachModulePort

```
attachModulePort
[-help]
moduleName
portName
netName
[-noNewPort]
```

Attaches a port in the specified hinst (or top level) to a net.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `attachModulePort`. For a detailed description of the command and all of its parameters, use the man command: man `attachModulePort`
`moduleName`	Specifies the module to which you want to attach the port. To specify the top module, enter '-'.
`netName`	Specifies the net on the module.
`portName`	Specifies the port on the module.
`-noNewPort`	Prevents creation of hierarchical ports if a module port is attached. If the module port does not connect to the net in a different hierarchy through the existing ports, the software displays an error message and the command stops running. *Default*: If you do not specify this parameter, the software creates hierarchical ports as required.

Examples

- The following commands create a port `p1` on hinst `i1/i2/i3` and a net `i1/i2/n1`. The `attachModulePort` command then connects the created port `p1` on hinst `i1/i2/i3` to the net `i1/i2/n1`:

  ```
  addModulePort i1/i2/i3 p1 input
  addNet i1/i2/n1
  attachModulePort i1/i2/i3 p1 i1/i2/n1
  ```

- The following command attaches port `in` on the top module to `net123`:

  ```
  attachModulePort - in net123
  ```

Related Information

- `addNet`
- `detachModulePort`

attachTerm

```
attachTerm
[-help]
[-moduleBased verilogModule]
[-noNewPort]
instName
termName
netName
[-port portName]
[-pin refInstName refPinName]
```

Attaches a terminal to a net. If the terminal already connects to a different net, the software first detaches the terminal from the current net, then attaches it to the new net.

It removes term order dependency while attaching multiple terms to a net, especially when both output and input terms are involved.

Note: Detaching a terminal that drives an output terminal of a module produces a Verilog violation at the output terminal if you use `detachTerm`. Instead, use `attachTerm` to attach the terminal to a new net. The `attachTerm` command automatically detaches the terminal from the net connecting to the output terminal, then attaches the terminal to the net you specify. This command also enables you to specify a hierarchical net name, in addition to a flat net name.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `attachTerm`. For a detailed description of the command and all of its parameters, use the man command: `man attachTerm`
instName	Specifies the instance containing the terminal. If the instance name does not exist, the software displays an error message and the command stops.
`-moduleBased` *verilogModule*	Attaches the terminal to the specified verilog module.
netName	Specifies the name of the net to attach to the terminal. If the net name does not exist, Innovus displays an error message and the command stops.The reserved names of 1'b1 and 1'b0 can be used to set a constant directly on the terminal rather than connect it to a net.
`-noNewPort`	Prohibits Innovus from creating hierarchical ports when it attaches a terminal. If the terminal cannot connect to the net through existing ports, Innovus displays an error message and the command stops. *Default:* If you do not specify this parameter, Innovus creates hierarchical ports as needed.
`-pin` *refInstName refPinName*	Specifies the pin *refPinName* on instance *refInstName* connected to the net that Innovus connects to the terminal. You cannot specify the `-port` parameter if you use this parameter.
`-port` *portName*	Specifies the hierarchical port used to connect the terminal with the net. If you specify this parameter, the hierarchical port must exist in the module that contains the instance. The hierarchical port must connect to the net. This parameter lets you use a specific port to maintain the same netlist topology, which simplifies equivalence checking later in the design flow. You cannot specify the `-pin` parameter if you use this parameter. *Default:* If you do not specify this parameter, Innovus uses existing ports or creates new hierarchical ports as necessary to connect the terminal to the net.
termName	Specifies the name of the terminal that Innovus connects to the specified net. If the terminal name does not exist, Innovus displays an error message and the command stops.

Examples

- The following command attaches terminal `in1` of instance `i1/i2/i3` to net `i1/i2/net26`:

  ```
  attachTerm i1/i2/i3 in1 i1/i2/net26
  ```

  If `i1/i2/i3` does not exist, or if `in1` is not a terminal of `i1/i2/i3`, or if `i1/i2/net26` does not exist, the software displays an error message and the command stops.

- The following command attaches terminal `in1` of instance `i1/i2/i3` to net `net27`, using hierarchical port `myPort`:

  ```
  attachTerm i1/i2/i3 in1 net27 -port myPort
  ```

  The `myPort` port must exist in the module definition for `i1/i2`, and `myPort` must already connect to `net27`. If this is not the case, the software displays an

error message and the command stops.

- The following command attaches terminal `in3` on instance `i1/i2/i3` through existing ports to `net28`:

  ```
  attachTerm -noNewPorts i1/i2/i3 in3 net28
  ```

  If ports do not exist, the software displays an error message and the command stops.
- The following command attaches terminal `Y` of instance `testInst` to the verilog module `hier_t3` using net `testnet`:

  ```
  attachTerm -moduleBased hier_t3 testInst Y testnet
  ```

Related Information

- `detachTerm`

bitblast_ports

```
bitblast_ports
[-help]
topCell|vCell|hInst+
[-bus busname]
```

Bitblasts the specified port bus (or hport bus) of the specified design, module, or module of the specified hinst, so they are scalars rather than bus-bits. This can be useful to allow optimization for flexibility such as changing the inversion of just some bits of the bus. The name of the bitblasted ports will follow the nomenclature specified by the bit_blasted_port_style global variable. The default style is:

%s_%d

where %s is the bus name, and %d is the bus-bit value. Each bus-bit that is renamed is reported for each module that is changed.

Names used for SDC timing constraints can only be modified if they are loaded into the memory. So, you must ensure that all the timing views are loaded with `set_analysis_view` before running this command. You can either write out the modified SDC files with the new names for later usage or write constraints and Tcl scripts in a way that does not use the original bus-bit names.

There is a limitation that port names used inside a CPF power_intent file cannot be changed. CPF usage assumes that the CPF file is golden and should not be modified. If you need to change names used inside a CPF file, you need to update the CPF file manually, and then read in the new CPF file after running `bitblast_ports`. In contrast, an IEEE1801 power_intent file is allowed to change during the design flow, so changing any port names with bitblast_ports will automatically update the IEEE 1801 names. You can write out the new IEEE1801 file with the updated names.

For non-uniquified netlist, if you bit-blast the hinst, the module and the cloned hinsts also get bit-blasted.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `bitblast_ports`. For a detailed description of the command and all of its parameters, use the man command: `man bitblast_ports`
`topCell|vCell|hInst+`	Specifies the list of design|module|hinst.
`-bus` *`busname`*	Bit-blasts just the specified bus (just “A” not “A[3:0]”), rather than all busses for the module.

Examples

- In the following example, the design top has two-bit input port AI:

```
AI[1:0]
@Innovus> bitblast_ports design:top
#New bitblasted names
Module: top
AI[0]      AI_0
AI[1]      AI_1
@Innovus> get_db ports .name
> AI_0 AI_1
```

- In the following example, hinst1 has two-bit port IN:

```
IN[1:0]
@Innovus> bitblast_ports hinst:top/hinst1 -bus IN
#New bitblasted names
Module: mod1
IN[0]      IN_0
IN[1]      IN_1
@Innovus> get_db hinst:top/hinst1 .hports.name
> hinst1/IN_0 hinst1/IN_1
```

- In the following example, design top has 2 two-bit input ports AI, BI:

```
AI[1:0] BI[1:0]
@Innovus> bitblast_ports design:top -bus AI
#New bitblasted names
Module: mod1
IN[0]      IN_0
IN[1]      IN_1
@Innovus> get_db ports .name
> AI_0 AI_1 BI[0] BI[1]
```

You can bit-blast all ports of two different hinsts:

```
>bitblast_ports {hinst:top/h1 hinst:top/h2} > bitblast.rpt
>
```

Related Information

- set_analysis_view

delete_feedthru_buffer

```
delete_feedthru_buffer
[-help]
[-dontDelDanglingPort]
[-non_preferred_keep_nets netNamePattern]
[-preferred_keep_nets netNamePattern]
{{-bufInst bufInstName} | {-instPrefix instPrefixName}
```

Removes the feedthrough buffer specified in the `-bufInst` option. It also removes all possible dangling hterms/hnets that are associated with the buffer removed. The `delete_feedthru_buffer` command supports multiple-instantiated buffer cells.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `delete_feedthru_buffer` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man delete_feedthru_buffer`
`-bufInst bufInstName`	Specifies the name of the feedthrough buffer to be removed.
`-dontDelDanglingPort`	Is used if you do not want to remove the dangling ports created by this command.
`-instPrefix instPrefixName`	Specifies the prefix name for the feedthrough buffer. It removes all buffer instances that were created by the `insertPtnFeedthrough` command if `insertPtnFeedthrough` also used this option to specify the exactly same `instPrefixName`. Therefore, you need to specify exactly the same instance name prefix in the `-instPrefix` option of both the commands. **Note**: The `-instPrefix` specified here must be unique to all instance names in the current design.
`-non_preferred_keep_nets netNamePattern`	Specifies the non-preferred keep net name pattern. The nets whose names match the pattern will not be used by buffer deletion.
`-preferred_keep_nets netNamePattern`	Specifies the preferred keep net name pattern. The nets whose names match the pattern will be used by buffer deletion.

Example

The following command deletes feedthrough buffer `i1/i2/FE_FEED_BUF_1`, and also keeps the dangling ports:

```
delete_feedthru_buffer -bufInst i1/i2/FE_FEED_BUF_1 -dontDelDanglingPort
```

Related Information

- `insertPtnFeedthrough`

deleteBNet

```
deleteBNet
[-help]
[-moduleBased moduleName]
{-bus busName | -busFromBit busBitName}
```

Given a bussed net or a single bit of a bussed net, logically removes the entire bussed net from a design.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `deleteBNet`. For a detailed description of the command and all of its parameters, use the man command: `man deleteBNet`
`-moduleBased moduleName`	Specifies the module name that contains the bus net which needs to be deleted. This parameter is optional.
`-bus busName`	Specifies the base name of the top-level bus net, or the base name of a bus net in verilog module when used with `-moduleBased` option
`-busFromBit busBitName`	Specifies the bus bit name of a top level or a non-top level bus net, or a bus bit name of a bus net in verilog module when used together with the `-moduleBased` option.

⚠ The `deleteBNet` command does not support wildcards.
It is not possible to delete a single bit of a bussed net. To change the bus width of an existing net, the net needs to be deleted and re-created with `addNet`.

Examples

Non-top level bus net

- The following command deletes the bus net x/y/z.

  ```
  deleteBNet -busFromBit x/y/z[2]
  ```

- The following command deletes a bus net from a verilog module, used with `-moduleBased` and `-busFromBit busBitName`.

  ```
  deleteBNet -busFromBit z[2] -moduleBased Y
  ```

- The following command deletes a bus net from a verilog module, used with `-moduleBased` and `-bus busName`.

  ```
  deleteBNet -bus z -moduleBased Y
  ```

Top level bus net

- The following command deletes the top-level bus net, using the option `-busFromBit busBitName`.
  ```
  deleteBNet -busFromBit x[2]
  ```
- The following command deletes the top-level bus net, using the option `-bus busName`.

  ```
  deleteBNet -bus x
  ```

Related Information

- `addNet`

deleteEmptyModule

```
deleteEmptyModule
[-help]
[-deleteEmpty1801Modules]
```

Deletes modules and their instantiations. Modules and their instantiations are deleted if the following criteria are met:

- The netlist is unique
- The module does not contain any instances, or the module contains only unconnected instances of other empty modules
- The instances of the module are not connected to other instances or ports

The `deleteEmptyModule` command does not delete used empty modules, where there exists at least one connected instance of the empty cell. For example, black boxes typically are empty, but they are still connected to other instances or ports.

At times, the lowest hierarchy is connected to the immediate higher-level hierarchy but the module is dangling and should be deleted. You can delete the dangling modules by first deleting the dangling ports followed by the deletion of the empty modules as given below:

```
deleteDanglingPort
```

```
deleteEmptyModule
```

Note: A design can contain empty modules for different reasons. Modules can become empty due to optimization processes. A design also can contain MCPO modules that were read in with the netlist. To convert empty modules into special leaf cells when reading in the netlist, see the `setImportMode` command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `deleteEmptyModule`. For a detailed description of the command and all of its parameters, use the man command: `man deleteEmptyModule`
`-deleteEmpty1801Modules`	Deletes empty UPF modules.

Related Information

- `setImportMode`
- `deleteDanglingPort`

deleteInst

```
deleteInst
[-help]
listOfInst
[-moduleBased moduleName]
[-verbose]
```

Deletes an instance from a design. Innovus checks whether the instance is physical or logical, and deletes the instance accordingly. You can use deleteInst to delete the list of logical instances in one HECO session.

You can use wildcards (`*?`) to specify the instances you want the tool to delete.

As `deleteInst` supports deletion of a list of instance, you can get the list of instances using the `dbGet` command The correct way to use `dbGet` is to use TCL `join` command. The following example shows the correct usage of `deleteInst` command with `dbGet`:

```
deleteInst [ join [dbGet top.insts.name]]
```

Notes:

- If the `deleteInst` command deletes a constrained instance, the command will delete the timing graph to avoid other crashes because constraints would be referring to deleted objects and a message will be displayed.
- The `deleteInst` command cannot be used in the post-mask ECO. Please use `loadECO` *`ecofile`* `-postMask` to delete instances in the post-mask ECO.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `deleteInst`. For a detailed description of the command and all of its parameters, use the man command: man `deleteInst`
`listOfInst`	Specifies the list of the instances to delete.
`-moduleBased` *`moduleName`*	Specifies the name of the Verilog module.
`-verbose`	Prints out the deleted instance message.

Example

- The following command deletes instance `i1/i2`:
  ```
  deleteInst i1/i2
  ```
- The following command deletes all instances whose names begin with `i` inside the hierarchical instance `i1`:
  ```
  deleteInst i1/i*
  ```
- The following command deletes the instance `insta` from the verilog module `HIER_2`:
  ```
  deleteInst -moduleBased HIER_2 insta
  ```
- The following command deletes all instances in the `SPGM` module:
  ```
  deleteInst * -moduleBased SPGM
  ```

Related Information

- `addInst`
- `loadECO`

deleteModulePort

```
deleteModulePort
[-help]
moduleName
portName
[-bus startId:endId]
```

Disconnects the specified port name from its net and deletes the port. Individual bits of a bus cannot be deleted.

Parameters

`-bus startId:endId`	Specifies the startId and the endId of the bus bit. **Note**: • When a bit port or bit net is connected to something else, the bit will notbe removed. • Bus bit ports to be deleted must be adjacent to each other and adjacent to either msb or lsb of the existing bus.
`-help`	Outputs a brief description that includes the type and default information for each `deleteModulePort`. For a detailed description of the command and all of its parameters, use the man command: man `deleteModulePort`
moduleName	Specifies the name of the hierarchical instance whose port is to be deleted. Specify "-" for the top hierarchical instance.
portName	Specifies the name of the port to be deleted. Wildcards are not supported.

Examples

- The following command deletes port '`rst_i`' from the top hierarchical instance:
  ```
  deleteModulePort - rst_i
  ```
- The following command deletes all bits of the bus port '`data_i`' of the hierarchical instance `moduleB_inst`:
  ```
  deleteModulePort moduleA_inst/moduleB_inst data_i
  ```
- The following command deletes bus bits out[7], out[6], out[5], and out[4] from existing top-level bus port out[7:0]:
  ```
  deleteModulePort - out -bus 7:4
  ```

Related Information

- `addModulePort`

deleteNet

```
deleteNet
[-help]
netName
[-bus startId:endId]
[-moduleBased verilogModule]
```

Logically deletes nets from a design. If a net is routed, wire segments associated with the net are also deleted.

If you plan to call `ecoRoute -modifyOnlyLayers bottomLayer:topLayer` later, ensure that the net to be deleted only has wire segments on the specified layer.

Note: To delete wire segments associated with a net without deleting it logically, use the `editDelete` command.

You can use wildcards (`*?`) to specify the nets you want Innovus to delete.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `deleteNet`. For a detailed description of the command and all of its parameters, use the man command: man `deleteNet`
`-bus startId:endId`	Deletes the specified bus bits. The specified bus bit net must be a one pin net, which means that the bus bit net is floating on the other side. The specified range must be adjacent to the most significant bit or the least significant bit of the existing bus. Also, it must have the same ascending or descending order as the existing bus. **Note**: PG bus net is not supported.
`-moduleBased verilogModule`	Deletes the net from the specified verilog module.
netName	Specifies the name of the net to delete.

Example

- The following command deletes one bit h1/net2[3] from existing bus h1/net2[3:0]:
  ```
  deleteNet h1/net2 -bus 3:3
  ```
- The following command deletes two bits h1/net2[3], h1/net2[2] from existing bus h1/net2[3:0]:
  ```
  deleteNet h1/net2 -bus 3:2
  ```
- The following command deletes `net1`:
  ```
  deleteNet net1
  ```
- The following command deletes all nets whose name begin with `net1`:
  ```
  deleteNet net1*
  ```

Related Information

- `addNet`
- `ecoRoute`
- `editDelete`

deleteNotchFill

`deleteNotchFill`

Deletes all gaps, notches, acute angles, and hole geometries that were inserted by the `fillNotch` command. Also deletes geometry with + SHAPE DRCFILL in DEF.

- A gap is a minimum spacing violation.
- A notch is a minimum step violation.
- An acute angle is a 45 degree violation.
- A hole is a minimum enclosed area violation.

Parameters

None

Related Information

- `fillNotch`
- ECO Flows chapter in the *Innovus User Guide*

deleteUninstantiatedModules

```
deleteUninstantiatedModules
[-help]
[-reportOnly]
```

Deletes uninstantiated modules.

Parameters

`-help`	Prints out the command usage. For a detailed description of the command, use the man command: `man deleteUninstantiatedModules`
`-reportOnly`	Reports all uninstantiated vcells instead of deleting them. All uninstantiated vcells will be deleted if `-reportOnly` is not specified. *Data_type*: bool, optional

Related Information

- ECO Flows chapter in the *Innovus User Guide*

detachModulePort

```
detachModulePort
[-help]
hinstName
portName
```

Detaches the net connected to the specified port on the specified hierarchical instance.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `detachModulePort`. For a detailed description of the command and all of its parameters, use the man command: man `detachModulePort`
`hinstName`	Specifies the name of the hierarchical instance. To detach a top-level port, specify "-" as the *`hinstName`*. For example, the following command detaches the port 'a' from the net connected to it: `>detachModulePort - a`
`portName`	Specifies the port on the module.

Example

- The following command detaches port `p1` from `moduleA`:
  ```
  detachModulePort moduleA p1
  ```

Related Information

- `attachModulePort`
- `deleteModulePort`

detachTerm

```
detachTerm
[-help]
[-moduleBased verilogModule]
instName
termName
[netName]
```

Disconnects a terminal from a net.

Note: Detaching a terminal that drives an output terminal of a module produces a Verilog violation at the output terminal if you use `detachTerm`. Instead, use `attachTerm` to attach the terminal to a new net. The `attachTerm` command automatically detaches the terminal from the net connecting to the output terminal, then attaches the terminal to the net you specify.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `detachTerm`. For a detailed description of the command and all of its parameters, use the man command: man `detachTerm`
`instName`	Specifies the instance that contains the terminal you want to detach.
`-moduleBased` *`verilogModule`*	Detaches the terminal from the verilog module.
`netName`	Specifies the net that is already connected to the terminal. If the terminal does not connect to the specified net, or if the net does not exist, the software displays an error message and the command stops. The software uses this parameter for error checking only.
`termName`	Specifies the terminal to disconnect. If the terminal does not exist on the specified instance, the software displays an error message and the command stops.

Example

- The following command disconnects terminal `in1` of instance `i1/i2/i3`:

  ```
  detachTerm i1/i2/i3 in1 i1/i2/net26
  ```

  If instance `i1/i2/i3` does not exist, or terminal `in1` is not a terminal of `i1/i2/i3`, the software displays an error message and the command stops. The net `i1/i2/net26` is specified, so if net `i1/i2/net26` does not exist, or if the terminal is not already connected to net `i1/i2/net26`, the software displays an error message and the command stops.

Related Information

- `attachTerm`

displayBufTree

```
displayBufTree
[-help]
-net netName
[-outfile fileName]
```

Displays a buffer tree associated with the specified net.

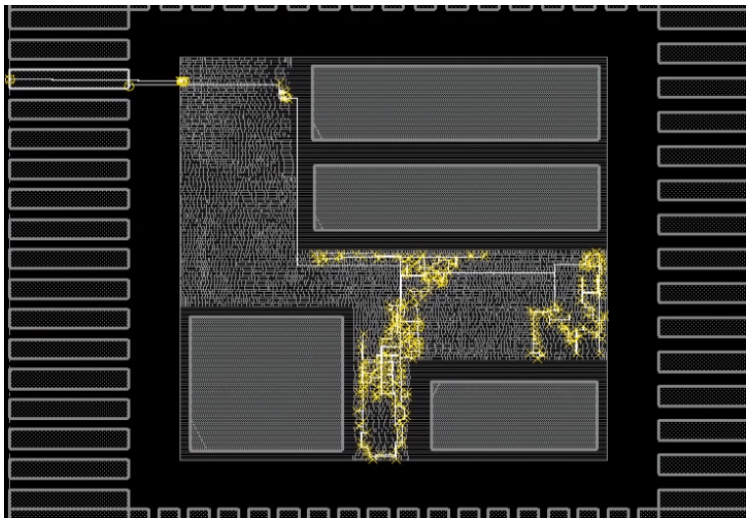
Parameters

`-help`	Outputs a brief description that includes type and default information for each `displayBufTree` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man displayBufTree`.
`-net netName`	Specifies the name of the net for which you want to display the buffer tree.
`-outfile fileName`	Specifies the text file containing buffer locations.

Example

- The following command highlights instances and wires in the buffer tree associated with the net `reset` in the design display area:

```
displayBufTree -net reset
```



```
displayBufTree -outfile reset_buftree
```

```

ecoAddRepeater

```
ecoAddRepeater
[-help]
{-net netName | -term term1 term2… }
[-hinstGuide hinstName | -spreadDist distance | -spreadCount number ]
[-name instName | -spreadDist distance | -spreadCount number ]
[-spreadDist distance | -spreadCount number ]
[-newNetName netName | -spreadDist distance | -spreadCount number ]
[-loc {xLoc yLoc} | { xLoc yLoc inv_xLoc inv_yLoc} | -offLoadAtLoc {x1a y1a x1b y1b x2a y2a x2b y2b ....} | { xLoc yLoc inv_xLoc inv_yLoc} |
-offLoadSlack slack | -spreadDist distance | -spreadCount number ]
[-radius µm | -logicalChangeOnly | -spreadDist distance | -spreadCount number ]
[-offLoadAtLoc {x1a y1a x1b y1b x2a y2a x2b y2b ....} | { xLoc yLoc inv_xLoc inv_yLoc} | -offLoadSlack slack | -spreadDist distance | -
spreadCount number ]
[{[-loc {xLoc yLoc} | { xLoc yLoc inv_xLoc inv_yLoc}]
[-relativeDistToSink sinkWeight]
[-offLoadAtLoc {x1a y1a x1b y1b x2a y2a x2b y2b ....} | { xLoc yLoc inv_xLoc inv_yLoc}]} [ -radius µm ] ]
[-loc {xLoc yLoc} | { xLoc yLoc inv_xLoc inv_yLoc} [-bufOrient {R0 | R90 | R180 | R270 | MX | MX90 | MY | MY90}]]
[-net netName [-spreadDist distance]]
[-spreadPrefix prefix]] [-spreadDist distance [-firstSpreadDist distance]]
[-cell cell1 cell2]
[-relativeDistToSink sinkWeight | -offLoadAtLoc {x1a y1a x1b y1b x2a y2a x2b y2b ....} | { xLoc yLoc inv_xLoc inv_yLoc} | -offLoadSlack
slack | -spreadDist distance | -spreadCount number ]
[-loc {xLoc yLoc} | { xLoc yLoc inv_xLoc inv_yLoc} | -noPlace ]
```

Adds either a single buffer or two inverters on a net. This allows you to optionally specify the location and radius, the location relative to the sink pin, and the buffer insertion based on the slack. This command also checks for and observes power domains based on the specified instance name and location. This command cuts wires by default.

This command does not modify `dont_touch` nets if `setEcoMode -honorDontTouch` is set to `true`.

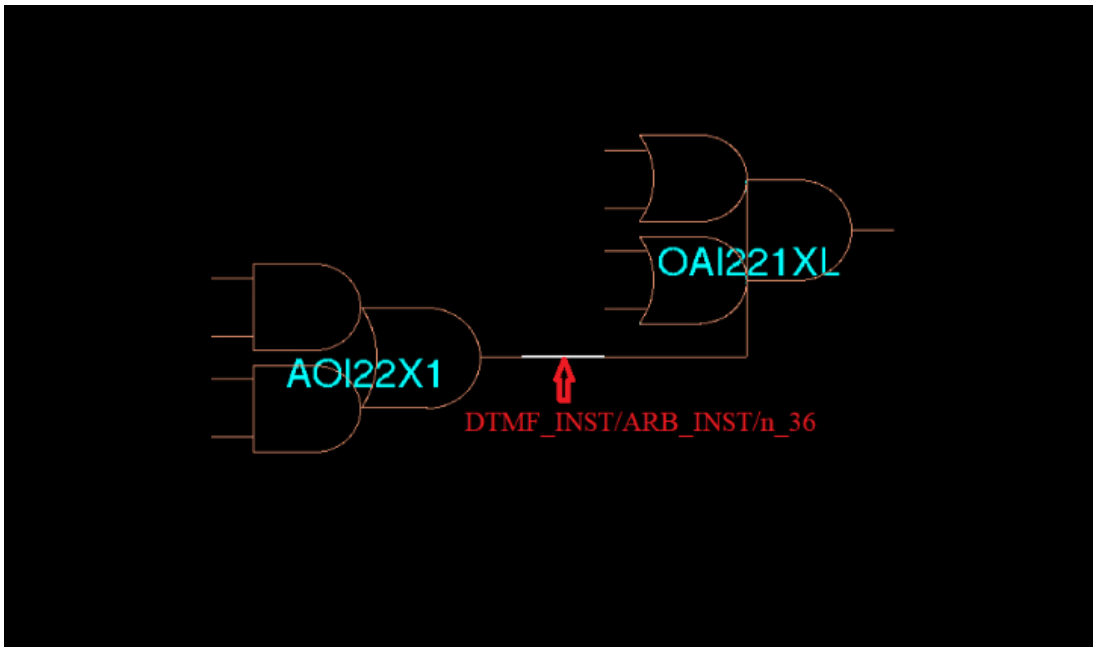
Notes:

- The `ecoAddRepeater` command is simultaneous setup/hold and MMMC aware. To make the command simultaneous setup/hold aware, set the global variable `set_global timing_enable_simultaneous_setup_hold_mode` to `true`. The simultaneous setup/hold mode can only be used for timing analysis. It cannot be used for any physical implementation steps.
  By default, if you specify an inverter as the master cell, `ecoAddRepeater` adds a pair of inverters but if you set `setEcoMode -LEQCheck` as `false`, `ecoAddRepeater` adds a single inverter only.
- `ecoAddRepeater` can return new instance and net name: `newInstName inputNet outputNet`
  Example
  ```
  set result [ecoAddRepeater -net s2_hresp0 -cell inv_32 \
  -loc {1069.018666 128.2435714}]
  set newInstName [lindex $result 0]
  set inputNetName [lindex $result 1]
  set outputNetName [lindex $result 2]
  ```
  If a pair of inverter is added then the return list could be the following, assuming `inv1OutputNet` drives the input pin of `inv2InstName`:
  ```
  {inv1InstName inv1InputNet inv1OutputNet inv2InstName inv2InputNet inv2OutputNet}
  ```
- When `ecoAddRepeater` is used in the post-mask ECO, ensure that it is used with the `-noPlace` option to avoid base layer change. Also, call `ecoPlace -useSpareCells` or `ecoSwapSpareCell` to map the new repeater to the spare cell. If you plan to call `ecoRoute -modifyOnlyLayers bottomLayer:topLayer` later, ensure that the added repeater can be connected through the specified layer. Otherwise, please do not use the `ecoAddRepeater` command. You can also use `loadECO <ecofile> -postMask` to add repeaters in the post-mask ECO.

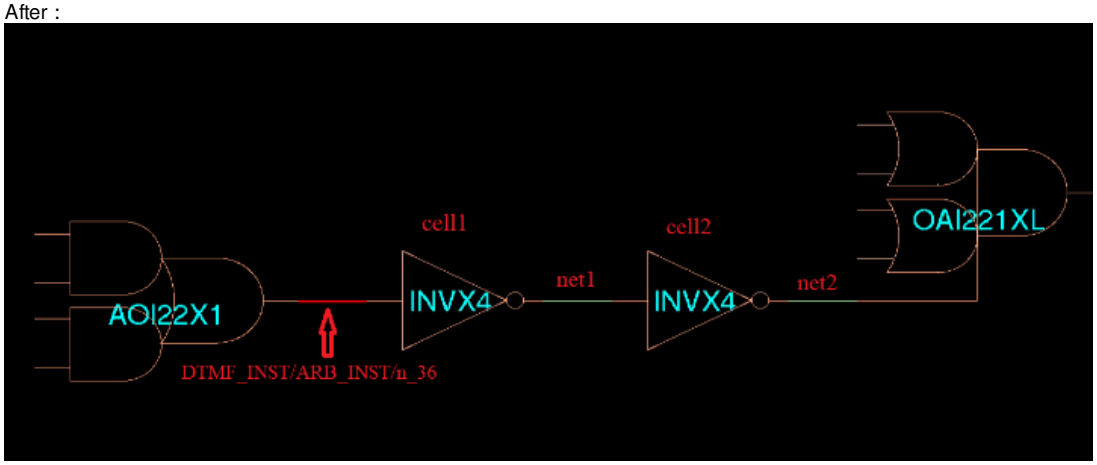
Parameters

`-help`	Outputs a brief description that includes the type and default information for each `ecoAddRepeater`. For a detailed description of the command and all of its parameters, use the man command: man `ecoAddRepeater`

`-bufOrient {R0 | R90 | R180 | R270 | MX | MX90 | MY | MY90}`	Specifies the legalized orientation for the instance. Valid orientation values are: R0, R90, R180, R270, MX, MX90, MY, MY90. **Note**: The `-loc` option is required with `-bufOrient`. For more information on orientation keys, see "Orientation Key" in the Floorplanning the Design chapter of the *Innovus User Guide*.
`-cell` *cell1 cell2 ...*	Specifies the name of the cell(s) which is to be inserted as repeater.
`-firstSpreadDist` *distance*	Specifies the distance (from the driver) after which the first repeater is to be added. With the `-firstSpreadDist` option, you must specify `-spreadDist`. *Minimum*: 2.2250738585072e-308 *Maximum*: 1073741.823
`-hinstGuide` *hinstName*	Indicates the module hierarchy in which the `inst` is inserted by Tempus or a third party tool so that Innovus is able to make the association in case the instance appears in the `-termList` option of an ECO command at a later stage. This option can be only used when `setEcoMode -batchMode true` command is specified. You also need to specify the `-name` option along with it.
`-loc {x y | x1 y1 x2 y2}`	Specifies the x and y coordinates for the location of the buffer or inverter pair to insert. If no location is specified, the tool will automatically determine a location. • If the cell is a buffer and location is specified, the newly created buffer is placed at the specified location (x y). • If multiple buffers are added in the same `ecoAddRepeater` command, the buffers are added in the order of their locations, starting from the buffer farthest from the net's driver. • If the cell is an inverter pair and two locations are specified, the first inverter will be placed at location (x1 y1) and the second inverter will be placed at location (x2 y2). • If the cell is an inverter pair and only one location is specified, both inverters will be placed at the same location (x y).
`-logicalChangeOnly`	Specifies that buffer/inverter addition should be done in the logical-only mode.
`-name` *instName*	Specifies the base name for the repeater to be inserted. When `-cell` is inverter, you can specify two names for inverter pair enclosed in {{ }}.
`-net` *netName*	Specifies the name of the net where the buffer will be inserted.
`-newNetName` *netName*	Specifies the base name for the new net created for the repeater insertion. When `-cell` is inverter, you can specify two names for inverter pair enclosed in {{ }}. Example：`ecoAddRepeater -net DTMF_INST/ARB_INST/n_36 -cell INVX4 -name {{cell1 cell2}} -newNetName {{net1 net2}}` Before：



After :



`-noPlace`	Specifies that the inserted cells should not be placed. Only the logical change in connectivity will be made.
`-offLoadAtLoc {x1a y1a x1b y1b x2a y2a x2b y2b ....}`	Specifies the location(s) at which buffer (or inverter-pair) should be inserted to drive the sinks downstream from the location(s).
`-offLoadSlack` *slack*	Inserts a buffer to offload the paths with less than the specified slack threshold from the driver of a net with multiple cells. This option ignores the *term* option, if it is provided. This option is used to connect the added buffer to drive only noncritical receivers, selected By Slack. This checks the timing graph for noncritical receivers and offloads those from the critical path, and could improve critical path timing by penalizing noncritical path delays. **Note**: • The `-offLoadAtLoc` and `-offLoadSlack` options are mutually exclusive. • The `-loc` and `-offLoadSlack` options are mutually exclusive.

`-radius µm`	Specifies the radius in which the added instances are free to move. If no legal location can be found in the specified radius, the cells would be placed at the specified location resulting in an overlap with other cells. In that case, you should perform legalization. **Note**: When the `-radius` option is used in `ecoAddRepeater`, `{[-loc] [-relativeDistToSink] [-offLoadAtLoc]}` must be specified.
`-relativeDistToSink` *sinkWeight*	Specifies the location of the buffer based on its distance from the sink or the driver pin. The value is a number between 0 and 1. A low value (0.1) places the buffer near the sink; a high value (0.9) places the buffer near the driver. The fraction is based on the length of the wire. This option works: • When one `term` is provided; it does not work if no `term` or multiple terms are specified. • When `-net` with 1-sink net is provided. It does not work if the specified net is not a 1-sink net.
`-spreadCount` *number*	Specifies the number of repeaters to be added for buffering. *Minimum*: 1 *Maximum*: INT_MAX
`-spreadDist` *distance*	Specifies the distance (starting from the driver) after which repeaters are to be added. *Minimum*: 2.2250738585072e-308 *Maximum*: 1073741.823
`-spreadPrefix` *prefix*	Specifies the prefix to be used for new instances and nets added during the spread buffering.
`-term` *term1 term2…*	Specifies a list of terms. The terms specified in the list should be connected to a common net and the tool adds buffer to the common net. If `-term` is not specified, all the terms of the net will be buffered.

Note: You can specify the following in the `setEcoMode` command:

```
setEcoMode -honorFixedStatus false #to modify FIXED instance.

setEcoMode -honorDontUse false #to modify instances which have dontUse attribute on cells.

setEcoMode -honorDontTouch false #to modify instance/nets which are marked dontUse.

setECOMode -honorFixedNetWire false #to insert a cell on wires with the FIXED/COVER status and change the status of these wires from
FIXED/COVER to ROUTED.
```

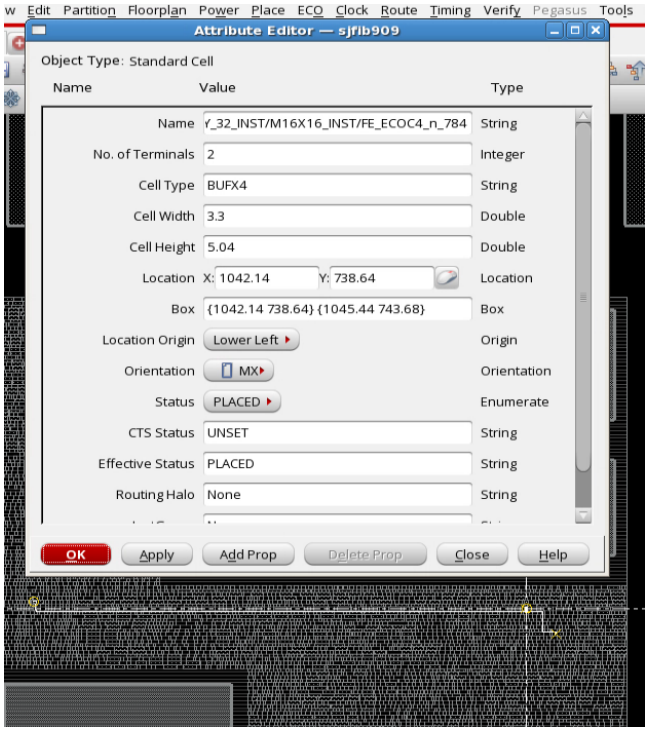
Examples

- The following syntax shows multiple buffer insertion:

  ```
  ecoAddRepeater  {-net|-term}  [-relativeDistToSink 0|1]  -cell {cell1 cell2 cell3..} [-loc <loc1> <loc2> <loc3>..] [-bufOrient
  <orient1> <orient2> <orient3>] [-name <name1> <name2> <name3>..] [-newNetName  <name1> <name2> <name3>...]
  ```

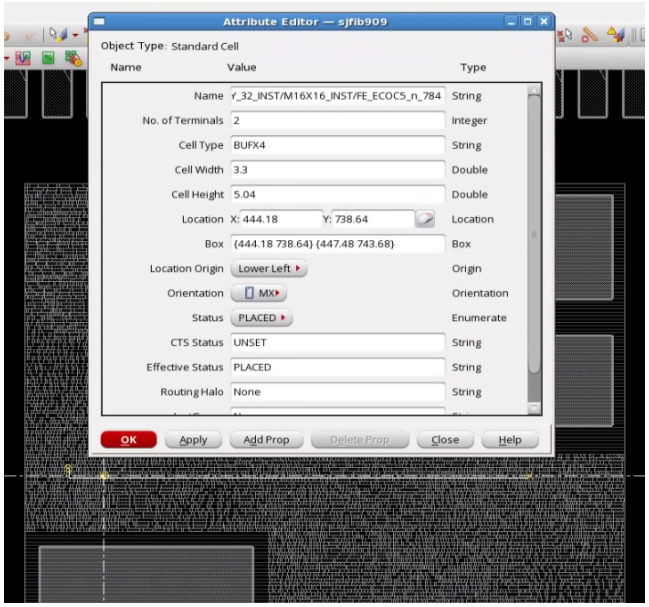
- The following command adds a buffer near the receiver:

  ```
  ecoAddRepeater -net DTMF_INST/TDSP_CORE_INST/MPY_32_INST/M16X16_INST/n_784 -cell BUFX4 -relativeDistToSink 0.1
  ```



- The following command adds a buffer near the driver:

  ```
  ecoAddRepeater -net DTMF_INST/TDSP_CORE_INST/MPY_32_INST/M16X16_INST/n_784 -cell BUFX4 -relativeDistToSink 0.9
  ```



- The following command adds a buffer in a specified location
  ```
  ecoAddRepeater -net wire_I10 -loc {51.5 85.67} -cell BUFFX4
  ```
- The following command adds a buffer by specifying the terminal list:
  ```
  ecoAddRepeater -net n1 -cell INVX4 -term {i1/i2/in1 i1/i2/in2 i1/i2/in3}
  ```
- The following command adds an inverter pair by specifying the slack time:
  ```
  ecoAddRepeater -net wire1_B2 -cell INVX4 -offLoadSlack -0.1
  ```
- The following command adds an inverter pair:
  ```
  ecoAddRepeater -net myNet -cell INVX4 -loc {123 450 145 480} -name {{cell1 cell2}} -newNetName {{net1 net2}}
  ```
- The following command adds inverter pairs and multiple buffers:
  ```
  ecoAddRepeater -cell {inv_1 inv_2} -offLoadAtLoc  {x1a y1a x1b y1b x2a y2a x2b y2b}
  ```
  In the above example, {x1a y1a } {x1b y1b} buffers are for inverter pair 1 (inv_1) and {x2a y2a} {x2b y2b} buffers are for inverter pair2 (inv_2).

Related Information

- `ecoDeleteRepeater`
- `ecoPlace`
- `ecoSwapSpareCell`
- `setEcoMode`
- `timing_enable_simultaneous_setup_hold_mode`
- For more information on orientation keys, see "Orientation Key" in the Floorplanning the Design chapter of the *Innovus User Guide*.

ecoChangeCell

```
ecoChangeCell
[-help]
-cell list_of_cells |-upsize | -downsize
-inst instNames
[-loc {xLoc yLoc} [-orient {R0 | R90 | R180 | R270 | MX | MX90 | MY | MY90}]]
[-pinMap oldpin1 newpin1 oldpin2 newpin2 ...]
```

Upsizes or downsizes the specified instance based on the available footprint. Cell mapping is also possible as long as the output pins are functionally the same. This command also checks for and observes power domains.

This command does not modify `dont_touch` nets if `setEcoMode -honorDontTouch` is set to `true`.

Note: If you use the `ecoChangeCell` command to modify a `fixed' instance, the software issues a warning message.

Instead, you can specify the following using the `setEcoMode` command:

- `setEcoMode -honorFixedStatus false`, to modify FIXED instance.
- `setEcoMode -honorDontUse false` to modify instances which have dontUse attribute on cells.
- `setEcoMode -honorDontTouch false` to modify instance/nets which are marked dontTouch.

Notes:

- The `ecoChangeCell` command is simultaneous setup/hold and MMMC aware. To make the command simultaneous setup/hold aware, set the global variable `set_global timing_enable_simultaneous_setup_hold_mode` to `true`. The simultaneous setup/hold mode can only be used for timing analysis. It cannot be used for any physical implementation steps.
- When resizing instances inside multiple-instantiated blocks, the resize would be applied to all instantiations of the block.
- You can change a buffer to a pair of inverters using the `ecoDeleteRepeater` and `ecoAddRepeater` commands. You can change a buffer to an inverter by first using `setEcoMode -LEQCheck false` and then using `ecoChangeCell`. However, please note that it results in the change in logic.
- The `ecoChangeCell` command cannot be used in the post-mask ECO. Please use l`oadECO <ecofile> -postMask` to change cells in post-mask ECO.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `ecoChangeCell`. For a detailed description of the command and all of its parameters, use the man command: `man ecoChangeCell`
`-orient {R0 | R90 | R180 | R270 | MX | MX90 | MY | MY90}`	Specifies the legalized orientation for the instance. You can specify this parameter with the `-loc` parameter only.
`-inst instNames`	Specifies the names of the instances to be changed.
`-loc {xLoc yLoc}`	Specifies the legalized location where the instance will be placed.
`-upsize`	Upsizes the specified instance with the next available cell in the same footprint unless the specified cell is already of the highest driving strength. Upsizing an instance that drives a large load can improve the driver delay and the transition time at the receivers.
`-downsize`	Downsizes the specified instance with the next available cell in the same footprint unless the specified cell is already of the lowest driving strength. Downsizing an instance on the noncritical path can reduce the loading of its driver on the critical path.
`-cell list_of_cells`	Specifies the name of a specific cell(s) to be substituted in the design. The function of the original cell has to match the function of the new cell for all the outputs used by the old cell. The original master cell and the new master cell must have exactly same number of pins.
`-pinMap oldpin1 newpin1 oldpin2 newpin2`	Specifies the pin mapping for the new cell based on the old cell. This option is required if the new master cell has different pin names than the original cell. The net connected to *oldpin1* of the original cell should be connected to *newpin1* of the new cell, and so forth.

Examples

- Upsizes the specified instance:
  ```
  ecoChangeCell -inst Top_I18 -upsize
  ```

- Downsizes the specified instance:
  ```
  ecoChangeCell -inst Top_I18 -downsize
  ```
- Modifies the specified instance according to the specified cell:
  ```
  ecoChangeCell -inst Top_I18 -cell BUFX20
  ```
- Changes to another cell with a different pin name:
  ```
  ecoChangeCell -inst Top_I27 -cell TXOR2X2 -PINMAP A X B Y Y Z
  ```
- Downsizes the specified instance:
  ```
  ecoChangeCell -inst Top_I18 -downsize
  ```

Related Information

ecoCompareNetlist

```
ecoCompareNetlist
[-help]
-def referenceFileName
[-logical]
[-outfile fileName]
[-outputPhysicalInstInFile physicalInstFile]
[-referenceData {inMemory | external}]
```

Compares a specified netlist with the design in the database for structural or logical equivalence, and creates a file containing the differences found.

`ecoCompareNetlist` supports bus top-level port comparison.

ecoDisableNetRenamingForFlatNetlist

Global variable `ecoDisableNetRenamingForFlatNetlist` is introduced. If it is set to `1`, there would not be any net renaming for flat netlist. Net renaming will take place if net name is hierarchical and the terms it connects to do not fall under the same hierarchy or lies up in the hierarchy. Do `set ecoDisableNetRenamingForFlatNetlist 1` before the `ecoCompareNetlist` command to disable net renaming for flat netlist.

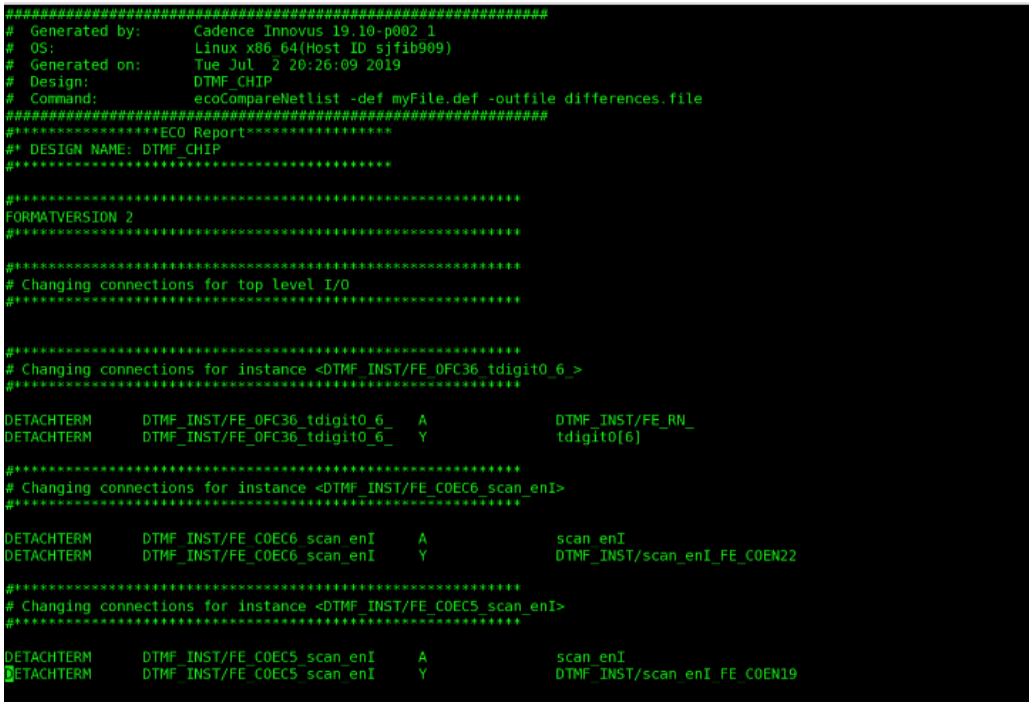
Parameters

`-help`	Prints out the command usage.
`-def referenceFileName`	Specifies the name of the DEF file that Innovus uses to compare with the design.
`-referenceData [inMemory | external]`	Specifies the data from where the post-ECO netlist is to be compared. • `inMemory` compares the post-ECO netlist to the netlist in memory. `inMemory` is the default behavior. • `external` compares the post-ECO netlist to an external netlist.
`-logical`	Compares the netlists for logical equivalence.
`-outfile fileName`	Specifies the file that contains the differences between the specified DEF file and the design in the database. If the directory specified to save the file does not exist, the tool creates the directory. For example, in the following command if `a/` does not exist, the tool will create it: `ecoCompareNetlist -def test.def -outfile ./a/test.rpt`
`-outputPhysicalInstInFile physicalInstFile`	When this option is specified, physical instance eco command is also written to eco file, and the added physical instances names one per line are dumped into the `physicalInstFile` file.

Example

- The following command compares the `myFile.def` file against the design, and writes the results to `differences.file`:

```
ecoCompareNetlist -def myFile.def -outfile differences.file
```



Related Information

- `ecoDisableNetRenamingForFlatNetlist`

ecoDefIn

```
ecoDefIn
[-help]
[-postMask [-suffix suffixName]]
[-useGACells GACoreSite]
[-reportFile fileName]
[-cleanFEData]
[-keepInstLoc]
[-mergeFloatingRouteToPGNet netName]
[-ecoDef {new_DEF_fileName}]
filename
```

Restores physical information from an old design and compares this information with the design in memory. This command uses the specified DEF file in the following ways for pre-mask and post-mask ECO:

- Used in pre-mask mode (without the `-postMask` parameter) this command behaves as follows:
  - New cells and nets
    Cells that exist in memory but not in the DEF file become unplaced.
  - Deleted cells or nets
    Cells and nets that exist in the DEF file but not in memory are discarded.
  - Modified nets
    Nets found both in the DEF file and in memory, but whose connections are different, are marked as "modified" for further processing during `ecoRoute`.
  - Matched cells/nets
    Nets and cells that exist both in the DEF file and in memory, and have the same connections, are placed as described in the DEF file. This includes the soft matching capability used in `defIn`.

Soft matching happens when a DEF net name does not have an equivalent name and another net is found in memory, that has the same connections as described in the DEF file.

The most common case for soft matching is when nets have multiple aliases in a hierarchical design `"net1" = "inst1/net2" = "inst1/inst2/net3"` and so on. Any of these net names can be used in the DEF and can have the same connections.

Without soft matching, net `a', for example, is removed and net `b' is created in it's place, resulting in ripping of the wire.

- In post-mask mode (with the -postMask parameter), the software can only change nets, not cells. This command behaves as follows:
  - New added cells and nets
    Cells that exist in memory but not in the DEF file become unplaced. Later, these cells will be mapped to spare cells when you use `ecoPlace-useSpareCells`.
  - Deleted cells
    Cells and instances that exist in DEF but not in memory are added to a spare cell list in Innovus: They are not discarded. Deleted cells are renamed with their original name and the suffix you specify. The default suffix is `_SPARE`. For example, `cellA` is renamed `cellA_SPARE`. The software retains deleted nets and their routing, which `ecoRoute` reroutes later.
  - Deleted nets
    Nets that exist in DEF but not in memory are kept and processed later when you use the `ecoRoute` command.
  - Modified nets
    Same behavior as in the pre-mask mode.
  - Matched cells and nets
    Same behavior as in the pre-mask mode.
  - Physical cells
    Cells that exist in the DEF file but not in memory, which are marked with `+SOURCE DIST` in the DEF file, are restored.

If you specify `-useGACells`, this implies a post-mask mode. This option behaves as follows:

- For cells that match the specified GA core site:
  - New added GA cell that exists in memory but not in the DEF file are left unplaced.
  - New GA cells that exist in the DEF file but not in memory are deleted.
- For cells that do not match the specified GA core site, the software treats them as standard cells as described in `-postMask` mode.

If you specify a report filename, this command reports the following information:

- New cells and nets found in memory but not in the DEF file
- Deleted cells and nets found in DEF but not in memory
- Nets whose connection does not match
- Cells and nets that match in Innovus and DEF

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `ecoDefIn`. For a detailed description of the command and all of its parameters, use the man command: `man ecoDefIn`
`-cleanFEData`	Specifies that the routed data is DRC clean. ECO routing will skip routing analysis.
`-ecoDef {new_def_fileName}`	Specifies the name of a partial DEF file. The tool compares the original routed DEF file or Innovus database with this file and marks the changed instances, changed location of the existing instances, and changed segments or wires.
fileName	Specifies the name of the routed/original DEF file to load.
`-keepInstLoc`	Applies the placement status and location of the instance in the DEF file to the instance in db. This option is only applicable in the following special situation: When an instance in DEF file and an instance in db have the same name but the master cell of the instance in the DEF and in the db do not match, then the instance in DEF is considered as deleted while the instance in db is added. In this case, if the option is not specified, the general rule for addition or deletion of an instance is applied as described earlier. For the added instance, the placement status is set to unplaced. If the option is specified, the placement status and location of the instance in the DEF file is applied to the instance in db.
`-mergeFloatingRouteToPGNet` *netName*	Merges the routing data to the specified PG net. In this case, the physical-only net will not be created. When this parameter is not specified, if a net is deleted in the new netlist but exists in the DEF file, then the `ecoDefIn` command discards the net in pre-mask ECO and creates a physical-only net in post-mask ECO to preserve the routing data on the net.
`-postMask`	Runs this command in post-route mode.
`-reportFile` *fileName*	Specifies the name for the report generated by the `ecoDefIn` command. *Default:* `ecoDefIn.rpt`
`-suffix` *suffixName*	Appends the specified suffix to cells that appear in the DEF file but have been deleted in the new netlist. *Default:* `_SPARE`
`-useGACells` *GACoreSite*	Specifies the GA Core Site.

Examples

The following example reads a DEF file, `myOld.def`, for post-mask ECO.

```
ecoDefIn -postMask -suffix _SPARE -reportFile ecoDefIn.rpt myOld.def
```

When the software converts a deleted instance to a spare cell, it adds the `_SPARE` suffix to the instance. This command generates a report `ecoDefIn.rpt`.

The following example shows a report file:

```
DELINST DTMF_INST/TDSP_CORE_INST/PROG_BUS_MACH_INST/i_9649 INVX1
(converted to spare cell
DTMF_INST/TDSP_CORE_INST/PROG_BUS_MACH_INST/i_9649_SPARE)

ADDINST DTMF_INST/TDSP_CORE_INST/PROG_BUS_MACH_INST/i_9649 BUFX8
MODIFYNET dtmf_chip_TIELO_Y_r2c1
ADDNET DTMF_INST/UNCONNECTED_000
ADDNET DTMF_INST/UNCONNECTED_001
ADDNET DTMF_INST/TDSP_CORE_INST/UNCONNECTED_000
ADDNET DTMF_INST/TDSP_CORE_INST/UNCONNECTED_009
ADDNET DTMF_INST/TDSP_CORE_INST/UNCONNECTED_010
```

Related Information

- ecoPlace
- ecoRoute

ecoDeleteRepeater

```
ecoDeleteRepeater
[-help][
-logicalChangeOnly]
{ -inst {list_of_instances} | -invPair {{inv1 inv2} {inv3 inv4} ...} }
```

Deletes a buffer or pair of inverters connected back-to-back. This command merges wires after ECO.

This command does not modify `dont_touch` nets if `setEcoMode -honorDontTouch` is set to `true`.

Notes:

- The `ecoDeleteRepeater` command is simultaneous setup/hold and MMMC aware. To make the command simultaneous setup/hold aware, set the global variable `set_global timing_enable_simultaneous_setup_hold_mode` to `true`. The simultaneous setup/hold mode can only be used for timing analysis. It cannot be used for any physical implementation steps.
- The `ecoDeleteRepeater` command cannot be used in the post-mask ECO. Please use `loadECO <ecofile> -postMask` to delete repeaters in the post-mask ECO.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `ecoDeleteRepeater`. For a detailed description of the command and all of its parameters, use the man command: `man ecoDeleteRepeater`
`-inst` *`list_of_instances`*	Specifies a buffer or inverter to delete. If you specify an inverter, the command finds another inverter on the net and deletes the back-to-back pair in order to preserve the logical equivalence. Instances are deleted only if they are tied to each other. To specify a pair of instances, enclose the instances in braces. `-inst` {*`inst1 inst2`*}
`-invPair {`*`inv1 inv2`*`} {`*`inv3 inv4`*`} ...`	Specifies pairs of inverters to be deleted/evaluated for deletion. You can specify a list of inverter pairs to be deleted.
`-logicalChangeOnly`	Specifies that buffer/inverter deletion should be done in the logical-only mode.During buffering, this would be useful when the design is unplaced, the location of new buffer is not available, and all terms of the net-being-buffered are unplaced. If you specify `-logicalChangeOnly` option, the tool will disable placement/legalization of the new buffer and proceed with buffering. During deletion, the tool will add a default resistance to replace the removed buffer/inverter, instead of calculating the accurate resistance based on locations.

Note: You can specify the following using the `setEcoMode` command:

- `setEcoMode -honorDontUse false` to modify instances which have dontUse attribute on cells.
- `setEcoMode -honorDontTouch false` to modify instance/nets which are marked dontTouch.

Examples

- The following command deletes the specified buffer, `A/inst1`:
  `ecoDeleteRepeater -inst A/inst1`
- The following command deletes a back-to-back inverter pair containing `A/inv1`:
  `ecoDeleteRepeater -inst A/inv1`
- The following command deletes instances `DTMF_INST/RESULTS_CONV_INST/FE_PHC845_r1644_2_` and `DTMF_INST/RESULTS_CONV_INST/FE_PHC845_r1643_3_`:
  `ecoDeleteRepeater -inst {DTMF_INST/RESULTS_CONV_INST/FE_PHC845_r1644_2_ DTMF_INST/RESULTS_CONV_INST/FE_PHC845_r1643_3_}`

[-useGACells GACoreSite | -useGAFillerCells list_of_filler_cells ]
```

Takes an Innovus database and a modified netlist as input and performs ECO operations. It restores the design, examines the changes in the new netlist, and automatically implements the required changes with `ecoPlace` and `ecoRoute`.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `ecoDesign`. For a detailed description of the command and all of its parameters, use the man command: man `ecoDesign`
`-1801File` *new1801File*	Specifies the name of the new 1801 file.
`-allow_to_load_binary_timing_file`	Allows the tool to load the binary timing graph or the timing constraint file. If you execute `ecoDesign` based on binary timing graph or timing constraints, the tool will give an error and stop loading the new design. This is because the timing graph or the timing constraints file from the loaded design is a binary file, and if you keep on loading it, it may cause fatal error. In such a case, you need to restore the original design and then save a new design with the no-binary timing file. Then, execute `ecoDesign` based on the new design. If you still want to load the current design, you need to run `ecoDesign -allow_to_load_binary_timing_file 1` to turn on the control.
`-addHierPortForTieOff`	Allows the added tie cells to connect to the tie pins across hierarchical boundaries if other constraints, such as maximum fanout and maximum distance, allow it. This parameter can be used only with `-postMask` and `-tieCell` options.
`-cpfFile` *newCPFFile*	Specifies the name of the CPF file.
`-def` *fileName*	Specifies the DEF file you want the software to load automatically when performing ECO. This parameter automatically assigns the location of the new ECO cells. As a result, you do not need to run `ecoPlace` after performing the ECO.
design	Specifies the top cell name of the design.
`-ecoMMMC` *newMMMCFile*	Specifies the name of the new view definition file.
`-ecoSDC` *newSDCFile*	Specifies the name of the new SDC file.

`-fillerPrefix prefix`	Specifies the filler cell instance prefix. The `ecoDesign` command removes all filler cells before placing the ECOs. If you do not specify a prefix, `deleteFiller` removes filler instances based on the `setFillerMode` command settings. If you have not set `setFillerMode`, then no filler cells are removed.
`-keepInstLoc`	Keeps the instance location of changed cells.
`-lef_files LEFFilesName`	Specifies the LEF files name for loading. Use this option if you want to replace the existing LEF files in the original design with new LEF files. Refer to `restoreDesign -lef_files` for more details and limitations. For example, tech.lef, A.lef are the existing LEFs used in original design. You can change A.lef to A_v2.lef using the following command: `ecoDesign original.enc.dat myDesign myDesign.new.v -lef_files {tech.lef A_v2.lef}`
`-noAddFiller`	Skips filler insertion in the pre-mask eco flow.
`-modifyOnlyLayers MLb:MLt`	Specifies the layers to be modified during the ECO process.
newNetList	Specifies the name of new netlist file.
`-noDeleteFiller`	Skips deleting filler.
`-noEcoPlace`	Prevents placement and routing during the ECO process. `ecoPlace` and/or `ecoRoute` must run manually based on the design's needs.
`-noEcoRoute`	Prevents routing during the ECO process.
`-noTiming`	Ignores timing libraries and MMMC configuration
`-place_detail_use_GA_filler_groups`	Specifies that filler cell instances will only be replaced by the logic instances that belong to the same GA groups. This option can only be used when there is a filler group created by `createGAFillerGroup`. `ecoDesign -place_detail_use_GA_filler_groups` first finds the optimal location for each instance based on its connectivity, then searches for the nearest GA filler cell that is included in the same filler group, places a GA cell at the GA filler location, and deletes the original GA filler. If the GA cell is smaller than the GA filler, the placer creates a new GA filler instance using the list of GA filler cells in the same filler group and places the filler in the gap.
`-postMask`	Specifies that the changes are being made on a post-mask design. `-postMask` is required when option `-suffix`, `-spareCells`, `-modifyOnlyLayers`, `-tieCell`, or `-addHierPortForTieOff` is specified.
`-reportFile reportFile`	Specifies the name of the report file. **Note**: By default, `ecoDesign` creates the default `ecoRestoreDesign.rpt` file. However, this default file will be overwritten by the file name specified using the `-reportFile` option in next eco RUN.
sessionDirectory	Specifies the .dat directory from which to load the files.
`-skipCcopt`	Skips restore ccopt config for `signoffTimeDesign`.
`-spareCells spareCellName`	Specifies the name of the spare cell to use during the ECO process.
`-suffix suffix`	Specifies the suffix to be appended to the spare cells. You can specify this parameter only if you specify `-postMask`. *Default:* `_SPARE`
`-tieCell "cellName1 cellName2"`	Specifies the existing tie cells to be reused to make tie connections for newly created SPARE instance in the design. You can only specify a maximum of two tie-cells, where one cell must be a tie-high driver, and the other a tie-low driver. The two tie-cell names must be surrounded by quotation marks. This parameter can be used only with `-postMask` option.
`-useGACells GA_site`	Specifies the site name of the GA cell. Check the site name defined in the LEF file.
`-useGAFillerCells list_of_filler_cells`	Specifies a list of Gate Array (GA)-style filler cells that the tool can replace with GA cells during post-mask ECO. You can only use this parameter in a post-mask ECO flow. **Note:** You cannot specify the `-useGACells` parameter if you use this parameter.

Examples

- The following command performs a pre-mask ECO:
  ```
  ecoDesign original.enc.dat myDesign myDesign.new.v
  ```
- The following command and options are used to implement a post-mask ECO:
  ```
  ecoDesign -postMask -modifyOnlyLayers 2:3 -spareCells *spare* original.enc.dat myDesign myDesign.new.v
  ```

Related Information

- `restoreDesign`
- ECO Flows

ecoOaDesign

```
ecoOaDesign
[-help]
lib
cell
view
-ecoVerilogFile input_fileName
[-postMask [-suffix suffixName]]
[-useGACells GACoreSite]
[-reportFile output_fileName]
```

Imports an OpenAccess database and an ECO-modified netlist. Restores the physical objects in the database, examines the changes in the new netlist, and implements the required connectivity changes in the logical database without making changes to the physical objects. It preserves the spare cell markings in the old `lib`/`cell`/`view`.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `ecoOaDesign` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man ecoOaDesign`.
`cell`	Specifies the OpenAccess cell name of the top cell to import.
`lib`	Specifies the OpenAccess library name.
`-ecoVerilogFile` *`input_fileName`*	Specifies the changed Verilog netlist. **Note:** The original netlist must be written out from the original *`lib cell view`* and it must be hand-modified to incorporate the required ECO changes.
`-reportFile` *`output_fileName`*	Specifies a report file that shows the additions and removals of instances and nets in the new Verilog netlist. *Default:* eco.log
`-postMask`	Specifies that `ecoOaDesign` works in the post-mask mode. If this parameter is not specified, then Innovus considers the mode as pre-mask by default.
`-suffix suffixName`	Specifies the suffix name for the the spare cells. By default, the suffix is _SPARE.
`-useGACells` *`GACoreSite`*	Specifies the GA core site. The `-useGACells` parameter is valid only in the post-mask mode. 1. For cells that match the specified GA core site: ◦ Newly added GA cells that exist in memory but not in the OpenAccess database are left unplaced. ◦ GA cells that exist in the OpenAccess database but not in the memory are deleted in the new database. 2. For cells that do not match the specified GA core site, Innovus treats them as standard cells as described in post-mask mode.
`view`	Specifies the OpenAccess view name to import.

Examples

The following command reads the modified Verilog from the `eco.v` file, complete physical pre-ECO database from the `lib`/`cell`/`view` `designLib`/`TOP`/`final` in the post-mask mode:

```
ecoOaDesign designLib TOP final -ecoVerilogFile eco.v -postMask
```

In post-mask mode, no physical database changes are allowed and the new logical changes coming through `eco.v` are incorporated using spare cells in successive `ecoPlace` and `ecoRoute` commands.

Related Information

- `ecoPlace`
- `ecoRoute`
- For more information, refer to the Innovus-Based ECO Flow section of the Chip Finishing and ECO Flows chapter of *Mixed Signal Interoperability Guide*.

ecoPlace

```
ecoPlace
[-help]
[-fixPlacedInsts {true|false}]
[-place_detail_use_GA_filler_groups {true|false}]
[-reportSpareCells fileName]
[-timing_driven {true|false}]
[-useGACells GACoreSite]
[-useGAFillerCells GAFillerCells]
[-useSpareCells {true|false}]
```

Incrementally places the unplaced standard cells. In a pre-mask flow, this command moves the unplaced standard cells into the core area. During an ECO loop, some new unplaced standard cells may get introduced. If the goal is to move the unplaced standard cells into the core area and place them without disturbing the original placement (pre-mask flow), it is recommended to run `ecoPlace` at this stage. In a post-mask flow, if you specify `-useSpareCells`, the software can map the unplaced cells to the available spare cells. When `-useGAFillerCells` is provided in a post-mask flow, the command can map existing unplaced cells to placed GAFillers in the design.

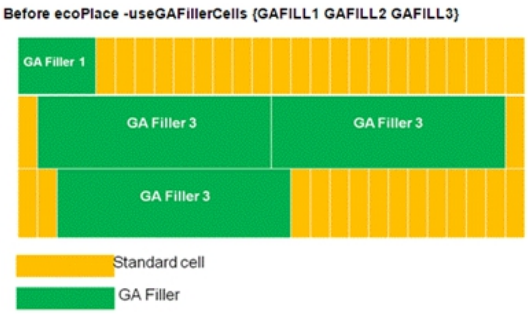
You can use this command after the `ecoDefIn` command when some newly added cells are still unplaced.

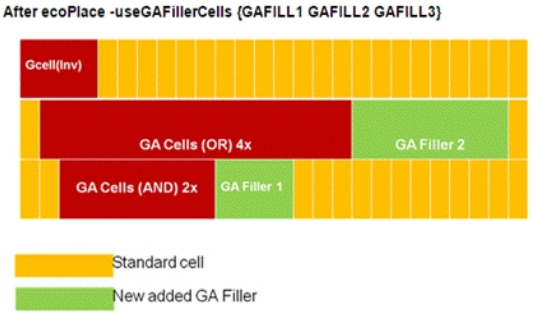
Parameters

`-fixPlacedInsts {true | false}`	
	Specifies that instances with the PLACED status are not moved.
`-help`	Outputs a brief description that includes type and default information for each `ecoPlace` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man ecoPlace`.
`-reportSpareCells` *`fileName`*	Specifies to report the spare gates that are selected to map the unplaced instances. This option works with –`useSpareCells` only.
`-timing_driven {true|false}`	Turns on the slack-driven placement for `ecoPlace`. *Default*: `false`
`-useGACells` *`GACoreSite`*	
	Selects and places the unplaced instances with techSite matching the provided GACoreSite. It is expected that there is free space to place the instances. If not, GA fillers could be deleted before `ecoPlace -useGACells` and re-inserted after the command. You can use this parameter only for post-mask ECO. **Note:** You cannot specify the `-useGAFillerCells` parameter if you use this parameter.
`-useGAFillerCells` *`GAFillerCells`*	
	Specifies a list of Gate Array (GA)-style filler cells that the tool can replace with GA cells during post-mask ECO. You can only use this parameter in a post-mask ECO flow. The new logic instances adding during a post-mask flow must already be present in the netlist. **Note:** You cannot specify the `-useGACells` parameter if you use this parameter.
`-place_detail_use_GA_filler_groups {true|false}`	
	Specifies that filler cell instances will only be replaced by logic instances that belong to the same GA groups. This option can only be used when there is a filler group created by `createGAFillerGroup`. `ecoPlace -place_detail_use_GA_filler_groups` first finds the optimal location for each instance based on its connectivity, then searches for the nearest GA filler cell that is included in the same filler group, places a GA cell at the GA filler location, and deletes the original GA filler. If the GA cell is smaller than the GA filler, the placer creates a new GA filler instance using the list of GA filler cells in the same filler group and places the filler in the gap. If there is only one filler group created, it equals to `ecoPlace - useGAFillerCells`. *Default*: `false`
`-useSpareCells {true | false}`	
	Maps unplaced cells to spare cells during placement. First, checks whether all unplaced cells match spare cells. Next, chooses a spare cell and changes the connections from the unplaced cell to the selected spare cell. Finally, deletes the unplaced cell. You can use this parameter only for post-mask ECO. This option observes the power domain when selecting the spare cell and maps an unplaced cell to the spare cell in the power domain, based on the instance name of the cell. For example, if module A/B is defined for power domain PD2, this option will map an unplaced cell A/B/inst1 to a spare cell in module A/B. *Default*: `false`

Examples

- The following command performs incremental placement:
  ```
  ecoPlace -useSpareCells true
  ```
- The flowing command places the GA-ECO cells on GACORE site.
  ```
  ecoPlace -useGACells GACoreSite
  ```
- The following command places GA-ECO cells on the specified GA-Fillers and fills remaining gaps with GA-Fillers.
  ```
  ecoPlace -useGAFillerCells {GAFiller1 GAFiller2 …}
  ```





- The following commands create GA Filler group that associates GA-Function cells with GA-Fillers. Then, `ecoPlace` will place GA-ECO cells on same group GA-Fillers.
  ```
  createGAFillerGroup -group GROUP1 -ga_cells {GA_Cell1 GA_Cell2… } -ga_fillers {GA_Filler1 GA_Filler2…}
  ```
  ```
  ecoPlace -place_detail_use_GA_filler_groups true
  ```

ecoRemoveTiedInputs

```
ecoRemoveTiedInputs
[-help]
[-base_cells cell_list]
[-ignore_base_cells cell_list]
[-ignore_insts inst_list]
[-insts inst_list]
[-relaxed_placement]
[-term term_list]
[-verbose]
[-report]
```

Remaps or restructures gates that have inputs connected to the same net. These gates are remapped into functionally equivalent logic such that none of the new gates has inputs tied together. Usually, such optimization is good in all objectives. For example, a 4-input OR gate with 3 of its inputs tied together (implementing function a+b+b+b) can safely be replaced with a 2-input OR gate (implementing a+b). This move is likely to be better in terms of area, power, and delay. However, in case of complex gates, it may not be possible to restructure a gate in a way that improves delay, but it may be possible to decompose it into smaller discrete gates, none of which has inputs tied together. Area and/or delay may be worse, but in some libraries, it is preferable to not have instances with inputs tied together. The `ecoRemoveTiedInputs` command fixes any gate with two or more inputs connected to the same net regardless of the improvement in delay/area/power. It tries to find improving moves, but it may accept moves that worsen delay/area/power.

The command can also insert buffers in nets tying inputs together. Inserting buffers should be used for the gates that cannot be automatically fixed or that are preserved. You need to specify which buffer cell(s) must be inserted before which input(s). There must be as many buffer cells specified as there are inputs specified. The only exception is specifying a single buffer cell; in that case it is understood that all inputs will be untied by using instances of that same buffer cell.

The command honors `setOptMode` settings for timing update and legalization. It does not call `ecoRoute` if run in the postRoute/ECO stages.

Note: MBFF cells are ignored by default as they always have tied inputs.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `ecoRemoveTiedInputs` parameter. For a detailed description of the command and all of its parameters, use the man command: `man ecoRemoveTiedInputs`
`-base_cells` *`cell_list`*	Specifies the buffer cells to be used for fixing.
`-ignore_base_cells` *`cell_list`*	Specifies to ignore instances of these cells from fixing.
`-ignore_insts` *`inst_list`*	Specifies to ignore these instances from fixing.
`-insts` *`inst_list`*	Specifies to fix only these instances. *Default*: All design minus ignored instances/cells.
`-relaxed_placement`	Accepts moves even if instances cannot be placed. You do not need to set this option if `ecoRemoveTiedInputs` can successfully fix all violations. In some cases, for example if an instance with tied inputs is in a very congested area, the tool may not be able to place the new instances. In such cases, you can use the `-relaxed_placement` option to fix such instances. However, the final placement may not be legal, and the new instances will likely overlap. For this, you can perform incremental placement to legalize the placement.
`-term` *`term_list`*	Specifies the terms to be buffered.
`-verbose`	Specifies to increase the detail of reports and fixing.
`-report`	Reports existing tied inputs, but does not provide fixing details by any method.

- `setOptMode`
- `ecoRoute`

ecoSwapSpareCell

```
  ecoSwapSpareCell
[-help]
instName
spareCellInstName
[-keepScan]
[-noScanTrace]
[-preservePin {list_of_spare_cell_pins}]
[-suffix string]
```

Swaps an unplaced or placed cell with a cell in the spare cell list.

You can specify this command only after you have run `specifySpareGate`.

This command can swap cells of the same cell type (same footprint and identical pin name). Cells of different sizes can also be swapped. The spare cell is connected according to the specified global net connections.

If the cell to be swapped is unplaced, it is mapped to the spare cell. *instName* is deleted, and its connection is transferred to the spare cell. If the cell to be swapped is placed, it is swapped with the spare cell and is renamed to *instNameSuffix* if the `-suffix` option is used. If a suffix is not specified, the *instName* cell is renamed to *spareCellInstName*. The *instName* cell's connections are transferred to *spareCellInstName*. The input of *instName* is `tielo`, based on the global connection definition.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `ecoSwapSpareCell` parameter. For a detailed description of the command and all of its parameters, use the man command: `man ecoSwapSpareCell`
`-keepScan`	Keeps the scan connection for both the spare cell and the specified instances. Before you can use this parameter, you must first identify the scan connections by running a scan trace.
instName	Specifies the name of the cell to swap.
`-noScanTrace`	Disables scan tracing while swapping.
`-preservePin {list_of_spare_cell_pins}`	Specifies a list of pins whose connection you want to preserve while swapping spare cells. The same pin on both the spare cell and specified instances is preserved. If both the instance and the spare cell are placed instances, the `-preservePin` parameter is effective for both cells. If the instance is unplaced, `-preservePin` only affects the spare cell because the instance is deleted.
spareCellInstName	Specifies the spare cell in the spare cell list to swap with the placed cell.
`-suffix` *string*	Specifies a string that is appended to the *instName* after swapping.

Examples

The following example swaps a placed cell, `DTMF_INST/TDSP_CORE_INST/PROG_BUS_MACH_INST/i_9649`, with spare cell `spare1`:

```
specifySpareGate -inst *spare*
ecoPlace -useSpareCells
checkPlace

ecoSwapSpareCell DTMF_INST/TDSP_CORE_INST/PROG_BUS_MACH_INST/i_9649 spare1
```

fillNotch

```
fillNotch
[-help]
[-area {x1 y1 x2 y2}]
[-report filename]
[-useExistingDrcResult]
[-useNonDefaultSpacing]
```

Detects and fills notches, gaps, and holes, and corrects acute angle (45 degree) violations.

Creates geometries in `DRCFILL` shapes as special wires attached to each net. Saves the geometries in DEF or GDSII Stream format. In a DEF file, the geometries are saved in the special net section. The software considers the geometries as active design objects.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `fillNotch`. For a detailed description of the command and all of its parameters, use the man command: `man fillNotch`
`-area {x1 y1 x2 y2}`	Specifies the area to check and fill. For example, `fillNotch -area {0 0 100 100}`. *Type:* Real
`-report filename`	Specifies the report file. The file includes the locations, types and number of violations corrected. For example, `fillNotch -report design_fill.rpt`. *Default:* *design*`.fill.rpt` *Type:* String
`-useExistingDrcResult`	Allows fixing the `convexCornerSpacing` issues based on Verify Geometry markers.
`-useNonDefaultSpacing`	Honors nondefault spacing rules when filling notches. This behavior matches the behavior of `verify_drc`; that is, when this parameter is specified, `fillNotch` honors both default and nondefault spacing rules. If this parameter is not specified, `fillNotch` honors default spacing rules but does not honor nondefault spacing rules.

Example

- The following commands check the notch issues and create drc markers with `verify_drc`, and adds drc fill shapes on the drc marker location:

  ```
  verify_drc
  fillNotch -useExistingDrcResult
  ```

fix_multi_drivers

```
fix_multi_drivers
[-help]
[-exclude_net netName | netNameList]
[-replace_bus_bit]
[-report_only]
```

Fixes multi-drive issues by disconnecting driving ports that do not have a real driver. The fix_multi_drivers command also works for looped multi-driver assign net.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `fix_multi_drivers` parameter.
`-exclude_net` *netName* | *netNameList*	Specifies the list of nets to be excluded.
`-replace_bus_bit`	Replaces all bus ports with wrong directions, if any, by new scalar ports. If not specified, just report without such replacement.
`-report_only`	Reports, but does not fix, ports with wrong directions.

getEcoMode

```
getEcoMode
[-help]
[-addPortAsNeeded]
[-delayCalcEffort]
[-batchMode]
[-honorDontTouch]
[-inheritNetAttr]
[-LEQCheck]
[-prefixName]
[-refinePlace]
[-spreadInverter]
[-updateTiming]
[-honorDontUse]
[-honorFixedNetWire]
[-honorFixedStatus]
[-honorPowerIntent]
[-modifyOnlyLayers]
[-quiet]
```

This command displays the following information about the parameters for the corresponding `setEcoMode` command in the Innovus log file and in the Innovus console: name, possible values, type (Boolean, string, and so on), and source of current setting (default, user).

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `getEcoMode`. For a detailed description of the command and all of its parameters, use the man command: `man getEcoMode`
`parameter_names`	Returns information for the specified parameters. You can specify one or more parameters. **Note:** `-inheritNetAttr` is for Cadence internal use only.
`-quiet`	Returns the current settings for the specified parameters in Tcl list format only. If you specify `-quiet` without any parameters, the software returns the current settings of all `setEcoMode` parameters in Tcl format.

Examples

- The following command returns the current setting for the `-LEQCheck` parameter:

  ```
  getEcoMode -LEQCheck
  ```

  The software returns the following information:

  ```
  -LEQCheck true # bool, default=true

  true
  ```

- The following command returns the parameters for all the `setEcoMode` command:

  ```
  getEcoMode
  ```

  The software returns the following information:

  ```
  -honorDontTouch true # bool, default=true

  -honorDontUse true # bool, default=true

  -honorFixedStatus true # bool, default=true

  -inheritNetAttr true # bool, default=true

  -LEQCheck true # bool, default=true
  ```

```
-prefixName {ECO} # string, default=ECO

-refinePlace true # bool, default=true

-spreadInverter true # bool, default=true

-updateTiming true # bool, default=true

{honorDontTouch true} {-honorDontUse true} {-honorFixedStatus true} {inheritNetAttr true} {LEQCheck true} {prefixName {ECO}}
{refinePlace true} {spreadInverter true} {updateTiming true}
```

- The following command returns the current setting for the `-spreadInverter` parameter in Tcl list format only:
  ```
  getEcoMode -spreadInverter -quiet
  ```
  The software returns the following information:
  ```
  true
  ```
- The following command returns the current settings for all `setEcoMode` parameters in Tcl list format only:
  ```
  getEcoMode -quiet
  ```
  The software returns the following information:
  ```
  {honorDontTouch true} {-honorDontUse true} {-honorFixedStatus true} {inheritNetAttr true} {LEQCheck true} {prefixName {ECO}}
  {refinePlace true} {spreadInverter true} {updateTiming true}
  ```

Related Information

- `setEcoMode`

group

```
group
[-help]
inst|hInst+
[[-module_name module_name -hinst_base_name hinst_base_name ]]
```

Creates a new module and hinst from a group of the specified hinsts or insts. You can only group hinsts and insts that belong to the same hierarchy (the same hinst parent). Returns the newly created hinst.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `group`. For a detailed description of the command and all of its parameters, use the man command: `man group`
`inst|hInst+`	Specifies the hinst(s) or inst(s), in the same hierarchy, to be grouped.
`-hinst_base_name` *`hinst_base_name`*	Specifies the hinst base name of the new group instantiation.
`-module_name` *`module_name`*	Specifies the module name of the new group.

Example

The following command groups two hinsts, `h1` and `h2`, at the top-level into a new module named `test`. The new hinst is named `testi` by default.

```
>group -module_name test -hinst_base_name baseName {DTMF_INST/TDSP_CORE_INST DTMF_INST/RESULTS_CONV_INST}
```

- ungroup

initECO

```
initECO
[-help]
ecoFileName
```

Logs ECO operations in a log file.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `initECO` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man initECO`.
`ecoFileName`	Specifies the name of the ECO log file.

Examples

- The following commands show the usage of `initECO` and `endECO`..

  ```
  initECO File1
  ....
  <ECO commands>
  ....
  endECO
  ```

  All operations performed by ECO Commands are logged in *`File1`*.

Related Information

- `endECO`
- `loadECO`

loadECO

```
loadECO
[-help]
[-postMask | -useGACells GACoreSiteName]
[-suffix suffix]
[-verbose]
fileName ...
```

Reads a file containing ECO directives and applies the changes to the current netlist.

You can use this command at any time after you import the design.

This command also performs consistency checks while the ECO commands are applied and after the changes are complete. It also checks for and observes power domains. This command produces results compatible with `ecoDefIn`, so you will use `ecoPlace` and `ecoRoute` to complete the ECO process.

The ECO directives do not affect routing, except in the following cases:

- `DELETENET` deletes routing attached to a specified deleted net.
- `DELETEINST` deletes an instance but leaves the wires attached to the instance dangling. You can then repair dangling wires with the router after ECO is complete.

If you want to reroute the entire design, delete routing before running the `loadECO` command.

This command supports ECOs for gate array designs through the `-useGACells` and `-postMask` parameters.

If an error occurs when the `loadECO` command reads the ECO file, the `loadECO` command stops without reading more commands from the file, and writes error messages to the `innovus.log` file.

Note: The first line of the ECO file you read must be the following:

```
FORMATVERSION 2
```

For information on the commands you can include in the ECO command file, see "ECO Directives," in the *Innovus User Guide*.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `loadECO`. For a detailed description of the command and all of its parameters, use the man command: `man loadECO`
`fileName`	Specifies the name of the file that contains the ECO directives. You can specify more than one file. File names must be separated by one space.
`-suffix`	Specifies the suffix this command adds to spare cells created by deleting instances. The default suffix is `SPARE`.
`-useGACells` *`GACoreSite`*	Uses gate array cells when adding or deleting instances. This parameter applies to gate array designs only. If `ADDINST` is specified in the ECO file, the default behavior for `ADDINST` applies. If `DELETEINST` is included in the ECO file, the software deletes an instance if the instance master uses the same site as the specified *`GACoreSite`*, which can be the name of any gate array site defined in the LEF file. If you do not specify this parameter, `DELETEINST` removes the instance from the netlist.
`-postMask`	When adding an instance, the new cell will be unplaced. The unplaced cell will map to the spare cell during placement with the `ecoPlace -useSpareCells` command. When the software deletes an instance, it renames the instance to an instance name at the original level of hierarchy, and appends the specified suffix. If you do not specify the `-suffix` parameter, this parameter appends `SPARE`.
`-verbose`	Provides a report for nets without drivers and the instance input pins with no net connections.

Example

- The following command reads `myfile` and runs the ECO commands it contains:
  ```
  loadECO myfile
  ```
- The `loadECO` command issues a summary report on completion, for example:

```
***************** Load ECO Summary *****************

    Number of New Nets:                          0
```

```
Number of New Instances:                        0
Number of New Ports:                            0
Number of New Assigns:                          0
Number of New Feedthroughs:                     0
Number of Changed Connections:                  0
Number of Changed Instances:                    0
Number of Deleted Nets:                         0
Number of Deleted Instances:                    1
Number of Deleted Ports:                        0
Number of Deleted Assigns:                      0
Number of Deleted Feedthroughs:                 0
```

- The following ECO summary is the output of the loadECO command with -verbose options:

```
***************** Load ECO Summary *****************
Number of New Nets:                               0
Number of New Instances:                          1
Number of New Ports:                              0
Number of New Assigns:                            0
Number of New Feedthroughs:                       0
Number of Changed Connections:                    0
Number of Changed Instances:                      0
Number of Deleted Nets:                           0
Number of Deleted Instances:                      0
Number of Deleted Ports:                          0
Number of Deleted Assigns:                        0
Number of Deleted Feedthroughs:                   0
Nets With No Driver:
        n_23
        u_counter_1/cnt[30]
Number of Nets With No Drivers:                  2
Input Instance Pins With No Net Connection:
        A of inst newInst
        TE of inst u_counter_2/ECO_reg_iflg_reg
Number of Input Instance Pins With No Net Connection:   2
```

remove_assigns

```
remove_assigns
[-help]
[-buffer bufName]
[-buffering [-buffer_tie_assigns ][-includeIdealNets ] [-includeClockPath]]
[-honordonttouch]
[-ignorePortConstraints]
[-net netName [-netBuffer netBufName]]
[-prefix bufNamePreFix]
[-report]
```

Removes assign statements from the Verilog as much as possible while keeping the same DEF netlist. This means that the placement and routing remain the same and timing is not disturbed.

The `remove_assigns` command removes all non-top module assign nets without adding buffers.There are cases where you do not want assign nets in your design. However, there are some assign nets in the original net list imported into Innovus, or you have a design with some unwanted assign nets. In such cases, you can use `remove_assigns` to remove all assigns or replace assigns with proper buffers that are automatically selected by the tool.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `remove_assigns`. For a detailed description of the command and all of its parameters, use the man command: `man remove_assigns`
`-buffer bufName`	Specifies the name of the buffer for all assign nets, disables automatic buffer selection.
`-buffer_tie_assigns`	Allows to buffer tie assigns.
`-buffering`	Specifies whether the assign net buffering feature is needed. If only “-buffering” is specified, all assigns, including top and non-top module assigns, will be replaced by buffers. The buffers for each module will be automatically selected to meet all power domain requirements with the minimum area cost.
`-honordonttouch`	Honors dont_touch. This setting prevents assign removal on modules which have preserve/dont_touch settings.
`-ignorePortConstraints`	Allows to ignore all port constraints during assign removal.
`-includeClockPath`	Removes assigns on clock path.
`-includeIdealNets`	Removes assigns on ideal nets.

`-net` *`netName`*	Specifies the name of net (s). Supports removing or buffering assigns of a list of assign nets,
	For example, the following command removes all assigns of assign nets n1, n2 and n3.
	`remove_assigns -net {n1 n2 n3}`
	
	The following command replaces all assigns of assign nets n1, n2 and n3 with buffers.
	`remove_assigns -buffering -net {n1 n2 n3}`
	
	If “-net” is used, “-buffering” must also be used for buffering those assign nets specified in *`netName`*. Otherwise, `remove_assigns` will work same as no options are specified (as default).
	Whenever option “-net” is used, *`netName`* must be provided. Otherwise, a warning message is issued.
	
	You can specify any of the following as the *`netName`*:
	• Single net name
	• Multiple net names separated with space
	• Single wildcard name (all matched assign nets will be collected for buffering)
	• Multiple wildcard names separated with space (all match assign nets will be collected for buffering)
	• Single bus name
	• Multiple bus names
	Note: For each bus, all or portion of bus bits can be assign nets and the others can be non-assign nets. The buffering code replaces only those assign bus bits while leave those non-assign bus bits unchanged.

`-netBuffer` *`netBufName`*	Specifies the name of the buffer for the specific net given in the `-net` option. This option, if specified, should come after the `-net` option.
`-prefix` *`bufNamePreFix`*	Specifies the user-specified prefix for buffer names. If `-prefix` is used, you need to specify a prefix `bufNamePreFix` for buffer names that may be used in this command. The default prefix for added buffers is “`buf_dummy_`” if you do not specify it.
`-report`	Reports list of all buffers and assign nets that were replaced by the buffers. If `-report` is used, a list of all buffers and assign nets that were replaced by the buffers will be reported in log file. If buffers are inserted to the netlist you may need to use Innovus to place and route them.

The `remove_assigns` command:

- Removes assigns that involve only internal "wires".
  For example, in the code below, `assign n2 = n1` is removed.

```
module top();
  wire n1, n2;
  assign n2 = n1;

  BUFX2 u1(.Y(n1));
  BUFX2 u2(.A(n2));
  endmodule
```

becomes

```
module top();
  wire n1;

  BUFX2 u1(.Y(n1));
  BUFX2 u2(.A(n1));
  endmodule
```

- Removes assigns that involve only one port.
  For example, in the code below, `assign p1 = n1` is removed.

```
module hier(p1);
output p1;
wire n1;
assign p1 = n1;
 BUFX2 u1(.Y(n1));
endmodule
```

  becomes

```
module hier(p1);
output p1;
 BUFX2 u1(.Y(p1));
endmodule
```

- Rewires nets with feedthrough assigns that involve at least two ports, at some higher level:

```
module hier2 (
          i,
          o);
    input i;
    output o;
    assign o = i ;
    BUFX2 u1 (.A(i));
endmodule
module hier (
          i,
          o);
    input i;
    output o;

    hier2 u1 (.i(i),
          .o(o));
endmodule
module top ();
    // Internal wires
    wire i;
    wire o;
    BUFX2 u1 (.Y(i));
    hier u2 (.i(i),
          .o(o));
    BUFX2 u3 (.A(o));
endmodule
```

  becomes

```
module hier2 (
          i,
          o);
     input i;
     output o;

     BUFX2 u1 (.A(i));
  endmodule
  module hier (
          i,
          o);
     input i;
     output o;
     hier2 u1 (.i(i));
  endmodule
  module top ();
     // Internal wires
     wire i;

     BUFX2 u1 (.Y(i));
     hier u2 (.i(i));
     BUFX2 u3 (.A(i));
  endmodule
```

setEcoMode

```
setEcoMode
[-help]
[-addPortAsNeeded {true|false}]
[-batchMode {true|false}]
[-reset]
[-honorDontTouch {true|false}]
[-honorDontUse {true|false}]
[-honorFixedNetWire {true|false}]
[-honorFixedStatus {true|false}]
[-honorPowerIntent {true|false}]
[-inheritNetAttr {true|false}]
[-LEQCheck {true|false}]
[-modifyOnlyLayers bottom_layer:top_layer]
[-prefixName prefix]
[-preserveModuleFunction {true|false}]
[-refinePlace {true|false}]
[-spreadInverter {true|false}]e
[-updateTiming {true|false}]
[-delayCalcEffort effort_level]
```

Controls certain behaviors of the `ecoAddRepeater`, `ecoChangeCell`, and `ecoDeleteRepeater` ECO commands.

Use the `getEcoMode` command to return the current settings for the `setEcoMode` command.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `setEcoMode` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setEcoMode`.
`-addPortAsNeeded {true|false}`	Controls whether timing optimization adds ports to the lower-level hierarchies of the design. It only works during ECO and overwrites the value of `setOptMode -addPortAsNeeded` for the ECO commands, `ecoAddRepeater`, `ecoChangeCell`, and `ecoDeleteRepeater`. *Default*: `true`

`-batchMode {true|false}`	Speeds up the runtime in case the user performs lots of interactive ECO operations. When the user specifies `batchMode true`, various ECO operations are performed in a batch and initialization steps are not performed for every ECO call. In addition, updating timing is performed only once for all the ECO operations. Tool will only perform timing initialization at the first ECO command in the batch mode and timing update at the time of exiting the batchMode. User needs to specify `batchMode false` to exit the `batchMode`.
	The batch mode is activated by `setEcoMode -batchMode true` and exited by `setEcoMode -batchMode false`, and only `ecoAddRepeater` , `ecoDeleteRepeater` and `ecoChangeCell` could be given in between `setEcoMode -batchMode true` and `setEcoMode -batchMode false`:
	`setEcoMode -batchMode true`
	`eco commands (ecoAddRepeater, ecoDeleteRepeater, ecoChangeCell)`
	`setEcoMode -batchMode false`
	If a user activates the batch mode, then the user needs to remember to exit it. If the user does not exit the batch mode, the user might see some unexpected results.
	The `refinePlace` command will not be called in batchMode. It will be called when the tool exits the batchMode and if `refinePlace` is set to `true`.
	All other `setEcoMode` settings should be made prior to activating batch mode. If you would like to change `setEcoMode` settings, you need to exit the batch mode first.
	Note: This option supports all commit ECO commands. Evaluation commands are not supported.

`-delayCalcEffort effort_level`	Specifies the delay calculation effort level { low | medium | high } used in timing update. *Default*: `high`

`-honorDontTouch {true|false}`	Checks for the don't touch attribute on nets and instances. If you specify a terminal list, this parameter checks each terminal for the don't touch attribute. The `ecoAddRepeater` command honors the don't touch nets. The `ecoDeleteRepeater` and `ecoChangeCell` commands honor don't touch instances. *Default:* `true`
`-honorDontUse {true|false}`	Checks for the don't use attribute on cells. The `ecoAddRepeater`, `ecoDeleteRepeater`, and `ecoChangeCell` commands honor don't use cells. *Default:* `true`
`-honorFixedNetWire {true|false}`	Checks for fixed net wires. It restricts the addition or deletion on fixed net so that the fixed status of the wires is not altered. *Default*: `true` When `-honorFixedNetWire` is set to false, `ecoAddRepeater` can insert a cell on the wires with the FIXED/COVER status and change the status of these wires from FIXED/COVER to ROUTED.
`-honorFixedStatus {true|false}`	Does not allow preplaced, fixed instances to be resized. *Default:* `true`

`-honorPowerIntent {true|false}`	Performs MSV checks during ECO. When set to `true`:
	• `ecoChangeCell` does not allow:
	  ◦ Resizing a regular cell with an always-on cell (and vice-versa).
	  ◦ Resizing with cells belonging to different power domains.
	• `ecoAddRepeater` does not allow:
	  ◦ Adding buffer to a power domain it doesn't belong to.
	  ◦ Buffering a cross power domain net if it can cause MSV violations.
	  ◦ Adding a regular buffer to a net that requires an always-on buffer.
	  ◦ Adding an always-on buffer to a net that does not require an always-on buffer.
	• `ecoDeleteRepeater` does not allow deletion of a buffer or an inverter-pair that will cause:
	  ◦ A redundant isolation cell.
	  ◦ A CPF-constrained net to be deleted.
	Note: To prevent buffer insertion failure due to MSV constraints, you need to set `-honorPowerIntent` to `false`.
	Default: `true`

`-inheritNetAttr {true | false}`	Inherits the net attribute. *Default*: `true`
`-LEQCheck {true|false}`	Enables functionality checking when swapping cells. The software can swap cells that are logically equivalent. When `-LEQCheck` is `true`: • `ecoAddRepeater` adds inverter pair if the specified cell is inverter. • `ecoDeleteRepeater` deletes inverter pair if the specified instance is inverter. • `ecoChangeCell` changes cell to another cell type with the same function as long as they have same number of pins. When `-LEQCheck` is set to `false`: • `ecoAddRepeater` can add only one single inverter if the specified cell is inverter. • `ecoDeleteRepeater` can delete only one single inverter if the specified instance is inverter. • `ecoChangeCell` can perform nonequivalent cell change as long as they have same number of pins. *Default:* `true`
`-modifyOnlyLayers` *`bottom_layer:top_layer`*	Modifies routes only on metal layers in this range (both inclusive). *Default*:""

`-prefixName prefix`	Adds a prefix to the inserted cells. *Default:* `ECO` **Note**: If the prefix name for eco cells is changed using the `-prefixName` option, it is not honored when the ECO batch mode is turned on.
`-preserveModuleFunction {true|false}`	Determines whether to preserve logical functions at hierarchical module ports. It only works for manual ECO commands and overwrites the value of `setOptMode -opt_preserve_hpin_function` for the ECO commands, `ecoAddRepeater`, `ecoChangeCell`, and `ecoDeleteRepeater`. *Default:* `false`
`-refinePlace {true|false}`	Legalizes placement whenever `ecoAddRepeater` or `ecoChangeCell` are used. If `false`, you must run `refinePlace` after ECO if you want to legalize placement. **Note:** Specifying `-refinePlace true` can affect performance when large numbers of cells are added or modified. *Default:* `true`
`-reset`	Resets parameters to their default values. The `-reset` parameter must be the first parameter specified. If you specify reset by itself, the software resets all `setEcoMode` parameters to their default values. If you specify parameters after `-reset`, the software resets only those parameters to their default values. Any values that do not already match the default value and are reset will be reported.
`-spreadInverter {true|false}`	Distributes an inverter pair evenly between the driver and the sink. It works when the buffering nets have only one driver and one sink. The design must be routed before you use this parameter. *Default:* `true`
`-updateTiming {true|false}`	Controls whether to `eco*` commands recompute timing. If `true`, the eco* commands recompute timing. If `false`, the commands do not recompute timing, and us can later use `report_timing` to recompute timing. *Default:* `true`

Examples

- The following command does not legalize placement whenever `ecoAddRepeater` or `ecoChangeCell` are used:
  ```
  setEcoMode -refinePlace false
  ```
- The following command resets the `-honorDontTouch` parameter to its default value:
  ```
  setEcoMode -reset -honorDontTouch
  ```
- The following command resets all `setEcoMode` parameters to their default values:
  ```
  setEcoMode -reset
  ```

ungroup

```
ungroup
[-help]
hInst+
[-exclude hinst+]
[-flatten]
[-honor_dont_touch]
[-threshold instance_count]
[-verbose]
[-simple  | -prefix prefix | -escaped ]
[-force | -only_user_hierarchy ]
```

Ungroups the specified hinsts. Ungrouping dissolves the hinsts and moves the contents into its parent directory. By default, an hinst or an inst inside one of the ungrouped hinsts is renamed by concatenating its name to its parent's name with "_". for example, "ungroup h1", would rename h1/i1 to h1_i1. Name collisions are resolved by appending _1, _2, etc. until a unique name is found. If a given hinst cannot be ungrouped, a warning is issued about why it cannot be ungrouped.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each ungroup. For a detailed description of the command and all of its parameters, use the man command: man ungroup
hInst+	Specifies the hinst(s) to be ungrouped.
`-escaped`	Flattened names use escaped hinst names. For example, h1/i1 becomes \h1/i1 in Verilog and h1\/i1 in DEF.
`-exclude` *hinst+*	Excludes specified hinst(s) as ungroup targets.
`-flatten`	Ungroups recursively below the specified hinst(s)
`-force`	Ungroups all hierarchy, mapped or not, and overrides ungroup_allowed if it is set to `false`.
`-honor_dont_touch`	Skips the hinst that is marked as dont touch.
`-only_user_hierarchy`	Ungroups only user hierarchy, synthesized module will not be ungrouped.
`-prefix` *prefix*	Flattened names use a prefix. For example, h1/i1 becomes <prefix>_i1.
`-simple`	Flattened names use the base_name. For example, h1/i1 becomes i1.
`-threshold` *instance_count*	Ungroups only those hinsts that have an instance count less than or equal to the specified integer.
`-verbose`	Prints the names of the hierarchies that are being ungrouped.

Example

- The following command will flatten h1, h2/h3. It will recursively flatten any lower hinsts that have an inst count <= 10 and do not have 'cpu' in their name.
  ```
  >ungroup {h1 h2/h3} -exclude *cpu* -flatten -threshold 10 -prefix test
  ```
- This command ungroups all hinsts matching `h1*` and uses escaped names for the flattened names. This is useful so external SDC files that only refer to inst and pin names will still work but it may cause problems in down-stream tools that do not support escaped names. Note that hpins and hnets of ungrouped hinsts will disappear, so usage of those names will no longer work.
  ```
  >ungroup h1* -escaped
  ```
  An inst named `h1/i1` will become `h1\/i1`. Various commands like `get_cells` will still "soft-match" `h1/i1` to the escaped `h1\/i1` name.

- ecoDisableNetRenamingForFlatNetlist
- group_instance_suffix
- init_no_new_assigns

bit_blasted_port_style

`bit_blasted_port_style %s_%d`

Type: String

Default: `%s_%d, persistent`

This global variable is used to define the bus bit blasted port name.

Specifies the naming style to be used if mapped ports are bit blasted with the command bitblast_ports. The values of this global need to contain elements %s and %d.

The following rules apply:

- A port name always starts with the base name (represented by %s)
- The suffix is appended to the base name to form port name, according to the format specified in the global value.
- %d represents the bit information.

Example

The default of %s_%d will convert a bus-bit A[0] to A_0.

If you want to keep the original bus-bit name but have it turned into an escaped scalar name you can use:

```
set_db bit_blasted_port_style {%s\[%d\]}
```

This will convert a bus-bit A[0] to an escaped scalar name A\[0\] in Tcl, so the port .name would be “A[0]”, the .escaped_name would be “A\[0\]”, the dual-ported-object name would look like {port:top/A\[0\]} with Tcl adding the {} around it to protect the \ chars, and the Verilog port would look like “\A[0] “.

One advantage of this is that SDC commands and Innovus Tcl commands that use port names with A[0] will still “soft-match” the new A\[0\] name, so they do not have to change. However, using escaped names may require careful Tcl scripting to make sure you do not inadvertently lose the escaped \ chars when you want them.

Related Information

- `bitblast_ports`

ecoDisableNetRenamingForFlatNetlist

`ecoDisableNetRenamingForFlatNetlist`

Type: Integer

Default: `0`

Specifies whether nets would be renamed in ECO report of `ecoCompareNetList`. When set to 1, there will not be any net renaming for flat netlist. The net renaming will take place if net name is hierarchical and the terms it connects to do not fall under the same hierarchy or lies up in the hierarchy. You need to set `ecoDisableNetRenamingForFlatNetlist` to `1` before `ecoCompareNetlist` command is issued to disable net renaming for flat netlists.

Related Information

- `ecoCompareNetlist`

group_instance_suffix

`group_instance_suffix` *`suffix`*

Type: String

Default: `i`

This suffix is added to a new hinst name created by the `group` command. So, `group -name abc` creates a new module named `abc`, and a new `hinst` named `abci`. If you do not want any suffix, you need to set the value to the empty string “”.

Related Information

- `group`

init_no_new_assigns

`init_no_new_assigns`

Type: Boolean

Default: `False`

Turns on an assign-free flow. By default, applications like optimization can add Verilog assigns to remove unnecessary buffers and reduce power. If you have external tools that do not support Verilog assigns, you can set this value to true to prevent applications from adding any new assign statements to the Verilog netlist. If there are existing assigns in the Verilog netlist you can remove them with the `remove_assigns` command.

```

The `addPowerSwitch` command supports five type of cells: switch cells, filler cells, corner cells (for the ring style only), and buffer cells. You can define a cell pattern when you create power switch rings.

The parameters of this command are categorized as below in the Parameters table depending upon their functionality based on how they are to be used:

- Column Type Insertion Parameters
- Power Switch Prototyping Parameters
- Ring Type Insertion Parameters

Column Type Insertion Parameters

Before you insert power switches in a column style, you must assign power switch cells to `CLASS CORE` and the correct `SITE` in the `.lef` file and connect power/ground nets and pins of the power switch cells. The distance between columns of switches (the horizontal pitch value) must be in µm.

The column style is favorable for channelless designs. In this case, all blocks are abutted and there is no space for rings. In ring style, you must have a space greater than the max ring cell height between the power domain and the adjacent power domain. This space is primarily occupied by ring switch cells and power routing.

If you create power switch columns within a specified power domain the distance between the columns of switches is determined by the `-horizontalPitch`. The first (left-most) column of switches is located `-leftOffset` from the power domain's left boundary. The `-enableNetIn`, which might consist of one or more enable nets, drives the `-enablePinIn` of the first switch cell of each column.

In column style, nets are assigned to pins sequentially if more nets than number of pins are specified. For example, if the list consists of three nets, and there are five columns of switches, net `1` drives the pin of the first switch in column `1` and `4`, net `2` connects to column `2` and `5`, and net `3` only drive the `-enablePinIn` of the first switch in column `3`.

Power Switch Prototyping Parameters

These are the parameters, which are used for power switch prototyping.

Ring Type Insertion Parameters

If you insert power switches in ring style, the power switches are added around the selected power domain in the minimum gap available. Unless specified, the power switches are added to the top level hierarchy but the user has a choice to specify to which level in the hierachy should the power switches be added. The command creates a switch ring on the top, bottom, left, and right sides of the specified power domain unless you assign a specific side.

Before you insert power switches in a ring style, you must assign power switch cells to `CLASS RING` in the `.lef` file (SYMMETRY X Y R90, recommended, but not required for switch cells) and connect power/ground nets and pins of the power switch cells. You must have existing enable nets to drive the buffer inside the power switch cells and acknowledge nets exiting the power switch cell. You need these net names when you specify `-enableNetIn` and `-enableNetOut`.

Rectilinear power domains are supported in both ring-style and column-style switch insertion.

Regardless of whether you insert columns or a ring, the software ties the `-enablePinOut` of the first switch cell to the `-enablePinIn` of the next switch cell in the same column or on the same side of a ring. All the enable pin of the switch cells in the same column/side are daisy-chained together. For the last switch of the column, the `-enablePinOut` is tied to `-enableNetOut`.

Note: The parameters which are applicable to both Column Type Insertions and Ring Type Insertions are listed in both sections.

The Syntax Conventions and Examples are listed out before apart from the description the the parameters. For conventions and examples, see:

- Syntax Conventions
- Syntax Examples

For Power Switch Chaining Unchaining Instances, see the description of the `rechainPowerSwitch` command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `addPowerSwitch` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man addPowerSwitch`.
`-getSwitchInstances` *string*	Returns the existing power switch instances previously added by `addPowerSwitch`. Returns the existing power switch instances previously added by `addPowerSwitch`. It returns all the power switches in the current design without any other option, and can be used with `-powerDomain`, `-column`, `-ring` and `-area` options to return specific power switches. By default, the command returns a Tcl list. Use the `-reportFile` option if you want to list the power switch information into a file. Refer to the following example: `addPowerSwitch -getSwitchInstances -powerDomain TDSPCore -area {189.0 31.36 318.0 190.36}`
Column Type Insertion Parameters	
`-1801PowerSwitchRuleName` *string*	Specifies the power switch rule name defined in the 1801 power intent file. By default, `addPowerSwitch` uses the first defined rule.

`-acknowledgeTreeCell` *cell_name*	Specifies the name of cell to use in acknowledge tree synthesis. If you specify this parameter but do not specify `-acknowledgeTreeHierInstance`, the tool builds the acknowledge tree at the top level of the design. This parameter provides control over the time it takes to switch a power domain off and on.
`-acknowledgeTreeHierInstance` *hier_instance*	Inserts an enable net out signal tree of specified cell instances in the specified hierarchical instance in the design. This parameter provides a power domain off and on; and works with option `-acknowledgeTreeCell`.
`-allowPartialStripeRowOverlap`	Allows placement of power switch cells on nearest row location even if crossing stripes do not completely ovelap the power switch cells. Use the option with the option `-placeByNetWireIntersect`.
`-area {`*x1 y1 x2 y2*`}`	Defines an area within a power domain where the tool can insert power switches. The option applies to rectangular area. *x1 y1* is the lower left coordinate of the rectangular area. *x2 y2* is the upper right coordinate corner of the rectangular area. You can specify `-leftOffset`, `-rightOffset`, `-topOffset`, or `-bottomOffset` to offset the switches from the boundaries of the area. **Note:** The power switch instances snap to placement grid so the actual location is slightly different from the specified coordinate.
`-backToBackChain {LtoR | RtoL}`	Specifies the distance between the bottom-most switch in the switch column and the bottom fence boundary of the power domain. You can use this parameter along with `-width`, `-height`, and other offsets to define a unique, specific area within the power domain for placing switches. By default, the switch column can abut the bottom fence boundary. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0`
`-bufferSwitchSameDirection` *string*	Used for chaining daisy chain with power switch cell having two enabled pins. The option usage is as follows: • `bufferSwitchSameDirection 0` (Default) Input Enable net `EnIn_1` and `EnIn_2` connect first switches at opposite ends; output `EnOut_1` and `EnOut_2` come out as last switch cells in daisy chain. • `bufferSwitchSameDirection 1` Input Enable net `EnIn_1` and `EnIn_2` connect first switches at the same end; output `EnOut_1` and `EnOut_2` come out as last switch cells in daisy chain.

`-cellEnablePin`	Specify this option to define/provide the pin names of PSO cells used in `addPowerSwitch` when the PSO cells pin names are different than given in the parameters `-enablePinIn` and `-enablePinOut`. This option can be used with ring as well as column insertion.
	The option usage is as follows for defining different cell pin signature:
	`-cellEnablePin {{cellname {enableInputPinList}\ {enableOutputPinList}}}`
	In the following example the I/O pin names of switch cells `Cell65_SW_type1` and `Cell65_SW_type2` are different. You can use the `-cellEnablePin` option to mention the pin name for switch cell `Cell65_SW_type2`.
	`addPowerSwitch -column -powerDomain PDoff \`
	`-enablePinIn { SLEEPIN } \`
	`-enablePinOut { SLEEPOUT } \`
	`-globalSwitchCellName { {Cell65_SW_type1 T1}\`
	`{Cell65_SW_type2 T2} } \`
	`-enableNetIn {Ctrl1_In } \`
	`-enableNetOut { Ctrl1_Out } -globalPattern { T1 T2 }`
	`-cellEnablePin { {Cell65_SW_type2 { SLEEPIN_1 }`
	`{SLEEPOUT_1 } }}`
	In the above example the two pins specified in `-cellEnablePin` are different from those specified in `-enablePinIn { SLEEPIN }` and `-enablePinOut { SLEEPOUT }`

`-chainByRow` *`LtoR RtoL`*	Gives additional control if you need to enable horizontal signal chaining. For example, in rows. By default, signal chaining is enabled from bottom to top. The signal chaining by this option can be: • `LtoR`: Signal chaining is enabled from Left to Right direction • `RtoL`: Signal chaining is enabled from Right to Left direction
`-checkerboard` *`string`*	Places the power switches in a checkerboard pattern within a power domain.
`-connectBottomSwitchEnablePins {`*`LtoR`* `|` *`RtoL`*`}`	Connects the first switch of the first column to the enable net specified. The software connects the first switch in the remaining columns to the output enable net of the first switch in the previous column. The following figure illustrates the `LtoR` option (default) for a rectilinear power domain.  **Note:** This parameter applies to power switch column creation only. *Default:* The enable pin of the first switch of each column is connected directly to the enable net signal specified.

`-cpfPowerSwitchRuleName` *rule_name*	Specify this option when there are multiple power switch rules specified for a power domain in CPF. By default, `addPowerSwitch` uses the first defined rule.
`-enableNetIn {listOfnets}`	Specifies the list of input nets that the software attaches to the enable input pins. The order in which you specify these nets determines the sequence in which nets are assigned to pins. Enable nets and pins are connected automatically if they reside at the same level in the hierarchy. If you have already specified `update_power_switch_rule -enable_condition` or `create_power_domain -shutoff_condition` in your CPF file, you do not need to specify this parameter. `update_power_switch_rule -enable_condition` takes precedence over `create_power_domain -shutoff_condition` for enable net In connection. For automatic enable connection to work, you should also specify `update_power_switch_rule -acknowledge_receiver` info in CPF for `enableNetOut` connection. Otherwise you should provide enable net connections using `-enableNetIn` and `-enableNetOut` options. If you specify `-enableNetIn`, it will override `create_power_domain -shutoff_condition`.
`-enableNetOut {`*netBaseName* `| {listOfNets}}`	Specifies the enable output nets that the software attaches to the enable output pins. The order in which you specify these nets determines the sequence in which nets are assigned to pins. If enable nets and pins reside at the same level in the hierarchy they are connected automatically. The `-enablePinOut` of the last switch of the last column is tied to `-enableNetOut`. If you have already specified `update_power_switch_rule -acknowledge_receiver` in your CPF file, you do not need to specify this parameter. For automatic enable connection to work, you should also specify `update_power_switch_rule -enable_condition` or `create_power_domain -shutoff_condition` in the CPF file. For enableNetIn connection you should provide enable net connections using `-enableNetIn` and `-enableNetOut` options. You must specify *netBaseName* for columns or a list of nets for rings. Automatic `enableNetOut` connection works if there is only one enable net out after insertion.
`-enablePinIn {listOfPins}`	Specifies the list of enable input pins of the buffers inside the switch cell. The order in which you specify these nets determines the sequence in which nets are assigned to pins. If enable nets and pins reside at the same level in the hierarchy they are connected automatically.The software ties the `-enablePinOut` of the first switch cell to the `-enablePinIn` of the next switch cell in the same ring: All the enable pin of the switch cells in the same column are daisy-chained together. The `-enablePinIn` of the first switch of the first column, is tied to `-enableNetIn`.
`-enablePinOut {listOfPins}`	Specifies the list of enable output pin(s) of the buffer(s) inside the switch cell. The order in which you specify these pins is important because nets are assigned to pins sequentially. The software ties the `-enablePinOut` of the first switch cell to the `-enablePinIn` of the next switch cell in the same column: All the enable pin of the switch cells in the same column are daisy-chained together. For the last switch of the column, the `-enablePinOut` is tied to `-enableNetOut`.
`-firstInstanceName` *instanceName*	Specifies the instance name of an existing switch cell in the netlist to use as the first cell in the column or ring. Usually, there is at least one switch instantiated in a module (specified by `-switchModuleInstance`) in the netlist. The software creates a unique instance name for each switch inserted. This parameter is optional. If the netlist does not contain switches, then this parameter is invalid.
`-globalBufferCellName` *cell_syntax*	Specifies the cell name of the buffer cell to insert in the power switch ring surrounding the specified power domain, or in the columns inside the power domain, if there are spaces available.

`-globalFillerCellName` *cell_syntax*	Specifies the cell name of the filler cell to insert in the power switch ring surrounding the specified power domain, or in the columns inside the power domain, if there are spaces available.
`-globalPattern` *pattern_syntax*	Specifies a pattern of cells to repeat either in the switch rings or switch columns. The pattern consists of a group of different types of cells in a specified order.
`-globalSwitchCellName` *cellName*	Specifies the cell name of the switch cell to insert in the power switch ring surrounding the specified power domain, or in the column inside the power domain. This parameter is required.
`-ground` {(*GND:GND1 GND2*...)...}	Specifies a list of ground nets and pin connections. If `-ground` has multiple ground nets, the software uses the last one in the list for tie-hi/lo connections. For example, specify `-ground (VSS:gnd vss!)` to indicate that the `gnd` and `vss!` pins of all the instances in a given power domain are connected to the `VSS` net.
`-height` *length_in_um*	Specifies the height of an area inside the power domain where switches can be placed. You can use this parameter along with `-width`, `-bottomOffset`, and `-leftOffset` to define a unique, specific area in the power domain for placing switches.
`-honorNonRegularPitchStripe`	Honors the option`-skipRows` when the pitch/distance between the power stripe specified in `-placeunderverticalnet` option is not regular. This option is related to column insertion.
`-horizontalPitch` *float*	Specifies the distance between switch columns in µm. This parameter is required. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*.
`-ignoreShifterRule`	Ignores the level shifter rules, which are applied to the power switches in both CPF and UPF.
`-ignoreSoftBlockage`	With this option `addPowerSwitch` can insert power switch cells in areas with soft or partial blockages. By default, `addPowerSwitch` does not add power switch cells in areas with any type of placement blockage: hard, soft, or partial.
`-incremental`	Inserts switches to the power domain without removing the existing switches. *Default:* Running the `addPowerSwitch` command removes the existing placed switches and inserts new switches.
`-instancePrefix` *prefix*	Adds prefix to power switch instances. **Note**: `-instancePrefix` overwrites the prefix specified in CPF by *update_power_switch_rule*.
`-leftOffset` *float*	Specifies the distance between the left-most switch in the switch column and the right fence boundary of the power domain. You can use this parameter along with `-width`, `-height`, and `-bottomOffset` to define a unique, specific area within the power domain for placing switches. By default, the switch column can abut the right fence boundary. **Note:** When you create a power domain, a `minGap` exists for this power domain, and the switches are inserted within this `minGap`. However, if the specified `minGap` is less than the switch dimension, then the tool automatically extends the `minGap` for this power domain. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*, and see commands `-bottomOffset`, `-rightOffset`, `-topOffset`, `-verticalOffset`, and `-horizontalOffset`. *Default:* `0` The switches abut the power domain fence if possible.
`-logical`	Inserts a logical power switch to the partition block so that the software writes out correct PG direction in dumped PG netlist.

-loopbackAtEnd	Connects the enablePinOut of the last cell in the chain to the enablePinIn of the same cell. This option useful or can be used when a power switch has two enablePin In and Out pins.
-maxChainDepth *integer*	Specifies the maximum number of instances in the enable chain. After the specified maximum, addPowerSwitch starts a new enable chain from the next power switch cell. This feature provides fine control over the time it takes to switch a power domain off and on.
-maxDistance *distance_in_microns*	During power switch insertion, maxDistance is the maximum distance within which the addPowerSwitch looks for the next switch to enable net connections to form an enable signal chain connection.
-maxFanout *integer*	During power switch insertion, maxFanout is the maximum number of PSO cell enable input pins that a PSO cell enable output pin may connect to. This option is to be used with maxDistance.
-noEnableChain	Inserts and places power switches without adding enable signal chaining.
-noFixedStdCellOverlap	Avoids placing PSO instances over fixed physical instances already placed on rows.
-noDoubleHeightCheck	Allows double height power switch insertion even if when SITE name is same for double height as well as single height cells. The recommended flow is to use different SITE names for single and double height cells.
-noRowVerify	Allows you to not verify row coverage at end of a column insertion. By default, the command verifies row coverage.
-offsetX	Specifies the offset number of intersections in X direction. With this, power switch instances can be inserted in checker board style with specified offset value. **Note:** This must used with -placeByNetWireIntersect and -skipX, options. The value should not be more than the value of -skipX.
-orientation *orientation_syntax*	Specifies the orientation of the switch to be placed in the row. The software checks the specified orientation of the switch against the legal orientation of the row in which the switch is to be placed. The software uses the row site information and the row orientation to determine whether the specified orientation is legal. *Default:* Follows the row orientation.
-parallelEnable	Connects a power switch's input pin in parallel style rather than daisy-chaining. You do not have to specify -enablePinOut or -enableNetOut.
-placeByNetWireIntersect {*h_net h_layer v_net v_layer*}	Places switches at the intersection of specified horizontal net and vertical net on the respective LEF layers of a pre-existing power grid. You must specify the horizontal net and layer first, then the vertical net and layer. By default, the switches are placed at the bottom-left intersection of the grid. You can offset the switches from the grid intersection by specifying -placementAdjustX, -placementAdjustXY, or -placementAdjustY in addition to this parameter.
-placementAdjustX {*delta_in_x*}	Specifies the horizontal offset (in micrometers) from the grid intersection specified by -placeByNetWireIntersect. The value can be positive or negative.
-placementAdjustXY {*delta_in_x delta_in_y*}	Specifies the x-y offset (in micrometers) from the grid intersection specified by -placeByNetWireIntersect. The values can be positive or negative.
-placementAdjustY {*delta_in_y*}	Specifies the vertical offset (in micrometers) from the grid intersection specified by -placeByNetWireIntersect. The values can be positive or negative.
-placeUnderVerticalNet {*vert_net vert_layer*}	Places switches under the vertical net of the specified LEF layer of a pre-existing power grid. By default, the switches are placed at the bottom-left intersection of the grid and row but in addition to this option, you can offset the switches from the row by specifying options like -placementAdjustX.

`-power {(VDD:VDD1 VDD2...)...}`	Specifies a list of power nets and pin connections. For example, specify `-power (Vdd1:Vdd Pwr) (Vdd2:VDD vdd!)` to indicate that the `Vdd` and `Pwr` pins of all the instances in a given power domain are connected to the `Vdd1` net, and the `VDD` and `vdd!` pins are connected to the `Vdd2` net. If `-power` has multiple power nets, the software uses the last one in the list for tie-hi/lo connections. For example, if `-power {(vdd1:VDD1)(vdd2:VDD2)}` is specified, then the software uses net `vdd2` for tie-hi connection. **Note:** You must specify both `-ground` and `-power` to ensure that the instance being moved contains the correct `(net:pin)` connections in the new power domain.
`-powerDomain powerDomainName`	Specifies the power domain that shuts off through the inserted power switches. Alternatively, you can use IDs and multipliers, as shown below: `addPowerSwitch -column -powerDomain PD0 \ -globalSwitchCellName {{switchCell_1 A} {switchCell_2 B}} \ -globalPattern {A {B*3}} ..."`
`-reportFile filename`	Writes switch instances and their corresponding input/output enable signal pin/net connections to the specified file name.
-rightOffset	Specifies the distance between the right-most switch in the switch column and the right fence boundary of the power domain. You can use this parameter along with `-width`, `-height`, and `-leftOffset` to define a unique, specific area within the power domain for placing switches. By default, the switch column can abut the right fence boundary. **Note:** When you create a power domain, a `minGap` exists for this power domain, and the switches are inserted within this `minGap`. However, if the specified `minGap` is less than the switch dimension, then the tool automatically extends the `minGap` for this power domain. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0`
-skipX	Specifies the number of intersections to skip in X direction. **Note:** This option is to be used with `-placeByNetWireIntersect`.
-skipY	Specifies the number of intersections to skip in Y direction. **Note:** This option is to be used with `-placeByNetWireIntersect`
`-skipRows integer`	Specifies the number of rows to skip when placing a switch in a column. For example, `-skipRows 2` skips two rows before placing the next switch in a column. You can use this parameter with or without the `-checkerboard` parameter.

-simplePrefix	Allows user to create a power switch instance name with simple numbers. By default power switch instance names are created in the format:
	`pso_PDname_SwitchCellName_X_andY_location_SequenceNumber`
	This option can be used with `-instancePrefix prefix`
	Example :
	`addPowerSwitch -column ... \`
	`-instancePrefix strongPsw_ -simplePrefix 1`
	With this command run, the created instance name will be: `strongPsw_1, strongPsw_2 ..`
	Note: `-simplePrefix` overwrites the prefix specified in CPF by `update_power_switch_rule`.

-snapToNearest	Snaps the cell placement to the nearest legal location. This parameter can be used when a hard macro blocks part of a column. The switches that would overlap the hard macro blockage are placed at legal locations nearest to the expected original location. You must specify either `-skipRows` or `-checkerboard` in order to create enough space for the cells to snap. If you specify `-skipRows`, you must set the value greater than zero.
`-spacerCellName` *cell_syntax*	Specifies the spacer cells to place on either side of power switch cells within a power domain to prevent the tool from placing standard cells next to the switch cells.
`-switchModuleInstance` *instanceName*	When this parameter is specified, all the switches are instantiated in the module instance specified. When not specified, the switch instances are inserted at the top level. This parameter is optional.

`-tapFromNearestEnableNet`	Enables `addPowerSwitch` to use the enable net from the nearest, already inserted/placed power switch instance. This option can be used during incremental power switch insertions.
	Example :
	`addPowerSwitch -column \`
	`-powerDomain PD1 -enablePinIn {PinIn} \`
	`-enablePinOut {PinOut} \`
	`-globalSwitchCellName PSO_SWITCH\`
	`-enableNetIn {pwr_on} -enableNetOut {pwr_ack}\`
	`-horizontalPitch 100 \`
	`-leftOffset 5 \`
	`-area { x1 y1 x2 y2 } -incremental \`
	`-tapfromnearesEnableNet`

`-topDown`	Adds switches from the top down rather than from the bottom up. The following figure shows how the software places switches from top to bottom. `-topOffset` *value*	Specifies the distance between the top-most switch in the switch column and the top fence boundary of the power domain that shuts off. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0`

`-width` *length_in_um*	Specifies the width of an area inside the power domain where switches can be placed. Specifies the distance between the bottom-most switch in the switch column and the bottom fence boundary of the power domain that shuts off. You can use this parameter along with `-bottomOffset`, `-height`, and `-leftOffset` to define a unique, specific area in the power domain for placing switches.
Power Switch Prototyping Parameters	
`-bufferDelay {`*value_in_seconds* `|` `{`*value_in_seconds value_in_seconds*`}}`	Specifies the delay of the enable buffer in switch. If the switch is a mother-daughter type (with two enables), you can specify two values corresponding to the stage-1 and stage-2 enable buffers respectively.
`-cellEM value_in_amps`	Specifies the maximum current that can pass through the switch due to the electromigration limit of the cell.
`-commitPrototype {1|0}`	Adds the number of switches determined by `-prototypeNumberSwitches`. This parameter does not work with any other prototyping commands. *Default*: If you specify `-commitPrototype` but do not specify a value, the default is 1. If you do not specify `-commitPrototype`, the default is 0.
`-deviceThresholdVolt` *value_in_volts*	Specifies the device threshold voltage for ramp up prototyping. If you do not specify this parameter, the tool computes a default value based on the switch characterization parameters.
`-idsat` `{`*value_in_amps* `|` *value_in_amps value_in_amps*`}`	Specifies the switch current when the switch is operated in saturation mode. If the switch is a mother-daughter type (with two enables), then you can specify two values corresponding to the stage-1 and stage-2 enables respectively.
`-ileak` *value_in_amps*	Specifies the switch cell leakage current when the switch is off.
`-loadCapacitance` *value_in_farads*	Specifies the total capacitive load of the domain for ramp-up analysis.
`-maxIRPercent` *float*	Specifies the maximum IR drop allowed inside power domain. *Default*: 2 percent
`-maxLeakageCurrent` *value_in_amps*	Specifies the maximum leakage current constraint of the power domain.
`-maxLeakagePercent` *float*	Specifies the maximum domain leakage constraint as a percentage of the total domain leakage current. *Default*: 50 percent
`-maxRampUpCurrent`*value_in_amps*	Specifies the maximum ramp up current value used in chain depth and switch delay prototyping. Use this parameter with `-prototypeChainDepthGivenRampUpCurrent` or `-prototypeDelayGivenRampUpCurrent`.
-maxSwitchIr*value_in_volts*	Specifies the maximum voltage drop allowed across the switch.

-netPrefix *prefix*	Adds a prefix to power switch enable nets.
	For example:
	`addPowerSwitch -instancePrefix myInst_ -netPrefix myNet_ \`
	`-column -powerDomain MPY -enableNetIn swcontrol_2 \`
	`-enableNetOut swack_2 -globalSwitchCellName CDN_COLUMN_SW \`
	`-enablePinIn A0 -enablePinOut Z0 -leftOffset 10 \`
	`-horizontalPitch 50 -skipRows 2 -reportFile PSWmpy.rpt \`
	`-switchModuleInstance DTMF_INST_4/TDSP_CORE_INST/MPY_32_INST`
	`## From PSWmpy.rpt file`
	`DTMF_INST_4/TDSP_CORE_INST/MPY_32_INST/myInst_psoI_MPY_1_CDN_COLUMN_SW_1415_330`
	`_1 (1415.32 330.87 MX)  # Domain MPY, Column 0, Sequence 1`
	`(A0) :`
	`DTMF_INST_4/TDSP_CORE_INST/MPY_32_INST/myNet_psoPSI_MPY_EnNet__1_1_1415_313_0`
	`(Z0) :`
	`DTMF_INST_4/TDSP_CORE_INST/MPY_32_INST/myNet_psoPSI_MPY_EnNet__1_2_1415_330_0`

`-noPgCapacitanceEstimate {0|1}`	Omits power grid capacitance estimation during ramp up analysis. *Default:* `0`
`-noPgDecapEstimate {0|1}`	Omits decoupling capacitance estimation during ramp up analysis. *Default:* `0`
`-numberSimultaneousRampUpChain integer`	Specifies the number of simultaneous ramp up chains for ramp up analysis.
`-protoReportFile`*fileName*	Specifies the file containing prototyping results.
`-pgCapacitance`*value_in_farads*	Specifies the total power grid capacitance for ramp up analysis.
`-pgCapacitanceFactor`*float*	Specifies the ratio of the power grid capacitance as a factor of the total load capacitance.
`-pgInductance`*value_in_henrys*	Specifies the effective power grid inductance associated with the power grid and package.
`-prototypeChainDepth {0|1}`	Performs prototyping on chain depth given maximum ramp up current. You must specify `-rampUpTime` when you specify this parameter.
`-prototypeChainDepthGivenRampUpCurrent {0|1}`	Performs prototyping on chain depth given maximum ramp up current. You must specify `-maxRampUpCurrent` when you specify this parameter.
`-prototypeDelayGivenRampUpCurrent {0|1}`	Analyzes optimum ramp up time given maximum ramp up current. You must specify `-maxRampUpCurrent` when you use this command.
`-prototypeIgnoreLeakage {0|1}`	Ignores leakage constraints during prototyping.
`-prototypeMaxChainDepth {0|1}`	Performs maximum chain depth prototyping based on ramp up time. You must specify `-rampUpTime` when you specify this parameter.
`-prototypeMinChainDepth {0|1}`	Performs minimum chain depth prototyping based on ramp up time. You must specify `-rampUpTime` when you specify this parameter.
`-prototypeNumberSwitches {0|1}`	Determines the optimum number of switches based on switch characteristics and domain constraints.
`-prototypeRampUpTime {0|1}`	Performs prototyping on ramp up time based on chain depth. You must specify `-rampUpChainDepth` when you specify this parameter.
`-prototypeSweepChainDepth {`*min_integer max_integer increment_integer*`}`	Explores various chain depths from minimum to maximum in specified increments, and reports ramp up metrics for each setting.

`-prototypeSweepSwitchNumber {`*`min_integer max_integer increment_integer`*`}`	Explores the number of switches from minimum to maximum in specified increments, and reports corresponding power domain operation metrics.
`-rampUpChainDepth integer`	Specifies the chain depth used in ramp up time prototyping. Specify this parameter when you specify `-prototypeRampUpTime`.
`-rampUpRailVoltagePercent float`	Specifies the percentage of the full domain voltage upon which the power domain is considered operable when ramping up. *Default*: 90 percent
`-rampUpTime {`*`min_value_in_seconds max_value_in_seconds`*`}`	Specifies the minimum and maximum ramp up time settings for chain depth prototyping. This parameter is required for `-prototypeChainDepth`, `-prototypeMinChainDepth`, and `-prototypeMaxChainDepth`.

`-readPowerSwitchCell`*`fileName`*	Specifies the file containing the switch characterization data. The file contains a list of characterization data per cell, on one line. If you do not put all of the information for a cell on one line, the tool issues an error message. The format is as follows:
	`CELL cell_name SUPPLY pin_name SWITCHED pin_name RON value_in_ohms IDSAT value_in_mA ILEAK value_in_mA`
	`CELL2...`
	For power switch prototyping, the tool only reads and uses the first line of the file and uses only one cell type.

`-rOn` *`value_in_ohms`*	Specifies the resistance when the switch is operated in linear mode. If the switch is a mother-daughter type (with two enables), you can specify two values corresponding to the stage-1 and stage2 enables respectively.
`-totalLeakagePower`*`value_in_watts`*	Specifies the total leakage power of the power domain before switches are added.
`-totalPower`*`value_in_watts`*	Specifies the total power consumed by the domain. If you do not specify this parameter, report_power computes power consumption.
`-voltage` *`value_in_volts`*	Specifies the primary rail voltage of the power domain.
Ring Type Insertion Parameters	
`-1801PowerSwitchRuleName` *`string`*	Specifies the power switch rule name defined in the 1801 power intent file. By default, *addPowerSwitch* uses the first defined rule.
`-bottomNumSwitch` *`integer`*	Specifies the number of switches to insert on the bottom side(s) of the power domain. **Note:** This parameter applies to power switch ring creation only. Three scenarios can occur: • If the spaces available match the number specified, the software fills these spaces with switches. • If the number exceeds the spaces available, the software issues a warning message. • If the number is less than the spaces available, the tool inserts the switches, then inserts filler cells to fill the space. Also, if you specify `f` instead of an integer, the tool automatically fills the bottom side with switches and filler cells. This parameter is optional. See `-horizontalNumSwitch`, `-verticalNumSwitch`, `-leftNumSwitch`, `-rightNumSwitch`, and `-topNumSwitch`. *Default:* `f`

`-bottomOffset` *float*	Specifies distance from the bottom edge outside of the power domain fence and the bottom side(s) of the power switch ring. See `-horizontalOffset, -verticalOffset, -leftOffset, -rightOffset, and -topOffset`. **Note:** When you create a power domain, a `minGap` exists for this power domain, and the switches are inserted within this `minGap`. However, if the specified `minGap` is less than the switch dimension, then the tool automatically extends the `minGap` for this power domain. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0`
`-bottomOrientation` *orientation_syntax*	Specifies the cell orientation for all bottom side(s) of the power switch ring.
`-bottomPattern` *pattern_syntax*	Defines a pattern for the bottom side(s) of the ring only.
`-bottomSide [0 | 1]`	Inserts switches on the bottom side(s) of the power domain. If you do not specify a side, the software creates a full power switch ring around the specified power domain. If you specify a side, the software inserts switches on that side. In this case, the tool sets `-bottomSide` to 1 and sets the other sides to `0`. You can specify multiple sides and the software inserts switches only on the sides you specify. The tool sets the specified sides to `1` and sets the unspecified sides to `0`. *Default:* `1`
`-bufferCellNameBottom` *cell_syntax*	Specifies the buffer cells to use on the bottom side(s) of the switch ring.
`-bufferCellNameHorizontal` *cell_syntax*	Specifies the buffer cells to use on the horizontal side(s) of the switch ring.
`-bufferCellNameLeft` *cell_syntax*	Specifies the buffer cells to use on the left side(s) of the switch ring.
`-bufferCellNameRight` *cell_syntax*	Specifies the buffer cells to use on the right side(s) of the switch ring.
`-bufferCellNameTop` *cell_syntax*	Specifies the buffer cells to use on the top side(s) of the switch ring.
`-bufferCellNameVertical` *cell_syntax*	Specifies the buffer cells to use on the vertical side(s) of the switch ring. This parameter applies to power switch ring creation only.

`-bufferCellSideList {`*cell_syntax* `…}`	Specifies that the buffer cells are inserted on each side of a power domain. The first value of the list indicates the first side related to `Corner 0`, which is the lower left corner of the ring. If the `-counterclockwise` parameter is specified, the first side is considered from from `Corner 0` in the counterclockwise direction. The following example shows the buffer cells specified for an eight-sided power switch ring:
	`-specifySideList {1 0 1 0 1 0 1 0}`
	`-switchCellSideList {cell1 cell1 cell2 cell2 cell3 cell3 cell4 cell4}`
	The `cell1` value is used for the first side. Specify `cell1` again to provide a valid cell type, even when there are no cells on the second side.
	Note: A space must be inserted between the list values. Additionally, only a valid cell name must be specified for each side, even if no cells can be specified for a side. The tools checks whether the number of specified cells is the same as the number specified with `-specifySideList`. In case of any discrepancy, an error message is displayed.

`-cellEnablePin` *string*	Specify this option to define/provide the pin names of PSO cells used in `addPowerSwitch` when the PSO cells pin names are different than given in the parameters `-enablePinIn` and `-enablePinOut`. This option can be used with ring as well as column insertion.
	
	The option usage is as follows for defining different cell pin signature:
	
	`-cellEnablePin {{cellname {enableInputPinList}\ {enableOutputPinList}}}`
	
	In the following example the I/O pin names of switch cells `Cell65_SW_type1` and `Cell65_SW_type2` are different. You can use the `-cellEnablePin` option to mention the pin name for switch cell `Cell65_SW_type2`.
	
	`addPowerSwitch -ring -powerDomain PDoff \`
	`-enablePinIn { SLEEPIN } \`
	`-enablePinOut { SLEEPOUT } \`
	`-globalSwitchCellName { {Cell65_SW_type1 T1}\{`
	`Cell65_SW_type2 T2} } \`
	`-enableNetIn {Ctrl1_In } \`
	`-enableNetOut { Ctrl1_Out } -globalPattern { T1 T2 }-cellEnablePin {`
	`{Cell65_SW_type2 { SLEEPIN_1 } { SLEEPOUT_1 } }}`
	
	In the above example the two pins specified in `-cellEnablePin` are different from those specified in `-enablePinIn { SLEEPIN }` and `-enablePinOut { SLEEPOUT }`

`-centerTapPins` *pinname_list*	Enables the center tap capability, and specifies the pins to use as center taps. You must use breaker cells to terminate the buffer signal propagation on both sides of the center tap buffer. The following figure shows that, depending on the specified pin name list, the software assigns a pin name to the enable net. This feature can be useful for debugging the enable signal. **Note:** This parameter applies to power switch ring creation only. `-continuePattern`	Continues a specified pattern from one side of the ring to the next side. You must also specify `-globalPattern` when you use this parameter. *Default:* If you do not use this parameter, the software stops the pattern at the end of a side and restarts the pattern from the beginning on the next side.
`-counterclockwise`	Places the cell pattern in a counterclockwise direction in a switch ring. Switch placement begins at the lower left corner of the ring. *Default:* If you do not specify this parameter, the software places the pattern in a clockwise direction.
`-cornerCellList {`*listOfCornerCells*`}`	Specifies the list of available corner cells that can be used by the tool to fill the corners of the ring. This parameter is optional. If user specifies only one corner cell, that same cell is used on all four corners with the appropriate orientation for a rectangular power domain.

`-cornerCellListByCorner` *`corner_cells_name_per_corner`*	Specifies the corner cells to be used at different corners. This is applicable for ring only. This option is optional.
	In an example of a rectangular power domain with four corners and two different corner cells, we name the cells: `CORNER_cell1` and `CORNER_cell2` using the option `-cornerCelllist` and then we map them to each corner as shown below:
	`addPowerSwitch -powerDomain PSO -ring \`
	`-globalSwitchCellName {{VDDISWITCH } \`
	`-globalFillerCellName {{FILLERCELL } \`
	`-specifySides {1 1 1 1 } \`
	`-globalOffset 4 \`
	`-cornercelllist { CORNER_cell1 CORNER_cell2 } \`
	`-cornerCellListByCorner { CORNER_cell1\ CORNER_cell2 CORNER_cell1 CORNER_cell2 }\`
	`.... \`

`-cornerOrientationList {`*`orientation_syntax`* `…}`	Specifies cell orientations for the tool to use for each corner of switch ring, starting with Corner 0 (the lower left corner). List the orientations in a list, with the first orientation corresponding to the first side, the second orientation to the second side, and so on. If you do not specify this parameter, the software determines the corner cell orientations.
`-cpfPowerSwitchRuleName` *`rule_name`*	Specify this option when there are multiple power switch rules specified for a power domain in CPF. By default, `addPowerSwitch` uses the first defined rule.
`-deviceThresholdVolt` *`value_in_volts`*	Specifies the device threshold voltage for ramp up prototyping.
`-distribute`	Distributes switches of different types as evenly as possible on a ring side. For example, if there are 40 available slots, and there are 20 switches and 20 fillers, the software will alternate switches and fillers in the available slots. Use this option together with `-horizontalNumSwitch`, `-verticalNumSwitch`, `-leftNumSwitch`, `-rightNumSwitch`, `-topNumSwitch`, or `-bottomNumSwitch`.
`-enableNetIn {listOfnets}`	Specifies the list of input nets that the software attaches to the enable input pins. The order in which you specify these nets determines the sequence in which nets are assigned to pins. Enable nets and pins are connected automatically if they reside at the same level in the hierarchy. If you have already specified `update_power_switch_rule -enable_condition` or `create_power_domain -shutoff_condition` in your CPF file, you do not need to specify this parameter. `update_power_switch_rule -enable_condition` takes precedence over `create_power_domain -shutoff_condition` for enable net In connection. For automatic enable connection to work, you should also specify `update_power_switch_rule -acknowledge_receiver` info in CPF for `enableNetOut` connection. Otherwise you should provide enable net connections using `-enableNetIn` and `-enableNetOut` options. If you specify `-enableNetIn`, it will override `create_power_domain -shutoff_condition`.

`-enableNetOut {`*`netBaseName`* `| {listOfNets}}`	Specifies the enable output nets that the software attaches to the enable output pins. The order in which you specify these nets determines the sequence in which nets are assigned to pins. If enable nets and pins reside at the same level in the hierarchy they are connected automatically. For the last switch of the ring, the `-enablePinOut` is tied to `-enableNetOut`. If you have already specified `update_power_switch_rule -acknowledge_receiver` in your CPF file, you do not need to specify this parameter. For automatic enable connection to work, you should also specify `update_power_switch_rule -enable_condition` or `create_power_domain -shutoff_condition` in the CPF file. For `enableNetIn` connection you should provide enable net connections using `-enableNetIn` and `-enableNetOut` options. You must specify *`netBaseName`* for columns or a list of nets for rings. Automatic `enableNetOut` connection works if there is only one enable net out after insertion.
-enablePinIn {listOfPins}	Specifies the list of enable input pins of the buffers inside the switch cell. The order in which you specify these nets determines the sequence in which nets are assigned to pins. If enable nets and pins reside at the same level in the hierarchy they are connected automatically.The software ties the `-enablePinOut` of the first switch cell to the `-enablePinIn` of the next switch cell in the same ring: All the enable pin of the switch cells in the same column are daisy-chained together. For the first switch of the ring, the `-enablePinIn` is tied to `-enableNetIn`.
-enablePinOut {listOfPins}	Specifies the list of enable output pin(s) of the buffer(s) inside the switch cell. The order in which you specify these pins is important because nets are assigned to pins sequentially. The software ties the `-enablePinOut` of the first switch cell to the `-enablePinIn` of the next switch cell in the same column: All the enable pin of the switch cells in the same column are daisy-chained together. For the last switch of the column, the `-enablePinOut` is tied to `-enableNetOut`.
`-endOffset` *`value`*	Places the last switch on every side of the power domain at the specified distance from the end of each side. The side end is not necessarily determined by the power domain boundary. You can use `-leftOffset`, `-rightOffset`, `-topOffset`, `-bottomOffset`, `-horizontalOffset`, and/or `-verticalOffset` to determine the side end relative to the power domain boundary. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default*: `0`
`-endOffsetBottom` *`value`*	Places the last switch on bottom side of the power domain at the specified distance from end of the side. The side end is not necessarily determined by the power domain boundary. You can use `-leftOffset`, `-rightOffset`, and/or `-verticalOffset` to determine the side end relative to the power domain boundary. • If the value is positive, the software places the switch to the right of the end location, or to the left of the end location if `-counterclockwise` is specified. • If the value is negative, the software places the switch to the left of the end location, or to the right of the end location if `-counterclockwise` is specified. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0`

`-endOffsetHoriztonal` *value*	Places the last switch on the horizontal side of the power domain at the specified distance from end of the side. The side end is not necessarily determined by the power domain boundary. You can use `-leftOffset`,`-rightOffset`, and/or `-verticalOffset` to determine the side end relative to the power domain boundary. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0`
`-endOffsetLeft` *value*	Places the last switch on the left side of the power domain at the specified distance from end of the side. The side end is not necessarily determined by the power domain boundary. You can use `-topOffset -bottomOffset` and/or `-horizontalOffset` to determine the side end location relative to the power domain boundary. • If the value is positive, the software places the switch below the end location, or above the end location if `-counterclockwise` is specified. • If the value is negative, the software places the switch above the end location, or above the end location if `-counterclockwise` is specified. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0`
`-endOffsetRight` *value*	Places the last switch on the right side of the power domain at the specified distance from end of the side. The side end is not necessarily determined by the power domain boundary. You can use the `-topOffset`, `-bottomOffset`, or `-horizontalOffset` to determine the side end relative to the power domain boundary. • If the value is positive, the software places the switch above the end location, or below the end location if `-counterclockwise` is specified. • If the value is negative, the software places the switch below the end location, or below the end location if `-counterclockwise` is specified. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0`
`-endOffsetTop` *value*	Places the last switch on the top side of the power switch ring at the specified distance from end of the side. The side end is not necessarily determined by the power domain boundary. You can use `-leftOffset`, `-rightOffset` or `-verticalOffset` to determine the side end relative to the power domain boundary. • If the value is positive, the software places the switch to the left of the end location, or to the right of the end location if `-counterclockwise` is specified. • If the value is negative, the software places the switch to the right of the end location, or to the left of the end location if `-counterclockwise` is specified. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0`

`-endOffsetVertical` *value*	Places the last switch on the vertical sides of the power switch ring at the specified distance from end of the side. The side end is not necessarily determined by the power domain boundary. You can use `-topOffset`, `-bottomOffset`, and/or `-horizontalOffset` to determine to the side end relative to the power domain boundary. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0`
`-fillerCellNameBottom` *cell_syntax*	Specifies the filler cell used for the bottom side(s) of the ring. You can specify a different filler cell for each side of the ring. This parameter is optional. *Default:* The filler cell specified by `-globalFillerCellName`.
`-fillerCellNameHorizontal` *cell_syntax*	Specifies the filler cell used for the horizontal side(s) of the ring. You can specify a different filler cell for each side of the ring. This parameter is optional. *Default:* The filler cell specified by `-globalFillerCellName`.
`-fillerCellNameLeft` *cell_syntax*	Specifies the filler cell used for the left side(s) of the ring. You can specify a different filler cell for each side of the ring. This parameter is optional. *Default:* The filler cell specified by `-globalFillerCellName`.
`-fillerCellNameRight` *cell_syntax*	Specifies the filler cell used for the right side(s) of the ring. You can specify a different filler cell for each side of the ring. This parameter is optional. *Default:* The filler cell specified by `-globalFillerCellName`.
`-fillerCellNameTop` *cell_syntax*	Specifies the filler cell used for the top side(s) of the ring. You can specify a different filler cell for each side of the ring. This parameter is optional. *Default:* The filler cell specified by `-globalFillerCellName`.
`-fillerCellNameVertical` *cell_syntax*	Specifies the filler cell used for the vertical side(s) of the ring. You can specify a different filler cell for each side of the ring. This parameter is optional. *Default:* The filler cell specified by `-globalFillerCellName`.

`-fillerCellSideList {`*cell_syntax* `…}`	Specifies the filler cells to insert on each side of a power domain. The first member of the list indicates the first side relative to Corner 0, which is the lower left corner of the ring. If `-counterclockwise` is specified, the first side is counterclockwise from Corner 0.
	The following example shows the filler cells specified for an eight-sided power switch ring:
	`-specifySideList {1 0 1 0 1 0 1 0}`
	`-fillerCellSideList {cell1 cell1 cell2 cell2 cell3 cell3 cell4\ cell4}`
	`cell1` is used for the first side. You can then specify `cell1` again to provide a valid cell type, even though there can be no cells on the second side.
	Info: You must include a space between each item in the list.
	You *must* specify a valid cell name for each side, even if no cells can be specified for a side.
	The tools checks that the number of cells you specify is the same number you specified with `-specifySideList`, and issues an error message if it finds a discrepancy.

`-fillGapWithFiller`	Forces filling of gap between ring-type power switches using the specified filler cell.

`-firstInstanceName` *instanceName*	Specifies the instance name of an existing switch cell in the netlist to use as the first cell in the column or ring. Usually, there is at least one switch instantiated in a module (specified by `-switchModuleInstance`) in the netlist. The software creates a unique instance name for each switch inserted. This parameter is optional. If the netlist does not contain switches, then this parameter is invalid.
`-forceOffset`	Forces the software to place ring switches at the exact offset you specify for all sides. Sides with unspecified offsets are forced to 0.0 µ. When you specify any other offset without specifying `-forceOffset`, the tool places switches at the smallest distance that is greater than or equal to the specified offset for each side, in order to maintain a contiguous ring. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. **Note:** Using this parameter might result in gaps in the ring.
`-globalBufferCellName` *cell_syntax*	Specifies the cell name of the buffer cell to insert in the power switch ring surrounding the specified power domain, or in the columns inside the power domain, if there are spaces available.
`-globalFillerCellName` *cell_syntax*	Specifies the cell name of the filler cell to insert in the power switch ring surrounding the specified power domain, or in the columns inside the power domain, if there are spaces available.
`-globalOffset` *value*	Offsets all sides of the power switch ring the specified distance from the power domain boundary. Specify the offset in µm. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0`
`-globalPattern` *pattern_syntax*	Specifies a pattern of cells to repeat either in the switch rings or switch columns. The pattern consists of a group of different types of cells in a specified order. In the ring style, you can use the `-continuePattern` parameter to continue the pattern around the corner, from one side of the ring to another.
`-globalSwitchCellName` *cellName*	Specifies the cell name of the switch cell to insert in the power switch ring surrounding the specified power domain, or in the column inside the power domain. This parameter is required.
`-ground {(`*GND:GND1 GND2*`...)...}`	Specifies a list of ground nets and pin connections. If `-ground` has multiple ground nets, the software uses the last one in the list for tie-hi/lo connections. For example, specify `-ground (VSS:gnd vss!)` to indicate that the `gnd` and `vss!` pins of all the instances in a given power domain are connected to the `VSS` net.
`-horizontalNumSwitch` *value*	Specifies the number of switches to insert on the horizontal side(s) of the power domain. **Note:** This parameter applies to power switch ring creation only. Three scenarios can occur: • If the spaces available match the number specified, the software fills these spaces with switches. • If the number exceeds the spaces available, the software issues the following error message. • If the number is less than the spaces available, the tool inserts the switches, then inserts filler cells to fill the space. This parameter is optional. See `-leftNumSwitch`, `-rightNumSwitch`, and `-topNumSwitch`.
`-horizontalPattern` *pattern_syntax*	Specifies a pattern of cells to repeat on the horizontal side(s) of the power domain when switches are inserted. The pattern consists of a group of different types of cells in a specified order.

`-horizontalOffset` *value*	Offsets the switch ring from the horizontal edge of the power domain. Specify the offset in µm. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0`
`-horizontalOrientation` *orientation_syntax*	Specifies the cell orientation for all horizontal side(s) of the power switch ring.
`-horizontalSide [0|1]`	Inserts switches on all horizontal side(s) of a power domain. You cannot specify this parameter in conjunction with `-verticalSide`, `-bottomSide`, `-topSide`, `-leftSide`, or `-rightSide`. *Default:* `1`
`-ignoreSoftBlockage`	With this option `addPowerSwitch` can insert power switch cells in areas with soft or partial blockages. By default, `addPowerSwitch` does not add power switch cells in areas with any type of placement blockage: hard, soft, or partial.
`-incremental`	Inserts switches to the power domain without removing the existing switches. *Default:* Running the `addPowerSwitch` command removes the existing placed switches and inserts new switches.
`-insideCornerCellList {`*cellName …*`}`	Specifies a list of cells for the tool to choose for the inside corners of the power domain. The following example specifies the corner cells any power switch ring: `-insideCornerCellList {cell1 cell2}` **Note:** You do not need to list a specific cell for a specific corner. The tool selects from the list you provide.
`-instancePrefix` *prefix*	Adds prefix to power switch instances. The option applies to column and ring insertion.
`-leftOffset` *float*	Specifies distance from the right edge outside of the power domain fence and the right side of the power switch ring. See`-horizontalOffset`, `-verticalOffset`, `-rightOffset`, `-bottomOffset`, and `-topOffset`. **Note:** When you create a power domain, a `minGap` exists for this power domain, and the switches are inserted within this `minGap`. However, if the specified `minGap` is less than the switch dimension, then the tool automatically extends the `minGap` for this power domain. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide* and see `-bottomOffset`, `-rightOffset`, `-topOffset`, `-verticalOffset`, and `-horizontalOffset`.. *Default:* `0` The switches abut the power domain fence if possible.
`-leftNumSwitch` *integer*	Specifies the number of switches to insert on left side(s) of the power domain. Three scenarios can occur: • If the spaces available match the number specified, then the software fills these spaces with switches. • If the number exceeds the spaces available, the software issues a warning message. • If the number is less than the spaces available, the tool inserts the switches, then inserts filler cells to fill the space. This parameter is optional. See `-bottomNumSwitch`,`-rightNumSwitch`, and `-topNumSwitch`. *Default:* `f`
`-leftOrientation` *orienation_syntax*	Specifies the cell orientation for all left side(s) of the power switch ring.

`-leftPattern` *pattern_syntax*	Defines a pattern for the left side(s) of the ring only. You can use this parameter with `-bottomPattern`, `-topPattern`, and `-rightPattern`.
`-leftSide [0 | 1]`	Inserts switches on the left side(s) of the power domain. If you do not specify a side, the software creates a full power switch ring around the specified power domain. If you specify a side, the software inserts switches on that side. In this case, the tool sets `-leftSide` to 1 and sets the other sides to `0`. You can specify multiple sides and the software inserts switches only on the sides you specify. The tool sets the specified sides to `1` and sets the unspecified sides to `0`. *Default:* 1
`-noFiller`	Suppresses the addition of filler cells in power switch rings.
`-noMinGapAdjust`	Can be used when the user does not want to extend the minimum power domain gaps to form the power switch ring.
`-noEnableChain`	Inserts and places power switches without adding enable signal chaining.
`-numSwitches`	Defines total number switches to be added around a power domain. This is applicable to ring type insertion only.
`-parallelEnable`	Connects a power switch's input pin in parallel style rather than daisy-chaining. You do not have to specify `-enablePinOut` or `-enableNetOut`.
`-power {(`*VDD:VDD1 VDD2*`...)...}`	Specifies a list of power nets and pin connections. For example, specify `-power (Vdd1:Vdd Pwr) (Vdd2:VDD vdd!)` to indicate that the `Vdd` and `Pwr` pins of all the instances in a given power domain are connected to the `Vdd1` net, and the `VDD` and `vdd!` pins are connected to the `Vdd2` net. If `-power` has multiple power nets, the software uses the last one in the list for tie-hi/lo connections. For example, if `-power {(vdd1:VDD1)(vdd2:VDD2)}` is specified, then the software uses net `vdd2` for tie-hi connection. **Note:** You must specify both `-ground` and `-power` to ensure that the instance being moved contains the correct `(net:pin)` connections in the new power domain.
`-powerDomain` *powerDomainName*	Specifies the power domain that shuts off through the inserted power switches. Alternatively, you can use IDs and multipliers, as shown below: `addPowerSwitch -ring -powerDomain PD0 \ -globalSwitchCellName {{switchCell_1 A} {switchCell_2 B}} \ -globalPattern {A {B*3}} ..."`
`-perSideNumSwitches` *value*	Specifies the number of switches to use on all sides of a power switch ring.
`-reportFile` *filename*	Writes switch instances and their corresponding input/output enable signal pin/net connections to the specified file name.
`-rightOffset`	Specifies distance from the right edge outside of the power domain fence and the right side of the power switch ring. See`-horizontalOffset, -verticalOffset, -leftOffset, -bottomOffset, and -topOffset`. **Note:** When you create a power domain, a `minGap` exists for this power domain, and the switches are inserted within this `minGap`. However, if the specified `minGap` is less than the switch dimension, then the tool automatically extends the `minGap` for this power domain. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0`

`-r0Corner` *corner_syntax*	Specifies the side where the corner cell instance can be placed in the `R0` orientation without rotation. • `UL` = Upper left • `LL` = Lower left • `LR` = Lower right • `UR` = Upper right The orientation rotates the corner cell 90 degrees for each corner, proceeding counterclockwise. *Default:* `UL` The corner cell in the upper left position in the ring is placed with orientation R0. Default orientations: • `UL = R0` • `LL = MX` • `LR = R180` • `UR = MY`
`-r0InsideCorner {LT | TR | RB | BL}`	Specifies the inside corner where to place the corner cell instance in the R0 orientation. Use this parameter for rectilinear switch rings containing inside corners. • `LT` = Corner of the left and top sides • `TR` = Corner of the top and right sides • `RB` = Corner of the right and bottom sides • `BL` = Corner of the bottom and left sides *Default:* `LT` The corner cell in the left top position in the ring is placed with the orientation R0. • `LT = R0` • `BL = MX` • `RB = R180` • `TR = MY`

`-r0Side {L | T | R | B}`	Specifies the side where the switch or filler instance can be placed in the `R0` orientation without rotation. The command adjusts the orientation of the remaining sides so that the switches form a continuous ring. The orientation rotates 90 degrees for each side, proceeding counterclockwise. • `L` = Left side • `T` = Top side • `R` = Right side • `B` = Bottom side The orientation rotates 90 degrees for each side, proceeding counterclockwise, unless `-counterClockwise` is specified. *Default:* `T` The switch and filler cells in the top row are placed with orientation `R0`. Default orientations: • `T = R0` • `L = R90` • `B = R180` • `R = R270`
`-r0SideOrientation orientation_syntax`	Enables the software to rotate or mirror the switch instances on the R0 side. The software automatically adjusts the orientation of the other sides of the domain to form a continuous ring.
`-ring`	Specifies ring style power switch insertion. Power switches are placed outside the power domain.
`-rightNumSwitch integer`	Specifies the number of switches to insert on right side(s) of the power domain. Three scenarios can occur: • If the spaces available match the number specified, then the software fills these spaces with switches. • If the number exceeds the spaces available, the software issues a warning message. • If the number is less than the spaces available, the tool inserts the switches, then inserts filler cells to fill the space. Also, if you specify `f` instead of an integer, the tool automatically fills the right side with switches and filler cells. This parameter is optional. See `-bottomNumSwitch`, `-leftNumSwitch`, and `-topNumSwitch`. *Default:* `f`
`-rightOrientation orientation_syntax`	Specifies the cell orientation for all right side(s) of the power switch ring.
`-rightPattern pattern_syntax`	Defines a pattern for the right side(s) of the ring only. You must use this parameter with `-bottomPattern`, `-topPattern`, and `-leftPattern`.

`-rightSide [0 | 1]`	Inserts switches on the right side(s) of the power domain. If you do not specify a side, the software creates a full power switch ring around the specified power domain. If you specify a side, the software inserts switches on that side. In this case, the tool sets `-rightSide` to 1 and sets other sides to `0`. You can specify multiple sides and the software inserts switches only on the sides you specify. The tool sets the specified sides to `1` and sets the unspecified sides to `0`. *Default:* `1`
`-sideEndOffsetList {value ...}`	Places the last switch at the specified distance from the end of the sides. Use this parameter with rectilinear power domains to specify a value for each side. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0`

`-sideOffsetList {value …}`	Lists the offset values representing the distance between the power domain fence boundary and each side of the power switch ring. Each value in the list corresponds to a side specified with `-specifySideList`.
	
	The following example show that all sides of an eight-sided power domain can have switches:
	
	`-specifySideList {1 1 1 1 1 1 1 1}`
	
	The following example shows an offset of 8 µm from side1, 8 µm from side2, 8 µm from side 3, 6 µm from side 4, 3 µm from side 5, 3 µm from side 6, 3 µm from side 7, and 6 µm from side 8.
	
	`-sideOffsetList {8 8 8 6 3 3 3 6}`
	
	Note: When you create a power domain, a `minGap` exists for this power domain, and the switches are inserted within this `minGap`. However, if the specified `minGap` is less than the switch dimension, then the tool automatically extends the `minGap` for this power domain.
	
	Info: You must include a space between each item in the list.
	
	You *must* specify a valid cell name for each side, even if no cells can be specified for a side.
	
	The tools checks that the number of cells you specify is the same number you specified with `-specifySideList`, and issues an error message if it finds a discrepancy.
	
	For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*.
	
	Default: `0`
	The switches abut the power domain fence if possible.

`-sideOrientationList {`*orientation_syntax* `…}`	Lists the orientations for cells in each side of the power switch ring. Each orientation in the list corresponds to a side specified
	
	The following example shows which sides of an eight-sided power domain can have switches:
	
	`-specifySideList {1 1 1 1 1 1 1 1 }`
	
	Ring switches can be placed on any side.
	
	The following example shows that cells in side 1 have orientation R90, R180 in side 3, R270 in side5, and R0 in side 7:
	
	`-sideOrientationList {R90 R90 R180 R180 R270 R270 R0 R0}`
	
	Info: You must include a space between each item in the list.
	You *must* specify a valid cell name for each side, even if no cells can be specified for a side.
	
	The tools checks that the number of cells you specify is the same number you specified with `-specifySideList`, and issues an error message if it finds a discrepancy.

`-sidePatternList {`*pattern_syntax* `…}`	Specifies the cell pattern per side of a power switch ring. Each pattern in the list corresponds to a side specified with `-specifySideList`.
	
	The following example shows which sides of an eight-sided power domain can have switches:
	
	`-specifySideList {1 0 1 0 1 0 1 0}`
	
	Ring switches can be placed at sides 1, 3, 5, and 7.
	
	The following example shows that cells in side 1 have orientation R90, R180 in side 3, R270 in side5, and R0 in side 7:
	
	`-sidePatternList {{cell1 cell2 {cell3 * 6}} {cell1 cell2 {cell3 * 6}} {cell2 cell3 {cell4 * 6}} {cell2 cell3 {cell4 * 6}} {cell1 cell2 {cell3 * 6}} {cell1 cell2 {cell3 * 6}} {cell2 cell3 {cell4 * 6}}{cell2 cell3 {cell4 * 6}}`
	
	Info: You must include a space between each item in the list.
	
	You must include a valid pattern for each side, regardless of whether the side has any switches.
	
	The tools checks that the number of cells you specify is the same number you specified with `-specifySideList`, and issues an error message if it finds a discrepancy.

`-startOffset` *value*	Places the first cell on every side of the power domain at the specified distance from the beginning of each side. The beginning of each side is not necessarily determined by the power domain boundary. You can use `-leftOffset`, `-rightOffset`, `-topOffset`, `-bottomOffset`, `-horizontalOffset`, and/or `-verticalOffset` to determine the beginning of each side relative to the power domain boundary. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default*: `0`

`-strictNegativeOffset`	Defines the offset from the domain boundary to the power switch edge facing the corresponding power domain boundary. See diagram for more details. `-sideStartOffsetList {`*`value ...`*`}`	Places the first cell at the specified distance from the starting location of the sides. Use this parameter with rectilinear power domains to specify a value for each side. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0`

`-simplePrefix`	Allows user to create a power switch instance name with simple numbers. By default power switch instance names are created in the format:
	`pso_`*`PDname_SwitchCellName_X_andY_location_SequenceNumber`*
	This option can be used with `-instancePrefix` *`prefix`*
	Example :
	`addPowerSwitch -column ...\`
	`-instancePrefix strongPsw_ -simplePrefix 1`
	With this command run, the created instance name will be: `strongPsw_1, strongPsw_2 ..`

`-specifySideList {0|1 …}`	Specifies the sides of a power switch ring that can and cannot contain ring switches. In the list, 1 indicates that the side can contain ring switches, and 0 indicates that the side cannot contain ring switches. The list must contain either 0 or 1 for each side of the shape. The first member of the list indicates the first side relative to Corner 0, which is the lower left corner of the ring. If `counterclockwise` is specified, the first side is counterclockwise from Corner 0. The following example shows which sides of an eight-sided power domain can have sw itches: `-specifySideList {1 0 1 0 1 0 1 0}` Ring switches can be inserted at sides 1, 3, 5, and 7. **Note:** You must include a space between each item in the list.
`-startEnableChainAtCorner` *`integer`* or *`corner_syntax`*	Specifies the corner where the switch ring insertion begins. This parameter can accept corner syntax or an integer, which accommodates more than four corners in a rectilinear power domain. The corner numbering starts with corner 0 at the lower left corner, and proceeds clockwise around the switch ring (unless `-counterclockwise` is specified). For example, `-startEnableChainAtCorner 1` starts the enable chain at the first corner found in a clockwise direction from corner 0.

`-startOffsetBottom` *value*	Places the first cell on the bottom side of the power domain at the specified distance from the beginning location of the side.The beginning location of the side is not necessarily determined by the power domain boundary. You can use `-leftOffset`, `-rightOffset` or `-verticalOffset` to determine the beginning location of the side relative to the power domain boundary. • If the value is positive, the software places the cell to the left of the starting location, or to the right of the starting location if `-counterclockwise` is specified. • If the value is negative, the software places the cell to the right of the starting location, or to the left of the starting location if `-counterclockwise` is specified. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0`
`-startOffsetHorizontal` *value*	Places the first cell on the horizontal side of the power domain at the specified distance from the beginning location of the sides. The beginning location of the side is not necessarily determined by the power domain boundary. You can use `-leftOffset`, `-rightOffset` or `-verticalOffset` to determine the beginning location of the side relative to the power domain boundary. • If the value is positive, the software places the cell to the left of the starting location, or to the right of the starting location if `-counterclockwise` is specified. • If the value is negative, the software places the cell to the right of the starting location, or to the left of the starting location if `-counterclockwise` is specified. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *Innovus User Guide*. *Default:* `0`
`-startOffsetLeft` *value*	Places the first cell on the left side of the power domain at the specified distance from the beginning location of the side. The beginning location of the side is not necessarily determined by the power domain boundary. You can use `-bottomOffset`, `-topOffset`, or`-horizontalOffset` to determine the beginning location of the side relative to the power domain boundary. • If the value is positive, the software places the cell above the starting location, or below the starting location if `-counterclockwise` is specified. • If the value is negative, the software places the cell below the starting location, or above the starting location if `-counterclockwise` is specified. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0`

`-startOffsetRight` *value*	Places the first cell on the right side of the power domain at the specified distance from the beginning location of the side. The beginning location of the side is not necessarily determined by the power domain boundary. You can use `-topOffset`, `-bottomOffset`, or `-horizontalOffset` to determine the beginning location of the side relative to the power domain boundary. • If the value is positive, the software places the first cell below the beginning location of the side, or above the beginning location of the side if `-counterclockwise` is specified. • If the value is negative, the software places the first cell above the beginning location of the side, or below the beginning location of the side if `-counterclockwise` is specified. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0`
`-startOffsetTop` *value*	Places the first cell at the specified distance from the starting location of the top offset. Use this parameter with `-leftOffset`, `-rightOffset`, or `-verticalOffset` to determine the beginning location of the side. • If the value is positive, the software places the first cell to the right of the beginning location of the side, or to the left of the beginning location of the side if `-counterclockwise` is specified. • If the value is negative, the software places the first cell to the left of the beginning location of the side, or to the right of the beginning location of the side if `-counterclockwise` is specified. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0`
`-startOffsetVertical` *value*	Places the first cell on the vertical sides of the power switch ring at the specified distance from beginning location of the vertical sides. The beginning location of the side is not necessarily determined by the power domain boundary. You can use `-topOffset`, `-bottomOffset`, or `-horizontalOffset` to determine the beginning location of the side relative to the power domain boundary. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0`
`-switchCellNameBottom` *cell_syntax*	Specifies a different switch cell for the bottom side(s) of the power switch ring.*Default:* The switch cell specified by `-globalSwitchCellName`.
`-switchCellNameHorizontal` *cell_syntax*	Specifies a different switch cell for the horizontal side(s) of a power switch ring. *Default:* The switch cell specified by `-globalSwitchCellName`.
`-switchCellNameLeft` *cell_syntax*	Specifies a different switch cell for the left side(s) of the power switch ring. *Default:* The switch cell specified by `-globalSwitchCellName`.
`-switchCellNameRight` *cell_syntax*	Specifies a different switch cell for the right side(s) of the power switch ring. *Default:* The switch cell specified by `-globalSwitchCellName`.
`-switchCellNameTop` *cell_syntax*	Specifies a different switch cell for the top side(s) of the power switch ring. *Default:* The switch cell specified by `-globalSwitchCellName`.

`-topSwitchCell` *float*	Specifies a different switch cell for the top side(s) of the power switch ring. *Default:* The switch cell specified by `-globalSwitchCellName`.
`-switchCellNameVertical` *cell_syntax*	Specifies a different switch cell for the vertical side(s) of a power switch ring. *Default:* The switch cell specified by `-globalSwitchCellName`.

`-switchCellSidesList {`*cell_syntax …*`}`	Specifies the switch cells to insert on each side of a power domain. The first member of the list indicates the first side relative to Corner 0, which is the lower left corner of the ring. If `-counterclockwise` is specified, the first side is counterclockwise from Corner 0.
	The following example shows the switch cells specified for an eight-sided power switch ring:
	`-specifySideList {1 0 1 0 1 0 1 0}`
	`-switchCellSideList {cell1 cell1 cell2 cell2 cell3 \ cell3 cell4 cell4}`
	`cell1` is used for the first side. You can then specify `cell1` again to provide a valid cell type, even though there can be no cells on the second side.
	Info: You must include a space between each item in the list.
	You *must* specify a valid cell name for each side, even if no cells can be specified for a side.
	The tools checks that the number of cells you specify is the same number you specified with `-specifySideList`, and issues an error message if it finds a discrepancy.

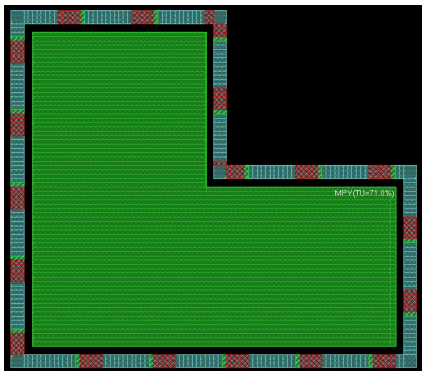
`-switchModuleInstance` *instanceName*	When this parameter is specified, all the switches are instantiated in the module instance specified. When not specified, the switch instances are inserted at the top level. This parameter is optional.
`-switchPitch`	Specifies the global switch pitch value. You cannot use this parameter with the `-switchPitch` parameters (left, right, top, bottom, horizontal, and vertical). For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0`
`-switchPitchBottom` *value*	Places a switch the specified distance from the right edge of the previous cell on the bottom side of the power domain. If `-counterclockwise` is specified, the distance is measured from the left edge of the previous cell. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0`
`-switchPitchHorizontal` *value*	Places the a switch the specified distance from the left edge of the previous cell on the horizontal side of the power domain. If `-counterclockwise` is specified, the distance is measured from the right edge of the previous cell. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0`
`-switchPitchLeft` *value*	Places the a switch the specified distance from the bottom edge of the previous cell on the left side of the power domain. If `-counterclockwise` is specified, the distance is measured from the top edge of the previous cell. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0`

`-switchPitchRight` *value*	Places the a switch the specified distance from the top edge of the previous cell on the right side of the power domain. If `-counterclockwise` is specified, the distance is measured from the bottom edge of the previous cell. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0`
`-switchPitchTop` *value*	Places the a switch the specified distance from the left edge of the previous cell on the top side of the power domain. If `-counterclockwise` is specified, the distance is measured from the right edge of the previous cell. You can use this parameter with `-switchPitch*`, `-endOffset*`, and `-*Offset` parameters. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0`
`-switchPitchSideList {`*value* `...}`	Places the a switch the specified distance from the edge of the previous cell on the sides specified in the list. Use this parameter for rectilinear power domains. You can use this parameter with `-switchPitch*`, `-endOffset*`, and `-*Offset` parameters. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0`
`-switchPitchVertical` *value*	Places the a switch the specified distance from the bottom edge of the previous cell on the vertical sides. If `-counterclockwise` is specified, the distance is measured from the top edge of the previous cell. You can use this parameter with `-switchPitch*`, `-endOffset*`, and `-*Offset` parameters. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0`
`-topOffset` *float*	Specifies the minimum offset from the top edge outside of the power domain fence boundary where the software can insert switches. See `-bottomOffset`, `-rightOffset`, and `-leftOffset`. **Note:** When you create a power domain, a `minGap` exists for this power domain, and the switches are inserted within this `minGap`. However, if the specified `minGap` is less than the switch dimension, then the tool automatically extends the `minGap` for this power domain. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0` The switches abut the power domain fence if possible. Otherwise, the switches are placed as close as possible to the power domain.

`-topNumSwitch` *integer*	Specifies the number of switches to insert on the top side(s) of the power domain. **Note:** This parameter applies to power switch ring creation only. Three scenarios can occur: • If the spaces available match the number specified, then the software fills these spaces with switches. • If the number exceeds the spaces available, the software issues a warning message. • If the number is less than the spaces available, the tool inserts the switches, then inserts filler cells to fill the space. Also, if you specify `f` instead of an integer, the tool automatically fills the top side with switches and filler cells. This parameter is optional. See `-horizontalNumSwitch`, `-verticalNumSwitch`, `-bottomNumSwitch`,`-leftNumSwitch`, and `-rightNumSwitch`. *Default:* `f`
`-topOrientation` *orientation_syntax*	Specifies the cell orientation for all top side(s) of the power switch ring.
`-topPattern` *pattern_syntax*	Defines a pattern for the top side(s) of the ring only. You must use this parameter with `-horizontalPattern`, `-verticalPattern`, `-bottomPattern`, `-leftPattern`, and `-rightPattern`.
`-topSide [0 | 1]`	Inserts switches on the top side(s) of the power domain. If you do not specify a side, the software creates a full power switch ring around the specified power domain. If you specify a side, the software inserts switches on that side. In this case, the tool sets `-topSide` to 1 and sets the other sides to `0`. You can specify multiple sides and the software inserts switches only on the sides you specify. The tool sets the specified sides to `1` and sets the unspecified sides to `0`. *Default:* `1`
`-totalLeakagePower` *value_in_watts*	Specifies the total leakage power of the power domain before switches are added.

`-totalNumberPatterns` *number_of_patterns*

Adds the defined number of patterns around a power domain in a ring-type insertion. The pattern type for the insertion can be defined by the option `-globalPattern`.



Example:

```
addPowerSwitch -ring -powerDomain MPY -specifySideList {1 1 1\ 1 1 1 } \
-enableNetIn swcontrol_1 -enableNetIn swack_1 \
-globalSwitchCellName {{CDN_RING_SW1 s} {CDN_RING_SW2 b}} \
-globalFillerCellName {{CDN_RING_FILLER f}} \
-cornerCellList CDN_RING_CORNER_UL \
-insideCornerCellList CDN_RING_CORNER_InCell \
-switchModuleInstance DTMF_INST_3 \
-enablePinIn A0 -enablePinOut Z0 -sideOffsetList { 3 3 3 3 3 \ 3 } \
-globalPattern { {s}*5 {b} } \
-distributePattern 1 \
-continuePattern 1 \
-totalNumberPatterns 19 \
-reportFile MPY.rpt
```

`-vertex {x1 y1 x2 y1 x2 y2 x3 y2 x3 y3 x1 y3 ... xn yn}`	Allows you to insert power switches in ring style around the power domain by specifying vertex locations around the power domain. In the ring the cells are towards the outer side of the edge.
	 	
	`addPowerSwitch \`
	`-ring -vertex \`
	
	`{478.90 461.50 478.90 511.70 444.50 511.70 \ 444.50 578.70 535.40 578.70 535.40 461.50 \ 478.90 461.50} -powerDomain TDSPCore...`

`-verticalNumSwitch value`	Specifies the number of switches to insert on all vertical side(s) of the power domain. Three scenarios can occur: • If the spaces available match the number specified, the software fills these spaces with switches. • If the number exceeds the spaces available, the software issues the following error message. • If the number is less than the spaces available, the tool inserts the switches, then inserts filler cells to fill the space. Also, if you specify `f` instead of an integer, the tool automatically fills the bottom side with switches and filler cells. This parameter is optional. See `-leftNumSwitch`, `-rightNumSwitch`, and `-topNumSwitch`. *Default:* `f`
`-verticalOffset value`	Offsets the switch ring from the vertical edge of the power domain. Specify the offset in µm. For more information, see "Using Pitch Control and Offsets" in the Low Power Design chapter of the *User Guide*. *Default:* `0`
`-verticalOrientation orientation_syntax`	Specifies the cell orientation for all vertical side(s) of the power switch ring.
`-verticalPattern pattern_syntax`	Specifies a pattern of cells to repeat on all vertical side(s) of the power domain. The pattern consists of a group of different types of cells in a specified order.
`-verticalSide [0|1]`	Inserts ring switches on all vertical side(s) of a power domain. *Default:* 1

Syntax Conventions

- Cell syntax
  cell_syntax
  cell (single cell)
  {*cell1 cell2 …*} (list of cells)
  {{*cell id*}} (cell with id assigned)
  (cell list with id assigned to each cell)
- Orientation syntax
  orientation_syntax
  R0|R90|R180|R270|MX|MY|MX90|MY90
- Corner syntax (Ring style only)
  corner_syntax
  LT|TR|RB|BL
- Pattern syntax (Ring style only)
  pattern_syntax
  {id1 id2 {id * n}} (Example: n=integer -> repeat id n times)
  - id, id1, id2 are defined in *cell_syntax*
  - Default id is the same as the cell name if *cell_syntax* does not define it.

Syntax Examples

Power switch cell name: CDN_SWT_CELL

Filler cell name: CDN_FLL_CELL

Buffer cell name: CDN_BUF_CELL

Breaker cell name: CDN_BRE_CELL

cell_syntax

cell (single cell): CDN_SWT_CELL

{*cell1 cell2*}: {CDN_SWT_CELL1X CDN_SWT_CELL2X …}

{{*cell id*}}: {{CDN_SWT_CELL S}} <- S can be any alphabetic character from A to Z or a to z, or any combination of alphabetic characters or numerals. The id must always start with an alphabetic character.

Precedence Rules

For the -*direction*Side parameters, the software applies their settings in the following precedence rules:

- -specifySides
- -topSide, -rightSide, -leftSide, -bottomSide
- -horizontalSide, -verticalSide

Higher precedence parameters override lower precedent parameters.

- The following command creates a power switch column within power domain PD:

  ```
  addPowerSwitch -column -powerDomain PD -globalSwitchCellName switchCell -switchModuleInstance switchBlock \
  -enablePinIn A0 -enablePinOut Z0 -enableNetIn {enableNetOn} -enableNetOut {enableNetOut} \
  -leftOffset 30 -bottomOffset 0 -horizontalPitch 240
  ```

  In this example, the software inserts switchCell into power domain PD. This switch cell has only one buffer inside. This example specifies one -enableNetIn (enableNetOn) and one -enableNetOut (enableNetOut). The input pin A0 on the first switch of every column is driven by the net enableNetOn. The enablePinOut (Z0) drives the enablePinIn pin of the next switch cell in the same column. The nets for this connection are created internally and the names are unique. The enablePinOut pin of the last switch for each column is tied to the net enableNetOut. The

first switch cell is placed 30 microns from the left side boundary of the selected power domain. The spacing between the columns is 240 microns.

- The following command creates a power switch ring around power domain `PD`.

```
addPowerSwitch -ring -powerDomain PD -switchModuleInstance switchBlock \
-enablePinIn {A0 A1} -enablePinOut {Z0 Z1} -enableNetIn enIn -enableNetOut enOut \
-globalSwitchCellName switchCell -globalFillerCellName fillerCell -firstInstanceName u1_switchCell \
-leftNumSwitch -rightNumSwitch 28 -topNumSwitch 40 -bottomNumSwitch 50
```

  In in this example, all `switchCell` switches are instantiated in the `switchBlock` module.

  Note: The bottom offset is zero in this example. The first switch cell is placed in the column in or on the bottom-most switch cell row.

  This example inserts the switches as follows:

- Switches are inserted in a full ring pattern (left, top, right, and bottom)
  The switch ring encircles the `PD` power domain fence. `PD` is the power domain that shuts off.
- A specified number of switches are inserted on each side of the ring. The `-numSwitchLeft` parameter has a value of `f` (autofill), so the tool fills the left side with as many switches as possible in the available space, then inserts filler cells.
- If the spaces available match the number of switches specified, then the software fills these spaces with switches. If the number of switches is less than the spaces available, the tool inserts the switches, then inserts filler cells `fillerCell` to fill the space. If the number exceeds the spaces available, then the software issues the following error message:

```
ERROR: number of switches exceeded space availability.
```

  Also in this example, the original netlist already has a switch instantiated inside the module `switchBlock`. The switch is fixed as the first instance in the ring by `-firstInstanceName u1_switchCell`. The tool then generates a unique instance name for each switch.

  You must specify the input and output enable pin names of the switch. You must specify the pins in order because the software attaches them to the enable nets you specify. In this example, there is a loopback type of enable nets, so you must specify one net for input (`-enableNetIn`) and one net for output (`-enableNetOut`). The input net (`enIn`) attaches to the first variable specified in the `-enablePinIn` list (`A0`) of the first switch, and the output net (`enOut`) attaches to the last variable specified in the `-enablePinOut` list (`Z1`) of the next switch inserted.

- The following command presents an example of column power switch insertion:

```
addPowerSwitch -column -powerDomain TDSPCore -switchModuleInstance TDSP_CORE_INST \
-enableNetOut swcontrol_out \
-leftOffset 20 -bottomOffset 0.0 -horizontalPitch 43 -checkerBoard -loopBackAtEnd
```

- The following command presents an example of ring power switch insertion:

```
addPowerSwitch -ring \
-powerDomain TDSPCore \
-switchModuleInstance TDSP_CORE_INST \
-globalSwitchCellName PScell \
-enablePinIn EnableIn \
-enablePinOut EnableOut \
-leftOffset -4.2 \
-topOffset -4.8 \
-rightOffset -4.2 \
-bottomOffset -5.4 \
-cornerCellList CornerCell \
-verticalOrientation R0
```

check_power_intent

```
check_power_intent
[-help]
-1801
-hierarchical
[-outfile string]
[-verbose]
```

Checks the IEEE1801 power intent coding style for the IEEE1801 partitioning. This command also reports potential IEEE1801 coding style, which is unsuitable for partitioning.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `check_power_intent` parameter. For a detailed description of the command and all its parameters, use the man command: `man check_power_intent`
`-1801`	Specifies that the power intent is IEEE 1801.
`-hierarchical`	Specifies the input power intent style.
`-outfile string`	Specifies the output filename.
`-verbose`	Prints the detailed information related to the `check_power_intent` command.

Related Information

cloneMSVGate

```
cloneMSVGate
[-help]
[-iso]
[-shifter]
[-instances inst1 inst2 .... ]
[-maxFanout integer]
[-maxTran num]
[-maxCap num]
[-honorPrePlaced]
[-honorDontTouch]
```

Ensures that the cloned isolation or level shifter can drive a group of the receivers and be placed close to this group of receivers. By doing this, the timing QoR can be improved.

Note: The command will not automatically update your CPF/IEEE1801 file to match the new netlist. It is advised that you run Conformal Low Power to check for any issues. When the enable signal for isolation cells is cloned (creating new ports on the boundary of the power domain), the users may need to update `create_isolation_rule` in CPF or `set_isolation` in IEEE1801 by defining the isolation control differently.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `cloneMSVGate` parameter. For a detailed description of the command and all its parameters, use the man command: `man cloneMSVGate`
`-honorDontTouch`	Does not clone don't touch instances or cells. The default is to clone don't touch instances.
`-honorPrePlaced`	Does not clone pre-placed (fixed) instances. The default is to clone fixed instances
`-instances inst1 inst2 ...`	Clones specified instances.
`-iso`	Clones isolation cells.
`-maxFanout integer`	Specifies the maximum fanout count.
`-maxCap num`	An optional check to clone instances with maximum capacitance violation. The default is not to use `-maxCap` violation.
`-maxTran num`	Cloning will be only on instances with maximum transition time violation. The default is `2ns`.
`-shifter`	Clones level shifters.

commit_power_intent

```
commit_power_intent
[-help]
[-clpLog string]
[-eco string]
[-isolation]
[-keepRows]
[-level_shifter]
[-power_domain]
[-power_switch]
[-state_retention]
[-verbose]
```

Commits IEEE1801 power intent specifications for the design for use in verification and implementation of the structure and behavior of the design in context of a given power management architecture. The method supports incremental refinement of power intent specifications required for IP-based design flows.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `commit_power_intent` parameter. For a detailed description of the command and all its parameters, use the man command: `man commit_power_intent`
`-clpLog string`	Specifies the CLP log file for CPF only.
`-eco string`	Specifies the eco CPF file. **Note:** The `-eco` option is available only for the CPF flow.
`-isolation`	Specifies the commit isolation.
`-keepRows`	Specifies the pre-existing rows to be retained. By default, rows are recreated based on the power domain information. The new rows might not match the original rows.
`-level_shifter`	Specifies the commit level shifter.
`-power_domain`	When specified, the command creates the power domains, makes the pg connection and saves the rules such as level shifter, isolation and state retention rule. **Note**: The command does not commit the rules
`-power_switch`	Specifies the commit power switch.
`-state_retention`	Specifies the commit state retention.
`-verbose`	Prints the detailed information related to the `commit_power_intent` command.

compare_power_intent

```
compare_power_intent
[-help]
[-domain_attr]
[-domain_boundary_port_constr]
[-domain_map_file file_name]
[-file_prefix prefix]
-golden1801 file_name
-hier1801 file_name
[-pin_effective_domain]
[-power_domains list_of_domains]
[-verbose]
```

Compares the golden IEEE1801 and the hierarchical IEEE1801 files generated by the Innovus hierarchical partition flow in terms of the low power database, and reports the mismatched category. If there is no mismatch, the two IEEE1801 files are considered to be equivalent in the Innovus low power flow.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `compare_power_intent` parameter. For a detailed description of the command and all its parameters, use the man command: `man compare_power_intent`
`-domain_attr`	Compares low power attributes and properties of all the attributes, which include instance count, low power cell count, primary supply, available supply, boundary, port low power constraint, and effective domain counter for the leaf instance pin, and port.
`-domain_boundary_port_constr`	Compares the domain boundary port IEEE1801 constraint against the golden IEEE1801.
`-domain_map_file file_name`	Specifies the domain map file saved during partition. The domain map file maps the golden IEEE1801 domain/supply set/low power signal with the hierarchical IEEE1801 domain/supply set/low power signal.
`-file_prefix prefix`	Specifies the file prefix for the report files.
`-golden1801 file_name`	Specifies the golden IEEE1801.
`-hier1801 file_name`	Specifies the hierarchical IEEE1801 to be compared.
`-pin_effective_domain`	Compares only the domain for leaf instance pin and port.
`-power_domains list_of_domains`	Specifies the list of specific power domains to be compared.
`-verbose`	Displays the detailed information related to each category.

cutBoxListFromPowerDomain

```
cutBoxListFromPowerDomain
[-help]
-powerdomain powerDomainName
-boxList {{box1} ...}
```

Cuts out default power domains from a non-default power domain. This command is mainly used to solve buffering related issues.

Use this command with other commands like `ecoAddRepeater` to insert buffers in the cutout box.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each cutBoxListFromPowerDomain parameter. For a detailed description of the command and all its parameters, use the `man` command: `man cutBoxListFromPowerDomain`
`-powerDomain`	Specifies the Power Domain in which you want to cut out.
`-boxList`	Specifies the list of boxes to be cut.

Examples

```
cutBoxListFromPowerDomain -powerDomain pd -boxList { {list1} {list2}......}
```

The list is numbers in the format: `{llx1 lly1 urx1 ury1}`

```
cutBoxListFromPowerDomain -powerDomain 1.0V_Domain \
-boxList {{10 10 20 20} {35 60 45 70}}
```

This will cut box `{10 10 20 20}` and `{35 60 45 70}` from the domain `1.0V_Domain`, and these two boxes will become the default domain.

Related Information

- Low Power Design chapter in the *Innovus User Guide*

cutPowerDomainByOverlaps

```
cutPowerDomainByOverlaps
powerDomainName
[-help]
```

When you floorplan one power domain (inner domain) completely inside the other power domain (outer domain), use this command to cut the outer domain as a hollow or donut shape.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `cutPowerDomainByOverlaps` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man cutPowerDomainByOverlaps`.
powerDomainName	Specifies the outer power domain where the nested power domain will reside.

Examples

Here is an example of using this command. In this example, the power domains, PD1 and PD2, are defined in the power intent file, and then the bounding box for each domain is specified:

```
modifyPowerDomainAttr PD1 -box llx lly urx usy
modifyPowerDomainAttr PD2 -box llx lly urs usy
....
```

Note: The bounding box for `PD2` must lie completely within the `PD1` bounding box.

Designate `PD1` as the hollow power domain:

```
cutPowerDomainByOverlaps PD1
```

Instances in `PD1` will not be placed within `PD2`.

The following figure shows the resulting power domains.

debugPtnBoundaryPorts

```
debugPtnBoundaryPorts
-pins
```

The `debugPtnBoundaryPorts` command prints out the boundary pins' debug information during partition in a log which shows how to assign the power domain for the partition pins.

This is useful when debugging CPF partitions as you get the information about how Innovus assigns the power domain for the partition boundary pins during debugging.

Parameters

-pins	Specifies a list of the partition pins. If wildcard * is specified, it means all partition pins.

Example

Specify the partition pins(Hterm) you want to debug:

```
debugPtnBoundaryPorts -pins "I2/d I2/clk"
```

After partition, the command will execute the partition command to print the following DBG info in the log file:
DBG: deriving hterm I2/d power domain
DBG: ….

deletePowerSwitch

```
deletePowerSwitch
[-help]
[-1801PowerSwitchRuleName ruleName]
{{-column | -ring}
-powerDomain powerDomainName}
[-instanceList {instName ...}]
[-isCustomChain]
```

Removes all switches and filler cells that were inserted by the `addPowerSwitch` command, from either columns or rings, or removes specified power switch defined in CPF.

This command retains and unplaces switches added by `addPowerSwitch -switchInstances`, whose cells were already instantiated in the netlist.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `deletePowerSwitch` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man deletePowerSwitch`
`-1801PowerSwitchRuleName ruleName`	Removes power switches based on the specified IEEE 1801 rule.
`-column`	Removes all switches and filler cells that were inserted by the `addPowerSwitch` command, from columns in the specified power domain.
`-instanceList {instName …}`	Specifies the power switch cell instances to delete. The wildcard characters (* or ?) can also be used for specifying the power switch instance name.
`-isCustomChain`	Keeps the rest chain connection for the rest power switches, after deleting the specified power switches, when those power switches are chained in a customized manner.
`-powerDomain powerDomainName`	Specifies the power domain next to which the columns are placed.
`-ring`	Removes all switches and filler cells that were inserted by the `addPowerSwitch` command, from the ring around the specified power domain.

Examples

- The following command removes instances `psoI_TDSP3_instA` and `psoI_TDSP3_InstB` that were added by the `addPowerSwitch` command:
  ```
  deletePowerSwitch -instanceList {psoI_TDSP3_instA psoI_TDSP3_InstB}
  ```
- The following command removes all power switch instances that were inserted by `addPowerSwitch` in columns inside the power domain `PD2`:
  ```
  deletePowerSwitch -column -powerDomain PD2
  ```
- The following command removes all power switch instances that were inserted by `addPowerSwitch` in the ring around `PD1`:
  ```
  deletePowerSwitch -ring -powerDomain PD1
  ```

- `importPowerSwitch`
- `movePowerSwitch`
- `rechainPowerSwitch`
- `replacePowerSwitch`
- `verifyPowerSwitch`
- Low Power Design chapter in the *Innovus User Guide*

exportPowerSwitch

```
exportPowerSwitch
[-help]
[-powerDomain powerDomainName]
[-file fileName]
```

Exports power switch database. The command is needed in cases of defIn-based flows where power switch database required for power switch related operations is not loaded through `defIn`. So, use `exportPowerSwitch` to save power switch database after power switch insertion using `addPowerSwitch` for later use, which can be loaded back using `importPowerSwitch`.

For example, in case power switches are inserted at the Floor Plan stage and the power switch database is exported for further use in the flow, the following command executed after floorplan for power Domain PD1, will save the power switch information into the PD1_powerswitch.db file:

```
exportPowerSwitch -powerDomain PD1 -file PD1_powerswitch.db
```

Post running the above command, if the floorplan DEF is used in the flow from synthesis, the stored power switch information needs to be restored using the `importPowerSwitch` command from the database, which was earlier stored using the `exportPowerSwitch` command after floorplan and before placement.

Note: The enable net IN and OUT connections should remain the same in the netlist in power switch database export/import process and the commands need not be run when `saveDesign` and `defOut` are run because the power switch database is automatically saved and restored.

PSO File Generation and Usage

A PSO file gets generated as an output of the `exportPowerSwitch` command, which can be used in a future session, if needed. One scenario where this file can be needed is when a DEF file containing a power switch chain is not used in the power switch synthesis and hence the incoming netlist to Innovus would not have any power switches. The power switch chain is then created at the `init` stage of Innovus using the `addPowerSwitch` command in such a run. A database saved using `write_db` after running the `addPowerSwitch` command, will have the power switch chain saved in a `<design.pso>` file. When restored, this database can also be used to write out the saved PSO file using the `exportPowerSwitch` command. When the power switches are added using the `addPowerSwitch` command, the `reportPowerSwitch` command can be used to validate their addition.

To avoid regenerating power switches in future implementation runs, save the power switch chain using the `exportPowerSwitch` command along with the floorplan DEF. Ensure that the `-routing` parameter of the `defOut` command is also used along with `-floorplan` and `-noStdCells` to save the power switch network under the NETS section of the DEF.

Refer to the following flows to understand the usage of the PSO file:

Innovus Session 1:

```
<init Design1 - incoming design has no power switches>
addPowerSwitch
exportPowerSwitch test.pso
defOut -floorplan -noStdCells -routing test.def
```

Innovus Session 2:

```
<init Design2 - incoming design has no power switches>
importPowerSwitch -file test.pso
defIn test.def
```

While reading the DEF file, you can identify the power switches using the database commands, such as `get_db` and `dbIsCellPowerSwitch`, even without using the `importPowerSwitch` command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `exportPowerSwitch` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man exportPowerSwitch`.
`-powerDomain` *powerDomainName*	Specifies the power domain whose power switch information is to be exported.
`-file` *fileName*	Specifies the name of the export file.

free_power_intent

```
  free_power_intent
[-help]
[-keep_fence]
```

The command deletes all the power intent data stored by the `commit_power_intent` command in current session and cleans up the design.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `free_power_intent` parameter. For a detailed description of the command and all its parameters, use the man command: `man free_power_intent`
`-keep_fence`	Retains domain groups and their fences at the time of removing the the power intent. Use `read_power_intent` and `commit_power_intent -keepRows` to reload power intent after using this parameter.

Related Information

- `commit_power_intent`
- `read_power_intent`
- `write_power_intent`
- Low Power Design chapter in the *Innovus User Guide*

getCPFUserAttributes

```
getCPFUserAttributes
[-help]
-domain domainName | -net netName
```

Reports the `user_attributes` of the power domain or net specified in the CPF file. If the domain or net has no `user_attributes` in the CPF file, then this command reports an empty string.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `getCPFUserAttributes` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man getCPFUserAttribute`.
`-domain`	Specifies the name of the power domain containing the user_attributes.
`-net`	Specifies the name of the net having the `user_attributes`.

getInstPowerDomain

```
getInstPowerDomain
instanceName
-help
```

Returns the power domain of the instance.

Parameters

`-help`	Outputs a brief description that includes the type and default information for `getInstPowerDomain`. For a detailed description of the command and all its parameters, use the man command: `man getInstPowerDomain`

Example

The following command returns the power domain of the instance:

```
getInstPowerDomain a/ff1

PD1
```

getMsvMode

```
  getMsvMode
[-help]
[-allowNestedDefaultDomain]
[-allowPowerDomainMinGapZero]
[-checkAllNetsForDomainCrossing]
[-handleBackToBackIsolation]
[-handlePD {true|false}]
[-handlePDComplex {true|false}]
[-honorCpfGlobalConnectionSpecForAoBuffer]
[-honorCpfGlobalConnectionSpecForShifter]
[-honorDotLibRelatedPGPin]
[-honorEffectiveDomainForIsoLsInsertion]
[-markIsoEnablePinAsAlwaysOn]
[-notUseTopFTermDomainForVoltage]
[-nonDefault]
[-shareWellAOBufferingSupport]
[-upf_allow_shifter_voltage_mismatch]
[-upf_insert_on_floating_pins]
[-quiet]
```

Gets the special handling for inter-domain nets and uses effective power domains for ISO/LS insertion. For more details see `setMsvMode`.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each getMvsMode parameter. For a detailed description of the command and all its parameters, use the `man` command: `man` getMvsMode.
parameter_names	Returns information for the specified parameters. You can specify one or more parameters.
`-quiet`	Displays the current settings in Tcl list format only.

Related Information

- `setMsvMode`
- Low Power Design chapter in the *Innovus User Guide*

getPGPinUseSignalRoute

```
getPGPinUseSignalRoute
[-help]
```

Returns all the existing MSV settings that were set by the `setPGPinUseSignalRoute` command in the current database. Use this command to identify the cell PG pins, which are routed by the signal router.

Parameters

`-help`	Prints out the command usage. For a detailed description of the command and all its parameters, use the `man` command: `man getPGPinUseSignalRoute`

Related Information

- `setPGPinUseSignalRoute`
- `routePGPinUseSignalRoute`

getUPFPortAttr

```
  getUPFPortAttr
[-help]
hport_name
```

Returns UPF port attributes from UPF or for the specified values. Run this command before design partitioning. Following is the output format of this command:

```
list of {attr_name val}
```

Parameters

`-help`	Prints a brief description that includes the type and default information for each `getUPFPortAttr` parameter. For a detailed description of the command and all its parameters, use the man command: `man getUPFPortAttr`
`hport_name`	Specifies the module term name for which UPF port attributes need to be returned.

Example

The following command returns UPF port attributes for the `iC/in hport`:

```
getUPFPortAttr iC/in
```

Following is the output of the above command:

```
{-driver_supply supplySetName} {attr_name value2} {is_analog FALSE} …
```

Related Information

Low Power Design chapter in the *Innovus User Guide*

getValidPowerSwitchLocation

```
getValidPowerSwitchLocation
-help
-cell cell_name
-loc location
[-orient string]
[-searchArea string]
```

Returns a valid location of the power switch cells according to the specified placement grid, cell name, and nearest location. This valid location of the power switch cells can be used to specify offsets while using the addPowerSwitch command.

Parameters

-help	Prints a brief description that includes the type and default information for each getValidPowerSwitchLocation parameter. For a detailed description of the command and all its parameters, use the man command: man getValidPowerSwitchLocation
-cell *cell_name*	Specifies the name of the power switch cell whose valid location needs to be identified.
-loc *location*	Specifies the nearest location from where the valid location needs to be identified.
-orient *string*	Specifies the orientation. The orientation can be one of the following: r0, r90, r180, r270, mx, mx90, my, and my90.
-searchArea *string*	Specifies the area within which the valid location needs to be identified.

Example

The following command identifies a valid location for the HSWX1 power switch cell:

```
getValidPowerSwitchLocation -cell HSWX1 -orient MX -loc {382 970}
```

Following is the output of the above command:

```
382.0350 970.0750 MX
```

Related Topics

addPowerSwitch

importPowerSwitch

```
importPowerSwitch
[-help]
[-powerDomain powerDomainName]
[-file fileName]
```

Imports power switch databases. The need for this commands arises in case of defIn-based flows where power switch database required for power switch related operations is not loaded through defOut.

So, using `exportPowerSwitch` a user can save power switch database after power switch insertion using `addPowerSwitch` for later use and it can be loaded back using `importPowerSwitch`.

Note: The enable net IN and OUT connections should remain the same in the netlist in power switch database export/import process and the commands need not be run when saveDesign and `defOut` are run because the power switch database is automatically saved and restored.

PSO File Generation and Usage

A PSO file gets generated as an output of the `exportPowerSwitch` command, which can be used in a future session, if needed. One scenario where this file can be needed is when a DEF file containing a power switch chain is not used in the power switch synthesis and hence the incoming netlist to Innovus would not have any power switches. The power switch chain is then created at the `init` stage of Innovus using the `addPowerSwitch` command in such a run. A database saved using `write_db` after running the `addPowerSwitch` command, will have the power switch chain saved in a `<design.pso>` file. When restored, this database can also be used to write out the saved PSO file using the `exportPowerSwitch` command. When the power switches are added using the `addPowerSwitch` command, the `reportPowerSwitch` command can be used to validate their addition.

To avoid regenerating power switches in future implementation runs, save the power switch chain using the `exportPowerSwitch` command along with the floorplan DEF. Ensure that the `-routing` parameter of the `defOut` command is also used along with `-floorplan` and `-noStdCells` to save the power switch network under the NETS section of the DEF.

Refer to the following flows to understand the usage of the PSO file:

Innovus Session 1:

```
<init Design1 - incoming design has no power switches>
addPowerSwitch
exportPowerSwitch test.pso
defOut -floorplan -noStdCells -routing test.def
```

Innovus Session 2:

```
<init Design2 - incoming design has no power switches>
importPowerSwitch -file test.pso
defIn test.def
```

While reading the DEF file, you can identify the power switches using the database commands, such as `get_db` and `dbIsCellPowerSwitch`, even without using the `importPowerSwitch` command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each importPowerSwitch parameter. For a detailed description of the command and all its parameters, use the `man` command: `man importPowerSwitch`.
`-powerDomain` *powerDomainName*	Specifies the power domain whose power switch information is to be imported.
`-file` *fileName*	Specifies the name of the import file.

mark_physical_power_domains

```
mark_physical_power_domains
[-help]
{-domains physical_domain_list | -reset | -checkOnly}
[-groupPhyLogicalDomains {{phyPd lpd1 lpd2 ...} ...}]
```

Marks the physical power domains that need fences in case the power domains share the same primary supply net and the available supply net setting (if specified). The command also enables the logical domains to exist without any fence.

Note: `mark_physical_power_domains` needs to be called again (after the initial use), whenever the tool reads in an power intent file. Else, the file content is not recognized.

Parameters

`-help`	Prints out the command usage. For a detailed description of the command and all its parameters, use the `man` command: `man mark_physical_power_domains`
`-checkOnly`	Checks the fence sharing against Power/Ground (P/G) nets.
`-domains physical_domain_list`	Marks listed power domains as physical domains (a physical power domain must have a fence). Once a physical domain is marked, the power domain sharing the same P/G nets (not marked in this command) are recognized as logical domain (or fenceless domain). Therefore, this domain can be implemented without a fence. The instances within logical domain are placed within the fence of its corresponding physical domain. This parameter also executes the`-checkOnly` parameter, by default. **Note:** Default power domain is not required to be marked, it is marked by default. This command needs to be called after each run of `commit_power_intent`. Otherwise the physical/logical power domain information will be lost in the database.
`-groupPhyLogicalDomains {{phyPd lpd1 lpd2 ...} ...}`	Groups a list of physical and logical domains for the `mark_physical_power_domains` command.
`-reset`	Resets the status marking settings after running `commit_power_intent`.

Example

The following command marks `PDdefault` as physical domain:

```
mark_physical_power_domains -domains {PDdefault}
```

Related Information

- `commit_power_intent`
- Low Power Design chapter in the *Innovus User Guide*

modifyPowerDomainAttr

```
modifyPowerDomainAttr
[-help]
[-addBlockBox string]
[-core2Left valueInMicron]
[-core2Right valueInMicron]
[-core2Top valueInMicron]
[-core2Bot valueInMicron]
[-defaultTechSite string]
[-disjointHInstBoxList string]
[-firstRowSiteIndex integer]
[-lastRowSiteIndex integer]
[-minGaps {values}|-gapEdges {values}]
powerDomainName
[-rowFlip {first second noflip auto}]
[-rowPatternSite site_name]
[-rowSpaceType {0 1 2}]
[-rowSpacing float]
[-rsExts {values}|-extEdges {values}]
```

Renames a power domain or changes its structure.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `modifyPowerDomainAttr` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man modifyPowerDomainAttr`.
`-addBlockBox string`	Adds a hard block to the disjoint power domain. `-addBlockBox` supports both rectangular and rectilinear macros.
`-core2Left valueInMicron`	Specifies the row margin from left boundary.
`-core2Right valueInMicron`	Specifies the row margin from right boundary.
`-core2Top valueInMicron`	Specifies the row margin from top boundary.
`-core2Bot valueInMicron`	Specifies the row margin from bottom boundary.
`-defaultTechSite string`	Allows selection of one of the tech sites to be not picked by the software, in case there are two smallest tech sites of the same size in a power domain. **Note:** The specified `-defaultTechSite` size value must be same as the current default tech site in the power domain.
`-disjointHInstBoxList`	Specifies a region for an Hinst. It is defined as an Hinst and Region pair.
`-firstRowSiteIndex integer`	Specifies the first row site index value.
`-lastRowSiteIndex integer`	Specifies the last row site index value.
`-extEdges {values}`	Specifies the maximum search distance for power extension connections by domain edge in microns. You can specify the value per edge in clockwise order, starting with the vertical edge at the lower-left corner (smallest Y, and then smallest X).

`-gapEdges {values}`	Specifies the minimum space value to other domain by power domain edge in microns. You can specify the value per edge in clockwise order, starting with the vertical edge at the lower-left corner (smallest Y, and then smallest X).
`-minGaps` *`T B L R`*	Defines the distance, in microns, that must be reserved from the power domain boundary edges for power routing. You can specify four values, one for each edge.
`powerDomainName`	Specifies the current name of the power domain to be modified. This is a positional parameter, and you must specify this value immediately after the command name.

`-rowFlip {first | second | noFlip | auto}`	Flips the orientation of either the first or second row, then follows the flipped and abutted row pattern.
	`first`
	(from bottom to top). MX -> R0 -> MX -> R0 - > …
	`second`
	(from bottom to top). R0 -> MX -> R0 - > MX -> …
	`noFlip`
	(from bottom to top). R0 -> R0 -> R0 - > R0 -> …
	The noFlip option preserves the R0 orientation for all rows (above).
	`auto`
	Detects orientation of row outside of power domain and aligns with power domain bottom. Orientation is applied to the first row at the bottom of power domain.
	So if row on left is R0, the pattern will be (from bottom to top). R0 -> MX -> R0 - > MX -> …
	If row on left is MX, the pattern will be (from bottom to top). MX -> R0 -> MX - > R0 - > …
	The `auto` option resets the software for this automatic behavior if you have previously specified `first`, `second`, or `noFlip`.
	Default: `auto`
	Note: *saveRowImage* resets the option `-rowFlip` to `auto`. In this case, try moving the power domain and check the row changes.

`-rowPatternSite` *`site_name`*	Specifies the site name for the row pattern.
`-rowSpacing` *`value`*	Specifies the row spacing between each row (1) or each pair of rows (2) as specified in `-rowSpaceType`.
`-rowSpaceType {1|2}`	Determines whether the row spacing value applies between each row (1) or each pair of rows (2).
`-rsExts` *`T B L R`*	Specifies the boundary for legal targets to be used by the power planning and routing commands, in conjunction with the power domain boundary. You can specify four values, one for each edge.

Examples

- The following command changes the route search extension values of `PowerDomain1` to 15 µm on each side:
  ```
  modifyPowerDomainAttr PowerDomain1 -rsExts 15 15 15 15
  ```
- The following command defines a disjoint power domain named `PowerDomain2` using the `-disjointHInstBoxList` parameter:
  ```
  modifyPowerDomainAttr PowerDomain2 -disjointHInstBoxList {{disjoint_hinst1 {llx lly urx ury}} {disjoint_hinst2 { llx lly urx ury}}.....}
  ```

movePowerSwitch

```
movePowerSwitch
[-help]
[-area {x1 y1 x2 y2}]
[-columnx string]
[-fixOverlap]
[-honorSoftBlockage]
[-powerDomain string]
[-reportFile string]
[-selected]
[-switchInstances string]
[-xOffset float]
[-yOffset float]
```

The command is used to move power switch instances by offset value in X or Y direction. You can specify multiple power switch instances to be moved in the same offset value.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `movePowerSwitch` parameter. For a detailed description of the command and all its parameters, use the man command: man `movePowerSwitch`
`-area {x1 y1 x2 y2}`	Specifies moving the switches inside the indicated area.
`-columnx string`	Specifies moving columns at the indicated x locations.
`-fixOverlap`	Internally checks any overlap and fixes it with the suggested offset value.
`-honorSoftBlockage`	When used, prevents the `movePowerSwitch` command from moving power switch cells in areas having soft placement blockage.
`-powerDomain string`	Specifies moving the switches found in the indicated power domain.
`-reportFile string`	Specifies the name of the report file that stores information about the moved switches.
`-selected`	Specifies moving the selected switches.
`-switchInstances string`	Specifies moving the switches in the list.
`-xOffset float`	Specifies moving switches by the indicated amount in the x direction.
`-yOffset float`	Specifies moving switches by the indicated amount in the y direction.

read_power_intent

```
read_power_intent
[-help]
fileName
{-cpf | -1801 | -msvDB }
```

Reads-in power intent file and do syntax check. The method supports incremental refinement of power intent specifications required for IP-based design flows.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `read_power_intent` parameter. For a detailed description of the command and all its parameters, use the man command: `man read_power_intent`
fileName	Specifies the name of the power intent file to be read.
`-cpf`	Specifies that the CPF format power intent file will be used.
`-1801`	Specifies that the IEEE1801 format power intent file will be used.
`-msvDB`	Specifies that the IEEE1801 data format `(.cpfdb)` power intent file will be used. **Note:** `-msvDB` is for partition flow and must be read for power intent in partition implementation.

rechainPowerSwitch

```
rechainPowerSwitch
-help
[-backToBackChain]
[-cascade]
[-cellEnablePin]
[-chainByInstances]
[-chainByRow]
[-chainDirectionX LtoR|RtoL]
[-chainDirectionY BtoT|TtoB]
[-chainStyle {min_length_tree single_output_chain}]
[-chainXbeforeY]
[-chainYbeforeX]
[-enableNetIn]
[-enableNetOut]
[-enablePinIn]
[-enablePinOut]
[-maxDistanceX um]
[-maxDistanceY um]
[-mergeDistanceX um]
[-mergeDistanceY um]
[-parallelEnable]
[-reportFile]
[-reverseOrder]
[-selected]
[-switchInstances]
[-unchainByInstances]
```

Enables flexible power switch enable chaining and unchaining after power switch insertion.

Note: It is recommended that you use this command for PSO enable chaining.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each rechainPowerSwitch parameter. For a detailed description of the command and all its parameters, use the `man` command: `man` rechainPowerSwitch.
`-backToBackChain`	Connects the `enableNetOut` at the top of a column to the `enableNetIn` at the top of the next column, and connects the `enableNetOut` at the bottom of the column to the `enableNetIn` at the bottom of the next column. The chain proceeds left to right or right to left. By default, the `enableNetIn` is connected to the bottom of each column, and the `enableNetOut` exits from the top of each column, in parallel.  default -backToBackChain This parameter is optional.
`-cascade`	Connects switches in cascade  default -cascade

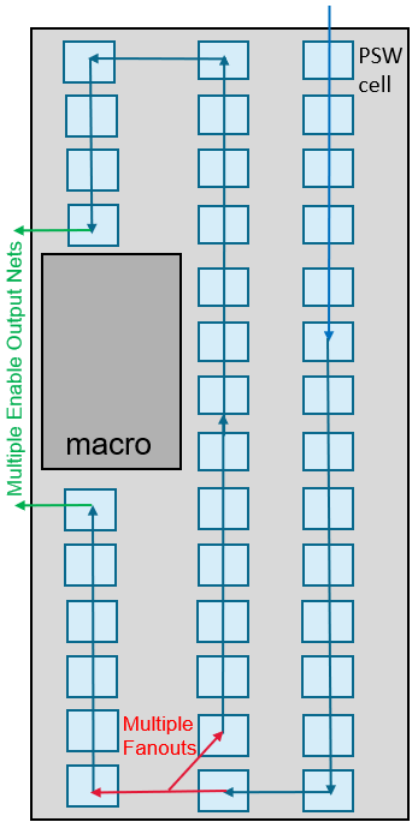
`-cellEnablePin`	Provides the pin names of power switch cells when the power switch cell pin names are different than the specified instance's cell. This option is also useful in cases where all enable pins of instances are not connected by enabling a way to provide pin map.
	Example:
	`set INST [ addPowerSwitch -getSwitchInstances -powerDomain PD1 -column ]`
	
	`rechainPowerSwitch -chainByInstances -chainYbeforeX \`
	`-unchainByInstances -enablePinIn SW_IN -enablePinOut SW_OUT \`
	`-enableNetIn NETin -enableNetOut NETout \`
	`-chainDirectionX RToL -reportFile pd1_chain.rpt \`
	`-backToBackChain \`
	`-cellEnablePin { { SW_withDiff_pinNames {SW_IN_1} {SW_OUT_1} }} \`
	`-switchInstances $INST`

`-chainByInstances`	To chain the instances. This option is used for chaining the instances defined by `-selected` or instances given in `-switchByInstances`.
	 	
	Select all PSO instances of power domain ALU
	`set ALUinst [addPowerSwitch -column -getSwitchInstances -powerDomain ALU]`
	The below command make the changes in the connection of the switch enable
	`rechainPowerSwitch -unchainByInstances\`
	`-chainByInstances \`
	`-switchInstances $ALUinst -enablePinIn A -enablePinOut Y \`
	`-enableNetIn swcontrol_2 -enableNetOut swack_2 \`
	`-cascade -chainDirectionY BtoT`

`-chainByRow`	Gives additional control if you need to enable horizontal signal chaining. For example, in rows. By default, signal chaining is enabled from bottom to top.
`-chainDirectionX` *`LtoR|RtoL`*	Defines the direction of the chain along X axis.
`-chainDirectionY` *`BtoT|TtoB`*	Defines the direction of the chain along Y axis.

`-chainStyle {min_length_tree single_output_chain}`	Specifies the chain style for enabling power switches and making enable chain connections. The specified chain styles help in optimizing the wire length with longer enable chains, and connecting all the power switches in single pass to avoid blockages. Following are the chain style values specified by this parameter:
	• `min_length_tree`: Connects the enable pin of the switches with a chain, which has multiple branch outputs. The following command presents the usage of this parameter value:
	`rechainPowerSwitch -powerDomain PD1 -selected \`
	`-chainStyle min_length_tree \`

```
-maxDistanceX 40 -maxDistanceY 100 -startLoc "200 6400" \
-enableNetIn pso1 -enableNetOut pso1_out ….
```



- `single_output_chain`: Connects the enable pin of the switches with a chain, which has single branch output. This parameter value can be specified with `-max_distance_x` and `-max_distance_y` parameters. The following command presents the usage of this parameter value:

  ```
  rechainPowerSwitch -powerDomain PD1 -selected \
  -chainStyle single_output_chain \
  -maxDistanceX 40 -maxDistanceY 100 -startLoc "200 6400" \
  -enableNetIn pso1 -enableNetOut pso1_out ….
  ```

	`-chainXbeforeY`	Defines row chain over column.
`-chainYbeforeX`	Defines column chain over row. This is the default option.
`-enableNetIn {listOfnets}`	Specifies the list of input nets that the software attaches to the enable input pins. The order in which you specify these nets determines the sequence in which nets are assigned to pins. Enable nets and pins are connected automatically if they reside at the same level in the hierarchy.
`-enableNetOut {`*`netBaseName`* `| {listOfNets}}`	Specifies the enable output nets that the software attaches to the enable output pins. The order in which you specify these nets determines the sequence in which nets are assigned to pins. If enable nets and pins reside at the same level in the hierarchy they are connected automatically. For the last switch of the ring, the `-enablePinOut` is tied to `-enableNetOut`.
`-enablePinIn {listOfPins}`	Specifies the list of enable input pins of the buffers inside the switch cell. The order in which you specify these nets determines the sequence in which nets are assigned to pins. If enable nets and pins reside at the same level in the hierarchy they are connected automatically.The software ties the `-enablePinOut` of the first switch cell to the `-enablePinIn` of the next switch cell in the same ring: All the enable pin of the switch cells in the same column are daisy-chained together. For the first switch of the ring, the `-enablePinIn` is tied to `-enableNetIn`.
`-enablePinOut {listOfPins}`	Specifies the list of enable output pin(s) of the buffer(s) inside the switch cell. The order in which you specify these pins is important because nets are assigned to pins sequentially. The software ties the `-enablePinOut` of the first switch cell to the `-enablePinIn` of the next switch cell in the same column: All the enable pin of the switch cells in the same column are daisy-chained together. For the last switch of the column, the `-enablePinOut` is tied to `-enableNetOut`.
`-maxDistanceX` *um*	Maximum X distance a switch can drive.
`-maxDistanceY` *um*	Maximum Y distance a switch can drive.
`-mergeDistanceX` *um*	To consider switches within this in the same column.
`-mergeDistanceY` *um*	To consider switches within this in the same row.
`-parallelEnable`	Connects enable Net In to all switches in parallel type connection. 
`-reportFile`	Writes switch instances and their corresponding input/output enable signal pin/net connections to the specified file name.
`-reverseOrder`	The reverse order of the `-switchInstances`.
`-selected`	Selects switches to be chained and unchained. **Note:** This option must be used with `-chainByInstances` and `-unchainByInstances`.
`-switchInstances`	Specifies the instances to be chained/unchained. When chaining is requested, the sequence of the final chain is taken from the sequence of the instance names given in the provided list.
`-unchainByInstances`	To unchain the instances. This option is used for unchaining the instances defined by `-selected` or instances given in `-switchByInstances`.

replacePowerSwitch

```
replacePowerSwitch
[-help]
-insts inst_name_list
-cell cell_name
[-xoffset value_in_microns]
[-yoffset value_in_microns]
[-orientation orienation_syntax]
[-cellEnablePin {{cellname {enableInputPinList} {enableOutputPinList}}}]
[-xyRangeFromCenterInst]
```

Replaces the cell of a power switch instance. You can also change the orientation of the instance after cell substitution, and provide a new location for the instance origin relative to the original instance origin.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `replacePowerSwitch` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man` replacePowerSwitch.
`-cell` *`cell_name`*	Specifies the cell to substitute for the instance's cell.
`-cellEnablePin` {{*`cellname`* {*`enableInputPinList`*} {*`enableOutputPinList`*}}}	Provides the pin names of power switch cell specified thru `-cell` option in `replacePowerSwitch` when the power switch cell pin names are different than the specified instance's cell. This option is also useful in cases where all enable pins of instances are not connected by enabling a way to provide pin map.
`-insts` *`inst_name_list`*	Specifies the instance whose cell you want to replace.
`-orientation` *`orientation_syntax`*	Specifies the orientation of the instance after the cell substitution. Choose one of the following values: `R0|R90|R180|R270|MX|MY|MX90|MY90` *Default:* The same orientation as the original instance.
`-xoffset` *`value_in_microns`*	Specifies the instance placement in the x direction after the cell substitution. A positive value moves the instance to the right of the original instance origin. A negative value moves the instance to the left of the original instance origin.

`-xyRangeFromCenterInst`	Selects the power switch instances whose lower left corner is in the range from lower left corner of the specified instance (`-insts`) for replacement with switch cell (`-cell`).  Note: The first instance specified in the `-insts` will be used for the area computation. The rest of the instances in the `-insts` list will be ignored and will not be replaced. For Example: `replacePowerSwitch -insts psoI_TDSP2_1_CDN_COLUMN_SW_669_1622_3 \ -xyRangeFromCenterInst { 60.3 20 } -cell \ CDN_COLUMN_SW`
`-yoffset` *value_in_microns*	Specifies the instance placement in the y direction after the cell substitution. A positive value moves the instance above the original instance origin. A negative value moves the instance above the original instance origin.

Examples

- The following example substitutes cell `CDN_RING_SW1` for the original cell for instance `pso1_TDSP2_1_CDN_RING_SW_636_1309_6`:
  `replacePowerSwtich -insts pso1_TDSP2_1_CDN_RING_SW_636_1309_6 -cell CDN_RING_SW1`
- The following example substitutes cell `CDN_RING_SW1` for the original cell for instance `pso1_TDSP2_1_CDN_RING_SW_636_1315_8` and changes the orientation of the instance to `MY90`:
  `replacePowerSwitch -insts pso1_TDSP2_1_CDN_RING_SW_636_1315_8 -cell CDN_RING_SW1 -orientation MY90`

reportIsolation

```
reportIsolation
[-help]
[-highlight]
[-outfile fileName]
[-from powerDomain]
[-to powerDomain]
```

Reports or shows the added isolation cells and instances.

Note: Use this command after you add isolation cells.

Parameters

-help	Outputs a brief description that includes the type and default information for each reportIsolation parameter. For a detailed description of the command and all its parameters, use the `man` command: `man` reportIsolation.
`-from`	Reports all the isolation instances connected to the output pins of the power domain specified in `-from` option. *Default:* Reports all isolation cells.
`-highlight`	Highlights isolation instances in the main window.
`-outfile` *fileName*	Writes isolation cell and instance names to a report. *Default:* The software writes the report to a default file: *designName*`.isolation.rpt`
`-to`	Reports all the isolation instances connected to the input pins of the power domain specified in `-to` option. *Default:* Reports all isolation cells.

Examples

The following command highlights isolation cells and writes the cell names to `isolationCellReport`:

```
reportIsolationCell -highlight -outfile isolationCellReport
```

reportPowerDomain

```
reportPowerDomain
[-help]
[-bindLib]
[-file outFile]
[-inst inst_name]
[-isoInst]
[-module {list_of_modules}]
[-net net_name]
[-partitionHports pin | port | hpin+]
[-pgNet]
[-pin]
[-powerDomain powerDomainName [-checkPgScope]]
[-powerDomainBoundaryPort string]
[-powerDomainCoverage pd1 pd2]
[-shifter]
[-supplyCrossing supp1 supp2]
[-verbose]
[-voltage]
```

Reports information about power domains. The report includes the following attributes:

- Power domain name
- Power domain bounding box
- Timing library
- Mingap
- RS extension
- Row type
- Row spacing

The command also reports whether the power domain is always on.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each reportPowerDomain parameter. For a detailed description of the command and all its parameters, use the `man` command: `man` reportPowerDomain.
`-bindLib`	Reports the timing library bound to each instance of a power domain.
`-checkPgScope`	Checks if there are any PG connections that cross UPF-defined scope. All PG connections for UPF scope should be at the boundary PG port. This parameter is used with the `-powerDomain` parameter.
`-file` *outFile*	Specifies the name of the output file. *Default:* *designName*`-powerdomain.rpt`
`-inst` *inst_name*	Reports the power domain-related information for the specified instance: the input, output, and power/ground connections. When `-inst` is used along with the `-verbose` parameter, as `reportPowerDomain -inst -verbose`, the instance PG and tie-high/low pin connections along their its global connection rule are reported.
`-isoInst`	Reports all isolation cells in the power domain.

`-module {list of modules}`	Checks whether the specified instances or hierarchical instances are in the power domain. *Default:* The software does not perform this check.
`-net` *net_name*	Reports power domain-related information for the specified net: • The driver instance of the net and its power domain. • The receiver instances of the net and their power domains.
`-partitionHports` *pin | port | hpin+*	Reports the hierarchical partition (Hinst) boundary port's domain at the time of partitioning.
`-pin` *pin1, pin2 ...*	Specifies the lists the pins and the option is of type string. This option is optional.
`-powerDomain` *powerDomainName*	Specifies the power domain whose attributes you want to report. *Default:* If you do not specify the power domain, this command report data about all power domains.
`-powerDomainBoundaryPort` *string*	Reports if the specified port name of the power domain boundary has an IEEE1801 constraint.
`-powerDomainCoverage` *pd1 pd2*	Reports the coverage between two specified domains.
`-pgNet`	Reports all the power/ground nets in the power domain.
`-shifter`	Reports all shifters in the power domain.
`-supplyCrossing` *supp1 supp2*	Reports if the two specified supplies have the on/off and low/high crossing.
`-verbose`	Prints out the detail information and is optional.
`-voltage`	Reports domain voltage.

Examples

- The following command checks the `I1/PD1` instances to identify if there are any PG connections that do not use the `UPF I1` PG nets. If those are found, an error occurs specifying the instance name and its out-of-scope PG connection.

  ```
  reportPowerDomain -checkPgScope true -powerDomain I1/PD1
  ```

- The following command reports all shifter cells, all isolation cells, and all power/ground nets in power domain `PD1`. The command also checks whether HInst `instA` is contained in `PD1`, and reports all results to `myDesign-powerdomain.rpt`.

  ```
  reportPowerDomain -powerDomain PD1 -file myDesign-powerdomain.rpt -module {instA} -shifter -isoInst -pgNet
  ```

- The following example shows how output file `outfile` contains the binding between the timing libraries and instances in power domain VCORE:

  ```
  reportPowerDomain -bindLib -powerDomain VCORE -file outfile

  Timing library for instance(s):
  ============================
  INST = uLSCVSocDownVCore/uACLKEND/uLVHL (lvl_slow_1v08_1v08)
  INST = uLSCVSocDownVCore/uACLKENI/uLVLHL (lvl_slow_1v08_1v08)
  INST = uLSCVSocDownvCore/uaCLKENP/uLVLHL (lvl_slow_1v08_1v08)
  INST = uLSCVSocDownvCore/uaCLKENRW/uLVLHL (lvl_slow_1v08_1v08)
  INST = uLSCVSocDownvCore/uaBIGENDINIT/uLVHlL (lvl_slow_1v08_1v08)
  INST = uLSCVSocDownvCore/uaCLKIN/uLVHL (lvl_slow_1v08_1v08)
  ```

```
INST = uLSCVSocDownvCore/uCP15SDISABLE/uLVHL (lvl_slow_1v08_1v08)
```

- The following command reports the power domain-related information about instance `PM_INST/state_inst/g45`:

  ```
  reportPowerDomain -inst PM_INST/state_inst/g45
  ```

  Result:

  ```
  Analyzing PM_INST/state_inst/g45 (Cell: AN2D1) power domain:AO
  ------from side ------
  Pin A2 => Net PM_INST/state_inst/n_28
  PM_INST/state_inst/g71/ZN in power domain A0
  Pin A1 => Net PM_INST/state_inst/n_25
  PM_INST/state_inst/g47/Z in power domain A0
  ------to side ------
  Pin Z => Net PM_INST/state_inst/n_36
  PM_INST/state_inst/fsm_reg[1]/qi_reg/D in power domain A0
  ==========PG pins =============
  VDD conneted to Net: VDD
  VSS connected to Net:VSS
  ```

- The following command reports the instance PG and tie-high/low pin connections along their its global connection rule:

  ```
  reportPowerDomain -inst inst2/ls_rule1_0_in1 -verbose
  Analyzing inst2/ls_rule1_0_in1 (Cell: PTLVLANY) power domain: PD2
  ```

  Result:

  ```
  ------- from side --------
    Pin I (related power pin VDDI) => Net inst1_out
      inst1/ff2/Q in power domain PD1
  ------- to side --------
    Pin Z (related power pin VDDO) => Net inst2/n_1
      inst2/ff1/D in power domain PD2
  =============PG pins =================
  VSS connected to Net: VSS
  VDDO connected to Net: VDD2
  VDDI connected to Net: VDD1
  VDD connected to Net: VDD2

  VSS is connected to net 'VSS' by GNC rule: -net VSS -pin VSS -module inst2
  VDDO is connected to net 'VDD2' by GNC rule: -net VDD2 -pin VDDO -singleInst inst2/ls_rule1_0_in1
  VDDI is connected to net 'VDD1' by GNC rule: -net VDD1 -pin VDDI -singleInst inst2/ls_rule1_0_in1
  VDD is connected to net 'VDD2' by GNC rule: -net VDD2 -pin VDD -module inst2
  ```

reportPowerSwitch

```
reportPowerSwitch
[-help]
-outFile file_name
```

Reports each power switch instance, the location, and pin/net connections. The report format is as follows:

```
#InstName (x,y)
#   (pin1): net1
#   (pin2): net2
```

Parameters

`-help`	Outputs a brief description that includes the type and default information for each reportPowerSwitch parameter. For a detailed description of the command and all its parameters, use the `man` command: `man reportPowerSwitch.`
`-outFile file_name`	Specifies the name of the report file where the information is written. This is a required parameter.

reportShifter

```
reportShifter
[-help]
[-cell cellName]
[-from powerDomainName]
[-to powerDomainName]
[-outfile fileName]
[-highlight]
```

Reports the level shifters that have been read into or defined for the Innovus software.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `reportShifter` parameter. For a detailed description of the command and all its parameters, use the man command: `man reportShifter`.
`-cell`	Reports shifters with the specified cell. *Default:* Reports all level shifters.
`-from powerDomainName`	Reports all the shifter instances connected to the output pins of the power domain specified in the `-from` option. *Default:* Reports all level shifters.
`-highlight`	Highlights placed level shifters.
`-outfile fileName`	Reports all instances in an output file. *Default:* The instances will be reported to a default output file `designName.shifter.rpt`. A warning message is printed to indicate a default output file is created.
`-to powerDomainName`	Reports shifter instances connected to the input pins of the power domain specified in the `-to` option. *Default:* Reports all level shifters.

Related Information

For more information, see the following topics in the Low Power Design chapter of the *User Guide*.

reportVoltage

```
reportVoltage
[-help]
[-early]
[-inst string]
[-late]
[-net string]
[-quiet]
[-term string]
[-view string]
```

This command reports the voltage for the net/pin (term)/inst in the specific view under a specific corner.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `reportVoltage` parameter. For a detailed description of the command and all its parameters, use the man command: `man reportVoltage`
`-early`	Specifies that the voltage is repoted in the early mode.
`-inst string`	Reports the specified instance's power domain, cell name, timing library, view, mode, power net, and voltage information.
`-late`	Specifies that the voltage is reported in the late mode.
`-net string`	Specifies the net voltage (driver's pin voltage).
`-quiet`	Displays only the pin voltage-related information without other additional unnecessary information to avoid huge log size.
`-term string`	Specifies the term voltage.
`-view string`	Specifies the analysis view.

Related Information

For more information, see the Low Power Design chapter of the *User Guide*.

restorePowerSwitch

```
restorePowerSwitch
[-help]
[-file string]
```

Restores the information stored in the power switch databases. You can use this command to load back the power switch information only after completing power switch insertion using the `addPowerSwitch` command and then saving the database information using the `savePowerSwitch` command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `restorePowerSwitch` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man restorePowerSwitch`
`-file string`	Specifies the name of the file from which the power switch database information will be restored.

Related Information

- `addPowerSwitch`
- `savePowerSwitch`

routePGPinUseSignalRoute

```
routePGPinUseSignalRoute
[help]
[-all]
[-maxFanout number]
[-nets {listofNets}]
[-nonDefaultRule ruleName]
[-pattern {trunk | steiner}]
[-well]
```

Routes the secondary power/ground pins of always-on cells to the specified power/ground nets in signal route. You can also control the routing pattern and wire by specifying the pattern, the maximum number of pins per cluster, and non-default rules.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `routePGPinUseSignalRoute` parameter. For a detailed description of the command and all its parameters, use the man command: `man routePGPinUseSignalRoute`
`-all`	Routes non-primary power/ground pins of all the cells.
`-nets` *`listOfNets`*	Specifies the power/ground nets to be connected to the secondary power/ground pins. *Default*: If this parameter is not specified, the software will get all the nets from global connections for the cells and pins defined in the command `setPGPinUseSignalRoute`.
`-pattern {trunk | steiner}`	Specifies how the signal router routes the secondary power/ground pins. `Trunk`: When option `maxFanout` value is 1, routes the pins to nearest power grid. When the value is more than 1, routes all pins per cluster to the trunk. `Steiner`: Routes all pins to a trunk. *Default:* `trunk`
`-maxFanout` *`number`*	Specifies the maximum number of pins per cluster in the trunk rotating pattern. *Default:* 5.
`-nonDefaultRule` *`ruleName`*	Specifies the non-default rule the signal router uses to route the secondary power/ground pins. *Default:* Regular signal routing rule is used by default.
`-well`	Includes nwell and pwell pins Type: Boolean, Optional

Related Topics

- `getPGPinUseSignalRoute`
- `setPGPinUseSignalRoute`
- Low Power Design chapter in the *Innovus User Guide*

savePowerSwitch

```
savePowerSwitch
[-help]
[-outFile string]
```

Stores the power switch database information, which can later be restored in the same floorplan through the `restorePowerSwitch` command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `savePowerSwitch` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man savePowerSwitch`
`-outFile` *string*	Specifies the output file for storing the power switch database information.

Related Information

- `addPowerSwitch`
- `restorePowerSwitch`

setMsvMode

```
setMsvMode
[-help]
[-allowNestedDefaultDomain {true | false}]
[-allowPowerDomainMinGapZero {true | false}]
[-checkAllNetsForDomainCrossing {true | false}]
[-handleBackToBackIsolation {true | false}]
[-handlePD {true|false}]
[-handlePDComplex {true|false}]
[-honorCpfGlobalConnectionSpecForAoBuffer {true | false}]
[-honorCpfGlobalConnectionSpecForShifter {true | false}]
[-honorDotLibRelatedPGPin {true | false}]
[-honorEffectiveDomainForIsoLsInsertion {true | false}]
[-markIsoEnablePinAsAlwaysOn {true | false}]
[-notUseTopFTermDomainForVoltage {true|false}]
[-reset]
[-shareWellAOBufferingSupport {true|false}]
[-upf_allow_shifter_voltage_mismatch {true|false}]
[-upf_insert_on_floating_pins {true|false}]
```

Sets the special handling for inter-domain nets and to use effective power domains for ISO/LS insertion.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each setMvsMode parameter. For a detailed description of the command and all its parameters, use the `man` command: `man setMvsMode`
`-allowNestedDefaultDomain {true | false}`	

	Allows a non-default power domain member to be logically nested in a default power domain. This default power domain member has fence constraint.
	
	By default, due to grouping, the fence constraint is lost for the non-default power domain member. Set `true` to enable.
	
	 	
	In the netlist: modules `HInst11` and `HInst12` are under `HInst1`; and `HInst1` is under the top.
	
	You have the following:
	
	`create_power_domain -instances HInst1`
	
	`create_power_domain -default -instances {HInst11 HInst12}...`
	
	That means `HInst11` and `HInst12` are cut from `HInst1` to default power domain. If there is a fence/region constraint for `HInst11` and `HInst12` in default power domain, then please turn this global on. Otherwise, the fence/region for `HInst11` and `HInst12` will be lost.
	
	Default: `true`

`-allowPowerDomainMinGapZero {true | false}`	
	Allows users to set power domain zero `minGap`. *Default*: `true`
`-checkAllNetsForDomainCrossing {true | false}`	
	Checks all the nets for domain crossings. Set `true` to enable. *Default*: `true`
`-handleBackToBackIsolation {true | false}`	
	Supports back-to-back isolation insertion along one cross-domain net based on the CPF ISO rule. Set `true` to enable. *Default*: `false`

`-handlePD {true|false}`	Routes intra-power domain and global nets using the specifications of the power domains. On using this option, earlyGlobalRoute routes intra-power domain nets only within their power domains. Global nets that do not connect with a power domain do not get routed through that power domain. *Default*: `true`
`-handlePDComplex {true|false}`	Routes nets belonging to more than one power domain so that the routing does not violate power domain boundaries, in addition to routing intra-power domain and global nets using the specifications of the power domains. For example, when you specify `-handlePDComplex true`, if a net belongs to power domains PD1 and PD3, but not PD2, earlyGlobalRoute routes the net without going over the PD2 power domain boundary. *Default*: `true`
`-honorCpfGlobalConnectionSpecForAoBuffer {true | false}`	
	Honors connection pecs for AO buffer based on the CPF rules. Set `true` to enable. *Default*: `false`
`-honorCpfGlobalConnectionSpecForShifter {true | false}`	
	Honors connection specs for shifters based on the CPF rules. Set `true` to enable. *Default*: `false`
`-honorDotLibRelatedPGPin {true | false}`	
	Honors library related PG pins. Set `true` to enable. *Default*: `true`
`-honorEffectiveDomainForIsoLsInsertion {true | false}`	
	Honors effective domains for ISO/LS insertions. Set `true` to enable. *Default*: `true`
`-markIsoEnablePinAsAlwaysOn {true | false}`	
	Insert ISO/LS for all the inter-domain nets using effective domain based on the CPF rules. Set `true` to enable. *Default*: `true`
`-notUseTopFTermDomainForVoltage {true|false}`	
	Controls voltage using top fterm domain for IO pin voltage. *Default*: `false`
`-reset`	Resets the MSV mode to the default value. Any values that do not already match the default value and are reset. will be reported.
`-shareWellAOBufferingSupport {true|false}`	
	Shares the isolated Nwell AO buffers. *Default*: `false`
`-upf_allow_shifter_voltage_mismatch {true|false}`	
	When set to false, it prevents insertion of level shifters by allowing voltage tolerance. *Default*: `true`

`-upf_insert_on_floating_pins {true|false}`	
	Allows controlling of low power cell insertion on the floating pins. *Default*: `true`

Examples

- In the following example, allows the non-default power domain members nested in the default power domain member are allowed logically and physically and this default power domain has the fence constraint:
  ```
  setMsvMode -allowNestedDefaultDomain true
  ```
- In the following example, all the nets for the iso/ls insertion are checked:
  ```
  setMsvMode -checkAllNetsForDomainCrossing true
  ```
- In the following example, back-to-back isolation along with one net are inserted:
  ```
  setMsvMode -handleBackToBackIsolation true
  ```
- In the following example, the CPF specification (`create_global_connection -domain`) are used for the ISO/LS PG pin connection:
  ```
  setMsvMode -honorCpfGlobalConnectionSpecForShifter true
  ```
- In the following example, the pin power domain is assigned based on the related power pin specified in `*.lib`:
  ```
  setMsvMode -honorDotLibRelatedPGPin true
  ```
- In the following example, effective domain for the iso/ls insertion is used：
  ```
  setMsvMode -honorEffectiveDomainForIsoLsInsertion true
  ```
- In the following example, the iso enable based on the tag (power modes) is marked:
  ```
  setMsvMode -markIsoEnablePinAsAlwaysOn false
  ```

setPGPinUseSignalRoute

```
setPGPinUseSignalRoute
[-off]
[-all]
cellPins cellName:pinName cellName:pinName2 ...
[-well]
```

Sets the internal bit for a given cell/pin pair to be routed by the signal router. Use this command to enable NanoRoute to route always-on-pins in SRPG (state retention power gating) or always-on buffer cells.

Parameters

`-all`	Routes all backup and non-main_rail primary power/ground pins. Type: Boolean, Optional
`cellPins` *`cellName:pinName`*	• *`cellName`*: Specifies the cell containing the pin for NanoRoute to route. You can use a wildcard to specify all cells of certain type. • *`pinName`*: Specifies the pin name of the secondary PG pin to be routed.
`-off`	Unsets this feature for the specified list of `cellPins` or `cellName:pinName`.
`-well`	Includes nwell and pwell pins. Type: Boolean, Optional

Examples

- The following commands set both the `vddo` and `vsso` pins for the signal router, but NanoRoute will only route `vddo`:

  ```
  setPGPinUseSignalRoute SDRFF:vddo SDRFF:vsso
  routePGPinUseSignalRoute -nets VDD
  ```

- The following command sets NanoRoute to route the `VDD1` pin of all `NAND` cells:

  ```
  setPGPinUseSignalRoute NAND*:VDD1
  ```

- The following command unsets NanoRoute to route the `VDD1` pin of all the `NAND` cells, which were set earlier:

  ```
  setPGPinUseSignalRoute NAND*:VDD1 -off
  ```

swapRegularCellWithAlwaysOnCell

```
swapRegularCellWithAlwaysOnCell
[-help]
[-cellMapFile filename]
[-defaultAlwaysOnCell AoCellNames]
[-nets LPErrorNetList]
[-verbose]
```

Identifies the regular buffer/inverter and swaps it with always-on buffer/inverter. The regular buffer/inverter causes the LP error. Hence, this command fixes the LP error through the regular to always-on buffer/inverter swapping.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `swapRegularCellWithAlwaysOnCell` parameter. For a detailed description of the command and all its parameters, use the man command: `man swapRegularCellWithAlwaysOnCell`
`-cellMapFile` *filename*	Specifies the map file name. The map file provides the equivalent driving strength between the regular buffer/inverter and AO buffer/inverter. This means that the timing will not be degraded with using this parameter, when the mapped always-on cell is swapped in. Following is the map file format: `regularBufCellName AoBufCellName`
`-defaultAlwaysOnCell` *AoCellNames*	Specifies the default always-on buffer/inverter to be used to replace the regular buffer/inverter. When using default always-on buffer/inverter, this parameter just corrects the LP error. Additionally, this parameter may degrade the timing, and you need to run optimization in flow.
`-nets` *LPErrorNetList*	Specifies the list of LP-error nets. By default, the `swapRegularCellWithAlwaysOnCell` command works on all the buffer/inverter trees. When this parameter is used, the command works on the buffer/inverter tree for the specified nets.
`-verbose`	Displays the detailed trace information for the specified nets.

Examples

- The following command swaps the incorrect regular buffer with `AoBuf1`, and the incorrect regular inverter with `AoInverter1`:
  ```
  swapRegularCellWithAlwaysOnCell -defaultAlwaysOnCell "AoBuf1 AoInverter1"
  ```
- The following command swaps the incorrect regular buffer/inverter using the specified mapping cells or the default always-on cells:
  ```
  swapRegularCellWithAlwaysOnCell -cellMapFile mapfile1 -defaultAlwaysOnCell "AoBuf1 AoInverter1"
  ```
- The following command swaps the incorrect regular buffer/inverter using the default always-on cells for the buffer/inverter trees along with the `net1` and `net2` paths:
  ```
  swapRegularCellWithAlwaysOnCell -nets "net1 net2" -defaultAlwaysOnCell "AoBuf1 AoInverter1"
  ```
- The following command swaps the incorrect buffer/inverter along with the `net1` and `net2` paths and displays the detailed trace information:
  ```
  swapRegularCellWithAlwaysOnCell -nets "net1 net2" -defaultAlwaysOnCell "AoBuf1 AoInverter1 -verbose"
  ```

verifyPowerDomain

```
verifyPowerDomain
[-help]
[-allInstInPD]
[-aobBiasConn]
[-aoBufferType]
[-bind]
[-cell_bind {cell ...}]
[-drcFile string]
[-gconn [module_name_list]]
[-isoNetPD [fileName]
[-libBindingVoltage]
[-noFTermIsoC]
[-noFTermShifter]
[-place [-place_rpt report_name]]
[-powerSwitch]
[-pwrWithinMinGap]
[-retention {fileName ...}]
[-xNetPD {fileName}]
```

Verifies whether the power domains are set up correctly in terms of timing library binding and PG connection. This command also checks whether any power domains overlap. The `verifyPowerDomain` command checks that libraries specified for each power domain of each `dc_corner` are complete for each power domain member list. The command also checks if the inserted isolation is consistent with the isolation rule.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `verifyPowerDomain` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man verifyPowerDomain`.
`-allInstInPD`	Verifies all instances are in the power domain.
`-aobBiasConn`	Checks the AOB bias net connection.
`-aoBufferType`	Checks if the AO buffer in each domain has correct type in terms of AO Nwell design and IEEE1801 Nwell specification.
`-bind`	Verifies that all cells are bound to correct timing library cells.
`-cell_bind {cell ...}`	
	Checks if the specified cells are bound in the domain's library set for all active views and domains.
`-drcFile string`	Creates DRC violation markers and save those in the specified file.
`-gconn module_name_list`	

	Verifies that power and ground pins of instances within the power domain are connected to the power and ground nets of that power domain. In addition, this parameter verifies that the tie-high and tie-low connections of an instance are connected to the same power and ground nets of the power domain to which the cell belongs. If you do not specify a list of module names, all modules are verified.
`-isoNetPD`	Verifies if the nets are missing isolation instances according to the power intent file. It also checks if the isolation uses right type of cell specified in the IEEE1801 map_isolation_cell command (if any).
`-libBindingVoltage`	Checks voltage against the binding library.
`-noFTermIsoC`	Ignores the nets connecting to I/O when verifying isolation using `-isoNetPD`.
`-noFTermShifter`	Ignores the nets connecting to I/O when verifying shifter using `-xNetPD`.
`-place`	Verifies if the instances are placed in the boundary of their power domain.
`-place_rpt` *report_name*	
	Specifies a name and location for the report generated when you use this command with the `-place` parameter.
`-powerSwitch`	Verifies whether each row in the power domains contain at least one power switch. The command issues a warning message detailing which rows do not contain at least one switch. It also checks if the power switch uses right type of cell specified in the IEEE1801 map_power_switch_cell command (if any).
`-pwrWithinMinGap`	
	Verifies that the power domain ring is within the distance specified by the `modifyPowerDomainAttr -minGaps` or `createPowerDomain -minGaps` command.
`-retention {`*fileName ...*`}`	
	Specifies a name for storing the verify retention information. It checks if the retention uses the right type of cell specified in the IEEE1801 map_retention_cell command (if any).
`-xNetPD`	Verifies if the nets are missing level shifter according to the power intent file. It also checks if the level shifter uses right type of cell specified in the IEEE1801 map_level_shifter_cell command (if any).

Examples

The following command issues warning messages if instances that are not members of a power domain are placed within that power domain boundary, or if any power domains overlap:

```
verifyPowerDomain -place
```

verifyPowerSwitch

```
verifyPowerSwitch
[-help]
[-powerDomain powerDomain]
[-checkFloatingInput]
[-checkFloatingOutput]
[-checkFloating]
[-checkOverlap]
[-checkPlace]
[-checkLoop]
[-checkRowCoverage]
[-checkAll]
[-hilite]
[-reportFile]
[-reportLongestChain]
[-startingNet]
```

Verifies power switch placement and enable connections, including the row coverage for column insertion. The command issues a warning message detailing which rows do not contain power switches. The options also enable reporting for the longest signal chain starting from a given enable net. If the start of the enable net is not available, all enable nets of all domains will be used as starting points and all chains will be reported. Both the length of the chain and the switch instances involved in the longest chain will be reported.

The `verifyPowerDomain -powerSwitch` parameter performs the same function.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each verifyPowerSwitch parameter. For a detailed description of the command and all its parameters, use the `man` command: `man verifyPowerSwitch`.
`-checkFloatingInput`	To check floating input enable pins.
`-checkFloatingOutput`	To check floating output enable pins.
`-checkFloating`	To check both floating input and output enable pins.
`-checkOverlap`	To check any overlap among the pins.
`-checkPlace`	To check for unplaced power switches.
`-checkLoop`	To check for accidentally created enable signal loops.
`-checkRowCoverage`	To check if every row is covered by power switch.
`-checkAll`	To verify all the checks.
`-hilite`	To select the violation.
`-startingNet`	To start the net to report longest chain.
`-reportFile`	To report output to a file.
`-reportLongestChain [startingNet` *`enableNet`*`]`	
	Reports the longest chain starting from the given enable net. If `-startingNet` is not given, all enable nets of all domains will be used as the starting point and all chains will be reported. The report will include both: the length of the chain, and the switch instances involved in the longest chain.
`-powerDomain powerDomain`	Verify only the specified power domain.

Examples

The following command verifies the placement status of power switch cells and checks the row coverage by power switch cells for the `powerDomain TDSPCore`:

```
verifyPowerSwitch -powerDomain TDSPCore -checkPlace -checkRowCoverage
Verifying domain: TDSPCore.
Verifying power switch row coverage ...
Verifying power switch placement status ...
Switch verification completed on domain: TDSPCore.
Number of warnings on domain TDSPCore : 0.
Power switch verification completed with 0 warnings..
1
```

write_power_intent

```
write_power_intent
[-help]
fileName
{-cpf [[-hierInst -topHier] | [-inst]] | -1801 | -incremental_1801}
[-no_extra_connects]
```

Writes the CPF/IEEE1801 file. The command options help to write the file for CPF as well as for the IEEE1801 standard.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `write_power_intent` parameter. For a detailed description of the command and all its parameters, use the man command: `man write_power_intent`
`fileName`	Specifies name of the IEEE1801 input file.
For CPF	
`-cpf`	When specified, Innovus writes out the CPF file.
`-inst`	Specifies the hierarchical instance name. Writes (partitions) the CPF for the hierarchical instance specified in this option. **Note:** Must be used along with `-cpf` option.
`-hierInst`	Writes top-level CPF where the hierarchical instances specified in `-hierInst` option are hard blocks when specified together with `-topHier -cpf`.
`-topHier`	Writes top-level CPF when specified together with `-hierInst` and `-cpf`.
For IEEE1801	
`-1801`	Writes the IEEE1801 file from the low-power database. It filters out the non-existing instances from the original IEEE1801 file and appends to it the following: • PG connection for the newly-inserted always-on buffers • Nwell/Pwell connections for the low-power cells • `-no_isolation`/`shifter` for the isolation/level shifter strategies for the newly-created ports along the power domain boundary
`-incremental_1801`	Specifies the incremental IEEE1801 power intent.
`-no_extra_connects`	If this parameter is specified, `write_power_intent -1801` does not write out any extra `connect_supply_net` (PG connection). For example: `write_power_intent -1801 -no_extra_connects out.upf` **Note:** Extra connects means that the extra `connect_supply_net` commands appended by the tool, which are not included in the original UPF.

Machine Learning Commands

- init_ml
- write_ml_design
- write_ml_library
- write_ml_timing_graph
- write_ml_timing_path

init_ml

```
init_ml
[-help]
[-comment string]
[-flow_phase string]
[-name string]
-prefix string
[-scenario string]
```

Initializes the environment to start writing data for JedAI. Run this command before using any of the following commands to ensure that content is properly labeled for big data ingestion and registration:

- `write_ml_design`
- `write_ml_library`
- `write_ml_timing_graph`
- `write_ml_timing_path`

Parameters

`-help`	Prints a brief description that includes the type and default information for each `init_ml` parameter. For a detailed description of the command and all of its parameters, use the man command `man init_ml`.
`-comment` *string*	Specifies a comment. *Data_type*: string, optional
`-flow_phase` *string*	Specifies the flow phase. *Data_type*: string, optional
`-name` *string*	Specifies the design name. *Data_type*: string, optional
`-prefix` *string*	Specifies the prefix for the output files. *Data_type*: string, required
`-scenario` *string*	Specifies the scenario. *Data_type*: string, optional

Example

- The following command the environment to start writing data for JedAI for the `cts` flow phase with the `default` scenario for the `dtmf` design.

  ```
  init_ml -prefix out/ -name dtmf -flow_phase cts -scenario default -comment "This is a demo."
  ```

Related Information

- write_ml_design
- write_ml_library
- write_ml_timing_graph
- write_ml_timing_path

write_ml_design

```
write_ml_design
[-help]
[-no_power]
[-objects object_list]
-prefix string
[-verbose]
[-views view_list]
```

Writes design-related data for JedAI to csv files with specified prefix. It includes data that is design specific and relates to logical, physical, and timing type objects.

Before running `write_ml_design`, the following two commands should be run:

- `report_timing`
- `write_global_slack_report -include_ports`

Parameters

`-help`	Prints a brief description that includes the type and default information for each `write_ml_design` parameter. For a detailed description of the command and all of its parameters, use the man command `man write_ml_design`.
`-no_power`	Specifies that power attributes should not be dumped. *Data_type*: bool, optional
`-objects` *object_list*	

	Specifies the list of db object(s) to be dumped, which could include one or more of the following values:
	`analysis_view arc base_cell base_pin blockage clock congestion constraint_mode`
	`delay_corner design gcell_grid hinst hnet hpin hport inst layer marker net netlist`
	`opcond option p2p partition patch_wire pg_base_pin pg_pin pin pin_shape port`
	`rc_corner route_rule row site skew_group special_net timing_condition track_pattern unit_parasitic via_def`
	Use curly braces to enclose multiple values.
	Data_type: tcl_obj, optional

`-prefix` *string*	Specifies the prefix for the output files. *Data_type*: string, required
`-verbose`	Displays a more detailed message. *Data_type*: bool, optional
`-views` *view_list*	
	Dumps the data for the specified analysis view(s). *Data_type*: tcl_obj, optional

Example

- The following command writes the attributes of all design objects to csv files with the specified prefix:

```
write_ml_design -prefix out/
```

Related Information

- init_ml
- report_timing
- write_global_slack_report
- write_ml_library
- write_ml_timing_graph
- write_ml_timing_path

write_ml_library

```
write_ml_library
[-help]
[-objects object_list]
-prefix string
```

Writes library-related data for JedAI to csv files with the specified prefix. It includes data that is library specific and relates to lib_cells, timing_tables, and power_tables.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `write_ml_library` parameter. For a detailed description of the command and all of its parameters, use the man command `man write_ml_library`.
`-objects object_list`	
	Specifies the list of db object(s) to be dumped, which could include one or more of the following values: `lib_arc lib_cell lib_feature lib_pin library library_set power_table timing_table` Use curly braces to enclose multiple values. *Data_type*: tcl_obj, optional
`-prefix string`	Specifies the prefix for the output files. *Data_type*: string, required

Example

- The following command writes library-related data for JedAI to csv files with the specified prefix:
  ```
  write_ml_library -prefix out/
  ```

Related Information

- init_ml
- write_ml_design
- write_ml_timing_graph
- write_ml_timing_path

write_ml_timing_graph

```
write_ml_timing_graph
[-help]
[-noedge]
-prefix string
[-register_only]
[-views view_list]
```

Writes timing-related data for JedAI to csv files. It includes data representing the complete timing graph for a given set of analysis views.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `write_ml_timing_graph` parameter. For a detailed description of the command and all of its parameters, use the man command `man write_ml_timing_graph`.
`-noedge`	Specifies that edge data should not be dumped. This option can be used to save time. *Data_type*: int, optional
`-prefix string`	Specifies the prefix for the output files. *Data_type*: string, required
`-register_only`	Specifies that only nodes for register should be dumped. *Data_type*: bool, optional
`-views view_list`	Dumps the data for the specified analysis view(s). *Data_type*: tcl_obj, optional

Example

- The following command writes the timing-related data for JedAI to csv files with the specified prefix:

```
write_ml_timing_graph -prefix out/
```

Related Information

- init_ml
- write_ml_design
- write_ml_library
- write_ml_timing_path

write_ml_timing_path

```
write_ml_timing_path
[-help]
[-anchor_file string]
[-each_endpoint]
[-gen_anchor]
[-hpin]
[-io_only]
[-max_paths int]
[-max_slack float]
[-nworst int]
[-path_group string]
[-per_partition]
-prefix string
[-retime {aocv ssta path_slew_propagation aocv_path_slew_propagation}]
[-start_pathid int]
[-verbose]
[-views view_list]
```

Writes timing-related data for JedAI to csv files. It includes data for individual timing paths. Timing path data can be computed in either graph-based analysis (GBA) or path-based analysis (PBA) fashion using the `-retime` option.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `write_ml_timing_path` parameter. For a detailed description of the command and all of its parameters, use the man command `man write_ml_timing_path`.
`-anchor_file string`	Specifies the name of the anchor file to be used as input. *Data_type*: string, optional
`-each_endpoint`	Specifies whether to dump at least one path for each end point. *Data_type*: bool, optional

`-gen_anchor`	Generates the anchor file. *Data_type*: bool, optional
`-hpin`	Dumps hpin in timing points. *Data_type*: bool, optional
`-io_only`	Specifies that only the io path should be dumped. *Data_type*: bool, optional
`-max_paths` *int*	Specifies the max_paths for `report_timing`. *Data_type*: int, optional
`-max_slack` *float*	Specifies the max_slack for `report_timing`. *Data_type*: float, optional
`-nworst` *int*	Specifies the nworst for `report_timing`. *Default*: `100` *Data_type*: int, optional
`-path_group` *string*	Specifies the path_group for `report_timing`. *Data_type*: string, optional
`-per_partition`	Specifies that only paths through top level partitions should be dumped. *Data_type*: bool, optional
`-prefix` *string*	Specifies the prefix for the output files. *Data_type*: string, required
`-retime {aocv ssta path_slew_propagation aocv_path_slew_propagation}`	
	Specifies the method to be used for reanalysis of specified set of paths with `report_timing`. *Data_type*: enum, optional
`-start_pathid` *int*	Specifies the starting path id. *Default*: `1` *Data_type*: int, optional

`-verbose`	Displays a more detailed message. *Data_type*: bool, optional
`-views` *view_list*	Dumps the timing path for the specified analysis view(s). *Data_type*: tcl_obj, optional

Example

- The following command writes out the attributes of timing paths to csv files with the specified prefix:

```
write_ml_timing_path -prefix out/ -max_paths 10000 -nworst 1
```

[-window_size float]
[-window_step float]
```

Runs the signoff metal fill flow as per specified primary and sub options.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `add_metal_fill_signoff` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man add_metal_fill_signoff`
`-and_area_size` *`size_value`*	Specifies a value for sizing up the changed area to use shapes within this area. This parameter helps in calculating the density and creating areas to be filled, if they fall below the minimum density. The default value of this parameter is 10. A value lesser than the default value may be used to improve the flow performance, if no accuracy issues occur. A value greater than the default value can be used to fix the accuracy issues. The minimum value of this parameter is `0.001` and maximum value is `1000`.
`-area {x1 y1 x2 y2}`	Specifies a set of coordinates within metal fill can be trimmed.
`-attach_instance_name` *`attr_num`*	Specifies the instance name to attach.
`-attach_net_name` *`attr_num`*	Specifies the net name to attach.
`-attach_net_prop {{`*`prop_name`* `attr_num} ...}`	
	Specifies the net property to attach.
`-auto_load_fills`	Updates the FILL data automatically in the software after when the `add_metal_fill_signoff` command modifies the HMF database. In case the HMF database is not modified, the FILL data will be hidden in the software's design.
`-bg`	Runs metal fill in the background mode without locking up the software license. **Note:** All the metal fill options running in the background must be used with the `-bg` parameter.
`-clock`	Specifies whether to trim metal fill around all clock nets.

`-common_blockage {`*`layer_num1 layer_datatype1 ...`*`}`	Specifies common blockage fill layers. This allows you to specify the blockage layer only once, instead of multiple individual blockages for the metal fill layers. The parameter value format is `{`*`layer_number layer_datatype`*`}`. You can also specify multiple layers, and each blockage layer should specify a set of two values. The *`layer_number`* must be an integer. Following are the examples of the usage of this parameter:
	`add_metal_fill_signoff -common_blockage {150 28}`
	`add_metal_fill_signoff -common_blockage {150 28 120 55}`

`-control` *`file_name`*	Specifies the control file, which is created automatically when a job is submitted from the PVS GUI. This parameter can be used, if you have run a directory submitted from the GUI. Use this parameter to rerun the PVS job from the command line and get the results, which are exactly the same as the GUI submission. The control file is placed in the run directory with the `pvsdrcctl` name and has only the command entries for certain fields in the GUI. You must not modify the file by adding commands or parameters that are not available in the GUI. If you do that, the commands can be ignored by the PVS rule compiler or the results can be indeterminate.
`-delete_area {{`*`layer_list1`*`} {`*`x1 y1 x2 y2`*`} ...}`	Specifies the x and y coordinates of the area where metal fill is deleted. Following is the usage example of this parameter: `add_metal_fill_signoff -delete_area {{M1 M2 M6} {0 0 50 50}}`
`-delete_fill`	Deletes metal fills in the specified window or coordinates.
`-delete_flatten_fills`	Deletes flattened metal fills without updating the HMF database.
`-delete_point {{`*`layer_list1`*`}{`*`x1 y1`*`}...}`	Specifies the x and y coordinates of the point where metal fill is deleted. Following is the usage example of this parameter: `add_metal_fill_signoff -delete_point {{M2} {134.7 14.21}}`
`-die_area_as_boundary`	Specifies the die area as boundary.

`-dp` *n*	Specifies the number of local cores to use. The default value is fetched from the EDI settings.
`-dp_timeout` *value*	Specifies the time to wait for the slave processes to start.
`-excl_area_size` *size_value*	Specifies the area to be created around the metal fill area to check for the existing metal fill shapes and to avoid creation of metal fill shapes too close to the existing metal fill shapes. The default value of this parameter is `1.6`. A value lesser than the default value may be used to improve the flow performance, if no accuracy issues occur. A value greater than the default value can be used to fix the accuracy issues. The minimum value of this parameter is `0.001` and maximum value is `1000`. The following picture shows the usage of `-and_area_size` and `-excl_area_size` parameters: `-fill`	Runs the signoff metal fill flow to generate hierarchical metal fills database.
`-fill_cell` *cell_name*	Specifies metal fill cell name.
`-fill_layer {`*layers_list*`}`	Fills only a set of specified metal and/or via metal layers. Following is the usage example of this parameter: `add_metal_fill_signoff -fill_layer {M1 VIA12 M2}`
`-fill_output_mode {gdsii | oasis}`	Generates metal fill database in the `gdsii` or `oasis` format. The default format is `gdsii`.
`-flatten`	Flattens metal fills database and loads into the software.
`-incremental`	Runs incremental metal fill post ECO.

`-layer_map_file` *streamOut_map_file*	Specifies the `streamOut` metal layer map file.
`-license_timeout`	Specifies the time (in seconds) to wait if the software license is not immediately available while initiating the run. The default value of this parameter is 300 seconds.
`-license_dp_continue`	Initiates the software run using fewer available CPUs based on the number of licenses obtained. Use this parameter in case PVS cannot obtain the required number of licenses in the multiprocessing mode.
`-lib_name library_name`	Specifies the library name.
`-lsf`	Distributes the processing of the software run to different CPUs using LSF. While using this parameter, the `DP_LSF_RESOURCE` environment variable must be set to specify the LSF resource string, as shown below: `setenv DP_LSF_RESOURCE 'resource string for slave processes'` Additionally, the `-temp_working_dir` *work_dir* should be used to specify local working directory for the LSF run.
`-master_lsf`	Submits the master PVS process on LSF. While using this parameter, the `MASTER_LSF_RESOURCE` environment variable should be set to specify LSF resource string, as shown below: `setenv MASTER_LSF_RESOURCE 'resource string for master process'`
`-merge` *list_of_external_stream_files*	
	Merges the external stream files.
`-merge_fill_edits`	Updates metal fill database with the metal fill edits executed in the software.
`-min_density percent1` *layer_list1*	Specifies percentage value of the minimum metal density. The default value of this parameter is `0` for each metal layer. This parameter trims metal fill below when the specified window density percentage could cause any metal density violations. This parameter is controlled by the `-window_size` and `-window_step` values, as shown in the below example: `add_metal_fill_signoff -min_density {20 {M1 M2} 35 M3}`
`-net net_names`	Specifies a list of critical net names or pointers, which are surrounded by the metal fill area.
`-no_structure_name`	Merges the GDSII file without loading the design.
`-no_via_fills`	Specifies not to generate metal via fills.
`-offset {`*x y*`}`	Defines the offset displacement to be applied.
`-output_macros`	Displays the LEF abstract information about macros, such as LEF pin geometries and obstructions.
`-report_file`	Displays the cell name, which is changed to file.
`-rule_file` *rule_file_name*	Specifies metal fill rule file name.
`-skip_map_check`	Ignores the cross-referencing of the `-layer_map_file` parameter and the Innovus layer names.
`-slack_threshold` *float*	Trims any critical net(s) in the timing aware flow with the slack lesser than the specified value (in nanoseconds). Following is the usage example of this parameter: `add_metal_fill_signoff -slack_threshold 0.1`
`-spacing` *float*	Trims metal fill on the specified metal layer around critical net routes. **Note:** The `-spacing` and `-trim_effort` parameters are mutually exclusive.
`-spacing_above` *float*	Trims metal fill on above the specified metal layer around critical net routes.
`-spacing_below` *float*	Trims metal fill on below the specified metal layer around critical net routes.

`-stripes` *number*	Specifies the number of stripes that divide the design. The default is value of this parameter is `1`.
`-structure_name` *structureName*	Specifies the superstructure that consists of all the geometries that the map file writes out.
`-tech_lib` *string*	Specifies the PVS technology library for `-fill` and `-incremental`.
`-tech_set` *string*	Specifies the PVS technology set for `-fill` and `-incremental`.
`-technology` *string*	Specifies the PVS technology to use for identifying the sign-off rules file. **Note:** You can use this parameter with either the `-rule_file` or `-technology` parameter.
`-temp_working_dir` *work_dir*	Specifies the working directory for the background or LSF run.
`-trim`	Trims metal fills in the metal fills database for timing. This parameter is density-related.
`-trim_effort {high | med | low}`	Trims metal fill area with the high, medium, or low effort around the critical net routes. This parameter also helps in determining the blockage size for trimming metal fill. Following are the parameter values: • `high`: Presents area of two times of the layer pitch value. • `med`: : Presents area of 1.5 times of the layer pitch value. • `low`: : Presents the same area of the layer pitch value. Following is the usage example of this parameter: `add_metal_fill_signoff -trim_effort med` Here, if the M2 layer pitch is `0.8 um`, M2 fills will be trimmed around selected nets within the distance of `1.2 um`. **Note:** The `-trim_effort` and `-spacing` parameters are mutually exclusive.
`-trim_layer {`*layers_list*`}`	Trims only the set of specified layers. Following is the usage example of this parameter: `add_metal_fill_signoff -trim_layer {M1 M2}`

`-trim_mf` *spacing_file*	Specifies the spacing file containing information related to trim metal fill in the incremental run. Spacing file contains spacing values between the routed metal, non-OPC and OPC metal fill layers. Metal fills are trimmed around ECO changes according to the specified spacing values, post which incremental run generates fill data in the trimmed area. Following is the format of the spacing file:
	`#layer f-a o-a`
	`M1 0.60 0.16`
	`M2 0.60 0.16`
	`M3 0.60 0.16`
	`M4 0.60 0.16`
	`M5 0.60 0.16`
	`M6 0.60 NA`
	Here:
	• `Mx`: Specifies the LEF layer name.
	• `f-a`: Specifies the metal fill active spacing.
	• `o-a`: Specifies the is OPC fill active spacing.
	• `NA`: Refers to no trimming.
	The following picture shows the usage of `-trim_mf` parameter:
	 	
	The spacing file for the above example has the following settings for the M2 layer:
	`M2 1.5 0.6`
	In this example, the non-OPC metal fills, which are 1.5 um or closer to the modified wire, are trimmed. Additionally, the metal fill data is regenerated in the trimmed area.

`-union_density {`*percent1 layer_list1* `[{`*percent2 layer_list2*`}]...}`	
	Specifies percentage value of the union metal density. The default value of this parameter is `0` for each metal layer. Union density for a layer is the sum of metal density of the current layer, layer below, and layer above the specified windows. Metal fills are trimmed not to violate the `-union_density` settings for the current metal. Following is the usage example of this parameter: `add_metal_fill_signoff -union_density {20 M1}`
`-uniquify_cell_names`	Creates unique cell names, if there are name collisions while using the `-merge` parameter.
`-units {100 | 200 | 400 | 800 | 1000 | 2000 | 4000 | 8000 | 10000 | 20000}`	
	Specifies the resolution of the input/output file. The default value of this parameter is obtained from software database.
`-view_fills`	Loads the existing HMF database into the software to view the metal fills.

`-window_size float`	Specifies the size of the window, which the metal trim uses to examine the metal density. The default value of this parameter is `100`. Following is the usage example of this parameter: `add_metal_fill_signoff -window_size 50`
`-window_step float`	Specifies the stepping distance between two successive positions of the window for a stepped-window trim density check. The default value of this parameter is `50`. Following is the usage example of this parameter: `add_metal_fill_signoff -window_step 25`

Examples

- The following command runs the background LSF job by setting the resource master and slave LSF resource string before launching the software:
  ```
  setenv MASTER_LSF_RESOURCE'-q lnx64 -W "40:00" -n 4 -P "PVS15.23:PE:test"'
  setenv DP_LSF_RESOURCE'-q lnx64 -W "15:00" -P "PVS15.23:PE:test"'
  ```
- The following commands launch a background LSF job in both the master and slave on LSF:
  ```
  Puts "Launching background lsf job; both master and slave on lsf"
  set Bgdir "./LSF_RUN"
  add_metal_fill_signoff -fill -bg -master_lsf -lsf -temp_working_dir $Bgdir
  ```
  It starts HMF generation in the working directory. Post that, you can choose to continue working in the software or exit from the session. The software license is released, as shown below:

  ```
  ################################################################################
  ###### Running add_metal_fill_signoff
  ################################################################################
  ###### Mode '-fill background mode' on cell 'tdsp'
  ################################################################################

  ######  FILL DB Preparing design data
  Ending "FILL DB Preparing design data" (total cpu=0:00:00.2, real=0:00:00.0, peak res=550.0M, current mem=550.0M)

  ######  FILL DB Submitting -fill background run on LSF
  Job <724739> is submitted to queue <lnx64>.
  Ending "FILL DB Submitting -fill background run on LSF" (total cpu=0:00:00.0, real=0:00:01.0, peak res=550.0M, current mem=532.5M)
  Working directory: "/lan/dfm/pvsqa_test01/PVS/HMF_TESTING/FILL_RUN"

  ################################################################################
  Ending "FILL DB add_metal_fill_signoff" (total cpu=0:00:00.3, real=0:00:01.0, peak res=550.0M, current mem=532.5M)
  ```
- The following command checks the status of the background job:
  ```
  add_metal_fill_signoff -check_bg_run $Bgdir
  ```
  Following is the output of the above command:

```
Run is in progress:
        ################################################################################
        ###### Running add_metal_fill_signoff
        ################################################################################
        BG run information:
         fill_cell:       'tdsp'
         fill_layer:      {M1 M2 M3 M4 M5 M6}
         output_format:   'gdsii'
         LSF job queue:   'lnx64'
         LSF job id:      '724739'

        Checking status of BG run:
         run status:      IN PROGRESS
         operation group:  194/1815
         output files:    NOT READY

Run completed:
        ################################################################################
        ###### Running add_metal_fill_signoff
        ################################################################################
        BG run information:
         fill_cell:       'tdsp'
         fill_layer:      {M1 M2 M3 M4 M5 M6}
         output_format:   'gdsii'
         LSF job queue:   'lnx64'
         LSF job id:      '724739'

        Checking status of BG run:
         run status:      COMPLETED
         operation group:  1815/1815
         output files:    READY
        ################################################################################
        Ending "FILL DB add_metal_fill_signoff" (total cpu=0:00:00.0, real=0:00:01.0, peak res=533.3M, current mem=533.2M)
```

- The following command restores initial software database link and generates HMF:
  ```
  add_metal_fill_signoff -load_fill_db $Bgdir
  ```
- The following command kills the background run that is in progress:
  ```
  add_metal_fill_signoff -kill_bg_run $Bgdir
  ```
  Following is the output of the above command:
  ```
  ################################################################################
  ###### Running add_metal_fill_signoff
  ################################################################################

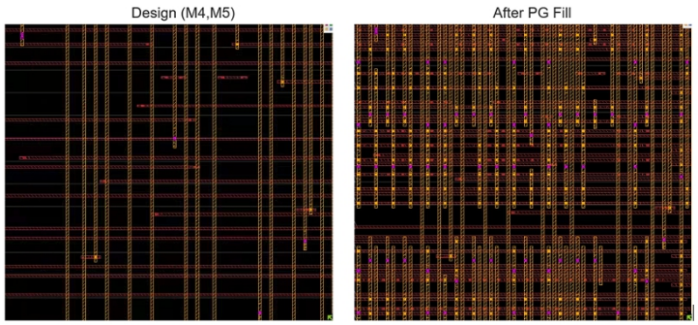
Runs Pegasus PG Fill with default settings and any specified options. This command adds only the floating Track-based Fill (TBF).

Pegasus PG Fill

Pegasus PG Fill is an in-design software used to insert fills connected to Power and/or Ground. PG Fill is generally used for power integrity. These fills are available on the design routing tracks and follow the same DRC rules as design. Pegasus PG Fill:

- Improves IR drop in worst scenarios
- Ensures no negative slack after PG Fill insertion
- Keeps power increase under control

The following example design of the M4 and M5 layers in which fills are inserted post Pegasus PG Fill processing:



Parameters

`-help`	Outputs a brief description that includes the type and default information for each `add_pg_fill` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man add_pg_fill`
`-attach_instance_name` *attr_num*	Specifies the instance name to be attached.
`-attach_net_name` *attr_num*	Specifies the net name to be attached.
`-attach_net_prop {{`*prop_name attr_num*`} ... }`	Specifies the net property to be attached.
`-bsub` *resource_string*	Runs the fill process through BSUB with the specified resource string.
`-core_license` *license_combination*	Sets an exact combination of licenses to be used.
`-die_area_as_boundary`	Writes the die area as a polygon or a boundary. When this parameter is not specified, the `streamOut` command writes the die area as a rectangle or a box.
`-dp` *n*	Runs Pegasus in a multi-processor mode. The *n* variable specified with this parameter presents the number of processors. By default, this value is taken from the Innovus multi-CPU usage.
`-dp_timeout` *seconds*	Specifies the wait time for the DP processes to start.
`-extra_options` *options*	Specifies the additional run options.
`-fix_post_process_drc`	Runs the fill clean-up utility to resolve the DRC issues, which appear post the fill steps.
`-format {stream oasis}`	Specifies the format of the flow.
`-incremental`	Runs Pegasus incremental PG fill. **Note**: This parameter is used with the `-initial_working_dir` and `-working_dir` parameters.
`-initial_working_dir` *string* `-initial_working_dir` *string*	Specifies the working directory with taking information from the previous run.
`-layer_map_file` *streamOut_map_file*	Specifies the name of the `streamOut` layer map file.
`-lib_name` *library_name*	Specifies the library name.
`-license_dp_continue`	Specifies that if the required number of licenses cannot be obtained in the DP processes, the software continues with fewer CPUs based on the number of licenses obtained.
`-license_timeout` *seconds*	Specifies the wait time (in seconds) to run the software, if a license is not immediately available. *Default*: `300`
`-merge` *list_of_external_stream_files*	Specifies the list of external stream files.
`-nc` *resource_string*	Runs the fill process through NC with the specified resource string.
`-no_structure_name`	Merges the GDSII file without loading the software database. **Note:** This parameter is used with the `-merge` parameter.
`-offset {`*x y*`}`	Specifies the location (in microns) of the design in the GDSII output file.
`-output_macros`	Displays the LEF abstract information, such as LEF pin geometries and obstructions for macros.
`-pg_fill_config_file` *file_name*	Specifies the configuration file for the PG fill flow. Any overrides to the default behavior are written in this file.
`-pg_hookup_flow {ALL | PG_ONLY | FLOAT_ONLY}`	Specifies the type of fills to be generated. *Default*: `PG_ONLY`
`-qsub` *resource_string*	Runs the fill process through QSUB with the specified resource string.
`-report_file`	Specifies the cell name to be changed to the file.

`-stripes` *number*	Specifies the number of stripes that divide the design. *Default*: 1
`-structure_name` *structureName*	Specifies the superstructure that consists of all the geometries that the map file writes out.
`-turbo` *jobs_num*	Speeds up the fill process by running the specified number of parallel fill jobs.
`-uniquify_cell_names`	Creates unique cell names if there are name collisions, when the software merges files.
`-units {100 | 200 | 400 | 800 | 1000 | 2000 | 4000 | 8000 | 10000 | 20000}`	
	Specifies the resolution for values in the GDSII/OASIS file.
`-working_dir` *working_directory*	Specifies the working directory.
`-xor_via_layers`	Switches on comparison of via during incremental fill. **Note:** Via-XOR consumes more time on large databases.

add_track_fill

```
add_track_fill
[-help]
[-attach_instance_name attr_num]
[-attach_net_name attr_num]
[-attach_net_prop {{prop_name attr_num} ... }]
[-bsub resource_string]

[-working_dir working_directory]
```

Adds the Track-Based Fill (TBF) flow to the metal fill layers. Pegasus TBF flow is designed to reuse empty tracks for metal filling. It provides a better fill rate than the signoff fill, because the TBF fills are more homogeneous to the design. The TBF solution is timing aware and DRC-neutral. The flow can be run at any stage of the design and does not require any manual input, since all the required information is fetched from the Innovus database.

The TBF flow also allows altering the default TBF behavior through the various configuration parameters. It supports incremental mode to update TBF fills during the ECO cycles. For better performance and scalability, the TBF flow supports partitioning through the `-turbo` parameter, and job distribution through the `-bsub`, `-qsub`, and `-nc` parameters.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `add_tra` For a detailed description of the command and all its parameters, use the `man` command: `man add_track_fill`
`-attach_instance_name attr_num`	Specifies the instance name to be attached.
`-attach_net_name attr_num`	Specifies the net name to be attached.
`-attach_net_prop {{prop_name attr_num} ... }`	Specifies the net property to be attached.
`-bsub resource_string`	Runs the fill process through BSUB with the specified resource string.
`-core_license license_combination`	Sets an exact combination of licenses to be used.
`-die_area_as_boundary`	Writes the die area as a polygon or a boundary. When this parameter is not specified, the
`-dp n`	Runs Pegasus in a multi-processor mode. The `n` variable specified with this parameter pr Innovus multi-CPU usage.
`-dp_timeout seconds`	Specifies the wait time for the DP processes to start.
`-extra_options options`	Specifies the additional run options.

`-fix_post_process_drc`	Runs the fill clean-up utility to resolve the DRC issues, which appear post the fill steps.
`-format {stream oasis}`	Specifies the format of the flow.
`-incremental`	Runs Pegasus incremental track metal fill. **Note**: This parameter is used with the `-initial_working_dir` and `-working_dir` paramete
`-initial_working_dir` *string*`-initial_working_dir` *string*	Specifies the working directory with taking information from the previous run.
`-layer_map_file` *streamOut_map_file*	Specifies the name of the `streamOut` layer map file.
`-lib_name` *library_name*	Specifies the library name.
`-license_dp_continue`	Specifies that if the required number of licenses cannot be obtained in the DP processes, licenses obtained.
`-license_timeout` *seconds*	Specifies the wait time (in seconds) to run the software, if a license is not immediately ava *Default*: `300`
`-merge` *list_of_external_stream_files*	Specifies the list of external stream files.
`-nc` *resource_string*	Runs the fill process through NC with the specified resource string.
`-no_structure_name`	Merges the GDSII file without loading the software database. **Note:** This parameter is used with the `-merge` parameter.
`-offset {`*x y*`}`	Specifies the location (in microns) of the design in the GDSII output file.
`-output_macros`	Displays the LEF abstract information, such as LEF pin geometries and obstructions for m
`-qsub` *resource_string*	Runs the fill process through QSUB with the specified resource string.
`-report_file`	Specifies the cell name to be changed to the file.
`-stripes` *number*	Specifies the number of stripes that divide the design. *Default*: 1
`-structure_name` *structureName*	Specifies the superstructure that consists of all the geometries that the map file writes out.
`-track_fill_config_file` *file_name*	Specifies the configuration file for Track fill flow.
`-turbo` *jobs_num*	Speeds up the fill process by running the specified number of parallel fill jobs.
`-uniquify_cell_names`	Creates unique cell names if there are name collisions, when the software merges files.
`-units {100 | 200 | 400 | 800 | 1000 | 2000 | 4000 | 8000 | 10000 | 20000}`	
	Specifies the resolution for values in the GDSII/OASIS file.
`-working_dir` *working_directory*	Specifies the working directory.

addViaFill

```
addViaFill
[-help]
[-area x1 y1 x2 y2]
[-layer [cutLayerNumber | {list_of_cut_layer_numbers}]]
[-includeVia vias]
[-mode {all | floatingOnly | connectedOnly | {floating connectToPG connectBetweenFill}}]
[-snap]
```

Uses the values specified by the `setMetalFill` command to determine sizes of vias to create. Via fill is inserted to get uniform cut density. Only vias that meet Minimum Area Rule requirements are used. `addViaFill` also uses values from `setViaFill` for the window size, step, and density values.

For information, see the `setMetalFill` and `setViaFill` commands.

Note: Default values from `setMetalFill` for `minWidth` and `minLength` are biased towards the need of `add_metal_fill_signoff` use and should be overridden with values that are more useful for via generation.

Add via fill in the following areas immediately before adding metal fill:

- Where metal fill shapes would intersect with power or ground nets on consecutive layers if no via fill was added.
- Where metal fill shapes on consecutive layers would intersect if no via fill was added.

To reduce the need for via fill, insert multiple-cut vias with the NanoRoute router. For information, see `setNanoRouteMode`.

Also note that this command does not support the 20nm and below node design rules. It is strongly recommended to use the PVS metal fill solution for 20nm and below modes. The same solution should also be used for the sign-off metal fill rule deck of 28nm and above.

Adding Via Fill in Multi-Threading Mode

You can add via fill in multi-threading mode by using the following command before adding the via fill:

- `setMultiCpuUsage`

Via Fill supports the new `setMultiCpuUsage` command use model. For more information, see the following documents:

- Multiple-CPU Processing Commands chapter of the *Innovus Text Command Reference*.
- Accelerating the Design Process by Using Multiple-CPU Processing chapter of the *User Guide*.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `addViaFill` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man addViaFill`.
`-area` *x1 y1 x2 y2*	Specifies a set of coordinates within which to add via fill. For example, specify `-area 0 0 100 100`. *Default:* If you do not specify this parameter, adds via fill to the entire design area.

`-includeVia` *vias*	Specifies a list of vias (VIA in LEF) to be included or via rules (VIARULE GENERATE in LEF) to be used or a combination of the two. Separate the arguments with spaces. You can specify both via names and via rules.
	• The following example shows how to specify a list of via names:
	`-includeVia {VIA12 VIA23}`
	• The following example shows how to specify a list of via rules:
	`-includeVia {via1Array via2Array}`
	• The following example shows how to specify both via names and via rules:
	`-includeVia {VIA12 VIA23 via1Array via2Array}`
	Note: Non-default rule (NDR) vias can also be specified with `-includeVia`.

`-layer {`*cutLayerNumber* | `{`*list_of_cut_layer_numbers*`}}`	Specifies the cut layers for adding via fill. If you specify more than one layer, separate each layer with a space and enclose the list in braces or double quotation marks. To specify *cut12*, *cut23*, and *cut34*, type one of the following commands:
	`addViaFill -layer "VIA12 VIA23 VIA34"`
	`addViaFill -layer {VIA12 VIA23 VIA34}`
	Default: If you do not specify this parameter, adds via fill to all cut layers.

`-mode {all | floatingOnly | connectedOnly | {floating connectToPG connectBetweenFill}}`	
	Specifies the connection mode for via fill. Via fill can be connected to power or ground nets (tied off), or connected between floating metal fill, or unconnected to metal fill (floating). Via fill cannot be connected to signal nets. Specify one or more of the following parameters, as required: • `all`: Enables addition of unconnected and connectToPG via fill. • `floatingOnly`: Adds unconnected via fill only. The option will be made obsolete in the future release. • `floating`: Adds unconnected via fill. It is equivalent to `-mode floatingOnly`, which will be made obsolete in the future release. • `connectToPG`: Adds connected via fill to PG. It is equivalent to `-mode connectOnly`, which will be made obsolete in the future release. • `connectBetweenFill`: Adds connected via fill between floating metal fill. • `connectedOnly`: Adds connected via fill to PG only. The option will be made obsolete in the future release. *Default:* `all`
`-snap`	Snaps edges of via fill shapes and centers of cuts to a user-defined snap grid that is a multiple of the manufacturing grid. When via shapes are snapped to this grid, the edges and centers of the via shapes lie on the grid. If a grid is not specified, the software snaps the shapes to the manufacturing grid. You can define a grid using the `setSnapGrid` command. For more information, see setSnapGrid.

Example

The following set of command inserts unconnected via fill and connected via fill between floating metal fill in layers `VIA1` to `VIA8` and `RV` based on existing `setMetalFill` and `setViaFill` settings:

```
setViaFill -layer {VIA1 VIA2 VIA3 VIA4 VIA5 VIA6 VIA7} /
           -windowSize 100 100 -windowStep 50 50 -minDensity 0.01 /
           -maxDensity 30 -preferredDensity 1

setViaFill -layer {VIA8 RV} -windowSize 100 100 -windowStep 50 50 /
           -minDensity 0.25 -maxDensity 30 -preferredDensity 10

addViaFill -layer {VIA1 VIA2 VIA3 VIA4 VIA5 VIA6 VIA7 VIA8 RV} /
```

```
-mode {floating connectBetweenFill}
```

Related Information

deleteMetalFill

```
deleteMetalFill
[-help]
[-area {x1 y1 x2 y2}]
[-layer {layerNumber | {list_of_layer_numbers} } ]
[-mode {all | connectedOnly | floatingOnly} ]
[-shape {[FILLWIRE] [FILLWIREOPC]} ]
```

Removes metal and via fill in order to start over with the metal fill process. If you run this command without specifying parameters, it deletes all the metal and via fill in the design.

Note: Deleting via fill with this command might create open violations.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `deleteMetalFill` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man deleteMetalFill`.
`-area {x1 y1 x2 y2}`	Specifies a set of coordinates within which to delete metal and via fill. For example, `-area {0 0 100 100}`. *Default:* If you do not specify this parameter, deletes fill from the entire design area.

`-layer {layerNumber | {list_of_layer_numbers}}`	Specifies the layers from which to remove metal and via fill. If you specify more than one layer, separate each layer with a space and enclose the list in braces or double quotation marks. This parameter accepts metal layers, cut layers, or a combination.
	• If you specify a cut layer, the command removes vias that contain that cut layer only. For example:
	`deleteMetalFill -layer {VIA2 VIA3}`
	• If you specify a metal layer, metal fill shapes on that layer and vias that contain that layer are removed. For example:
	`deleteMetalFill -layer {metal2 metal3}`
	Default: If you do not specify this parameter, removes metal and via fill from all layers.

`-mode {all | connectedOnly | floatingOnly}`	Specifies whether the command removes only connected fill, only floating fill, or all fill.
	Default: `all`
	Removes all the connected and floating metal and via fill.
	`connectedOnly`
	Removes only connected metal and via fill.
	`floatingOnly`
	Removes only floating metal and via fill.

`-shape {[FILLWIRE] [FILLWIREOPC]}`	Specifies whether the command removes `FILLWIRE` or `FILLWIREOPC` shapes or both kinds of shapes. *Default:* `FILLWIRE FILLWIREOPC`

Examples

- The following command removes via fill from cut layers `VIA12`, `VIA23`, `VIA34`, `VIA45`, `VIA56`:
  ```
  deleteMetalFill -layer {VIA12 VIA23 VIA34 VIA45 VIA56}
  ```
- The following command removes `metal2` floating fill with `FILLWIREOPC` shape and via fill connected to `metal2`:
  ```
  deleteMetalFill -layer metal2 -mode floatingOnly -shape FILLWIREOPC
  ```

fixOpenFill

```
fixOpenFill
[-help]
[-net list_of_net_names]
[-area x1 y1 x2 y2]
[-remove]
```

Fixes any isolated power/ground (PG) fills. Isolated PG fills are FILL shapes attached to a power-ground (PG) net that are not connected to at least one non-FILL shape.

In designs with floating fill, the trimMetalFill command is used after routing signal nets to trim fill that causes DRC violations. In designs with tied fill, i.e. metal or via fill connected to special nets, `trimMetalFill` causes isolated fills to appear. In such cases, use the `fixOpenFill` command after `trimMetalFill` to either change the isolated fills to floating fills or to remove them from the design.

If you choose to remove the isolated fills with `fixOpenFill -remove`, you can then run incremental `add_metal_fill_signoff` to see if any of those islands can be tied, either to the same or to another PG rail.

If you run the `fixOpenFill` command without specifying any parameters, it changes all isolated fills in the design to floating fills.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `fixOpenFill` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man fixOpenFill`
`-area x1 y1 x2 y2`	Specifies a set of coordinates within which to fix open fill issues. *Default:* If you do not specify this parameter, fixes open fills in the entire design area.
`-net list_of_net_names`	Specifies a list of special net names to fix.
`-remove`	Specifies whether to remove the open fills. If this option is not specified, `fixOpenFill` changes isolated PG fills to floating fills.

Example

The following command removes all isolated PG fills from the design:

```
fixOpenFill -remove
```

```

Returns information about the signoff metal fill flow global variables set by the `set_metal_fill_signoff_mode` command. You can specify one or more parameter. When you invoke this command without any argument, the software prints the current values stored in the database for all the options. If you provide any option, then the software prints the value currently stored in the database.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `get_metal_fill_signoff_mode` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man get_metal_fill_signoff_mode`
`-parameter_names`	Returns information for the specified parameters. You can specify one or more parameters. See `set_metal_fill_signoff_mode` for descriptions of the `get_metal_fill_signoff_mode` parameters.
`-quiet`	Returns the current settings for the specified parameters in Tcl list format only. If you specify `-quiet` without any parameters, the software returns the current settings of all `set_metal_fill_signoff_mode` parameters in Tcl list format.

Examples

- The following command displays values for all the set parameters:
  ```
  get_metal_fill_signoff_mode
  ```
  Following is the output of the above command:
  ```
  -die_area_as_boundary
  -dp 4
  -fill_cell tdsp
  -fill_output_mode gdsii
  -layer_map_file ./RULE/stream.map
  ```
- The following command displays the value of the `-layer_map_file` parameter:
  ```
  get_metal_fill_signoff_mode -layer_map_file
  ```
  Following is the output of the above command:
  ```
  -layer_map_file ./RULE/stream.map
  ```
- Following is an example of getting values of multiple parameters using the `get_metal_fill_signoff_mode` command:
  get_metal_fill_signoff_mode -layer_map_file -dp -units
  Output:
  -dp 4
  -layer_map_file ./RULE/stream.map
  -units 2000

get_pg_fill_config

```
get_pg_fill_config
[-help]
[-attach_instance_name]
[-attach_net_name]
[-attach_net_prop]
[-core_license]
[-die_area_as_boundary]
[-dp]
[-dp_dir]
[-dp_timeout]
[-extra_options]
[-format]
[-layer_map_file]
[-license_dp_continue]
[-license_timeout]
[-merge]
[-no_structure_name]
[-offset]
[-output_macros]
[-pg_fill_config_file]
[-pg_hookup_flow]
[-report_file]
[-stripes]
[-structure_name]
[-uniquify_cell_names]
[-units]
[-working_dir]
```

Prints the parameters of the `add_pg_fill` command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `get_pg_fill_config` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man get_pg_fill_config`
`-attach_instance_name`	Prints the instance name to be attached.
`-attach_net_name`	Prints the net name to be attached.
`-attach_net_prop`	Prints the net property to be attached.
`-core_license`	Prints an exact combination of licenses to be used.
`-die_area_as_boundary`	Prints the die area as a polygon or a boundary.
`-dp`	Runs Pegasus in a multi-processor mode. The *n* variable specified with this parameter presents the number of processors. By default, this value is taken from the Innovus multi-CPU usage.
`-dp_dir`	Prints the name of the distributed directory.
`-dp_timeout`	Prints the wait time for the DP processes to start.
`-extra_options`	Prints the additional run options.
`-format`	Prints the format of the flow.
`-layer_map_file`	Prints the name of the `streamOut` layer map file.
`-lib_name`	Prints the library name.
`-license_dp_continue`	Specifies that if the required number of licenses cannot be obtained in the DP processes, the software continues with fewer CPUs based on the number of licenses obtained.
`-license_timeout`	Prints the wait time (in seconds) to run the software, if a license is not immediately available. *Default*: `300`
`-merge`	Prints the list of external stream files.
`-no_structure_name`	Merges the GDSII file without loading the software database. **Note:** This parameter is used with the `-merge` parameter.
`-offset`	Prints the location (in microns) of the design in the GDSII output file.
`-output_macros`	Prints the LEF abstract information, such as LEF pin geometries and obstructions for macros.
`-pg_fill_config_file`	Prints the configuration file for the PG fill flow. Any overrides to the default behavior are written in this file.
`-pg_hookup_flow`	Prints the type of fills to be generated. *Default*: `PG_ONLY`
`-report_file`	Prints the cell name to be changed to the file.
`-stripes`	Prints the number of stripes that divide the design. *Default*: 1
`-structure_name`	Prints the superstructure that consists of all the geometries that the map file writes out.
`-uniquify_cell_names`	Creates unique cell names if there are name collisions, when the software merges files.
`-units`	Prints the resolution for values in the GDSII/OASIS file.
`-working_dir` *working_directory*	Prints the working directory.

get_track_fill_config

```
get_track_fill_config
[-help]
[-attach_instance_name]
[-attach_net_name]
[-attach_net_prop]
[-core_license]
[-die_area_as_boundary]
[-dp]
[-dp_dir]
[-dp_timeout]
[-extra_options]
[-format]
[-layer_map_file]
[-license_dp_continue]
[-license_timeout]
[-merge]
[-no_structure_name]
[-offset]
[-output_macros]
[-report_file]
[-stripes]
[-structure_name]
[-track_fill_config_file file_name]
[-uniquify_cell_names]
[-units]
[-working_dir]
```

Prints the parameters of the `add_track_fill` command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `get_track_fill_config` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man get_track_fill_config`
`-attach_instance_name`	Prints the instance name to be attached.
`-attach_net_name`	Prints the net name to be attached.
`-attach_net_prop`	Prints the net property to be attached.
`-core_license`	Prints an exact combination of licenses to be used.
`-die_area_as_boundary`	Prints the die area as a polygon or a boundary.
`-dp`	Runs Pegasus in a multi-processor mode. The *n* variable specified with this parameter presents the number of processors. By default, this value is taken from the Innovus multi-CPU usage.
`-dp_dir`	Prints the name of the distributed directory.
`-dp_timeout`	Prints the wait time for the DP processes to start.
`-extra_options`	Prints the additional run options.
`-format`	Prints the format of the flow.
`-layer_map_file`	Prints the name of the `streamOut` layer map file.
`-lib_name`	Prints the library name.
`-license_dp_continue`	Specifies that if the required number of licenses cannot be obtained in the DP processes, the software continues with fewer CPUs based on the number of licenses obtained.
`-license_timeout`	Prints the wait time (in seconds) to run the software, if a license is not immediately available. *Default*: `300`
`-merge`	Prints the list of external stream files.
`-no_structure_name`	Merges the GDSII file without loading the software database. **Note:** This parameter is used with the `-merge` parameter.
`-offset`	Prints the location (in microns) of the design in the GDSII output file.
`-output_macros`	Prints the LEF abstract information, such as LEF pin geometries and obstructions for macros.
`-report_file`	Prints the cell name to be changed to the file.
`-stripes`	Prints the number of stripes that divide the design. *Default*: 1
`-structure_name`	Prints the superstructure that consists of all the geometries that the map file writes out.
`-track_fill_config_file` *file_name*	Specifies the configuration file for Track fill flow.
`-uniquify_cell_names`	Creates unique cell names if there are name collisions, when the software merges files.
`-units`	Prints the resolution for values in the GDSII/OASIS file.
`-working_dir` *working_directory*	Prints the working directory.

getMetalFillSpacingTable

```
getMetalFillSpacingTable
[-help]
[-layer layer_name_list]
[-fill_to_active]
[-fill_to_fill]
[-fill_to_opc]
[-opc_to_active]
[-opc_to_opc]
```

Prints the spacing table for specified or for all layers. If no option is specified, prints all spacing tables for all layers.

To specify spacing table based on existing metal fill width, use the `setMetalFillSpacingTable` command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `getMetalFillSpacingTable` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man getMetalFillSpacingTable`.
`-layer` *`layer_name_list`*	Prints spacing table for specified layers. *Default*: Prints spacing table for all layers
`-fill_to_active`	Prints the fill to active spacing table for specified or all layers.
`-fill_to_fill`	Prints the fill to fill spacing table for specified or all layers.
`-fill_to_opc`	Prints the fill to OPC spacing table for specified or all layers.
`-opc_to_active`	Prints the OPC to active spacing table for specified or all layers.
`-opc_to_opc`	Prints the OPC to OPC spacing table for specified or all layers.

Example

- The following command prints the fill to active spacing table for layer `METAL2`:

  ```
  getMetalFillSpacingTable -layer 2 -fill_to_active
  ```

  The output is as follows:

  ```
  Layer 2,

  fill_to_active {0.08 0.27}{0.14 0.36}{0.32 0.63}
  ```

- The following command prints all spacing tables for all layers:

  ```
  getMetalFillSpacingTable
  ```

  The output is as follows:

  ```
  Layer metal2,

  fill_to_active {0.08 0.27}{0.14 0.36}{0.32 0.63}

  Layer metal3,

  fill_to_fill {0.08 0.2}{0.14 0.3}{0.32 0.6}

  Layer metal3,

  opc_to_active {0.05 0.08}{0.08 0.1}{0.1 0.12}
  ```

[-mesh]
```

Generates a report on metal fill to summarize the number and area of fill shapes on a per-net and per-layer basis. Use the generated report to tune the `add_metal_fill_signoff` flow parameters to achieve the desired distribution across multiple nets and layers as well as to minimize floating fill.

Before generating a metal fill report, you should have:

- Imported the design
- Completed detailed routing
- Added metal fill

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `report_metal_fill` parameter. For a detailed description of the command and all its parameters, use `man report_metal_fill`.
`-file file_name`	Writes the report to a file with the specified name. *Default*: *topCellName*`_metal_fill_report.rpt`
`-fill_area`	Reports area information for metal fill for each layer.
`-fill_length`	Reports length information for metal fill for each layer.
`-mesh`	Reports mesh information for metal fill.

Examples

- The following command writes a metal fill report to the dtmf_metal_fill.rpt file.

  ```
  report_metal_fill -file dtmf_metal_fill.rpt
  ```

  The output is as follows:

  ```
  ############################################################
  #  Generated by:      Cadence Innovus 19.10-p002_1
  #  Design:            DTMF_CHIP
  #  Command:           report_metal_fill -file dtmf_metal_fill.rpt
  ############################################################
  Metal Fill Summary
  <numFillShapes>=<fillArea>squm(<percentTotal>)
  |floating    |total
  ------------------------------------------------------
  M1| 25214= 349610.52 (100.00%)  | 25214= 349610.52
  M2| 27905= 372408.83 (100.00%)  | 27905= 372408.83

run_pvs_drc_rules

```
run_pvs_drc_rules
[-help]
pvlFile
[-area {x1 y1 x2 y2}]
[-dp N]
[-error integer]
[-extraPvsOptions pvs_option_string]
[-gds_file fileName | -oasis_file fileName]
-mapfile fileName
[-merge list_files]
[-noclean]
[-oa_view view_name]
[-output fileName]
[-repRoutingOnly]
[-report string]
[-stream_out]
[-units integer]
[-version]
[-work_directory working_directory]
```

Calls the Cadence Physical Verification System application to check DRC rules with a sign-off PVS rule deck.

This command is loaded only if you have a PVS installation and the PVS bin directory is in your Linux search path (e.g. the command `pvs` can be run).

It is possible there are different options than described here depending on the version of PVS that you have installed. Use `run_pvs_drc_rules -help` to view the exact command syntax for your current PVS installation.

`run_pvs_drc_rules` will assemble the necessary files, call `pvs`, and then read back the PVS violations so they are visible in the Innovus violation browser. The call to `pvs` requires the appropriate PVS licenses in order to run.

The `run_pvs_drc_rules` command takes as input:

- A GDSII/OASIS layout file (normally created by streamOut command in Innovus)
- A layer map file
- A PVL rule file that contains the DRC rules to check
- The name of the output PVS results database file to be created
- Other optional arguments, such as distributed processing, area to check, number of errors to output, and so on.

Details about the various file formats can be found in the PVS documentation.

This command returns a status of `0 (tcl_OK)` or `1 (tcl_ERROR)`. Error messages or warnings are written to the Innovus log file.

Parameters

`-help`	Prints out the command usage.
`pvlFile`	Specifies the PVS rule file.
`-area {x1 y1 x2 y2}`	
	Defines the area to be checked. The default is the entire chip window.
`-dp N`	Specifies the number of local cores to use. The default is 1.
`-error integer`	Specifies the maximum number of errors to output. The default is 1000000.
`-extraPvsOptions pvs_option_string`	
	Specifies the additional PVS run options.
`-gds_file fileName`	
	Specifies a GDSII file to be read by PVS. If this parameter is specified, then the `-mapfile` parameter is ignored and `streamOut` is not run.

`-mapfile fileName`	Specifies a stream map file. In the usual case, the Innovus map file used by the Innovus `streamOut` command is specified. If this parameter is specified and neither of the parameters `-gds_file` or `-oasis_file` is specified, then the `streamOut` command is automatically run before PVS starts. The `streamOut` command is: `streamOut .pvs_xxx/topcell.gds.gz -mapFile mapfile -libName designLib -outputMacro -mode ALL [-units integer]` Here, *`topcell`* is the topcell name of the design and *`mapfile`* is the file name specified with the `-mapfile` parameter. The optional `-units integer` is taken from the `run_pvs_drc_rules -units` value (if given). If not given, Innovus `streamOut` uses the Innovus DB unit value. Refer to the Innovus streamOut command for more details. For information on the map file format, see "About the GDSII or OASIS Map File" in the Importing and Exporting Designs chapter of the *Innovus User Guide*. **Note:** The `-mapfile` parameter is currently mandatory, even if it is not used due to the presence of `-gds_file` or `-oasis_file`. It will become optional in future release.
`-merge list_files`	Specifies the list of external stream files for `streamOut`.
`-noclean`	Specifies that the working directory, which is created while the `run_pvs_drc_rules` command is running, should not be removed after the run. The working directory name begins with `.pvs`.
`-oa_view view_name`	Specifies the temporary OA view.
`-oasis_file fileName`	
	Specifies an Oasis file to be read by PVS. If this parameter is specified, then the `-mapfile` parameter is ignored and `streamOut` is not run.
`-output fileName`	Specifies the error markers result database in ASCII format. If not specified, *`topCellName`*`.ascii` is used.
`-repRoutingOnly`	Ignores standard cell violations. This parameter is equivalent to setting "`abort_on_layout_error no`" in PVS rule deck. `abort_on_layout_error` checks for problems such as missing cell masters and duplicate cell references. If `-repRoutingOnly` is specified, PVS does not abort even if any of these errors happen. For more information, refer to the *Cadence Physical Verification System Developer Guide*.
`-report fileName`	Specifies the name of the PVS DRC summary report file to be created. When a relative path has been specified, the report file is created relative to the Innovus invocation directory. The default is no report file.
`-stream_out`	Uses the `streamOut` command for GDS in the OA flow.
`-units integer`	Specifies the user-defined DB unit value used for `streamOut` (see `-mapfile` above). This value should be consistent with the DB unit value in PVL rules.
`-version`	Prints the PVS version.
`-work_directory working_directory`	
	Specifies the current working directory.

Examples

- The following command runs sign-off DRC check with the gds file from Innovus using the PVS rule file `28nm.pvl`. The gds file will be streamed out with the specified map file, `gds.map`, and the gds unit will be 1000 as specified:

  ```
  run_pvs_drc_rules 28nm.pvl -mapfile gds.map -units 1000
  ```

- The following command runs sign-off DRC check on routing layers within the specified area {0 0 100 100} using 8 local CPUs. The command will report only up to 1000 DRC issues:

  ```
  run_pvs_drc_rules 28nm.pvl -area {0 0 100 100} -dp 8 -error 1000 -mapfile gds.map
  ```

- The following command runs sign-off check on the existing gds file `ios.gds`, and writes the report file to `pvs.signoff.db`:

  ```
  run_pvs_drc_rules 28nm.pvl -report pvs.signoff.db -gds_file ios.gds
  ```

Sets option parameters for the signoff metal fill flow. The options are saved after the `saveDesign` process of the software with the existing design data. To get the list of stored options, use the `get_metal_fill_signoff_mode` command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `set_metal_fill_signoff_mode` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man set_metal_fill_signoff_mode`
`-and_area_size` *size_value*	Specifies a value for sizing up the changed area to use shapes within this area. This parameter helps in calculating the density and creating areas to be filled, if they fall below the minimum density. The default value of this parameter is 10. A value lesser than the default value may be used to improve the flow performance, if no accuracy issues occur. A value greater than the default value can be used to fix the accuracy issues. The minimum value of this parameter is `0.001` and maximum value is `1000`.
`-area {x1 y1 x2 y2}`	Specifies a set of coordinates within metal fill can be trimmed.
`-attach_instance_name` *attr_num*	Specifies the instance name to attach.
`-attach_net_name` *attr_num*	Specifies the net name to attach.
`-attach_net_prop {{`*prop_name* `attr_num} ...}`	
	Specifies the net property to attach.
`-auto_load_fills`	Updates the FILL data automatically in the software after when the `add_metal_fill_signoff` command modifies the HMF database. In case the HMF database is not modified, the FILL data will be hidden in the software's design.
`-bg`	Runs metal fill in the background mode without locking up the software license. **Note:** All the metal fill options running in the background must be used with the `-bg` parameter.
`-clock`	Specifies whether to trim metal fill around all clock nets.

`-common_blockage {`*layer_num1 layer_datatype1* `...}`	Specifies common blockage fill layers. This allows you to specify the blockage layer only once, instead of multiple individual blockages for the metal fill layers. The parameter value format is `{`*layer_number layer_datatype*`}`. You can also specify multiple layers, and each blockage layer should specify a set of two values. The *layer_number* must be an integer. Following are the examples of the usage of this parameter:
	`set_metal_fill_signoff_mode -common_blockage {150 28}`
	`set_metal_fill_signoff_mode -common_blockage {150 28 120 55}`

`-control` *file_name*	Specifies the control file, which is created automatically when a job is submitted from the PVS GUI. This parameter can be used, if you have run a directory submitted from the GUI. Use this parameter to rerun the PVS job from the command line and get the results, which are exactly the same as the GUI submission. The control file is placed in the run directory with the `pvsdrcctl` name and has only the command entries for certain fields in the GUI. You must not modify the file by adding commands or parameters that are not available in the GUI. If you do that, the commands can be ignored by the PVS rule compiler or the results can be indeterminate.
`-delete_area {{`*layer_list1*`} {`*x1 y1 x2 y2*`} ...}`	Specifies the x and y coordinates of the area where metal fill is deleted. Following is the usage example of this parameter: `set_metal_fill_signoff_mode -delete_area {{M1 M2 M6} {0 0 50 50}}`
`-delete_point {{`*layer_list1*`}{`*x1 y1*`}...}`	Specifies the x and y coordinates of the point where metal fill is deleted. Following is the usage example of this parameter: `set_metal_fill_signoff_mode -delete_point {{M2} {134.7 14.21}}`
`-die_area_as_boundary`	Specifies the die area as boundary.

`-dp` *n*	Specifies the number of local cores to use. The default value is fetched from the EDI settings.
`-dp_timeout` *value*	Specifies the time to wait for the slave processes to start.
`-excl_area_size` *size_value*	Specifies the area to be created around the metal fill area to check for the existing metal fill shapes and to avoid creation of metal fill shapes too close to the existing metal fill shapes. The default value of this parameter is `1.6`. A value lesser than the default value may be used to improve the flow performance, if no accuracy issues occur. A value greater than the default value can be used to fix the accuracy issues. The minimum value of this parameter is `0.001` and maximum value is `1000`. The following picture shows the usage of `-and_area_size` and `-excl_area_size` parameters: `-fill_cell` *cell_name*	Specifies metal fill cell name.
`-fill_layer {`*layers_list*`}`	Fills only a set of specified metal and/or via metal layers. Following is the usage example of this parameter: `set_metal_fill_signoff_mode -fill_layer {M1 VIA12 M2}`
`-fill_output_mode {gdsii | oasis}`	Generates metal fill database in the `gdsii` or `oasis` format. The default format is `gdsii`.

`-layer_map_file` *streamOut_map_file*	Specifies the `streamOut` metal layer map file.
`-license_timeout`	Specifies the time (in seconds) to wait if the software license is not immediately available while initiating the run. The default value of this parameter is 300 seconds.
`-license_dp_continue`	Initiates the software run using fewer available CPUs based on the number of licenses obtained. Use this parameter in case PVS cannot obtain the required number of licenses in the multiprocessing mode.
`-lib_name library_name`	Specifies the library name.
`-lsf`	Distributes the processing of the software run to different CPUs using LSF. While using this parameter, the `DP_LSF_RESOURCE` environment variable must be set to specify the LSF resource string, as shown below: `setenv DP_LSF_RESOURCE 'resource string for slave processes'` Additionally, the `-temp_working_dir` *work_dir* should be used to specify local working directory for the LSF run.
`-master_lsf`	Submits the master PVS process on LSF. While using this parameter, the `MASTER_LSF_RESOURCE` environment variable should be set to specify LSF resource string, as shown below: `setenv MASTER_LSF_RESOURCE 'resource string for master process'`
`-` `merge` *list_of_external_stream_files*	Merges the external stream files.
`-min_density percent1` *layer_list1*	Specifies percentage value of the minimum metal density. The default value of this parameter is `0` for each metal layer. This parameter trims metal fill below when the specified window density percentage could cause any metal density violations. This parameter is controlled by the `-window_size` and `-window_step` values, as shown in the below example: `set_metal_fill_signoff_mode -min_density {20 {M1 M2} 35 M3}`
`-net net_names`	Specifies a list of critical net names or pointers, which are surrounded by the metal fill area.
`-no_structure_name`	Merges the GDSII file without loading the design.
`-no_via_fills`	Specifies not to generate metal via fills.
`-offset {`*x y*`}`	Defines the offset displacement to be applied.
`-output_macros`	Displays the LEF abstract information about macros, such as LEF pin geometries and obstructions.
`-report_file`	Displays the cell name, which is changed to file.
`-reset {`*parameter_name* `|` *all*`}`	Removes any applied HMF settings.
`-rule_file` *rule_file_name*	Specifies metal fill rule file name.
`-slack_threshold` *float*	Trims any critical net(s) in the timing aware flow with the slack lesser than the specified value (in nanoseconds). Following is the usage example of this parameter: `set_metal_fill_signoff_mode -slack_threshold 0.1`
`-spacing` *float*	Trims metal fill on the specified metal layer around critical net routes. **Note:** The `-spacing` and `-trim_effort` parameters are mutually exclusive.
`-spacing_above` *float*	Trims metal fill on above the specified metal layer around critical net routes.
`-spacing_below` *float*	Trims metal fill on below the specified metal layer around critical net routes.
`-stripes` *number*	Specifies the number of stripes that divide the design. The default is value of this parameter is `1`.

`-structure_name` *structureName*	Specifies the superstructure that consists of all the geometries that the map file writes out.
`-tech_lib` *string*	Specifies the PVS technology library for `-fill` and `-incremental`.
`-tech_set` *string*	Specifies the PVS technology set for `-fill` and `-incremental`.
`-technology` *string*	Specifies the PVS technology to use for identifying the sign-off rules file. **Note:** You can use this parameter with either the `-rule_file` or `-technology` parameter.
`-temp_working_dir` *work_dir*	Specifies the working directory for the background or LSF run.
`-trim_effort {high | med | low}`	Trims metal fill area with the high, medium, or low effort around the critical net routes. This parameter also helps in determining the blockage size for trimming metal fill. Following are the parameter values: • `high`: Presents area of two times of the layer pitch value. • `med`: : Presents area of 1.5 times of the layer pitch value. • `low`: : Presents the same area of the layer pitch value. Following is the usage example of this parameter: `set_metal_fill_signoff_mode -trim_effort med` Here, if the M2 layer pitch is `0.8 um`, M2 fills will be trimmed around selected nets within the distance of `1.2 um`. **Note:** The `-trim_effort` and `-spacing` parameters are mutually exclusive.
`-trim_layer {`*layers_list*`}`	Trims only the set of specified layers. Following is the usage example of this parameter: `set_metal_fill_signoff_mode -trim_layer {M1 M2}`

`-trim_mf` *spacing_file*	Specifies the spacing file containing information related to trim metal fill in the incremental run. Spacing file contains spacing values between the routed metal, non-OPC and OPC metal fill layers. Metal fills are trimmed around ECO changes according to the specified spacing values, post which incremental run generates fill data in the trimmed area. Following is the format of the spacing file:
	`#layer f-a o-a`
	`M1 0.60 0.16`
	`M2 0.60 0.16`
	`M3 0.60 0.16`
	`M4 0.60 0.16`
	`M5 0.60 0.16`
	`M6 0.60 NA`
	Here:
	• `Mx`: Specifies the LEF layer name.
	• `f-a`: Specifies the metal fill active spacing.
	• `o-a`: Specifies the is OPC fill active spacing.
	• `NA`: Refers to no trimming.
	The following picture shows the usage of `-trim_mf` parameter:
	 	
	The spacing file for the above example has the following settings for the M2 layer:
	`M2 1.5 0.6`
	In this example, the non-OPC metal fills are trimmed in the area of 1.5 times of the modified. Additionally, the metal fill data is regenerated in the trimmed area.

`-union_density` {*percent1 layer_list1* [{*percent2 layer_list2*}]...}	
	Specifies percentage value of the union metal density. The default value of this parameter is `0` for each metal layer. Union density for a layer is the sum of metal density of the current layer, layer below, and layer above the specified windows. Metal fills are trimmed not to violate the `-union_density` settings for the current metal. Following is the usage example of this parameter: `set_metal_fill_signoff_mode -union_density {20 M1}`
`-uniquify_cell_names`	Creates unique cell names, if there are name collisions while using the `-merge` parameter.
`-units {100 | 200 | 400 | 800 | 1000 | 2000 | 4000 | 8000 | 10000 | 20000}`	
	Specifies the resolution of the input/output file. The default value of this parameter is obtained from software database.

`-window_size float`	Specifies the size of the window, which the metal trim uses to examine the metal density. The default value of this parameter is `100`. Following is the usage example of this parameter: `set_metal_fill_signoff_mode -window_size 50`
`-window_step float`	Specifies the stepping distance between two successive positions of the window for a stepped-window trim density check. The default value of this parameter is `50`. Following is the usage example of this parameter: `set_metal_fill_signoff_mode -window_step 25`

Examples

- The following command sets a new option for the signoff metal fill flow:
  `set_metal_fill_signoff_mode -layer_map_file ./RULE/stream.map`
- The following command sets multiple new options for the signoff metal fill flow:
  `set_metal_fill_signoff_mode -layer_map_file ./stream.map -units 2000`
- The following command sets a new option with several parameters for the signoff metal fill flow:
  `set_metal_fill_signoff_mode -union_density {{50 M1} {53 M3}}`
- The following command removes a list of options for the signoff metal fill flow:
  `set_metal_fill_signoff_mode -reset {-layer_map_file}`
- The following command removes all the options for the signoff metal fill flow:
  `set_metal_fill_signoff_mode -reset all`

```

Sets the parameters of the `add_pg_fill` command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `set_pg_fill_config` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man set_pg_fill_config`
`-attach_instance_name attr_num`	Specifies the instance name to be attached.
`-attach_net_name attr_num`	Specifies the net name to be attached.
`-attach_net_prop {{prop_name attr_num} ... }`	Specifies the net property to be attached.
`-core_license license_combination`	Sets an exact combination of licenses to be used.
`-die_area_as_boundary`	Writes the die area as a polygon or a boundary. When this parameter is not specified, the `streamOut` command writes the die area as a rectangle or a box.
`-dp n`	Runs Pegasus in a multi-processor mode. The `n` variable specified with this parameter presents the number of processors. By default, this value is taken from the Innovus multi-CPU usage.
`-dp_timeout seconds`	Specifies the wait time for the DP processes to start.
`-extra_options options`	Specifies the additional run options.
`-format {stream oasis}`	Specifies the format of the flow.
`-layer_map_file streamOut_map_file`	Specifies the name of the `streamOut` layer map file.
`-lib_name library_name`	Specifies the library name.

`-license_dp_continue`	Specifies that if the required number of licenses cannot be obtained in the DP processes, the software continues with fewer CPUs based on the number of licenses obtained.
`-license_timeout` *seconds*	Specifies the wait time (in seconds) to run the software, if a license is not immediately available. *Default*: `300`
`-merge` *list_of_external_stream_files*	Specifies the list of external stream files.
`-no_structure_name`	Merges the GDSII file without loading the software database. **Note:** This parameter is used with the `-merge` parameter.
`-offset {`*x y*`}`	Specifies the location (in microns) of the design in the GDSII output file.
`-output_macros`	Displays the LEF abstract information, such as LEF pin geometries and obstructions for macros.
`-pg_fill_config_file` *file_name*	Specifies the configuration file for the PG fill flow. Any overrides to the default behavior are written in this file.
`-pg_hookup_flow {ALL | PG_ONLY | FLOAT_ONLY}`	Specifies the type of fills to be generated. *Default*: `PG_ONLY`
`-report_file`	Specifies the cell name to be changed to the file.
`-reset {`*parameter_name* `|` *all*`}`	Resets a specified parameter or all parameters to the default value.
`-stripes` *number*	Specifies the number of stripes that divide the design. *Default*: 1
`-structure_name` *structureName*	Specifies the superstructure that consists of all the geometries that the map file writes out.
`-uniquify_cell_names`	Creates unique cell names if there are name collisions, when the software merges files.
`-units {100 | 200 | 400 | 800 | 1000 | 2000 | 4000 | 8000 | 10000 | 20000}`	
	Specifies the resolution for values in the GDSII/OASIS file.
`-working_dir` *working_directory*	Specifies the working directory.

set_track_fill_config

```
set_track_fill_config
[-help]
[-attach_instance_name attr_num]
[-attach_net_name attr_num]
[-attach_net_prop {{prop_name attr_num} ... }]
[-core_license license_combination]
[-die_area_as_boundary]
[-dp n]
[-dp_timeout seconds]
[-extra_options options]
[-format {stream oasis}]
[-layer_map_file streamOut_map_file]
[-lib_name library_name]
[-license_dp_continue]
[-license_timeout seconds]
[-merge list_of_external_stream_files]
[-no_structure_name]
[-offset {x y}]
[-output_macros]
[-report_file]
[-reset {parameter_name | all}]
[-stripes number]
[-structure_name structureName]
[-track_fill_config_file file_name]
[-uniquify_cell_names]
[-units {100 | 200 | 400 | 800 | 1000 | 2000 | 4000 | 8000 | 10000 | 20000}]
[-working_dir working_directory]
```

Sets the parameters of the add_track_fill command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `set_track_fi` For a detailed description of the command and all its parameters, use the `man` command: `man set_track_fill_config`
`-attach_instance_name` *attr_num*	Specifies the instance name to be attached.
`-attach_net_name` *attr_num*	Specifies the net name to be attached.
`-attach_net_prop {{`*prop_name attr_num*`} ... }`	Specifies the net property to be attached.
`-core_license` *license_combination*	Sets an exact combination of licenses to be used.
`-die_area_as_boundary`	Writes the die area as a polygon or a boundary. When this parameter is not specified, the `strea`
`-dp` *n*	Runs Pegasus in a multi-processor mode. The *n* variable specified with this parameter presents Innovus multi-CPU usage.
`-dp_timeout` *seconds*	Specifies the wait time for the DP processes to start.
`-extra_options` *options*	Specifies the additional run options.
`-format {stream oasis}`	Specifies the format of the flow.
`-layer_map_file` *streamOut_map_file*	Specifies the name of the `streamOut` layer map file.
`-lib_name` *library_name*	Specifies the library name.
`-license_dp_continue`	Specifies that if the required number of licenses cannot be obtained in the DP processes, the s licenses obtained.
`-license_timeout` *seconds*	Specifies the wait time (in seconds) to run the software, if a license is not immediately available *Default*: `300`
`-merge` *list_of_external_stream_files*	Specifies the list of external stream files.
`-no_structure_name`	Merges the GDSII file without loading the software database. **Note:** This parameter is used with the `-merge` parameter.
`-offset {`*x y*`}`	Specifies the location (in microns) of the design in the GDSII output file.
`-output_macros`	Displays the LEF abstract information, such as LEF pin geometries and obstructions for macros
`-report_file`	Specifies the cell name to be changed to the file.
`-reset {`*parameter_name* `|` *all*`}`	Resets a specified parameter or all parameters to the default value.
`-stripes` *number*	Specifies the number of stripes that divide the design. *Default*: 1
`-structure_name` *structureName*	Specifies the superstructure that consists of all the geometries that the map file writes out.
`-track_fill_config_file` *file_name*	Specifies the configuration file for Track fill flow.
`-uniquify_cell_names`	Creates unique cell names if there are name collisions, when the software merges files.
`-units {100 | 200 | 400 | 800 | 1000 | 2000 | 4000 | 8000 | 10000 | 20000}`	
	Specifies the resolution for values in the GDSII/OASIS file.
`-working_dir` *working_directory*	Specifies the working directory.

setMetalFill

```
setMetalFill
[-help]
[-layer {layerNumber} | {list_of_layer_numbers}]
[-activeSpacing spacing]
[-opcActiveSpacing spacing]
[-borderSpacing spacing]
[-decrement value]
[-diagOffset x y]
[-externalDensity percent]
[-gapSpacing spacing]
[-honorLefValue]
[-iterationName name]
[-maxDensity percent]
[-maxLength length]
[-maxUnionDensityToAboveLayer value]
[-maxWidth width]
[-minDensity percent]
[-minLength length]
[-minUnionDensityToAboveLayer value]
[-minWidth width]
[-opc | -regular]
[-preferredDensity percent]
[-windowSize xSize ySize]
[-windowStep xStep yStep]
```

Specifies values for parameters that the `add_metal_fill_signoff`, `trimMetalFill`, and `verifyMetalDensity` commands use for metal fill size, spacing, verification, and metal density. You can also specify some of these parameters in the Layer (Routing) section of the LEF file - they are identified in the "Parameters" section below.

If you want your metal fill settings to be saved in the .init file when saving the design, you must set the `fill_setting_save` global to `1` before saving the design. You can easily reload your settings by restoring the saved design

Note: Check the chip manufacturer's DRC manual specifications for metal fill (sometimes called dummy fill) for the correct values if they are not specified in the LEF file.

- For more information on LEF, see the "LEF Syntax" chapter in the *LEF/DEF Language Reference*.
- For more information on the metal fill commands, see `add_metal_fill_signoff`, `trimMetalFill`, and `verifyMetalDensity`.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `setMetalFill` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man setMetalFill`.
`-activeSpacing spacing`	Specifies the minimum distance in microns between a metal fill shape and any other type of object in the design. For example, `setMetalFill -activeSpacing 0.6`. **Note:** The `setMetalFill -activeSpacing` settings are used for creating regular `FILLWIRE` shapes. For `FILLWIREOPC` shapes, design rules are used. LEF equivalent: `FILLACTIVESPACING` *Default:* `FILLACTIVESPACING` in the LEF file; if not specified, `0.6` for thin layers (less than 0.24), `0.8` for thick layers

`-borderSpacing` *spacing*	Specifies the space in microns along the design border that needs to be kept free of metal fill. This parameter is useful if you want open space next to the place and route border. If you have set border spacing, the `add_metal_fill_signoff` and `verifyMetalDensity` commands consider the density in the specified border space area as 0. `-decrement` *value*	Specifies the number of microns the software decreases the size of each successively smaller piece of metal fill or via fill until it reaches the size specified by the `-minWidth` parameter. The software uses the maximum fill size specified unless it is impossible to fit a piece of fill into a particular area. The software then attempts to use successively smaller pieces of fill until the minimum length value is reached. This parameter allows you to control how many different sizes of metal fill or via fill can appear within the design. For example, if the value of `-maxWidth` is `8`, the value of `-minWidth` is `4`, and the value of `-decrement` is `2`, the software can add fill shapes with widths of `8`, `6`, and `4` microns. The software tries to add fill shapes with the width specified by `-maxWidth`. If a shape of that width does not fit in the available space without creating a violation, the software decreases the width by the amount specified by the `-decrement` parameter. It continues to decrease the width until it reaches the width specified by the `-minWidth` parameter. To increase flexibility in adding metal or via fill, decrease the value of this parameter. For example, if the value of `-decrement` is `1`, metal fill with widths of `8`, `7`, `6`, `5`, and `4` microns can be added. *Default:* `WIDTH` value specified in the `Layer` (Routing) statement of the LEF file
`-diagOffset` *x y*	Specifies the offset for staggering metal fill. To enable this parameter, `add_metal_fill_signoff` must be used. *x* Specifies the horizontal offset. *y* Specifies the vertical offset. **setMetalFill diagOffset *x y*** `-externalDensity` *percent*	Specifies a percentage value for the external metal density for a layer when `add_metal_fill_signoff` windows lie partially outside of the die area. For each layer, a different external density value can be specified. Metal fill uses the external density value in the estimation of layer density outside of the blocks being developed.

`-gapSpacing` *spacing*	Specifies the minimum distance in microns between one metal fill shape and another metal fill shape. For example, `setMetalFill -gapSpacing 0.4`. *Default:* `0.4` for thin layers (less than 0.24 width/minWidth), `0.8` for thick layers
`-honorLefValue`	Specifies that the LEF values `MINIMUMDENSITY`, `MAXIMUMDENSITY`, `DENSITYCHECKWINDOW`, and `DENSITYCHECKSTEP` should be used to overwrite the `minDensity`, `maxDensity`, `windowSize`, and `windowStep` parameters of `setMetalFill` if the values specified for these parameters are not valid. If the `-layer` option is used with `setMetalFill`, only the specified layers are changed to the LEF values. **Note:** If one of the keywords `-MINIMUMDENSITY`, `MAXIMUMDENSITY`, `DENSITYCHECKWINDOW`, or `DENSITYCHECKSTEP`-is not defined in the LEF, an error message like the following is displayed: `ERROR: DENSITYCHECKWINDOW of MetalX is not defined in the LEF.`

`-iterationName` *name*	Specifies a name for a set of values for `setMetalFill` parameters that the software stores and uses during a later `add_metal_fill_signoff` run. Use `add_metal_fill_signoff` to add the metal fill using the stored set of parameters.
	The window size and step must be the same for all iterations of a specific layer. For example, the following specifications are not allowed because the values are not consistent:
	`setMetalFill -iterationName step1 -layer 1 \`
	`  -minDensity 20 -windowSize 100 100 -windowStep 50 50`
	`setMetalFill -iterationName step1 -layer 1 \`
	`  -minDensity 25 -windowSize 50 50 -windowStep 25 25`
	Important Specifying `setMetalFill -iterationName default` is the same as running `setMetalFill` without specifying the `-iterationName` parameter.
	`setMetalFill -iterationName default` is expected before `verifyMetalDenstiy`. `verifyMetalDenstiy` honors only `default iterationName`. If `default iterationName` is not set, `default` value will be used in `verifyMetalDenstiy`.
	Default: "`default`"

`-layer {`*layerNumber*|`{`*list_of_layer_numbers*`}`	Specifies the layers to which the parameters of the `setMetalFill` command apply. If you specify more than one layer, separate each layer with a space and enclose the list in braces or double quotation marks.
	To specify metal layers Metal1, Metal2, and Metal3, type one of the following commands:
	`setMetalFill -layer "METAL1 METAL2 METAL3"`
	`setMetalFill -layer {METAL1 METAL2 METAL3}`

`-maxDensity` *percent*	Specifies a percentage value for the maximum metal density allowed. LEF equivalent: `MAXIMUMDENSITY` *Default:* `MAXIMUMDENSITY`. If this value is not defined, the default is `80`. **Note:** This parameter only overrides a value in the LEF file if it is more restrictive than the LEF value. For example, if the value specified in the LEF file is 80, and you specify `-maxDensity 70`, metal fill uses 70 percent as the maximum density.
`-maxLength` *length*	Specifies the maximum length of the metal fill shapes, in microns. Metal fill stops at the chip boundary if the specified maximum length would cause it to extend outside the boundary. *Default:* `10.0`
`-maxUnionDensityToAboveLayer` *value*	Specifies the maximum allowed sum union density of the current layer and its top layer window. This avoids the union density violations found while verifying density results of trim metal fill flow using PVS or Pegasus. *Default:* `0`
`-maxWidth` *width*	Specifies the maximum width of metal fill shapes, in microns. Metal fill stops at the chip boundary if the specified maximum length would cause it to extend outside the boundary. *Default:* Maximum routing width defined in the LEF file; if not specified, `2.0` LEF equivalent: `MAXWIDTH` **Note:** This parameter only overrides a value in the LEF file if it is more restrictive than the LEF value.

`-minDensity` *percent*	Specifies a percentage value for the minimum metal density allowed in the design. LEF equivalent: `MINIMUMDENSITY` *Default:* `MINIMUMDENSITY`. If this value is not defined, the default is `20`. **Note:** This parameter only overrides a value in the LEF file if it is more restrictive than the LEF value. For example, if the value specified in the LEF file is 20, and you specify `-minDensity 25`, metal fill uses 25 percent as the minimum density.
`-minLength` *length*	Specifies the minimum length of metal fill shapes, in microns. *Default:* `1.0`
`-minUnionDensityToAboveLayer` *value*	Specifies the minimum allowed sum union density of the current layer and its top layer window. This avoids the union density violations found while verifying density results of trim metal fill flow using PVS or Pegasus. *Default:* `200`
`-minWidth` *width*	Specifies the minimum width of metal fill shapes, in microns. *Default:* `0.4` for thin layers (less than 0.24) and `0.8` for thick layers. **Note:** This parameter only overrides a value in the LEF file if it is more restrictive than the LEF value.
`-opc`	Specifies metal fill that will go through the optical proximity correction (OPC) process. This fill can be smaller than non-OPC metal fill and is governed by the same design rules as regular wires, instead of the rules that govern non-OPC metal fill. • OPC metal fill that is floating (unconnected) is included in the Fills statement of DEF 5.7. • OPC metal fill that is tied off (connected) is included in the Special Wiring statement of DEF 5.7. • The GDSII Stream/OASIS map file identifies the following object names for OPC and non-OPC metal fill: `FILL`, `FILLOPC`, `VIA`, `VIAFILL`. **Note:** `-opc` and `-regular` cannot be specified at the same time.
`-opcActiveSpacing` *spacing*	Specifies the minimum distance in microns between the OPC metal fill shapes (FILLWIREOPC) and main patterns. **Note:** If this parameter is not specified, the minimum DRC spacing is used by default.
`-preferredDensity` *percent*	Specifies a percentage value for the preferred metal density for the layer. When the metal density in a window is less than the minimum metal fill density value, adds metal fill to achieve a density slightly above the preferred density if possible. In addition, metal fill uses the preferred density value in the estimation of `MACRO` density for layers that have most of the `MACRO` covered by `OBS` shapes and for DEF `BLOCKAGES` without both `+ FILLS` and `+ PUSHDOWN`. Metal fill uses the following scheme for the treatment of DEF blockages with `+ FILLS` or `+ PUSHDOWN`: • DEF `BLOCKAGES` with `+ PUSHDOWN` = 100 percent density (the same as real metal segments) • DEF `BLOCKAGES` with `+ FILLS` = 0 percent density Cadence recommends modelling LEF `MACRO`s by using the `DENSITY` statement, with density windows that are smaller than the metal fill windows. For example, if the metal fill windows are 100 x 100, use 25 x 25 or smaller values for the density rectangles. For more information, see the "Adding Metal Fill Over Macros" section in the Optimizing Metal Density chapter of *User Guide*. *Default:* `35`

`-regular`	Specifies that regular metal fill shape is to be used. Use this option to switch to inserting regular metal fill without restarting the session after you have been adding OPC metal fill.
	`setMetalfill -opc`
	`add_metal_fill_signoff`
	`#Inserts opc metal fill`
	`setMetalfill -regular`
	`add_metal_fill_signoff`
	`#Inserts regular metal fill`

`-windowSize` *`xSize ySize`*	Specifies the x and y dimensions in microns of the area `setMetalFill` uses to examine the metal density. The software assesses the metal density in each window, moving the window iteratively through the design. For example, `setMetalFill -windowSize 100 100`. LEF equivalent: `DENSITYCHECKWINDOW` *Default:* `DENSITYCHECKWINDOW`. If this value is not defined, the default is 100 microns in each dimension.
`-windowStep` *`xStep yStep`*	Specifies the x and y step distance in microns the window moves for each iteration of metal density analysis. For example, `setMetalFill -windowStep 50 50`. LEF equivalent: `DENSITYCHECKSTEP` *Default:* `DENSITYCHECKSTEP`. If this value is not defined, the default is 50 microns in each dimension.

Examples

- The following command sets window size and step settings for layer `METAL1`:

  ```
  setMetalFill -layer METAL1 -windowSize 200 200 -windowStep 100 100
  ```

  These parameters are applied when you use the `add_metal_fill_signoff` command.

- The following command specifies an iteration `step1` with various settings for inserting metal fill:

  ```
  setMetalFill -layer {METAL1 METAL2 METAL3 METAL4 METAL5 METAL6 METAL7 METAL8} -iterationName step1 /
               -gapSpacing 0.140 -minWidth 1 -decrement 0.050 /
               -minLength 2 -maxWidth 5 -maxLength 20 -activeSpacing 0.8 /
               -windowSize 50 50 -windowStep 25 25 -minDensity 15 /
               -maxDensity 80 -preferredDensity 35 -diagOffset 1 1
  ```

setMetalFillSpacingTable

```
setMetalFillSpacingTable
[-help]
[-layer layer_name_list]
[-fill_to_active {{width1 spacing1}{width2 spacing2}...}]
[-fill_to_fill {{width1 spacing1}{width2 spacing2}...}]
[-fill_to_opc {{width1 spacing1}{width2 spacing2}...}]
[-opc_to_active {{width1 spacing1}{width2 spacing2}...}]
[-opc_to_opc {{width1 spacing1}{width2 spacing2}...}]
[-reset]
```

Specifies the spacing table used by `trimMetalFill` based on existing metal fill width. The spacing table includes the following spacing values:

- Fill to active spacing
- Fill to fill spacing
- Fill to OPC spacing
- OPC to OPC spacing
- OPC to active spacing

As `trimMetalFill` honors the spacing table, you can then run `trimMetalFill` to trim metal fill and get expected spacing. When required, you can use the `getMetalFillSpacingTable` command to print the spacing table.

Note: If no spacing table is specified, `trimMetalFill` honors the setMetalFill settings for `-activeSpacing` and `-gapSpacing`. If `setMetalFill` values are also not specified, trimMetalFill uses the default settings.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `setMetalFillSpacingTable` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man setMetalFillSpacingTable`.
`-layer` *layer_name_list*	Specifies the metal layers for the setting. Metal layers can be specified as numbers (`2`) or in the LEF format (`METAL2`) or as `M2`.
`-fill_to_active {{`*width1 spacing1*`}{`*width2 spacing2*`}...}`	Specifies a spacing table for fill to active spacing for trimming metal fill.
`-fill_to_fill {{`*width1 spacing1*`}{`*width2 spacing2*`}...}`	Specifies a spacing table for fill to fill spacing for trimming metal fill.
`-fill_to_opc {{`*width1 spacing1*`}{`*width2 spacing2*`}...}`	Specifies a spacing table for fill to OPC spacing for trimming metal fill.
`-opc_to_active {{`*width1 spacing1*`}{`*width2 spacing2*`}...}`	Specifies a spacing table for OPC to active spacing for trimming metal fill.
`-opc_to_opc {{`*width1 spacing1*`}{`*width2 spacing2*`}...}`	Specifies a spacing table for OPC to OPC spacing for trimming metal fill.
`-reset`	Resets the spacing tables.

Example

The following set of commands specifies the spacing table for fill to active spacing as given in the below table and trims metal fill accordingly:

```
+-------+---------------+-----------------+--------------------+
| Layer | Minwidth (=>) |   Maxwidth (<=) | activeSpacing (>=) |
+-------+---------------+-----------------+--------------------+
|   2   |      0.32     |        ∞        |        0.63        |
+-------+---------------+-----------------+--------------------+
|   2   |      0.14     |    0.32-1MFG    |        0.36        |
```

```
+-------+---------------+-----------------+--------------------+
|   2   |      0.08     |    0.14-1MFG    |        0.27        |
+-------+---------------+-----------------+--------------------+
```

```
setMetalFillSpacingTable -layer {2} -fill_to_active {{0.08 0.27}{0.14 0.36}{0.32 0.63}}
trimMetalFill -layer 2
```

The software checks the existing metal fill with the specified spacing table. If no violations are detected, existing metal fill is retained. If the existing metal fills have activeSpacing violations with other features, `trimMetalFill` uses the fill_to_active spacing table to trim metal fill.

Sample output is as follows:

```
*** START TRIM METALFILL *** (CPU Time: 0:00:00.0 MEM: 558.359M)
 Number of metal fills with spacing or/and short violations:4920
 Total number of deleted metal fills: 4920
 Total number of added metal fills: 4779
 (CPU Time: 0:00:01.2 MEM: 558.359M)
 *** END OF TRIM METALFILL ***
```

setViaFill

```
setViaFill
[-help]
[-layer {layerNumber | {list_of_layer_numbers}}]
[-windowSize xSize ySize]
[-windowStep xStep yStep]
[-minDensity percent]
[-maxDensity percent]
[-preferredDensity percent]
```

Specifies window and density values for inserting via fill. Use this command before running `addViaFill`.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `setViaFill` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man setViaFill`.

`-layer layerNumber | {list_of_layer_numbers}`	Specifies the cut layers to which the parameters of the `setViaFill` command apply. If you specify more than one layer, separate each layer with a space and enclose the list in braces or double quotation marks. To specify *cut12*, *cut23*, and *cut34*, type one of the following commands:
	`addViaFill -layer "Via12 Via23 Via34"`
	`addViaFill -layer {Via12 Via23 Via34}`

`-maxDensity percent`	Specifies a percentage value for the maximum cut density. For example, `setViaFill -maxDensity 30`. *Default:* `30`
`-minDensity percent`	Specifies a percentage value for the minimum cut density. For example, `setViaFill -minDensity 0.01`. *Default:* area of two cuts divided by 100 square microns
`-preferredDensity percent`	Specifies a percentage value for the preferred cut density. When the cut density in a window is less than the minimum cut density value, this parameter adds via fill to achieve a density as close as possible to the preferred value. To disable the preferred density feature, specify `0`. For example, `setViaFill -preferredDensity 0.02`. *Default:* area of two cuts in the cut layer
`-windowSize xSize ySize`	Specifies the x and y dimensions in microns of the area `setViaFill` uses to examine the cut density. The software assesses the cut density in each window, moving the window iteratively through the design. For example, `setViaFill windowSize 100 100`. *Default:* 10 microns in each dimension
`-windowStep xStep yStep`	Specifies the x and y step distance in microns the window moves for each iteration of cut density analysis. For example, `setViaFill -windowStep 50 50`. *Default:* 5 microns in each dimension

Example

The following command sets window and density values for inserting via fill in cut layers `VIA1` to `VIA7`:

```
setViaFill -layer {VIA1 VIA2 VIA3 VIA4 VIA5 VIA6 VIA7} -windowSize 100 100 /
-windowStep 50 50 -minDensity 0.01 -MaxDensity 30 /
-preferredDensity 1
```

Related Information

- `fill_setting_save`
- The following sections in the Optimizing Metal Density chapter of *User Guide*.
  - "Overview"
  - "Adding Via Fill"

trimMetalFill

```
trimMetalFill
[-help]
[-allowPolygon]
[-area x1 y1 x2 y2]
[-deleteViol]
[-ignoreSpecialNet]
[-layer {layer_num_list | layer_name_list}]
[-useNonDefaultSpacing]
```

Trims metal fill and via fill (`FILLWIRE` and `FILLWIREOPC` shapes) that causes DRC violations. This command uses the values set by the `setMetalFill` command. Therefore, you must ensure that you have correct `setMetalFill` settings before running `trimMetalFill` to avoid false violations.

Note: Use `setMetalFill` without `-iterationName` or with `-iterationName default` to set the DRC rules used by `trimMetalFill`. `setMetalFill -iterationName name`, where *name* is other than `default`, is used to set construction rules used by `add_metal_fill_signoff`.

Use this command to trim metal fill if the design has floating metal or via fill. By trimming the fill, you reduce the chance of introducing timing problems caused by cross-coupling.

If the design has metal or via fill that is connected to special nets, use `fixOpenFill` after using `trimMetalFill`.

Use the `trimMetalFill` command after routing signal nets. For more information, see Route Commands.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `trimMetalFill` parameter. For a detailed description of the command and all its parameters, use `man trimMetalFill`.
`-allowPolygon`	Allows rectilinear shapes after trimming metal fill (`FILLWIRE` and `FILLWIREOPC` shapes). By default, the Innovus software supports rectangular shapes only.
`-area x1 y1 x2 y2`	Specifies a set of coordinates within which metal fill needs to be trimmed. By limiting the area in which metal fill is trimmed, you can speed up the trimming process. **Note:** This option is recommended for use with only floating metal fill. If you use `trimMetalFill -area` on tied-off fill shapes, the command returns a warning message that some of the shapes may become isolated from the Power/Ground network.
`-deleteViol`	Deletes metal fill shapes that cause DRC violations or shorts, instead of trimming sections of the shapes. After running the `trimMetalFill` command with this parameter specified, the remaining shapes are still rectangles. If using this parameter causes metal density to drop below the target density, re-run the `add_metal_fill_signoff` command. Always specify this parameter in the following two cases: • If the design has minimum step rules, specify this parameter to avoid creating minimum step violations. • If you ran `add_metal_fill_signoff`, specify this parameter to delete entire shapes, instead of trimming sections of the shapes, otherwise the trimmed shapes will not be on-grid.
`-ignoreSpecialNet`	Ignores special nets while checking for DRC violations.
`-layer {layer_num_list | layer_name_list}`	Specifies the metal layers in which metal fill needs to be trimmed. **Note:** This option is recommended for use with only floating metal fill. If you use `trimMetalFill -layer` on tied-off fill shapes, the command returns a warning message that some of the shapes may become isolated from the Power/Ground network.
`-useNonDefaultSpacing`	Uses non-default spacing for trimming metal fill. Some critical nets use a non-default rule (NDR) for routing as they may need to have wider wires or wider spacing than other nets. Use `-useNonDefaultSpacing` to extend NDR control to `trimMetalFill`.

Example

- The following commands trim metal fill after ECO routing.
  ```
  setNanoRouteMode -route_with_eco true
  globalDetailRoute
  trimMetalFill
  ```
- The following command trims metal fill and allows rectilinear shapes:
  ```
  trimMetalFill -allowPolygon
  ```

trimMetalFillNearNet

```
trimMetalFillNearNet
[-help]
[-area {x1 y1 x2 y2}]
[-clock]
[-createFillBlockage blockage_name]
[-layer layer_name_list]
[-minTrimDensity {percent1layer_list1 [{percent2layer_list2}]}]
[-minTrimUnionDensityToAboveLayer {percent1 layer_list1 [{percent2 layer_list2}]..}]
[-net {net_name_list | net_object_pointer_list}]
[-recomputeDensity]
[-remove]
[-slackThreshold slack_in_ns]
[-spacing dist_in_um]
[-spacingAbove dist_in_um]
[-spacingBelow dist_in_um]
```

Trims any metal fill around critical nets. This command enables you to reduce the timing impact on critical nets due to metal fill on the layer above, below and the same layer for the routing of any critical net. Using this command, you can specify the critical net list, desired spacing around critical nets, and metal fill density limit.

The intended usage model is to run timing analysis before metal fill, add metal fill, then run timing analysis after metal fill, then trim the metal fill that caused timing to get worse. See the examples below.

Parameters

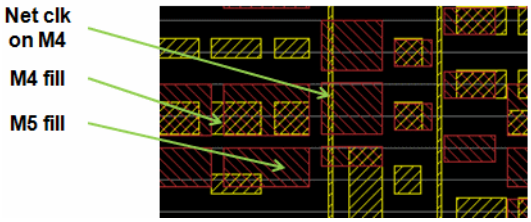
`-help`	Prints a brief description that includes the type and default information for each `trimMetalFillNearNet` parameter. For a detailed description of the command and all its parameters, use `man trimMetalFillNearNet`.
`-area {x1 y1 x2 y2}`	Specifies a set of coordinates within which to trim metal fill. If this parameter is not specified, metal fill is trimmed around critical nets in the entire design area
`-clock`	Specifies whether metal fill is to be trimmed around all clock.
`-createFillBlockage` *blockage_name*	Creates a fill blockage so that any subsequent fill steps do not refill the trimmed area. If you specify a name, the tool uses that name as the fill blockage name. If you do not specify a name, the tool uses the default name *netName_layerName_** for the fill blockage.
`-layer` *layer_name_list*	Trims metal fill only on the specified layers. If this parameter is not specified, metal fill is trimmed on all layers.
`-net {`*net_name_list* | *net_object_pointer_list*`}`	Specifies a list of critical net names or pointers which are surrounded by metal fill.
`-minTrimDensity {`*percent1layer_list1* `[{`*percent2layer_list2*`}]}`	Trims metal fill only until the specified window density percentage is reached to avoid causing any metal density violations. The window sizes are controlled by setMetalFill. verifyMetalDensity is used to compute the metal-density using the same setMetalFill settings. You can specify different window density percentages for different layers. For example, `{{20 1 2} {30 3}}` would set the min-density for metal1, metal2 windows to 20%, and for metal3 to 30%.
`-minTrimUnionDensityToAboveLayer {`*percent1 layer_list1* `[{`*percent2 layer_list2*`}]..}`	Trims metal fill only till meeting the specified percent window density. *Default:* `0`
`-recomputeDensity`	By default, if metal density values are required for -minTrimDensity, and they are available in the database from a previous call to verifyMetalDensity, the existing database values are used. This option forces a call to `verifyMetalDensity` to recompute window densities instead of using the stored values.
`-remove`	Specifies that the metal fill shapes overlapping the critical-net halo area should be removed entirely instead of being trimmed to the halo edge created with different `-spacing*` options. This avoids the possibility of smaller metal fill shapes that might be left over after trimming.
`-slackThreshold` *slack_in_ns*	Trims metal fill around nets with slack less than the specified value. The value specified should be in nanoseconds.
`-spacing` *dist_in_um*	Trims fill on the same layer by specified distance around critical net routes. The distance specified should be in micrometers (`um`). The default is 0 so no trimming is done.
`-spacingAbove` *dist_in_um*	Trims fill on the layer above the current layer by specified distance around critical net routes. The distance specified should be in micrometers (`um`). The default is 0 so no trimming is done.
`-spacingBelow` *dist_in_um*	Trims fill on the layer below the current layer by specified distance around critical net routes. The distance specified should be in micrometers (`um`). The default is 0 so no trimming is done.

Example

- The most common usage model is to run timing analysis before metal fill, add metal fill, run timing analysis after metal fill, and then trim the metal fill that causes timing to get worse. Suppose the WNS before metal fill was -0.2ns, and after metal fill the WNS is -0.4ns. This means the metal fill caused a 0.2ns degradation. One strategy is to trim any net that got pushed about beyond the original WNS of -0.2ns aggressively with a larger trim spacing value because the extra WNS is directly caused by metal-fill, and then trim any negative slack nets above 0.0ns to improve timing margins. The spacing values depend on the technology node and timing criticality. A reasonable starting point would be to choose between 5x to 10x min-spacing for the aggressive trim value. So you might use these commands:

```
#Trim by 1.0um the layer above/below/same for any net with worse slack than the pre-metal fill WNS of -0.2
#Do not trim if the metal density will fall below 20% for metal1, metal2, or 30% for metal3 using the setMetalFill window settings
trimMetalFillNearNet -slackThreshold -0.2 -spacing 1.0 -spacingAbove 1.0 -spacingBelow 1.0 -minTrimDensity {{20 1 2} {30 3}}
#Trim less aggressively using 0.4um spacing for any net with WNS above 0.0 to improve timing margins
trimMetalFillNearNet -slackThreshold 0.0 -spacing 0.4 -spacingAbove 0.4 -spacingBelow 0.4 -minTrimDensity {{20 1 2} {30 3}}
```

- In the following example, there is a critical net overlap with the metal fill on the upper layer, metal5:



The following command trims metal fill on the upper layer, metal5, and creates a fill blockage around the `clk` net.

```
trimMetalFillNearNet -net clk -layer {metal4 metal5} -createFillBlockage -spacingAbove 0.2
```

  - Trimming Metal Fill for Timing Closure

Metal and Via Fill Global Variables

- fill_setting_save

fill_setting_save

```
fill_setting_save {0 | 1}
```

Type: Integer

Default: `0`

Specifies whether metal fill settings are to be saved in the .init file when saving the design. Metal fill settings include setMetalFill, setMetalFillSpacingTable, and setViaFill settings. By default, these metal fill settings are lost when you exit Innovus. To enable Innovus to record metal fill settings in the .init file, you must set the `fill_setting_save` to `1` before saving the design. You can easily reload your settings by restoring the saved design:

```
set fill_setting_save 1

setMetalFill iterationName iter1 ...

saveDesign

restoreDesign

#The previous metal fill settings are reloaded.
```

Mixed Signal Commands

- deleteIntegRouteConstraint
- getIntegRouteConstraint
- pull_block_constraint
- run_vsr
- setIntegRouteConstraint
- writeIntegRouteConstraint

deleteIntegRouteConstraint

```
deleteIntegRouteConstraint
[-help]
{-net net1 net2 ... | -name string | -customConstraints  | -all | -additional }
```

Deletes the routing constraints in the database.

Note: Integration constraints are used to convey the design intent in a mixed signal design. These constraints are fully interoperable between the digital and custom environments.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `deleteIntegRouteConstraint` parameter. For a detailed description of the command and all of its parameters, use the man command `man deleteIntegRouteConstraint`.
`-additional`	Removes the additional constraint file, containing the maximum resistance target values for nets, from memory.
`-all`	Deletes all integration constraints, including constraints that are understood by NanoRoute and used to route nets with simple shield or NDR constraints.
`-customConstraints`	Deletes all diffPair, matchLength, complex shield, and complex netClass constraints.
`-name` *`string`*	Allows the deletion of a specific constraint by name. You can specify multiple constraint names, enclosed in braces. Use the `getIntegRouteConstraint` command to get the name of any constraint in the design.
`-net` *`net1 net2 ...`*	Indicates the nets for which the constraints will be deleted. If the net is part of a netClass, the netClass will be deleted as well.

Example

- The following command deletes all diffPair, matchLength, complex shield, and complex netClass constraints.

  ```
  deleteIntegRouteConstraint -customConstraints
  ```

- The following command deletes the constraints with the specified names:

  ```
  deleteIntegRouteConstraint -name {Constr_2__analogNW__DTMF_INST/analogNW_INST
  Constr_1__analogNW__DTMF_INST/analogNW_INST}
  ```

- The following command deletes all Integration constraints in the design.

  ```
  deleteIntegRouteConstraint -all
  ```

  The tool displays the following warning before deleting the constraints:

  ```
  **WARN: (ENCMSC-270): You are attempting to delete all routing constraints in this
  design. These include many constraints that are intended for use by NR for routing
  nets with simple shield, or NDR constraints.
  ```

Related Information

- `getIntegRouteConstraint`

getIntegRouteConstraint

```
getIntegRouteConstraint
[-help]
[-net net_name | -name constraint_name  | -additional]
```

Displays the settings needed for the `setIntegRouteConstraint` command.

If mixed-signal constraints have not yet been defined, the `getIntegRouteConstraint` command does not return anything.

If you run the `getIngegRouteConstraint` command without any option, all nets with all constraint names and the maximum resistance constraint (if already set) are displayed on the console window.

Note: The output is displayed only on the console window and is not written to the log file. You cannot use `>` to write to a file. The only way to send the output to a file is to run the following:

```
redirect {puts [getIntegRouteConstraint xxxx]} > filename
```

Alternatively, use the command `writeIntegRouteConstraint`.

Note: Integration constraints are used to convey the design intent in a mixed-signal design. These constraints are fully interoperable between the digital and custom environments.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `getIntegRouteConstraint` parameter. For a detailed description of the command and all of its parameters, use the man command `man getIntegRouteConstraint`.
`-additional`	Returns the path to the additional constraint file, which contains the maximum resistance target values for nets.
`-name constraint_name`	Returns a specific constraint by name. You can specify multiple constraint names, enclosed in braces.
`-net net_name`	Specifies the net for which the constraints will be returned. If the net is part of a netClass, the constraints for the netClass is returned. You can specify multiple net names, enclosed in braces.

Example

- The following command returns the constraint(s) defined for the net `scan_out_1`:

  ```
  getIntegRouteConstraint -net scan_out_1
  ```

  The output of the command is:

  ```
  {-type shield  -shieldNet { VSS } -shieldType side -shieldTolerance 30.0 -net {
  scan_out_1 }
  }
  ```

- The following command returns details of the constraint named `Constr_13__analogSW__DTMF_INST/analogSW_INST`:

  ```
  getIntegRouteConstraint -name Constr_13__analogSW__DTMF_INST/analogSW_INST
  ```

  The output of the command is:

  ```
  {-type netClass -name Constr_13__analogSW__DTMF_INST/analogSW_INST -shieldNet VSS -
  shieldType side -connectSupply anyPoint -rule NDR8 -net {analogW4I}
  }
  ```

- The following command returns the constraints on the specified nets:
  ```
  getIntegRouteConstraint -net {DTMF_INST/cntrlxo[3] DTMF_INST/cntrlxo[0]}
  ```
  The output of the command is:

  ```
  {-type diffPair -name Constr_2__analogNW__DTMF_INST/analogNW_INST -tolerance 20 -
  rule default -net {DTMF_INST/cntrlxo[3] DTMF_INST/cntrlxo[2]}
  } {-type diffPair -name Constr_1__analogNW__DTMF_INST/analogNW_INST -tolerance 5 -
  rule default -net {DTMF_INST/cntrlxo[0] DTMF_INST/cntrlxo[1]}
  }
  ```

- The following command returns all the constraints on all the nets in the design and the maximum resistance constraint (if already set):
  ```
  getIntegRouteConstraint
  ```

  A sample output of the command is displayed below:

  ```
  {-type diffPair -name Constr_3__analogNL__DTMF_INST/analogNL_INST  -tolerance 20

   -rule default -net {DTMF_INST/digsyncc DTMF_INST/digsyncd}

  } {-type diffPair -name Constr_2__analogNL__DTMF_INST/analogNL_INST  -tolerance

  20 -rule default -net {DTMF_INST/digsynca DTMF_INST/digsyncb}

  } {-type diffPair -name Constr_1__analogNW__DTMF_INST/analogNW_INST  -tolerance

  5 -rule default -net {DTMF_INST/cntrlxo[0] DTMF_INST/cntrlxo[1]}
  ```

```
} {-type diffPair -name Constr_2__analogNW__DTMF_INST/analogNW_INST  -tolerance

pull_block_constraint

```
pull_block_constraint
[-help]
[-file report_file_name]
[-override]
{-all_blocks | -block list_of_blocks | -inst list_of_instances | -cellview
{list_of_libName_cellName_viewName}}
```

Pulls the routing constraints stored on the interface nets of blocks in a design, to their corresponding top-level nets. The `pull_block_constraint` command uses a two-pass approach to handle conflicting constraints on the same net. In this approach, the `pull_block_constraint` command detects block-level and top-level conflicts and reports a warning.

If the `-override` parameter is not specified (non-override mode) and a block-level conflict is detected, no constraints are pulled.

If the `-override` parameter is specified (override mode), `pull_block_constraint` reports the conflicts but pulls the constraints such that the lower-level net constraints override any constraints that might exist on the top-level nets..

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `pull_block_constraint` parameter. For a detailed description of the command and all of its parameters, use the man command `man pull_block_constraint`
`-cellview {`*`list_of_libName_cellName_viewName`*`}`	
	Specifies the list of library, cell, and view names from which the constraints need to be pulled.
`-file` *`report_file_name`*	Specifies the report file name. Given that the standard out report is in the abbreviated format, more details are written out in this mode indicating: • The lower, and upper level net names, the type of constraints pulled. • All the associated parameters. • Any conflicts that need to be resolved. • Which constraint were written to a particular net. *Default*: `dumpPullInfo.log`
`-override`	When specified, the lower-level net constraints will override any constraints that might exist on the top-level nets. *Default*: `off`
`-all_blocks`	Specifies that constraints with hierarchical scope will be pulled from all blocks in the design.
`-block` *`list_of_blocks`*	Defines the list of block names of the instances in the design for which the constraints with hierarchical scope will be pulled.
`-inst` *`list_of_instances`*	Defines the instances in the design for which the constraints with hierarchical scope will be pulled.

Examples

- Using the following command, the constraints on the pins in the cellview binded to the block macro of all the instantiations of the block list `pll_clock` and `pwr_monitor` will be pulled up to the top-level nets connected to the instance pins.

  ```
  pull_block_constraint -block {pll_clock pwr_monitor}
  ```

- Using the following command, the constraints on the pins in the cellview binded to the macro instance `I1`/`I2` will be pulled up to the nets connected to the pins of the instance.

  ```
  pull_block_constraint -inst {I1/I2}
  ```

run_vsr

```
run_vsr
[-help]
[-log_file fileName]
[-no_taper_to_pinwidth]
[-post_load_script scriptname]
[-pre_load_script scriptname]
[-remove_existing_route]
[-route_type_order {bus diffPair match nets shield}]
[-run_VSR_Script scriptname]
[-share_shields]
[-sel_net list_of_selected_nets | -incl_net_type {bus diffPair match nets shield} | -nets_file fileName]
```

Launches the Virtuoso Space-based Router (VSR) from Innovus™ Implementation System. It works on OpenAccess design as well as restored non-OpenAccess designs. It routes the nets specified with the `-sel_net`, `-nets_file`, or `-incl_net_type` option. If the `-incl_net_type` option is used, the nets are routed in the following order: `diffPair`, `match`, `bus`, `nets`, and `shield`. To invoke this wrapper, make sure Virtuoso is available in your path.

Before running the `run_vsr` command, set the following:

```
setOaxMode -compressLevel 1
```

Notes

- Integration constraints are used to convey the design intent in a mixed-signal design. These constraints are fully interoperable between the digital and custom environments.
- If you run `run_vsr` on an abstract inferred from layout, you may see the following WARNING message:

  ```
  "The current database uses quick abstract inference and should be used only for floorplanning and not for routing purposes."
  ```

For more information on using `run_vsr`, see the Routing Constraint Interoperability chapter in the *Mixed Signal Interoperability Guide*.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `run_vsr` parameter. For a detailed description of the command and all of its parameters, use the man command `man run_vsr`
`-incl_net_type {bus diffPair match nets shield}`	
	Specifies the list of valid net types for VSR to route. **Note:** The `-sel_net`, `-nets_file`, and `-incl_net_type` parameters are mutually exclusive. Do not specify these parameters at the same time.
`-log_file` *`fileName`*	Specifies the file name for writing the routing report.
`-nets_file` *`fileName`*	Specifies the name of the file listing the nets to be routed. **Note:** The `-sel_net`, `-nets_file`, and `-incl_net_type` parameters are mutually exclusive. Do not specify these parameters at the same time.
`-no_taper_to_pinwidth`	Does not perform tapering based on the pin width. For instance, if the rule applied on a mixed signal net is NDR1 whose width exceeds the pin width for a particular layer, then VSR automatically tapers the wire to match the pin width. If this option is specified, then tapering is not done.
`-post_load_script` *`scriptname`*	Specifies the name of the script to be executed by VSR after loading the design.
`-pre_load_script` *`scriptname`*	Specifies the name of the script to be executed by VSR before loading the design.
`-remove_existing_route`	Deletes the nets (fixed, normal), including shield, and excluding power nets, which are specified by the -sel_net parameter before routing
`-route_type_order {bus diffPair match nets shield}`	
	Specifies the list of valid constraint types in the preferred routing order.

`-run_VSR_Script` *scriptname*	Specifies a user-defined script to be run by VSR for custom routing. If this option is specified, the router skips all presetting from VSR and routes the design by sourcing the complete custom script as provided.
`-share_shields`	Shares the shielded nets. Using this parameter, you can selectively specify the list of shared shielded nets.
`-sel_net` *list_of_selected_nets*	Specifies the list of nets that have to be routed.

Using Scripts and Environmental Variables with run_vsr

The `run_vsr` command in Innovus supports a limited set of options to route the analog/mixed-signal nets. To have more control of the VSR engine, you can set additional settings through the `.cdsenv` file.

Settings through .cdsenv

Here are two examples of how you can use `.cdsenv` settings to control VSR:

- To force VSR to route on-grid:
  ```
  layout routeUseGrid cyclic "Routing"
  ```

- To force VSR to use the rules from the specified route spec:
  ```
  layout wireConstraintGroup string "LEFDefaultRouteSpec"
  ```

If you set the above settings in the `.cdsenv` file before running the `run_vsr` command, Virtuoso initializes them before calling the VSR engine.

In addition to the settings through `.cdsenv` file, the `run_vsr` command is enhanced to pass additional variables or scripts through `-pre_load_script` and `-post_load_script`.

Preloadscript

Usage of settings through `-pre_load_script` is only for expert VSR users and generally not recommended.

Postloadscript

Example:

- To enable VSR to use the custom vias and not generated or derived vias:
  ```
  setvar db.enable_create_derived_vias false
  ```

- To enable VSR to connect the wires to the center of the pin

  ```
  setvar droute.snap_to_pin_center true
  ```

You can set the above environmental variables in a script and enable them through the following command:

```
run_vsr -sel_net { neta …..} -post_load_script scriptname…
```

For more information on the environmental variables which can be set, refer to the following documentation:

- "Environment Variables" chapter in the *Cadence Space-based Router and Chip Optimizer Command Reference*

Note: Consult Cadence for the best use of these variables to obtain the desired results.

Examples

- The following command routes the bus nets using VSR:

  ```
  run_vsr -sel_net {DATA[0] DATA[1] DATA[2] DATA[3] DATA[4] DATA[5] DATA[6] DATA[7]}
  ```

- The following command routes the given net `lbk_bstart` using mixed-signal constraint, if any constraint has been applied to this net which will be taken from OpenAccess database:

  ```
  run_vsr -sel_net lbk_bstart
  ```

- The following command routes all the nets which have `diffPair`, `matchPair` and then `net` class in the following order of constraint types:

  ```
  run_vsr -incl_net_type {diffPair match nets}
  ```

[-tolerance tolerance]
[-topLayer layerNum]
-type {bus diffPair matchLength NDR netClass shield simpleNet additional}
```

Applies specialty routing constraints in the database for nets in the designs. It allows creation of differential pair, match pair, shield nets, and nets with non-default rules.

If required, all routing constraints set by this command can be deleted from the database using the `deleteIntegRouteConstraint` command.

Also see, `getIntegRouteConstraint`.

Notes

- Integration constraints are used to convey the design intent in a mixed signal design. These constraints are fully interoperable between the digital and custom environments.
- If the design has a complex netClass constraint that has net members with different constraints, `setIntegRouteConstraint` will throw the an error. If you still wish to change the integration constraints in the design, check whether the netClass constraints under the *Complex NetClass* tab in the Integration Constraint Editor can be removed. If yes, use the `deleteIntegRouteConstraint` or the GUI to first delete such constraints, and then repeat the `setIntegRouteConstraint` command.
- The rule name `DefaultRule` is obsolete. It still works in this release and is automatically converted to the correct name `default`. Update your scripts to use `default` so that it work correctly in future releases.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `setIntegRouteConstraint` parameter. For a detailed description of the command and all of its parameters, use the man command `man setIntegRouteConstraint`.
`-accessStyle {none | straight | clustered}`	
	Specifies the preferred style for routing the bus after connecting to the bus pins. This parameter is applicable only for `-type bus`. *Default:* `clustered`

`-bottomLayer` *layerNum*	Specifies the bottom routing layer that is to be used.
`-busGroupWidth` *integer*	
	Specifies the width for the bus groups into which the router splits a bus. The width is specified as an integer value. For example, if a bus is 16 bits, you can specify `-busGroupWidth 4` to indicate that the router can route the bus as four bus groups of 4 bits each. *Default*: `1`
`-busSinkGroups` *busSinkGroupNameList*	
	Specifies the list of names of the busSinkGroups. It sets high-frequency/mixed signal constraints for the nets of the busSinkGroup sinks. It supports all constraints of type BUS. These constraints are honored by the NanoRoute high-frequency router.
`-connectSupply {`*float* `anyPoint}`	Indicates how the shield wires will be connected to the supply line. The default option, `anyPoint`, tells the router to connect the wire to supply, anywhere along the length of the shield wire. *Default:* `anyPoint`
`-cornerStyle {none | crossover | river}`	
	Specifies the type of corner style that the differential pair route or bus should follow when changing directions. This parameter is applicable only for `-type bus` and `-type diffPair`. *Default:* `crossover`
`-crossTieShieldInterval` *string*	

	Specifies the number of tracks between the cross-tie wires for opportunistic coaxial shielding. The *string* value should have the following format: `{integer | {layer interval1 layer2[:layerN] interval2 ...}}` The integer value specifies the interval in the form of the number of tracks between cross-ties created on a given layer. For example, a value of `0` means that there are no tracks between cross-ties, which means there is a cross-tie on every track. Similarly, a value of 1 means that there is one track between cross-tie wires, which results in a cross tie on every other track. A value of `2` means two tracks between the cross-tie wires and so on. **Note**: This parameter is applicable only if `-shieldType` is specified as `crosstie`. *Default:* `0`
`-crossTieShieldLayerLimit` *string*	
	Specifies the layer range that can be used to create cross-tie shields. Use the `-crossTieShieldLayerLimit` parameter if you want to use only specific layers to create cross-ties and keep the remaining layers free for other purposes. The *string* value should have the following format: `{layer_number:layer_number}` For example, if the layer range specified is `{METAL2:METAL7}`, cross-tie shields can be created on `METAL2`, `METAL3`, `METAL4`, `METAL5`, `METAL6`, and `METAL7` but not on `METAL8` or the layers above it. **Note**: This parameter is applicable only if `-shieldType` is specified as `crosstie`.
`-crossTieShieldedLayers` *string*	

	Specifies the layer range that will be shield with cross-ties from above and below. Use the `-crossTieShieldedLayers` parameter if you want to minimize congestion by shielding only specific routing layers with cross-ties. The *`string`* value should have the following format: `{layer:layer}` For example, if the layer range specified is `{METAL3:METAL6}`, cross-tie shields will be built for routes on the net on `METAL3`, `METAL4`, `METAL5`, and `METAL6`. **Note**: This parameter is applicable only if `-shieldType` is specified as `crosstie`.
`-file` *`string`*	Specifies the path for an additional constraint file, which contains the maximum resistance target values for nets. ⚠ • `-file` cannot be used with either `-net` or `-busSinkGroups`. • `-file` must be used only with `-type additional`.
`-groupToOutsideSpacing` *`layer1 spacing1 layer2`*`[:`*`layerN`*`]` *`spacing2`*`...`	
	Indicates the spacing per layer (in microns) between the nets in this net group, and the other nets in the design. This parameter is applicable only for bus nets. That is, `-groupToOutsideSpacing` should be specified only for routing constraints with `-type bus`. ⚠ While reading in an OpenAccess database for which constraints have been created elsewhere, Innovus checks for any non-bus net that has constraints with `-groupToOutsideSpacing` specified. Innovus treats such constraints as complex constraints and sets the `isMixedSignal` flag on the corresponding nets.

`-hard`	Indicates that the top or bottom layer routing constraint created should be of hard type. By default, Innovus places the top/bottom routing layer constraints as soft routing constraints in the resulting OpenAccess database.
`-hierarchicalScope {local local_above local_below local_above_below}`	
	Specifies whether the particular constraint is local, and/or can be pulled (above) or pushed (below) across the hierarchy. Setting this option to all possible values enables pull and push. If set to local, it is not saved to the database.
`-intergroupGap {`*`layer1 spacing1 layer2`*`[:`*`layerN`*`] `*`spacing2`*`...}`	
	Specifies the gap to be kept between the split bus groups when `-busGroupWidth` is specified. Default is min spacing.
`-layerGap {`*`layer1 gap1 layer2`*`[:`*`layerN`*`] `*`gap2`*`...}`	
	Indicates the layer names and the gap-spacing values for the nets routed as diffPair. For any layer not listed, the minimum legal spacing for that layer is used. For example: `-layerGap {`*`layer_1 gap_1 layer_2 gap_2`*`...}`
`-layerMatch`	Specifies that each separate layer should be matched for `matchLength` nets. By default, only the total length is matched
`-matchGap {`*`layer1 gap1 layer2`*`[:`*`layerN`*`] `*`gap2`*`...}`	
	Indicates the spacing between two rises of the accordion. This setting is applicable only when `-type` is `matchLength` and `-matchStyle` is `accordion`. You may want to control the spacing between two rises of the accordion if routing resources are restricted.
`-matchStyle {accordion | trombone | coil}`	

	Indicates the routing topology to be used for matching the nets routed as `matchLength`. It can be `accordion`, `trombone`, or `coil`. In `accordion`, pulse structures are used to match length while in `trombone` we use loops. **Matching in accordion style**  **Matching in trombone style**  *Default:* `accordion`
`-maxLength` *value*	Indicates the maximum length the router should route a net. The maximum length is specified as a float value. This parameter is applicable only for `-type matchLength` and `-type simpleNet`.
`-maxRes` *value*	Indicates the maximum resistance to be used for the specific net being routed or for the nets with a `matchLength` constraint if `-type` is `matchLength`. The maximum resistance is specified as a float value. This parameter is applicable only for `-type matchLength`.

`-minBusBit` *integer*	Indicates the minimum bits allowed for the router to split a bus. As channels get narrower, it becomes challenging to accommodate all the bus bits in the same channel. By default, `-minBusBit` value is undefined, not `0`. If you specify an integer value for `-minBusBit`, the router splits a bundle with a minimum of this value. For example, if you set -`minBusBit` to `4`, the router splits the bus such that each part has at least `4` bits.
`-minLength` *value*	Indicates the the minimum length the router should route a net. The minimum length is specified as a float value. This parameter is applicable only for `-type matchLength` and `-type simpleNet`.
`-minRes` *value*	Indicates the minimum resistance to be used for the specific net being routed or for the nets with a `matchLength` constraint if `-type` is `matchLength`. The minimum resistance is specified as a float value. This parameter is applicable only for `-type matchLength`.
`-name` *string*	Specifies the name of the constraint group being created, changing the default name given to the constraint by Innovus.
`-net {`*net1 net2 ...*`}`	
	Specifies the list of net names to be routed. For constraints of type `bus` and `matchLength`, a single net is also supported.
`-noshareshield`	Specifies that there should be individual shields, instead of a common shield, between the bus nets. This option is applicable only for constraints of type `bus`.
`-rule` *NDR_name*	Specifies the name of the routing rule that is used for routing a particular type of net(s). *Default:* `"default"`
`-shieldGap {`*layer1 gap1 layer2*`[:`*layerN*`] gap2 ...}`	
	Specifies the spacing between the shielded wire and the shield net in microns. For any layer not listed, the minimum legal spacing for that layer is used.

`-shieldNet {net1 net2}`	Indicates that the net group should be shielded by the specified nets. Valid net names that you can use with `-shieldNet` are all power and ground net names in the design. You can specify different shield nets for different sides of a wire. The routers then determine which shield net should be used on which side of the wire. **Note:** You can specify a maximum of two net names with this parameter. In addition, you can specify two shield net names only for the following shield types: • `side` • `topSide` • `bottomSide` • `coaxial` • `tandemSplit` For the `top`, `bottom`, or `topBottom` shield types, you can specify only one shield net. *Default*: The first ground net name in the list of ground nets.
`-shieldTolerance {net1 value1 net2 value2 ...}`	

	Indicates the percentage of length of the net that can remain unshielded. You can set the same tolerance value or different tolerance values on a group of nets.
	The examples below depict different use models:
	• In the following example, the same constraint shield tolerance is put on every member of the shield constraint group:
	`setIntegRouteConstraint -type shield -shieldNet {VSS} -shieldType side -shieldTolerance 25.0 -connectSupply anyPoint -net {scan_in_2, abc, xyz}`
	• In the example below, different groups of nets get different shieldTolerance values:
	`setIntegRouteConstraint -type shield -shieldNet {VSS} -shieldType side -shieldTolerance 25.0 -connectSupply anyPoint -net {scan_in_2, abc, xyz} -shieldTolerance {net1 30 net2 30 net3 30}`

- In the following example, the nets `scan_in_2`, `abc` and `xyz` are already nets with the shield constraint, but without tolerance values. The command below adds the tolerance value to the existing shielding constraint of the nets. Note that adding shield tolerance changes the net to a complex shield as opposed to a simple shield:

```
setIntegRouteConstraint -type shield -shieldTolerance 25 -net
{scan_in_2 abc xyz}
```

Note:

- The shield tolerance value can be set only on nets that are not intended to be routed by NanoRoute. This means that setting the shield tolerance on any net will make that net a complex shield.
- If you use the `setIntegRouteConstraint` command to set the shield tolerance on a net or a group of nets, those nets automatically get the MS bit in the DB and show up in the GUI as a complex shield.
- Percentage tolerance is considered by VSR as a soft constraint.
- PVS-cv is the only tool in the flow that checks the percentage tolerance against the geometries created by VSR, and flags any such violations.

Default: `20.0`

`-shieldType {unspecified side bottom bottomSide top topSide topBottom coaxial tandemSplit interleaved crosstie  tandemSplitFull tandemSplitNearBy tandemSplitSpecial none}`

	Specifies the shielding type for the net(s) being routed. For complex coaxial shields, shield type can be specified as explained below: • `tandemSplitNearBy` - Specifies that shielding should be added only where required. • `tandemSplitFull` - Specifies that one-layer tandem shielding with overhang should be added. The overhang can be specified using the new `-tandemOverhang` and `-tandemSideOverhang` parameters. • `tandemSplitSpecial` - Specifies that two-layer tandem shielding should be added for complete shielding from other nets. Use the new `-tandemCapWidth` parameter to specify the width of the tandem cap shield (second layer shield).  *Default:* `unspecified` for `diffPair`, `matchLength`, and `bus`; `side` for `NDR`, `simpleNet`, and `netClass`
`-shieldWidth {`*`layer1 width1 layer2`*`[:`*`layerN`*`] `*`width2...`*`}`	
	Indicates the width of the shield wire in microns per layer. This only applies to side shields.
`-tandemAggressorAdjacentLayerSeparation` *`layer separation`*	
	Specifies the minimum distance between the given signal layer and the above/below layers containing the aggressors.

`-tandemAggressorSameLayerTrackDistance {`*`layer1 n1 layer2`*`[:`*`layerN`*`] `*`n2`*`...}`	
	Specifies the minimum pitch tracks (distance) between the given signal net and any aggressors on the same layer.
`-tandemCapWidth {`*`layer1 width1 layer2`*`[:`*`layerN`*`] `*`width2`*`...}`	
	Specifies the wire width (in microns) of the tandem cap shield beyond the edge of the route being shielded. For any layer not listed, the minimum legal width for that layer is used. This parameter is needed only for the `tandemSplitSpecial` shield type.
`-tandemNearbyNonAggressorExceptByName {`*`nameString`*`}`	
	Specifies that only the nets mentioned by name are aggressors; the rest are not considered as aggressors for shielding.
`-tandemNearbyNonAggressorNets {`*`nameString`*`}`	
	Specifies the net names that are not considered as aggressors for shielding.
`-tandemNearbyNonAggressorType {`*`typeNameString`*`}`	
	Specifies those signal types that are not considered as signal types of aggressors. Even if they exist within a certain range, the signal net does not need to be protected by shielding.
`-tandemOverhang {`*`layer1 width1 layer2`*`[:`*`layerN`*`] `*`width2`*`...}`	
	Specifies the overhang value (in microns) for the tandem shield.
`-tandemSideOverhang {`*`layer1 width1 layer2`*`[:`*`layerN`*`] `*`width2`*`...}`	
	Specifies the overhang value (in microns) for the tandem side shield.
`-tandemWidth {`*`layer1 width1 layer2`*`[:`*`layerN`*`] `*`width2`*`...}`	
	Specifies the width (in microns) of the top and bottom shields, beyond the edge of the route being shielded. For any layer not listed, the minimum legal width for that layer is used.
`-tolerance` *`tolerance`*	Indicates the percentage difference in length that is allowed when routing nets as `matchLength` and `diffPair`. *Default:* 20%

`-topLayer layerNum`	Specifies the top routing layer that is to be used for routing.
`-type {bus diffPair matchLength NDR netClass shield simpleNet additional}`	
	Specifies the type of routing constraints to be created: • `bus` - Specifies constraints for bus nets. • `diffPair` - Specifies constraints for differential pair nets. • `matchLength` - Specifies constraints for matched nets. • `NDR` - Specifies constraints for a net with a non-default rule. • `netClass` - Specifies constraints for shielding a group of nets. It can also be used for a group of nets that have the same NDR. • `shield` - Specifies constraints for shielding a single net. • `simpleNet` - Specifies constraints for a simple net. • `additional` - Specifies the maximum resistance target constraints for nets. The NanoRoute High Frequency (NRHF) router routes to match the targets by wire widening. A prerequisite for the maximum resistance flow is that NDRs should be predefined for the used layers. ⚠ `-type additional` can be used only if `-file` is specified.

Examples

- The following command sets the layer 1 gap as 0.4, layer 2 gap as 0.39, and layer 3 gap as 0.38:

  ```
  setIntegRouteConstraint -type diffpair -net {n_7862 n_7875} -layerGap {1 0.4 2 0.39 3 0.38}
  ```

- The following command specifies a shield constraint for the `analogS41` net:

  ```
  setIntegRouteConstraint -type shield -shieldNet VSS -shieldType side -connectSupply anyPoint -rule NDR4 -net analogS4I
  ```

- The following command specifies a shield constraint for the net group comprising nets `analogW1I`, `analogW2I`, `analogW3I`, and `analogW4I`:

  ```
  setIntegRouteConstraint -type netClass -shieldNet VSS -shieldType side -connectSupply anyPoint -net {analogW1I analogW2I analogW3I analogW4I}
  ```

- The following command specifies minimum and maximum length constraints for the `xyz` net:

  ```
  setIntegRouteConstraint -type simpleNet -net xyz -minLength 2.0 -maxLength 3.0
  ```

- The following command specifies that individual shields should be used between the nets in the bus constraint:

  ```
  setIntegRouteConstraint -type bus -nets {nets_1 nets_2 ...} -shieldNet VSS -noshareshield ...
  ```

- The following command specifies maximum resistance constraints for nets as specified in the target file, `1.txt`:

  ```
  setIntegRouteConstraint -type additional -file 1.txt
  ```

Related Information

- `deleteIntegRouteConstraint`
- `getIntegRouteConstraint`
- `writeIntegRouteConstraint`
- Routing Constraint Interoperability chapter in the *Mixed Signal Interoperability Guide*
- Tools Menu chapter in the *Menu Reference*
  - Mixed Signal -> Integration Constraint Editor

writeIntegRouteConstraint

```
writeIntegRouteConstraint
[-help]
-file output_file
[-net net_name | -name string  | -additional]
```

Writes the constraints to an output file in the following order: `diffPair`, `matchLength`, `bus`, `netClass`, `NDR`, `shield`, and `additional`.

Notes

- Integration constraints are used to convey the design intent in a mixed-signal design. These constraints are fully interoperable between the digital and custom environments.
- If the design contains one or more complex netClass constraints with net members that have different constraints, `writeIntegRouteConstraint` reports the following warning:

  ```
  **WARN: (IMPOAX-2124): This design contains unknown complex constraint on
  complexNetClass 'contraint_name'. This is not an interoperable routing constraint
  for Innovus. When sourcing the resulting file from this command in Innovus, these
  complex constraints will be lost. You can see the complex constraints in the design
  in the integration constraint form.
  ```

Parameters

`-help`	Prints a brief description that includes the type and default information for each `writeIntegRouteConstraint` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man writeIntegRouteConstraint`
`-additional`	Writes the path to the additional constraint file, which contains the maximum resistance target values for nets.
`-file output_file`	Specifies the output file name that is to be written out.
`-name` *`string`*	Writes information for the specified constraint by name. Use the `getIntegRouteConstraint` command to get the name of any constraint in the design. You can specify multiple constraint names, enclosed in braces.
`-net` *`net_name`*	Writes the constraint defined on specified net. If the net is part of a netClass, writes constraints for the netClass. You can specify multiple net names, enclosed in braces.

Examples

- The following command writes the constraints in the output file called `myfile.rpt`:
  ```
  writeIntegRouteConstraint -file myfile.rpt
  ```
  The file `myfile.rpt` could have the following sample constraints that are written out:
  - For a `diffPair` constraint
    ```
    setIntegRouteConstraint -type diffPair -name
    Constr_3__analogNL__DTMF_INST/analogNL_INST -tolerance 20 \

    -rule default \
    -net { \
    DTMF_INST/digsyncc \
    DTMF_INST/digsyncd \
    }
    ```
  - For a `matchLength` constraint
    ```
    setIntegRouteConstraint -type matchLength -name
    Constr_4__analogNL__DTMF_INST/analogNL_INST -tolerance 20
    -matchStyle accordion \
    ```

```
-rule default \
-net { \
DTMF_INST/digsync3 \
DTMF_INST/digsync4 \
}
```

- For a `netClass` constraint

```
setIntegRouteConstraint -type netClass -name
Constr_11__analogSW__DTMF_INST/analogSW_INST \
-shieldNet VSS -shieldType side -connectSupply anyPoint \
-rule NDR8 \
-net { \
analogW2I \
}
```

- For a `shield` constraint

```
setIntegRouteConstraint -type shield -shieldNet {VSS} -shieldType side \
-shieldTolerance 30 -net {tdigit[0] tdigit[1] tdigit[2] tdigit[3] tdigit[4]
tdigit[5] \
tdigit[6]tdigit[7]}
```

- For an `additional` constraint

```
setIntegRouteConstraint -type additional -file 1.txt
```

- The following command writes a constraint file called `test.const` for the constraint named `Constr_2__analogNW__DTMF_INST/analogNW_INST`:

```
writeIntegRouteConstraint -file test.const -name
Constr_2__analogNW__DTMF_INST/analogNW_INST
```

The output is as follows:

```
setIntegRouteConstraint -type diffPair -name
Constr_2__analogNW__DTMF_INST/analogNW_INST -tolerance 20 \
-rule default \
-net { \
DTMF_INST/cntrlxo[3] \
DTMF_INST/cntrlxo[2] \
}
```

- The following command writes a constraint file with name `temp.const` for the constraint defined on net `analogW1I`:

```
writeIntegRouteConstraint -file temp.const -net analogW1I
```

The output is as follows:

```
setIntegRouteConstraint -type netClass -name
Constr_10__analogSW__DTMF_INST/analogSW_INST \
-shieldNet VSS -shieldType side -connectSupply anyPoint \
-rule NDR8 \
-net { \
analogW1I \
}
```

- The following command writes a constraint file named `test1.const` for the specified constraint names:

  ```
  writeIntegRouteConstraint -name {Constr_2__analogNW__DTMF_INST/analogNW_INST
  Constr_1__analogNW__DTMF_INST/analogNW_INST} -file test1.const
  ```

  The output is as follows:

  ```
  #Integration constraints ascii out for { ADTMF4 dtmf_chip NoConst_10_18 }

  setIntegRouteConstraint -type diffPair -name
  Constr_2__analogNW__DTMF_INST/analogNW_INST -tolerance 20 \
  -rule default \
  -net { \
  DTMF_INST/cntrlxo[3] \
  DTMF_INST/cntrlxo[2] \
  }
  setIntegRouteConstraint -type diffPair -name
  Constr_1__analogNW__DTMF_INST/analogNW_INST -tolerance 5 \
  -rule default \
  -net { \
  DTMF_INST/cntrlxo[0] \
  DTMF_INST/cntrlxo[1] \
  }
  ```

- The following command writes a constraint file named `test2.const` for the specified net names:

  ```
  writeIntegRouteConstraint -net {DTMF_INST/cntrlxo[3] DTMF_INST/cntrlxo[0]} -file
  test2.const
  ```

  The output is as follows:

  ```
  #Integration constraints ascii out for { ADTMF4 dtmf_chip NoConst_10_18 }

  setIntegRouteConstraint -type diffPair -name
  Constr_2__analogNW__DTMF_INST/analogNW_INST -tolerance 20 \
  -rule default \
  -net { \
  DTMF_INST/cntrlxo[3] \
  DTMF_INST/cntrlxo[2] \
  }
  setIntegRouteConstraint -type diffPair -name
  ```

```
Constr_1__analogNW__DTMF_INST/analogNW_INST -tolerance 5 \
-rule default \
-net { \
DTMF_INST/cntrlxo[0] \
DTMF_INST/cntrlxo[1] \
}
```

Multiple-CPU Processing Commands

- checkMultiCpuUsage
- getDistributeHost
- getMultiCpuUsage
- monitor_hosts
- report_resource
- setDistributeHost
- setMultiCpuUsage

checkMultiCpuUsage

```
checkMultiCpuUsage
[-help]
```

Checks if distributed processing can work in the software environment. This command also ensures that the working directory is accessible from the master machine as well as the client machines. The `checkMultiCpuUsage` command is specified after configuring the multi-CPU settings (`setDistributeHost` and `setMultiCpuUsage`) to check if all the specified CPUs can be accessed. This command should be invoked before running any commands that use multiple CPUs.

Parameters

`-help`	Outputs the command usage and a brief description about the command.

Examples

- Here are some examples.

- The following example command script checks the distributed computing environment when `set_distributed_hosts -local` is specified:

```
checkMultiCpuUsage

/it/sjclapa06p6_scr02/clre/exp_2017_05_30/0223/dy/2014/2017/0413
/it/sjclapa06p6_scr02/clre/exp_2017_05_30/0223/dy/2014/2017/0413

getDistributeHost

```
getDistributeHost
{-mode | -hosts | -queue | -resource | -custom_script | -env_script | -args | -
single_cpu_lsf_args | -timeout | -shellTimeout | -reportLsfInfo file | -waitForLsfInfo
value}
[-help]
```

Displays settings for the `setDistributeHost` command.

Parameters

`-args`	Displays the additional arguments when the software is running in the Sun Grid Engine (SGE) or Load Sharing Facility (LSF) mode.
`-custom_script`	Displays the name of the custom script when the software is running in `custom` mode.
`-env_script`	Displays the user-defined shell environment script that is run for each of the slave hosts.
`-hosts`	Displays the list of host names when the software is running in `rsh` mode.
`-help`	Outputs the command usage and a brief description about the command parameters.
`-mode`	Displays the distributed processing mode. The possible values are `local`, `sge`, `rsh` , `ssh` , `lsf` and `custom`. *Default*: `local`
`-queue`	Displays the queue name when the software is running in `sge` or `lsf` mode.

`-reportLsfInfo` *file*	Specifies to restore the LSF information to the specified file. This parameter can only be used when `setDistributeHost -reportLsfInfo` is specified in the current session. You must specify the `getDistributeHost -reportLsfInfo` only after the LSF tasks exit to obtain the task CPU time. If you specify this command before the task exits, the command gives a warning message.
`-resource`	Displays the resource string when the software is running in `sge` or `lsf` mode.
`-shellTimeout`	Displays the number of seconds the host machine waits for `rsh/ssh` machines to become available for multiple-CPU processing.
`-single_cpu_lsf_args`	Displays the lsf arguments when the software is running in `lsf` mode for a single CPU application.
`-timeout`	Displays the default timeout for a submitted job that will never start.
`-waitForLsfInfo` *value*	Specifies the timeout period required to wait for task exit and generate the LSF information.

Examples

- The following command displays the current setting for the `-mode` parameter:

  ```
  getDistributeHost -mode
  local
  ```

- The following command saves the LSF information to the `lsf.log` file:

  ```
  getDistributeHost -reportLsfInfo lsf.log
  ```

getMultiCpuUsage

```
getMultiCpuUsage
[-help]
[-autoPageFaultMonitor]
[-cpuPerRemoteHost]
[-keepLicense]
[-localCpu]
[-remoteHost]
[-threadInfo]
[-verbose]
```

Displays the requested number of threads or hosts.

To request threads or hosts, use `setMultiCpuUsage`.

Parameters

`-help`	Outputs the command usage and a brief description about the command parameters.
`-autoPageFaultMonitor`	Displays the warning rank set for performance issues caused by major page faults
`-cpuPerRemoteHost`	Displays the number of CPUs available on every remote host for Superthreading.
`-keepLicense`	Displays the current setting for the `setMultiCpuUsage -keepLicense` parameter.
`-localCpu`	Displays the number of available local CPUs for multi-threading.
`-remoteHost`	Displays the number of available remote hosts for distributed processing or Superthreading.
`-threadInfo`	Displays the level of informational messages for each thread.
`-verbose`	Displays a message with the current multiple-CPU setting.

Examples

- The following command displays the requested number of threads for multi-threading:

  ```
  getMultiCpuUsage -localCpu
  ```

- The following command displays the requested number of remote hosts for Superthreading or distributed processing:

  ```
  getMultiCpuUsage -remoteHost
  ```

- The following command displays the requested number of CPUs per remote hosts for Superthreading:

  ```
  getMultiCpuUsage -cpuPerRemoteHost
  ```

monitor_hosts

```
monitor_hosts
[-help]
[-log string]
[-overwrite]
[-period integer]
```

Monitors hosts and periodically prints the memory or CPU usage, and temporary disk speed of the hosts. This command automatically determines the hosts to be monitored. By default, after every 60 seconds hosts are monitored and the disk information is written to a log file.

This command is helpful to analyze and debug the performance of a session and helps check the machine load, the available memory, and track possible reasons for a slow down or unexpected exit during a session.

The `monitor_hosts` command is supported in STA, DSTA, and DMMMC flows.

The `monitor_hosts` command output is described below:

Status Keys/Tags	Memory (%age of Available Memory on the corresponding host)	CPU Usage	Disk Speed (Mb/sec)
E – Excellent	Memory used less than 75%	CPU Usage less than 85%	Disk speed more than 250
G – Good	Memory used between 75% and 85%	CPU Usage between 85% to 95%	Disk speed between 125 and 250
B – Bad (*)	Memory used between 85% and 99%	CPU Usage between 95% to 105%	Disk speed between 50 and 125

T – Terrible (**)	Memory used above 99%	CPU Usage more than 105%	Disk speed less than 50

The `monitor_hosts` command output will show host/machine specific information and not process specific information. So if multiple processes are running on the same machine, then the command output will show the combined impact of all the processes, on the machine's memory, machine's CPU usage etc.

The "T" or "B" state denotes that a session may be thrashing or may not give the best results with respect to the performance. For better performance, you must re-run this command with better machines.

Parameters

`-help`	Prints out the command usage. For a detailed description of the command and all of its parameters, use the `man` command: `man monitor_hosts`.
`-log` *string*	Specifies the log file name. *Default*: host-monitor.log
`-overwrite`	Overwrites the log file, if it already exists.
`-period` *integer*	Specifies the sampling period after which hosts will be monitored. *Default*: 60

Examples

- A sample monitor log file is shown below:

```
Status keys: E excellent, G good, B bad, T terrible.
Memory values:
total = Real memory of host
progs = Real memory used by processes, including swappable cache
used = Real memory used by processes, excluding swappable cache
Started at: 17/04/25 04:24:22
lgi15(0) TMPDIR is : /tmp/tempus_temp_20836_lgi15_ark_lEAcvw

============ ======== ======================== ========================
Host          CPU      Memory (GB)              TMPDIR (GB)       (Mb/s)
name(id)      util %   total progs used %used   total   avail     rate
```

```
============ ======== ===== ===== ===== ====== ========================
04:24:52
lgi15(0)         6 E     32    24    15    46 E    100.74  94.67 E  262 E
```

- The following example output shows that host “sjfqos011” has very high CPU utilization (123%) because of multiple clients (client 1 and client 3) running on same host. Also, %used more than 99T shows that the memory is ~100% consumed on the “sjfqos011” and “sjfqos010” host machines.

```
Status keys: E excellent, G good, B bad, T terrible.

report_resource

```
report_resource
[-help]
[-peak]
[-verbose]
[-start string | [-end string [-session_cpu]
[-diff_memory]]]
[-check_MemCpu {true | false} [-period integer]]
```

Displays the peak memory used during a software session. This command is used to measure the peak memory at any given point in the flow and and make the script better for automation flows.

Note: The `report_resource` command is only supported in the 64-bit version of the software and Linux port.

Parameters

`-help`	Outputs the command usage and a brief description about the command parameters.
`-check_MemCpu {true | false}`	Checks the machine's physical memory and CPU resources. When specified, the software enables memory/CPU checking and reports a warning if the free memory is below 5 percent of the total memory or if the average CPU load large.
`-diff_memory`	Outputs different peak memory and current memory between the step start and step end.
`-end string`	Specifies the end point to measure the peak memory attained during a specific command.
`-peak`	Reports current peak memory till a given point in a flow. This parameter also works with the `-start` and `-end` parameters of the `report_resource` command so that peak memory observed by an individual command can be reported.
`-period integer`	Specifies the period for checking the physical memory and CPU usage. *Default*: 1800s *Min*: 1 *Max*: INT_MAX

`-start` *`string`*	Specifies the start point to measure the peak memory attained during a specific command. **Note:** The `-start` and `-end` parameters support any user-specified string, such as fullFlow, timeDesign, and TD_PR. You must specify the same string for both the `-start` and `-end` parameters to measure the peak memory attained during a specific command.
`-session_cpu`	Reports the current CPU and real time after the reports last step status.
`-verbose`	Gives detailed memory usage information. It displays how much memory is being used at any time and of what form (physical vs. virtual). When specified, the following information is displayed: • `Cpu(s)` is the number of available processors in the machine. • `Load` average is the system load averages for the last 1 minute, 5 minutes, and 15 minutes. • `Mem` and `Swap` are the current memory information of the machine. • `Data Resident Set (DRS)` is the amount of physical memory devoted to other than executable code. "`current mem`" shows this value (Total current DRS) . • `Private Dirty (DRT)` is the memory which must be written to disk before the corresponding physical memory location can be used for some other virtual page. "`peak res`" shows this value (Total peak DRT). This is the minimum number that you must reserve to run the program. • `Virtual Size (VIRT)` is the total amount of virtual memory used by the task. • `Resident Size (RES)` is the non-swapped physical memory a task has used. The number of "Total Peak RES" is the recommended physical memory to reserve.

Examples

- The following command script specifies to display the peak memory attained during the `optDesign` command:

  ```
  report_resource -start "optD"
  optDesign
  report_resource -end "optD"
  ```

  The following message is displayed:

  ```
  Ending "optD" (total cpu=0:15:00, real=0:15:09, peak res=468.8M, current
  mem=396.3M)
  ```

- The following command script specifies to display the peak memory attained during the `timeDesign` command:

  ```
  report_resource -start fullFlow
  report_resource -start TD_PR
  timeDesign -postRoute
  report_resource -end TD_PR
  report_resource -start OD_PR
  optDesign -postRoute
  report_resource -end OD_PR
  report_resource -end fullFlow
  ```

  The following message is displayed:

  ```
  Ending TD_PR (total cpu=0:15:00, real=0:15:09, peak res=468.8M, current
  mem=396.3M)
  Ending OD_PR (total cpu=0:15:00, real=0:15:09, peak res=968.8M, current
  mem=796.3M)
  Ending fullFlow (total cpu=0:35:03, real=0:40:09, peak res=968.8M, current
  mem=796.3M)
  ```

- The following command script specifies to display the peak memory attained during the `optDesign` command:

  ```
  report_resource -peak -start optD1
  report_resource -start optD
  optDesign -postRoute
  ```

```
report_resource -end optD
`Ending "optD" (total cpu=0:00:12.9, real=0:00:48.0, peak res=358.8M, current
mem=300.2M)'
report_resource -peak -end optD1
`Ending "optD1" peak res=358.8M'
```

- The following command specifies to display detailed memory information:

  ```
  report_resource -verbose
  ```

  The following output is displayed:

  ```
  Current (total cpu=0:00:23.5, real=0:10:24, peak res=567.8M, current mem=567.8M)

  Cpu(s) 40, load average (past 1 minute): 7.41, load average (past 5 minutes):
  7.46, load average (past 15 minutes): 7.52
  Mem: 527321900k total, 317217944k used, 210103956k free, 3752k buffers
  Swap: 134217724k total, 0k used, 134217724k free, 183952200k cached

  Memory Detailed Usage :
                   Data Resident Set(DRS)  Private Dirty(DRT)  Virtual Size(VIRT)
  Resident Size(RES)
  Total current :   642.3M                 155.6M              1743.3M
   567.8M
  peak :            642.3M                 155.6M              1743.3M
   567.8M
  ```

setDistributeHost

```
setDistributeHost
[-help]
[-add string]
[-args string]
[-custom]
[-custom_script string]
[-custom_script_list string]
[-local]
[-lsf]
[-nc]
[-noWaitTaskComeUp]
[-queue string]
[-remove string]
[-reportLsfInfo]
[-resource string]
[-rsh]
[-shellTimeout integer]
[-single_cpu_lsf_args string]
[-ssh]
[-timeOut integer]
[-env_script string]
```

Specifies the multiple-CPU processing configuration for distributed processing or Superthreading. The software finds hosts from the last `setDistributeHost` command specified before a distributed processing or Superthreading command starts.

Use `getDistributeHost` to display the current settings for the `setDistributeHost` command.

> This command is required for distributed processing and Superthreading.

Parameters

`-help`	Prints out the command usage.

`-add` *string*	Adds the specified hosts to the `rsh/ssh` configuration. If you specify more than one host, separate each host name with a space.
	Each time you specify a host, the software uses it to run one client process. To run more than one client process on a host, specify it more than once. For example, if you have two machines that each has two CPUs and you want to use both CPUs in both machines, type a command like the following:
	`setDistributeHost -rsh -add {machine1 machine2 \`
	`machine1 machine2}`

`-args` *string*	Specifies any additional arguments you need to provide to the Sun Grid Engine (SGE) or Load Sharing Facility (LSF) job submission command.
`-custom`	Specifies to use the custom job submission script for distributed processing.
`-custom_script` *string*	Specifies a custom script to run distributed processing. You can use this parameter with `-custom` only.
`-custom_script_list` *string*	Specifies to customize the launch of multiple jobs, based on resources required for these jobs. This parameter allows you to specify multiple launch strings in order of priority with a maximum allowed job count for each string. If you request for N number of jobs, the command starts submitting jobs starting from *string1* , until the corresponding count is reached, at which point it starts submitting the next string in the list. Therefore, the command submits the first " *count1* " jobs with *string1* , the next " *count2* " jobs with *string2* and so on. It stops when the total submitted jobs has reached the requested number (N). **Note**: This parameter can only be specified with the `-custom` parameter.

`-env_script` *string*	Specifies a user-defined shell environment script that is run for each of the slave hosts. The parameter allows you to pass these environment settings to the slave hosts by including them in the shell environment script. The license variables used by the software are also automatically passed to the slave hosts to avoid license errors.
`-local`	Runs all distributed processing jobs on the master machine.
`-lsf`	Specifies a Load Sharing Facility configuration. If you do not specify any parameters for `-lsf`, the software uses default settings. **Note:** To use this parameter, LSF must already be set up (typically by specifying the LSF_ENVDIR and LSF_SERVERDIR environment variables) and bsub must be in your search path. Contact your LSF administrator for details.
`-nc`	Uses NC commands (Network Computer from RTDA) for distributed processing.
`-noWaitTaskComeUp`	Does not allow the software to wait for tasks that are delayed or are not likely to occur.
`-queue` *string*	Specifies the queue for the LSF or SGE configuration.
`-remove` *string*	Removes the specified hosts or all hosts from the `rsh/ssh` configuration. If you specify more than one host, separate each host name with a space.

`-reportLsfInfo`	Specifies to report LSF information in a single report. This parameter allows you to collect the system statistics on the status of the distributed jobs. It has the following information: • Host name for master and LSF tasks • Number of CPUs on each machine that are being used by a process • Job ID/PID for each task process • Total memory used on each machine • Total virtual memory used on each machine • Total CPU time used on each machine You must specify this parameter with the `-lsf` parameter. To get the LSF information, specify the `getDistributeHost -reportLsfInfo` command parameter. You must specify the `getDistributeHost -reportLsfInfo` only after the LSF tasks exit to obtain the task CPU time. If you specify this command before the task exits, the command gives a warning message.
`-resource` *string*	Specifies a resource string for the SGE or LSF queue. **Note:** The correct resource string is specific to your installation. Contact your LSF administrator for the appropriate parameters and values.
`-rsh`	Specifies a remote shell configuration. For information, see the `rsh` documentation.
`-shellTimeout` *integer*	Specifies the number of seconds the host machine waits for `rsh/ssh` machines to become available for multiple-CPU processing. *Default:* `5`
`-single_cpu_lsf_args` *string*	Specifies the `bsub` options. For information, see the LSF documentation. **Note:** You must use this parameter to adjust the LSF argument for a single CPU application. Alternatively, use the `-args` parameter to adjust the LSF argument for an application that runs in the Superthreading mode.
`-ssh`	Specifies a secure shell configuration.

`-timeout` *integer*	Specifies the default timeout for a submitted job that will never start. This functionality prevents the master machine from hanging when the clients do not come up for some reason. After timeout, a warning message appears informing you that the distributed CPUs did not come online within the expected time. The master will continue waiting for the clients and it is up to you to continue waiting or kill the run if there are problems with the Distributed Resource Management (DRM) system. A sample warning message is given below: Task id 2 did not come up within the specified timeout period (300 seconds). Use `setDistributeHost -timeout` to change the value. This may be a real error due to incorrect or incomplete platform/machine specification provided via setDistributeHost to your distributed resource management system (LSF/Sun Grid Engine etc.). If running locally (`setDistributeHost -local`), the current machine may be overloaded with too many jobs and swapping (check free memory and CPUs with top). For local runs, consider reducing the number of CPUs you are using via the setMultiCpuUsage command or free up some memory by killing other memory intensive processes. *Default:* 3600 for all the modes (LSF, NC, SGE, RSH, SSH, local and custom **Note**: When the `set_distribute_host` command is not specified, the software sets the default mode as local and the EDP timeout is `3600` seconds.

Examples

rsh

The following command creates an `rsh` configuration and adds hosts `host10`, `host11`, and `host12`:

```
setDistributeHost -rsh -add {host10 host11 host12}
```

The following commands create an `rsh` configuration with `host1` and `host2` as remote hosts and then adds `host3` and `host4` to the configuration:

```
setDistributeHost -rsh -add {host1 host2}
```

```
setDistributeHost -rsh -add {host3 host4}
```

LSF

The following command uses an existing LSF environment, and relies on the general LSF set up by the system administrator. In this example, the name of the queue implies that all the machines have 4 Gb of memory.

```
setDistributeHost -lsf -queue mem4G
```

The following command schedules a LSF job named `bigQueue` to run on a Linux machine for a maximum of 30 minutes. No other jobs can run on the machine while `bigQueue` is running.

```
setDistributeHost -lsf -queue bigQueue -args {-x -W 30} \
   -resource {OSNAME==Linux}
```

The following command schedules a LSF job named `smallQueue` to run on Linux machines with minimum speed of 2000 MHz.

```
setDistributeHost -lsf -queue smallQueue -args {-W 20} \
    -resource {OSNAME==Linux && SPEED>2000}
```

Note: Check with your LSF administrator for the correct values for the resource string, as the parameters and their values differ in each installation. For example, the parameter name for the speed of the machine might be `MHZ` instead of `SPEED` (as in the preceding example), and the units might be specified in gigahertz instead of megahertz.

The following command specifies to report LSF information:

```
setDistributeHost -lsf -args "-q lnx64" -reportLsfInfo
getDistributeHost -reportLsfInfo lsf.log
```

Note: Use the above two commands together to save the LSF information in the specified file.

Local

The following command runs all distributed processing jobs on the machine on which you are running the master version of the software:

```
setDistributeHost -local
```

Custom

The following command runs distributed processing with a custom script:

```
setDistributeHost -custom -custom_script {bsub -q bigQueue -x -R "OS==Linux && memory>20000"}
```

The following command runs distributed processing with a custom script list:

```
setDistributeHost -custom -custom_script_list {{{bsub -P ICD -W 2 -q admin -R "OSNAME==Linux && OSREL==EE50"}1} {{rsh hpc1 -e} 1}}
```

Examples

- The following command allows the client to source the `my_env_file` before start up on the same machine:

  ```
  setDistributeHost -local -env_script my_env_file
  ```

  This command allows the master to pass on the user-defined environment settings.

- The following command allows the client to run using the LSF:

  ```
  setDistributeHost -lsf -noWaitTaskComeUp
  ```

  When the `-noWaitTaskComeUp` parameter is specified, the software will not wait for all the clients to come up when parts of the clients are launching timeout.

  - Set Multiple CPU Usage
- `getDistributeHost`

setMultiCpuUsage

```
setMultiCpuUsage
[-help]
[-acquireLicense <integer>]
[-autoPageFaultMonitor {0 1 2 3}]
[-cpuPerRemoteHost <integer>]
[-keepLicense {true false}]
[-licenseList <string>]
[-localCpu <string>]
[-releaseLicense]
[-remoteHost <integer>]
[-reset]
[-threadInfo {0 1 2}]
[-verbose]
```

Specifies the number of threads to use for multi-threading, or the maximum number of computers to use for distributed processing, or the maximum number of computers and the number of threads to use for Superthreading. Optionally, reports usage information.

This command is required for multi-threading, distributed processing, and Superthreading.

The `setMultiCpuUsage` command enables multi-threaded timing reporting under the following conditions:

- `timing_report_group_based_mode` global variable is set to `true`. If there are multiple paths with the same slack then the selection can change on multiple runs. This may result in some changes in the `report_timing` output.
- `report_analysis_coverage` command is in non-verbose mode.
- `check_timing -include clock_crossing` parameter is specified.
- `-set_table_style -no_frame_fix_width` parameter is specified.

Parameters

`-help`	Outputs the command usage and a brief description about the command parameters.

`-acquireLicense` *integer*	Acquires licenses to enable the specified number of CPUs. For example, if you specify `-acquireLicense 5`, the software checks out enough licenses to enable 5 CPUs. After the licenses are checked out, they can be used for multi-threading, distributed processing, or super-threading.
`-autoPageFaultMonitor {0 | 1 | 2 | 3}`	Specifies to set a warning rank for performance issues caused by major page faults. The parameter supports the following values: • 0 - specifies to disable the reporting of major page faults. • 1 - specifies to set the warning rank as 1. This means PF/total PF > 0.8, b > 10, and wa > 85% • 2 - specifies to set the warning rank as 2. This means PF/total PF > 0.5, b > 5, and wa > 65% • 3 - specifies to set the warning rank as 3. This means PF/total PF > 0.2, b > 1, and wa > 40% where PF is the number of major page faults from the software, total PF is the total number of major page faults in the machine, b is the number of blocked processors, and wa is CPU waiting time.
`-cpuPerRemoteHost` *integer*	Specifies the number of CPUs used by clients for multi-threading. **Note:** For super threading, you must use this parameter in conjunction with the `-remoteHost` parameter. *Default:* 1
`-keepLicense {true | false}`	Specifies whether to keep the acquired multiple CPU-licenses until the current session ends. Specify this parameter before running any commands that require multiple-CPU applications. To release all multiple-CPU licenses immediately, use the `-releaseLicense` option. *Default:* `true`

`-licenseList {tpsmp}`	Specifies the list or order of licenses the software should use for checking out licenses during multiple-cpu processing. The parameter does not support an empty license list {}. This parameter allows the `tpsmp` option.
`-localCpu` *string*	Specifies the number of CPUs on a local machine. When the `-localcpu` parameter is set to `1` (default), the multi-threaded timing propagation mode is enabled. Also, both CPU multi-threading and distributed process are enabled. The `set_multi_cpu_usage -localCpu` command automatically controls the total number of threads used up to the specified number. The number of specified threads cannot be more than the number of CPUs available in the local computer. Consider a computer having 8 CPUs, then the following command will issue a warning that the number of specified local CPUs is greater than the actual number of CPUs available: `set_multi_cpu_usage -localCpu 10` The local CPU count can be the maximum value that is shown as “processors” on the system under “/proc/cpuinfo”. This value can be obtained by running the “checkSysConf” utility in the "tools/bin" folder. `$> tools/bin/checkSysConf` `============== checkSysConf: Version 3.53 ====================` `OS Version .............: Red Hat Enterprise Linux Workstation release 7.6 (Maipo)` `Kernel Version .........: 3.10.0-957.5.1.el7.x86_64` `Hardware Type ..........: x86_64` `Memory .................: 2063415 Megabyte` `CPU model ..............: Intel(R) Xeon(R) Gold 6254 CPU @ 3.10GHz` **`No. of CPUs ............: 72`** `Total Swap Space........: 131072 Megabyte` `==================================` `$> cat /proc/cpuinfo	grep "processor"	tail -1	awk -F ":" '{print $2 + 1}'` `72` *Default*: 1

`-releaseLicense`	Releases all multiple-CPU license(s) immediately. By default, the software holds multiple-CPU licenses until the end of the current session. To specify that the software release multiple-CPU licenses after every multiple-CPU command runs, use `-keepLicense`.
`-remoteHost` *integer*	Specifies the number of clients. This parameter is required for distributed processing and super threading. *Default:* 0
`-reset`	Resets the specified parameters back to default values.

`-threadInfo {0 | 1 | 2}`	Reports usage information.
	
	Default: 0
	
	Specify one of the following values:
	
	`0`: Does not write messages to the log file.
	
	`1`: Writes the final message to the log file.
	
	For example,
	
	All threaded jobs finished (10 elapsed sec: 0 processor sec (parent), 0 system sec (parent), 0 processor sec (threads), 0 system sec (threads)).
	
	`2`: Writes additional starting/ending information for each thread.
	
	For example,
	
	`Starting threaded job 1...`
	`Starting threaded job 2...`
	`Starting threaded job 3...`
	`Ending threaded job 2 (1 elapsed sec, 0 processor sec, 0 system sec, 1.160M).`
	`Ending threaded job 3 (2 elapsed sec, 0 processor sec, 0 system sec, 0.895M).`
	`Ending threaded job 1 (10 elapsed sec, 0 processor sec, 0 system sec, 1.172M).`
	`All threaded jobs finished (10 elapsed sec: 0 processor sec (parent), 0 system sec (parent), 0 processor sec (threads), 0 system sec (threads)).`

`-verbose`	Displays messages when changing the multiple-CPU settings.

Examples

To run global placement with the maximum number of 4 threads, specify the following commands:

```
setMultiCpuUsage -localCpu 4
place_design
```

To run global placement with the maximum number of available threads, specify the following commands:

```
setMultiCpuUsage -localCpu max
place_design
```

To run detailed routing with the NanoRoute router in Superthreading mode with two machines and six threads, using an LSF queue, specify the following commands:

```
setDistributeHost -lsf -queue myLSFqueue
setMultiCpuUsage -remoteHost 2 -cpuPerRemoteHost 6
detailRoute
```

22

OpenAccess Commands

- add_oa_library_property
- compare_cellview
- copyOaRestoreFiles
- createLib
- dd_get
- get_oa_default_rule_lib
- getOaxMode
- oaIn
- oaOut
- registerTrigger
- report_oa_lib
- save_abstract
- saveOaBlackboxes
- set_cell_binding
- setOaxMode
- unlockOaDesign
- update_oa_lib
- write_lef_library
- write_oa_techfile

add_oa_library_property

```
add_oa_library_property
[-help]
-lib libName
-name prop_name
-type {boolean integer float string}
-value propValue
```

Adds a new property to the specified OpenAccess library. This command cannot be used to change the value of an existing property.

Note: You cannot use the name `techLibName` for the property you are adding because this name is used by the OpenAccess infrastructure to store the property attached to the library.

Parameters

`-help`	Prints a brief description that includes type and default information for each `add_oa_library_property` parameter. For a detailed description of the command and all of its parameters, use the man command: `man add_oa_library_property`.
`-lib libName`	Specifies the name of the OpenAccess library to which the property has to be added.
`-name prop_name`	Specifies the name of the property being created.
`-type {boolean integer float string}`	
	Specifies the type of the property being created.
`-value propValue`	Specifies the value to be set for property being created. The value is interpreted from the input string and converted to the specified type.

Example

In Innovus, the following set of commands creates a library named *myLib*, adds the *prop1* property to it, and saves the design before exiting:

```
createLib myLib -attachTech adiTech

add_oa_lib_property -lib myLib -name prop1 -type string -value value1

saveDesign -cellview {myLib block1 layout}

exit
```

You can now add more properties to the library in Virtuoso. When you restore the design in Innovus, all properties previously added to the library, whether in Innovus or Virtuoso, reflect correctly.

Related Information

- `createLib`

compare_cellview

```
compare_cellview
[-help]
[-ignore {pin_purpose}]
[-log report_file_name]
{ {{-source {from_lib from_cell from_view} -compare {to_lib to_cell to_view}} | {-lib lib -cell cell -view
{sourceView compareView}}} }
```

Compares the boundary and terminal (name, direction, layer, location, size, and port) of the specified cell views. In addition, if both cell views are identified as abstract, the command also compares cell type, symmetry, and obstructions.

Use this command to compare two OpenAccess databases. For instance, you can use this command to compare the lib/cell/view specified using `-source` to the lib/cell/view specified with `-compare`. Typical uses are comparing two versions of a layout cell view or comparing an abstract cell view to a layout cell view.

This command can be used without design import.

Parameters

`-help`	Prints a brief description that includes type and default information for each `compare_cellview` parameter. For a detailed description of the command and all of its parameters, use the man command: `man compare_cellview`.
`-cell` *`cell`*	Specifies the cell for comparing two views.
`-compare {`*`to_lib to_cell to_view`*`}`	Specifies the library/cell/view that is to be compared.
`-ignore {pin_purpose}`	Specifies the list of attributes to be excluded from the cell comparison. As of now, the only attribute that can be ignored is the purpose, which is specified using the value `pin_purpose` with `-ignore`.
`-lib` *`lib`*	Specifies the library for comparing two views.
`-log` *`report_file_name`*	Specifies the report file in which all the comparison detail is to be written.
`-source {`*`from_lib from_cell from_view`*`}`	Specifies the source library, cell, and view.
`-view {`*`sourceView compareView`*`}`	Specifies different views of the same library/cell.

Examples

- The following command compares two views of the same cell that are present in the same library `zambezi45` and writes the report to the `test1a` file:

```
compare_cellview -source {zambezi45 pll_vcodiv layout} -compare {zambezi45 pll_vcodiv abstract} -log test1a
```

A sample output is displayed below:

```
################################################
# #
# Compare_cellview comparison #
# #
################################################

Source Design : 'zambezi45/pll_vcodiv/layout' is identified as layout design
Compare Design : 'zambezi45/pll_vcodiv/abstract' is identified as abstract design

Source Design seems to have been modified after the Compare Design has been created

Compare Celltype

Source Design has celltype 'none' & Compare Design has Celltype 'block'

Compare Cell Boundary

Source Design has different PRBoundary than Compare Design

Compare Terminals

Source Design has Pin 'en' which has Port with shape (36.215 0 36.355 0.14) on layer 'Metal5' and purpose
'pin' is not present in Compare Design
Compare Design has Pin 'en' which has a Port with shape (36.215 0 36.36 0.14) on layer 'Metal5' and purpose
'net' is not present in Source Design
...

Antenna Information

Antenna Information is defined for Pin 'en' in Compare but not defined in Source Design
Antenna Information is defined for Pin 'vcocalen' in Compare but not defined in Source Design
...

Source Design is not equivalent to Compare Design
```

- The following command compares the views `fplan1` and `fplan2` of the library `DesignLib` and the cell `myAlu`:

```
compare_cellview -lib DesignLib -cell myAlu -view {fplan1 fplan2}
```

copyOaRestoreFiles

```
copyOaRestoreFiles
fromLib fromCell fromView
toLib toCell toView
```

Copies Innovus-specific restore files from one OpenAccess database to another. The software copies all of the files (except `master.tag` and `layout.oa`) and renames those with the `cell` to match the `toCell` cell name. This feature supports the ECO flow, where a cellview saved with the `saveDesign` command and set of restore files is edited by an external tool (Virtuoso® Chip Editor), then saved to a new database to avoid overwriting the unedited version. The external tool does not copy the restore files to the new cellview.

If the originating database does not contain restore files (such as `cell.conf`, `cell.mode`, `siFix.options`, and `enc.pref.tcl`, then the software generates an error message such as the following:

```
ERROR: No restore Files found at specified source
/usr4/Tests/CE/OA22/PC44d_test/mydesign/top/layout
```

If the destination OpenAccess database already contains restore files, the software generates a warning message and overwrites the files.

You can use the `copyOaRestoreFiles` command after you start a new Innovus session, and before you use the `restoreDesign -cellview` command.

Parameters

fromLib fromCell fromView	Specifies the location of the files to copy. This is the design from the previous Innovus session.
toLib toCell toView	Specifies where to copy the files. This refers to the new design.

Examples

- The following command copies Innovus-specific restore files from `myDesign/topCell/layout` to `newDesign/newTopCell/newLayout`:

  ```
  copyOaRestoreFiles myDesign topCell layout newDesign newTopCell newLayout
  ```

- The following procedure performs ECOs with the Virtuoso Chip Editor:

  1. From an Innovus session, save the OpenAccess design.

     ```
     saveDesign -cellview {lib cell view}
     ```

  2. Exit the Innovus session.
  3. Open the OpenAccess database in the Virtuoso Chip Editor tool and edit the design. Exit the tool.
     Note: You must use either of the following: Virtuoso Chip Editor, Virtuoso Layout XL , or Virtuoso Layout GXL.
  4. Start an Innovus session.
  5. Copy Innovus-specific files from the old design to the new design.

     ```
     copyOaRestoreFiles fromLib fromCell fromView toLib toCell toView
     ```

  6. Restore the OpenAccess design.

     ```
     restoreDesign -cellview {lib cell view}
     ```

Related Information

- restoreDesign
- saveDesign

createLib

```
createLib
[-help]
libName
[-libPath path]
[-noCompress]
{-attachTech techlib |
-copyTech techlib |
-referenceTech techliblist}
```

Copies or attaches a technology database to a library. If the library exists, this command does not update the library.

Note: The parameters must appear in the order specified by the syntax.

The `createLib` command is part of the OpenAccess design flow. Use this command to create an OpenAccess library at the specified path. `createLib` needs to be called only once before the design is saved. Subsequent `saveDesign` calls to the same library will automatically find out the library path that gets stored in `cds.lib`.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `createLib` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man createLib`.
`libName`	Specifies the name of a library to be created. The software creates the library and adds its name to the `cds.lib` file.
`-libPath` *`path`*	Specifies the name of a directory in which to save the library. The path you specify must include the directory that will become the library itself. *Default:* *`./libName`* (Saves the library to the current working directory)
`-noCompress`	Creates a new library without any compression irrespective of the compression settings provided by the `setOaxMode` command.
`-attachTech` *`techlib`*	Attaches the technology database specified by the technology library to the library that is to be created.
`-copyTech` *`techlib`*	Copies the technology database specified by *`techLib`* to the library specified by *`libName`*, and saves the library to the current working directory.
`-referenceTech` *`techliblist`*	Creates a local technology database in the design library that can be modified incrementally.

Examples

- The following command creates the library `myLib` in the current directory, and attaches the technology database in `myRefLib` to `myLib`:

  ```
  createLib myLib -attachTech myRefLib
  ```

  Note: Note: If `myRefLib` is read-only, the `saveDesign -cellview` command generates an error if it needs to update the technology database.
- The following command creates the library `TEST_LIB` at the specified path, and attaches the technology database in `TEST_REF_LIB` to TEST_LIB:

  ```
  createLib TEST_LIB -libPath ./outputs/TEST_LIB -attachTech TEST_REF_LIB
  ```
- The following command generates an error because only one reference library can be specified:

  ```
  createLib myLib -attachTech {myRefLib1 myRefLib2}
  ```
- The following command creates the library `myLib`, and copies the technology database from `myRefLib` to `myLib`. If `myRefLib` is modified, the two technology databases will become out of sync. Additionally, any future write operations from the `saveDesign -cellview` command will modify the technology database copy in `myLib` and also cause the databases to be out of sync.

  ```
  createLib myLib -copyTech myRefLib
  ```
- The following command creates a new library which references existing technology databases (`refLib1` and `refLib2`), but allows local technology updates if required (typically to add new custom vias to the local technology database).

  ```
  createLib myLib -referenceTech {refLib1 refLib2}
  ```

- `saveDesign`
- `setOaxMode`

dd_get

```
dd_get
{-all_lib} |{-dd dd_objHandle | -lib libName | -cell {lib cell} | -cellview {lib cell view} }
[-children | -file | -path | -type |-name]}
```

Returns OpenAccess library information.

Parameters

`-all_lib`	Returns a list of design data (`dd`) object handles for the list of libraries present in the library definition file (`cds.lib`).
`-cell {lib cell}`	Specifies the names of the library and cell to be processed.
`-cellview {lib cell view}`	Specifies the names of the library, cell, and view to be processed.
`-children`	Returns the `dd` object handles of the children of the specified `dd` object handle. Children of libraries are cells. Children of cells are views.
`-dd dd_objHandle`	Specifies the `dd` object to be processed.
`-file`	Returns the `dd` object handles of all the files in the specified `dd` object handle.
`-lib libName`	Specifies the name of the library to be processed.
`-name`	Returns the name of the specified `dd` object handle.
`-path`	Returns the absolute path name (`dd` path) of the specified `dd` object handle.
`-type`	Returns the type of the specified `dd` object handle.

Examples

- The following command returns the path of the library/cell/view as shown below:

  ```
  dd_get -cellview {pdkLib cell1 abstract} -path
  ```

  returns:

  ```
  /libs/pkdLib/cell1/abstract
  ```

  This command is equivalent to the following SKILL function:

  ```
  ddGetObjReadPath(ddGetObj("pdkLib" "cell1" "abstract"))
  ```

- The following proc traverses the cds.lib structure (expanding #INCLUDE as required) to get the complete list of OpenAccess libraries and their full paths:

  ```
  # expand #INCLUDE as needed and print all libraries and their full paths
  proc print_all_lib_paths {} {
     puts [format "%16s -> %s" "Library Name" "Library Path"]
     puts "-----------------------------------------------------------------"
     foreach oa_lib [dd_get -all_lib] {
         puts [format "%16s -> %s" [dd_get -dd $oa_lib -name] [dd_get -dd $oa_lib -path]]
     }
  }
  ```

get_oa_default_rule_lib

```
get_oa_default_rule_lib
[-help]
[-rule rule_name]
[-libs lib_list]
[-verbose]
```

Searches through a specified library (or libraries) to check whether a specified LDRS exists or not. You can run this check before reading a library.

Parameters

`-help`	Prints a brief description that includes type and default information for each `get_oa_default_rule_lib` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man get_oa_default_rule_lib`
`-libs lib_list`	Specifies the list of library names to search through. If not specified, all libraries are searched.

`-rule rule_name`	Specifies the name of the rule to find.
	If not specified, the `init_oa_default_rule` variable is used. If the variable has an empty string value, the standard lookup (`LEFDefaultRouteSpec` by type, then by name) is used.
	If the specified *`rule_name`* does not exist, the command displays an error such as:
	`Rule '<rule_name>' was not found in specified libraries.`
	If the specified *`rule_name`* is found, the command returns the name of the library where the specified *`rule_name`* was found. This could be from the `-libs lib_list` or any ITDB that one of those libraries refers to.
	If the specified *`rule_name`* is found but is not a legal LDRS type as determined by the OAX reader code, the command displays an error such as:
	`Constraint group '<rule_name>' was found in library '<lib_name>', but is not a legal LEFDefaultRouteSpec`

`-verbose`	Echoes details of library name where the rule was found (including descending through technology references from libraries specified in the *`lib_list`*.

Examples

- The following example shows how `get_oa_default_rule_lib` can be used to search for a specific library and the graph of techs that it references:

```
set init_oa_ref_lib "tech_lib macro_lib"
set init_oa_default_rule LDRS_65nm_61m
set tech_lib [lindex $init_oa_ref_lib 0]
set lib_found [get_oa_default_rule_lib -libs $tech_lib] # use the init_oa_default_rule to look up the library
if {$lib_found != ""} {
Puts "$init_oa_default_rule was found in $lib_found or in the graph of libraries that $tech_lib references"
} else {
Puts "$init_oa_default_rule was not found in $tech_lib nor in the graph of libraries that $tech_lib
references"
}
```

- The following command shows how the `-verbose` option can be used:

```
get_oa_default_rule_lib -verbose
INFO: Default rule 'LEFDefaultRouteSpec' was found in library 'FEOAreflib8'.
FEOAreflib8
```

Related Information

- `init_oa_default_rule`
- `init_oa_ref_lib`

getOaxMode

```
getOaxMode
[-help]
[-allowAnalysisOnly]
[-allowBitConnection]
[-allowTechUpdate]
[-bindkeyFile]
[-compressLevel]
[-convertTo]
[-cut_pg_rail]
[-cutRows]

[-silently_ignore_unsupported_vias]
[-textPurpose]
[-tieNet]
[-updateMode]
[-useVirtuosoBindkey]
[-useVirtuosoColor]
[-viewSubType]
[-quiet]
```

Displays information about a specified OpenAccess mode parameter in the log file and at the console. The following information is included:

- Parameter name
- Current value
- Type (Boolean, string, and so on)
- Whether the current value was set by user

If you do not specify a parameter, the software displays information for all of the OpenAccess mode parameters.

Parameter

`-help`	Outputs a brief description that includes type and default information for each `setOaxMode` parameter. For a detailed description of the command and all of its parameters, use the man command: `man getOaxMode`.
`parameter_name`	Displays information for the specified parameters. You can specify one or more parameters. See `setOaxMode` for descriptions of the OpenAccess mode parameters you can specify.
`-quiet`	Displays the current settings for the specified parameters in Tcl list format only. If you specify `-quiet` without any parameters, the software displays the current settings of all `setOaxMode` parameters in Tcl list format.

Examples

- The following command displays the current setting of the `-fullPath` parameter:

  ```
  getOaxMode -fullPath
  ```

  The software displays the following information:

  ```
  -fullPath false # bool, default=false
  false
  ```

- The following command displays the current settings for all `setOaxMode` parameters:

  ```
  getOaxMode
  ```

- The following command displays the current setting for the `-fullPath` parameter in Tcl list format only:

  ```
  getOaxMode -fullPath -quiet
  ```

  The software displays the following information:

  ```
  false
  ```

- The following command displays the current settings for all `setOaxMode` parameters in Tcl list format only:

  ```
  getOaxMode -quiet
  ```

Related Information

- `setOaxMode`

oaIn

```
oaIn
[-help]
lib
cell
view
[-filter {block_insts blockages boundary fixed_core_insts floorplan pad_insts pin_shapes regions regular_routing
special_routing bump_insts}]
[-net {netnames}]
```

Restores floorplan, placement, and routing data using the OpenAccess format. This command only reads physical information from the OpenAccess database. For information on restoring an OpenAccess database, see restoreDesign.

You can use the `oaIn` command after importing the design.

Notes

- Innovus supports only the following begin/end extension values for DEF `NETS` style wiring segments: 0, width/2 or LEF `LAYER WIREEXTENSION`. If any of the wire extensions has unsupported extension value, then Innovus converts it to a special wire (DEF `SPECIALNETS`). While writing back OpenAccess (`oaOut` or `saveDesign -cellview`), these special wires will again be converted back to DEF `NETS` style wiring.
- `oaIn` issues an error if the `DESIGNRULEWIDTH` attribute is specified in blockage for 20nm and below design nodes. As a lot of spacing rules in advanced nodes no longer just rely on wire width, `DESIGNRULEWIDTH` is not allowed for 20nm and below nodes and a `SPACING` override should be used instead.

Parameters

`-help`	Outputs a brief description that includes type and default information for each parameter of the `oaIn` command. For a detailed description of the command and all of its parameters, use the `man` command: `man oaIn`.
`lib`	Specifies the OpenAccess library name.
`cell`	Specifies the name of the top cell to import.
`view`	Specifies cell view name to import.
`-filter {block_insts blockages boundary fixed_core_insts floorplan pad_insts pin_shapes regions regular_routing special_routing bump_insts}`	

	Lists the OpenAccess cellview information data to be read. When not specified, all information is read from the OpenAccess cellview. When `-filter` is specified, only the object types that are chosen will be read. Additionally, when reading pin_shapes or instances, information in the cellview that refers to terminals or instances that do not exist in memory will be ignored. The legal `-filter` options are: • `block_insts` - Indicates that any CLASS BLOCK instances should be updated. Physical-only block instances may be added to the database if the placement status is `fixed` or `cover`. • `blockages` - Indicates that blockages should be processed. If a blockage is attached to an instance that does not exist in the in-memory database, then it is ignored. • `boundary` - Indicates that the design boundary information, including rows and tracks, should be updated. When `boundary` is specified, the design boundary, rows and tracks are created from the new boundary. • `fixed_core_insts` - Indicates that any CLASS CORE instances that have placement status `fixed` or `cover` should be updated. Physical-only core instances may be added to the database if the placement status is `fixed` or `cover`. • `floorplan` - Is equivalent to specifying "`block_insts blockages boundary fixed_core_insts pad_insts pin_shapes regions special_routing`" • `pad_insts` - Indicates that any CLASS PAD instances should be updated. Physical-only pad instances may be added to the database if the placement status is `fixed` or `cover`. • `pin_shapes` - Indicates that pin shapes should be read. When `pin_shapes` is specified, the existing pins are replaced by the ones being read from the cellview. • `regions` - Indicates regions should be updated. • `regular_routing` - Indicates that nets should be processed and regular routing (and associated shield net wiring) and net constraints updated. • `special_routing` - Indicates that nets should be processed and special routing (except shield nets wiring) should be read. • `bump_insts` - Indicates that bump instances from the cell view need to be read. Use `oaIn -filter` to read floorplanning information from a cellview whose connectivity does not match the current Innovus in-memory connectivity. The`-filter` option allows you to load some data selectively, while not loading others. When `-filter` is used, error checking for database consistency (nets, instances, terminals, etc.) is disabled. While similar to Virtuoso Load Physical View (LPV), the `-filter` option is only a subset and not intended to be a complete replacement.
`-net {`*`netnames`*`}`	
	Specifies the list of nets whose routing (routing and special) and constraints have to be read with the `-filter` option. Shielding wiring/vias are also read in if they are used to shield any of the specified nets. If this option is used, typically `regular_routing` is not specified as part of the `-filter` objects.

Example

- The following command restores data using OpenAccess:
  ```
  oaIn design amba_usb layout
  ```

oaOut

```
oaOut
[-help]
lib
cell
view
[-autoRemaster]
[-copyTechFromReflib]
[-cutRows]
[-early_global_route]
[-leafViewNames {lefView1 lefView2 ...}]
[-noConnectivity [-noStdCells]]
[-noOverwriteAbstract]
[-refLibs {refLib1 refLib2 ...}]
```

Saves floorplan, placement, and routing data in the OpenAccess format.

You can use the `oaOut` command after importing the design.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `oaOut` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man oaOut`.
lib	Specifies the target OpenAccess library name.
cell	Specifies the target cell name.
view	Specifies the target view name.
`-autoRemaster`	Overrides the reference libraries and leaf view names specified binding, and utilizes the cell layout viewing binding stored on the library cell master for each leaf cell (stored in the library cell's layout library and layout view attributes). The binding can be specified using the `set_cell_binding` command.
`-copyTechFromReflib`	Copies the technology file to the current design library. *Default:* If you do not specify this parameter, Innovus attaches the technology to the current design library. **Note:** This parameter applies only when you create libraries.
`-cutRows`	Specifies that rows are cut against placement obstructions and block halos, similar to the behavior of the `defOut` command. *Default:* Does not cut rows.
`-early_global_route`	Writes out a design containing Early Global Route data.
`-leafViewNames {lefView1 lefView2 ...}`	
	Specifies a list of view names to be searched during leaf cell instance binding.

`-noConnectivity`	This option should be used if the OpenAccess layout cellviews that are being used in remastering (-autoRemaster or -refLibs/-leafViewNames) do not have any terminals (as is the case when the layout cellview is created from GDSII/Stream data), in which case it is not possible to maintain netlist connectivity. Writes out a design that contains instances and physical shapes. When specified, the software creates an OpenAccess module domain using the instance hierarchy, but does not attempt to create any nets, pins, or instance pins.  Designs written out using the `-noConnectivity` parameter cannot be reloaded into the Innovus software.
`-noOverwriteAbstract`	Prevents the software from overwriting abstracts of partitions and blackboxes. *Default:* Innovus overwrites abstracts of partitions and blackboxes. Innovus never overwrites abstracts of library data.
`-noStdCells`	Does not save instances of core cells to the OpenAccess database. However, if an instance is either fixed or covered, it is saved to the database. Use this parameter if you just need the preliminary design for DRC checks of the floorplan. In such cases, leaving out the standard cell information makes the file smaller and reduces the DRC run time. **Note**: The `-noStdCells` parameter must be used with the `-noConnectivity` parameter.
`-refLibs {`*`refLib1 refLib2 ...`*`}`	
	Specifies the names of the external libraries that will contain the leaf cell masters, LEF abstract, and technology file. This parameter only accepts library names, not paths. The mapping between the external library name and its path is defined in the `cds.lib` file. Innovus references technology information only from the first library in the list of libraries.

Example

- The following command shows the usage of ITDB style libraries:

```
createLib myDesignLib -referenceTech {techLib}
oaOut -autoRemaster myDesignLib myTopCell layout
```

registerTrigger

```
registerTrigger
[-help]
[{-pre | -post}
commandName
procName]
```

Registers the `-pre` or `-post` callback procedures with the specified commands.

The procedure registered with `-pre` parameter runs before the *`command_name`* parameter is used while the procedure registered with `-post` parameter runs after the *`command_name`* parameter is used.

Note: The arguments passed to *`command_name`* are passed to *`procedure_name`*. If the procedure registered with the `-pre` parameter returns a `TCL_ERROR`, then *`command_name`* is not run.

You can use the `registerTrigger` command after starting the Innovus software.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `registerTrigger` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man registerTrigger`.
`-pre`	Specifies the procedure to be called before the command.
`-post`	Specifies the procedure to be called after the command.
`commandName`	Specifies the command name. The supported command names are `saveDesign`, `restoreDesign`, `oaIn`, and `oaOut`.
`procName`	Specifies the procedure name that is to be registered as callback.

report_oa_lib

```
report_oa_lib
[-help]
lib_name
[-header]
[-filter {cdsinfo | compression | constraint_groups | property | tech_graph}]
```

Reports information about OpenAccess libraries from within Innovus. You can use this command to query for attributes that are controlled by some of the `setOaxMode` options and the `update_oa_lib` command.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `report_oa_lib` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man report_oa_lib`.
`-filter {cdsinfo | compression | constraint_groups | property | tech_graph}`	
	Specifies the list of information to be included in the report. You can choose from the following filter options: • `cdsinfo` - Reports whether the `cdsinfo.tag` exists in the specified library. • `compression` - Reports the compression level (0 = uncompressed) of the library. • `constraint_groups` - Reports the constraint groups defined in the libraries in the technology graph. Constraint groups that are compatible with the default rule and `NONDEFAULTRULE` requirements will be indicated. • `property` - Reports the property information that was added to the library. The `add_oa_library_property` command is one source of library properties. • `tech_graph` - Reports information about the technology graph from the specified library. If you do not specify a filter option, all the above information is included in the report.
`-header`	Indicates that header information should be displayed. This option is useful if the report is being redirected to a file.
`lib_name`	Specifies the name of the OpenAccess library to be queried.

Example

The following command reports information about the `zambezi45` OpenAccess library along with the header:

```
innovus 18> report_oa_lib zambezi45 -header

save_abstract

```
save_abstract
[-help]
[-PGpinLayers layerNameList]
[-cutObs]
[-cutObsMinSpacing]
[-extractBlockObs]
[-extractBlockPGPinLayers layerNameList]
[-lib lib]
[-specifyTopLayer topLayerName]
[-stripePin {top all none}]
[-view view]
```

Generates hierarchical design abstract information for the current block-level design. By default, `save_abstract` creates power and ground pins on the design and creates a single obstruction shape for each routing layer. The output abstract contains the antenna information, if you run antenna verification.

In a bottom-up flow (where the block was not created using the `definePartition` or `partition` command), you normally create a simple OpenAccess abstract that contains:

- one obstruction (`OBS`) shape per routing layer
- signal pins located along the block boundary
- power pins for the top metal layer

You can use the `save_abstract` command after loading a block-level design.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `save_abstract` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man save_abstract`.
`-cutObs`	Creates cut-outs (obstructions) in the blockages for signal pins, power and ground pins, vias, and power and ground stripes. *Default*: Creates a single obstruction shape for each routing layer.
`-cutObsMinSpacing`	Creates cut-outs (obstructions) in the blockages around pins using the minimum width to calculate the spacing.
`-extractBlockObs`	Extracts all obstruction (`OBS`) information from the instantiated `CLASS BLOCK` or `RING` macros and writes out the obstructions to the output OpenAccess file. `OBS` information is extracted for layers that are not already being completely covered under the normal routing layer range and for cut layers between routing layers that are completely covered.
`-extractBlockPGPinLayers layerNameList`	

	Extracts the power and ground pin information from any CLASS BLOCK and CLASS RING macros with pins on layers in the specified layer list and writes out the pin information to the OpenAccess file. You can use metal layer numbers (for example, specify `4` for `metal4)`. Specify a list of layer numbers by leaving a space between each number. For example, to create a list with layers `metal3, metal4,` and `metal5,` specify `-extractBlockPGPinLayers 3 4 5`. *Default*: Does not extract the pin information from any macros.
`-lib`	Specifies the target library name. *Default*: The abstract is written into the library from which the current data was loaded.
`-PGpinLayers` *layerNameList*	
	Specifies the list of layers.
`-specifyTopLayer` *topLayerName*	
	Writes out obstruction information only for layers up to the specified layer. You can use the metal layer number (for example, specify `4` for `metal4`). *Default:* Top routing layer (therefore, writes out obstruction information for all layers)
`-stripePin {top all none}`	Writes out power and ground stripes on the top metal layer as power and ground pins. You can use this parameter in a bottom-up methodology, when you create abstracts for blocks that you will use at the next higher level of a hierarchical design.
`-view` *view*	Specifies the target view name. *Default*: `abstract`

saveOaBlackboxes

```
saveOaBlackboxes
[-help]
-cell list_of_cells
-lib libName
[-view viewName]
```

Saves the specified blackbox abstracts, using the OpenAccess database format. You can use the `saveOaBlackboxes` command at any time after importing the design.

Note that when the design is saved using the `saveDesign` command, the tool automatically saves abstracts for any blackboxes in the design. However, if you are performing pin optimization or manipulating the blockages on a particular macro in the design, you may wish to save the abstract for only that particular macro. The `saveOaBlackboxes` command is useful in such situations.

Parameters

`-help`	Prints a brief description that includes type and default information for each `saveOaBlackboxes` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man saveOaBlackboxes`
`-cell` *`list_of_cells`*	Specifies one or more blackboxes to save. If you specify more than one blackbox, you must enclose them in either double quotation marks or curly braces, and separate them with an empty space.
`-lib` *`libName`*	Specifies the OpenAccess library to use to save the blackbox abstracts. If an OpenAccess library with the same name already exists, the software creates a cell view in that library. If the library does not exist, the software creates the library in the working directory, with the library name and the path name being the same. If a new library is created, the technology file is copied from the technology library to the new library.
`-view` *`viewName`*	Specifies the cell view to save. *Default:* Uses the view name `abstract`

Examples

- The following command saves the blackbox `myBlackbox` in the view `abstract`:
  ```
  saveOaBlackboxes -lib myLib -cell myBlackbox -view abstract
  ```
- The following command saves the blackboxes `myBlackbox1` and `myBlackbox2` in the view `abstract`:
  ```
  saveOaBlackboxes -lib myLib -cell "myBlackbox1 myBlackbox2" -view abstract
  ```
- The following command also saves the blackboxes `myBlackbox1` and `myBlackbox2` in the view `abstract`:
  ```
  saveOaBlackboxes -lib myLib -cell {myBlackbox1 myBlackbox2} -view abstract
  ```

Related Information

- `saveDesign`
- `setOaxMode`

set_cell_binding

```
set_cell_binding
[-help]
[-abstract ]
[-lib list_of_libs]
-cell list_of_cell_patterns
-view list_of_views
```

Changes the layout binding for a cell. This also affects the layout viewing and automatic remastering. When specified with `-abstract` parameter, this instead of affecting the abstract binding replaces the in-memory cell information with the matched cells.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `set_cell_binding` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man set_cell_binding`.
`-abstract`	Replaces in-memory cell information for the matched cells.
`-cell` *`list_of_cell_patterns`*	Specifies one or more cell name patterns that are to be replaced.
`-lib` *`list_of_libs`*	Specifies the OpenAccess library that is to be used to look for cell abstracts.
`-view` *`list_of_views`*	Specifies the cellview name.

Example

- The following command looks for the cells in the Innovus database that match the cell pattern and replaces their binding with the specified view found in the library list.

```
set lib_list1 {lib1 lib2}
set_cell_binding -lib $lib_list1 -cell {cell1 cell2 cell3} -view {abc}
```

```

Controls aspects of how the Innovus™ Implementation System software reads OpenAccess technology, and creates OpenAccess libraries.

Use the `getOaxMode` command to return the current settings for the `setOaxMode` command.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `setOaxMode` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setOaxMode`.
`-allowAnalysisOnly {true|false}`	
	Allows analysis only flow. `assembleDesign` is not allowed when `setOaxMode -allowAnalysisOnly` is set to `false` and `setOaxMode -updateMode` is set to `true`, thereby locking the OpenAccess databse. To allow `assembleDesign` to proceed, you must change `setOaxMode -allowAnalysisOnly` to `true`. If you set `-allowAnalysisOnly` to `true` and the Innovus session is in `updateMode` = `true` mode (whether set explicitly or internally on the fly), the `-updateMode` setting is ignored. Note that there may be loss of some semantic information, such as MPPs, while saving the design when `-allowAnalysisOnly` is set to `true`. However, the saved design would be geometrically correct.
`-allowBitConnection {true | false}`	
	Creates databases for instances that only have bit-based terminals, without requiring the corresponding bus terminals. When set to `true`, it saves the connectivity information by bits if the bus connections are not available. When set to false, an error will be issued if the abstract view is missing expected bus terminal information. *Default*: `false`
`-allowTechUpdate {true | false}`	
	Allows the technology database to be updated. The common reason that a technology database would need to be updated is that new vias have been added to the design that are not in a parameterized form. Via masters that are a simple list of rectangles require that a "custom via" be created in the technology database. If the design library had been created with an attached technology, the value should be set to `false`, allowing a reference library technology that is shared by multiple designs to have design-specific vias to be added to it. For design libraries that have been created in reference mode, allowing the technology database to be updated is typically fine but normally it is best to always use paramaterized vias for OpenAccess-based flows. Using `setViaGenMode -symmetrical_via_only true` before any power planning or routing will typically prevent the creation of non-parameterized vias in the flow. When `-allowTechUpdate` is set to `false`, the creation of the OpenAccess database will fail if any "custom vias" would need to be created within the design library. *Default*: `true`
`-bindkeyFile` *fileName*	

	Maps into Innovus-equivalent bindkeys. If the bindkey file is not specified, the Virtuoso default bindkey information is used. *Default*: This is a string value and its default value is " ". For more information, see the "SKILL to TCL Mapping" section in the Importing and Exporting Designs chapter of the *Innovus User Guide*.
`-compressLevel` *value*	Sets the compression level of a library during the library creation process. Cellviews written to a library will follow the compression level of the library and not the current `setOaxMode -compressLevel` setting. Valid values range between 0 to 9. A value of 0 indicates that compression is turned off. *Default*: `1`
`-convertTo {polygon | defaultStyle}`	
	Enables interoperability of the end style of geometries of type path segment between Virtuoso and Innovus. This parameter applies to the diagonal path segments only. If the end-style of a diagonal path segment is `custom`, then the end style is retained as is. If the end style of a diagonal path segment is not `custom`, then if you set the value to `polygon`, Innovus converts the path segment into a geometrically equivalent polygon. If the value specified is `defaultStyle`, then the end style of the path segment is set to `defaultStyle`. In this case, Innovus retains the semantics of the object to be a path segment. **Important**: To ensure that there is no loss of semantic or geometric information, the path segments in Virtuoso -XL and Virtuoso-GXL should use the `custom` end-style on diagonal path segments which can be created using *Create-Shape-Geometric Wire*. *Default*: `polygon`
`-cut_pg_rail {true | false}`	
	Cuts PG rails. *Default*: `true`
`-cutRows {true | false}`	
	Cuts rows against placement obstructions, block halos, or power domain fence minimum gaps. *Default*: `false`
`-displayDrfFile` *pathName*	
	Allows you to specify a specific `display.drf` file that is to be used. It overrides all the searching options and the specified file is used. *Default*: String
`-displayDrfInLibrary {true | false}`	

	Allows the tool to search for the `display.drf` file in the technology library (or complete technology graph in case of ITDB) when set to `true`. If not found, it looks for the file in the current working directory followed by the home directory. When set to `false`, the tool searches for the `display.drf` file first in the current working directory followed by the home directory. *Default*: `false`
`-drcFillPurpose {gap_fill|drawing}`	
	Specifies whether to save DRCFILL shapes to the `gap_fill` or `drawing` purpose. By default, DEF routes with + SHAPE DRCFILL are mapped to the `gapFill` purpose in OpenAccess. However, some OpenAccess tech files do not have this purpose defined so any shapes mapped to the `gapFill` purpose would not be visible in Virtuoso and would not be written out in GDS or OASIS. In such cases, set the `-drcFillPurpose` parameter to `drawing` to save these shapes to the `drawing` purpose. When you do so, these shapes get an additional internal attribute so they can round-trip back to DRCFILL shapes properly. *Default*: `gap_fill`
`-encloseQuickAbstractPins {true | false}`	
	Specifies that shapes enclosing the layout pin shapes should be included as part of the pins during Quick Abstract Inference (QAI) pin modeling. Check the Quick Abstract Inference chapter in the *Mixed Signal (MS) Interoperability Guide* for details. Default: true
`-fullLayerList {true | false}`	
	Imports the complete list of OpenAccess layers, when importing an OpenAccess design. If you specify `false`, only OpenAccess layers defined with `oacMaterial` an type are imported. *Default*: `true`
`-fullPath {true | false}`	
	Creates the `DEFINE` statements in the `lib.def` files using full paths. If you specify `-fullPath false`, the software creates the statements using relative paths. *Default*: `false`
`-hybridRows {true | false}`	
	Reads hybrid rows from the Process Design Kit (PDK). When this parameter is set to `true`, the tool checks whether the sites are abutted horizontally or vertically and calculates the complex site width and height accordingly. *Default*: `false`
`-instPlacedIfUnknown {true | false}`	
	Maps the placement status of instances in the OpenAccess database to the placement status in the Innovus software. When set to `true`, the instances in the OpenAccess database that have an unknown placement status are treated as "placed" in the Innovus software. When set to `false`, instances with an unknown placement status are treated as "unplaced." *Default*: `true`

`-libCreateMode {none | attach | copy | reference}`	
	Specifies the mode in which `saveDesign -cellview` creates a library. `none`: Turns off the ability to have `saveDesign` create a library if it does not already exist. `attach`: Attaches the technology database specified by the technology library to the library that is to be created. `copy`: Copies the technology database specified by `techLib` to the library specified by `libName`, and saves the library to the current working directory. `reference`: Creates a local technology database in the design library that can be modified incrementally. This is the recommended setting to handle the case where the design may have "custom vias" added at some point by power planning/routing. *Default*: `reference`
`-locking {true | false | errorIfLocked}`	
	Specifies whether or not the OpenAccess database will be locked when the design is restored in Innovus. You can specify one of the following options: • `false`: This is the default option. When set to `false`, the tool does not check whether the design cell view is locked before restoring the design. The OpenAccess database can continue to be edited by other processes even while the design is restored in Innovus. **Note**: If the `-updateMode` parameter is set to `true`, the software automatically locks the database, even if the `-locking` parameter is set to `false`. • `true`: When set to `true`, Innovus locks the design cell view during `restoreDesign`, provided that it is not already locked by some other tool. With this setting, other tools cannot edit the OpenAccess database as long as it is locked for the Innovus session but they can still access the database in the read-only mode. To remove the lock, specify the `unlockOaDesign` command or exit the Innovus software. **Note**: If the design cell view is already locked by some other tool before `restoreDesign`, Innovus issues a warning but continues to read in the cell view. • `errorIfLocked`: If you want the tool to be more restrictive, set the `-locking` parameter to `errorIfLocked`. With this option, if the design is already locked while importing or restoring a design, the tool aborts and reports the following error: `**ERROR: (IMPOAX-7995): updateMode/locking is on. Design is already locked by another tool. You are recommended to close this design from another application before proceeding.` *Default*: `false` ⓘ The value of `-locking` cannot be changed while a design is in memory.
`-logicOnlyImport {true | false}`	

	Controls what information the software reads when importing an OpenAccess maskLayout database. When set to `true`, the software only reads the logical (Verilog netlist equivalent) connectivity during the init_design process. When set to `false` (the default value), the software automatically reads physical information (floorplan, placement, routing, etc.) from the database, and updates physical net connectivity for power and ground connections. **Note:** The `-logicOnlyImport` parameter only applies to OpenAccess maskLayout databases. For other types of OpenAccess databases, the software always only reads the logical connectivity. *Default*: `false`
`-merge_trim {true | false}`	
	Merges the trim metal shapes during save when the trim metal gap is less than or equal to the max_gap in microns. *Default*: `true`
`-pinPurpose {true | false}`	
	Writes out pin shapes with the purpose `pin`. When set to `false`, writes out pin shapes with the purpose `drawing`. *Default*: `false`
`-pushPinConstraint {true | false}`	
	Specifies whether or not `saveDesign` or `saveOaBlackboxes` should push an interoperable pin constraint into its corresponding blackbox abstract cellview. **Note:** Interoperable pin constraints refer to pin constraints that are understood by Innovus, Virtuoso, and PVS. *Default*: `false`
`-quickAbstractForCustomCells {pcells | stdcells | all |off}`	
	Trims design shapes of custom cells. By default, this capability is turned on for all types of custom cells. The following settings are allowed for this parameter: • `pcells` - Trims design shapes of only custom parameterized cells (PCells). • `stdcells` - Trims design shapes of only custom standard cells. • `all` - Trims design shapes of all custom cells. • `off` - Does not trim design shapes of any custom cell. **Note**: This feature needs the INVS30 (Innovus Mixed Signal Option) license. If this license is not available, the abstract that gets generated for custom cells will not work properly in Innovus. *Default*: `all`
`-readSystemReservedLayers {all | text | off}`	

	Reads the system-reserved layers from the PDK. The following settings are supported: • `all` - All system-reserved layers are read. • `text` - Only text layer is read. • `off` - No system-reserved layer is read. *Default*: `all`
`-reset`	Resets parameters to their default values. The `-reset` parameter *must* be the first parameter specified. If you specify `-reset` by itself, the software resets all `setOaxMode` parameters to their default values. Any values that do not already match the default value and are reset will be reported. If you specify parameters after `-reset`, the software resets only those parameters to their default values.
`-saveCdsFixedVias {new_vias_only | off}`	
	Controls how fixed/custom vias are created in OpenAccess library when saving a design from Innovus to OpenAccess: • `off` - No cdsFixedVias are created. All fixed/custom vias in the design are saved as oaCustomVia. This is the default option. • `new_vias_only` - Any newly created custom via is saved as a fixed via while any pre-existing custom via in the Incremental Technology Database (ITDB) is reused when saving the design. **Note**: This feature needs the INVS30 (Innovus Mixed Signal Option) license. If this license is not available, the default `off` value will be used and no fixed vias will be created. *Default*: `off`
`-saveMaskDataLocked {true | false}`	
	Sets the shapes with mask coloring (mask values other than 0) to locked in the saved cellview, when set to `true`. By default, `oaOut` and `saveDesign` write out shapes with their mask coloring information in an unlocked state. Some tools treat the unlocked color information as the recommended color. However, for some foundry processes, shapes with unlocked mask coloring information are written to GDSII/Stream as gray (uncolored). In such cases, set the `-saveMaskDataLocked` parameter to `true` to lock the mask coloring of shapes explicitly. **Note**: This option affects only the saving of shapes with non-zero mask coloring values. Review the map file that will be used to create GDSII/Stream output from the OpenAccess cellview to determine if the map file requires shapes to be locked for them to be written out as colored. *Default*: `false`
`-saveNetVoltage {true | false}`	
	Saves the minimum and maximum net voltage across all loaded timing views to every net. When this parameter is set to `true`, `write_db` writes voltage information to the voltage attribute of oaBitNet. This is useful for Virtuoso, and other tools that may read the cellview, to understand the minimum and maximum net voltage without needing to interpret the CPF or .lib file to get that information. Roundtrip of the information into Innovus is not dependent on this setting. *Default*: `false`
`-saveRelativePath {true | false}`	

	Defines the current working directory (`$cwd`) in the configuration file as ".". When set to `true`, a design can be restored, even if the directory path of the design file is changed. *Default*: `true`
`-saveRestoreFile {true | false}`	
	Creates the `view.inn` file when the `saveDesign` command is run with the `-cellview` or `-view` arguments. The `view.inn` file is a file that can be sourced to read the cellview that was saved into a new Innovus session. The file name will be the specified view name with the `.inn` suffix added. When `saveDesign` is used in the *`sessionName`* style (without `-cellview` or `-view` specified), the `inn` file will always be created. In the *`sessionName`* style, the `inn` file will have the name specified by the user even if the view name has the `.inn` omitted (if the `.inn` suffix is not specified, the file and view names will be the same). Set the `-saveRestoreFile` parameter to `true` to create an `inn` file that can be sourced. The use of the `inn` file makes it easier to write scripts that are more generic and work across multiple designs by depending only on the view name and not the design library or cell name. *Default*: `false`
`-silently_ignore_unsupported_vias {true | false}`	
	Specifies whether `restoreDesign` should issue messages about vias that are not supported in Innovus when a Virtuoso design is read in. *Default*: `false`
`-textPurpose` *`purpose_name`*	
	Specifies the purpose name that will be used when text labels are written. By default, any text label created in Innovus (typically via the `add_text` command) is automatically mapped to the `drawing` purpose. Use the `-textPurpose` parameter to map the text labels to a user-defined purpose. **Note**: `setOaxMode -textPurpose` *`purpose_name`* overrides the default `drawing` purpose on output. *Default*: `drawing`
`-tieNet {`*`tieHighNetName tieLowNetName`*`}`	
	Specifies the global tie high and tie low net names to be created in the OpenAccess database. The nets are used to represent the Verilog `1'b1/1'b0` connections to the instance ports. Typically, `tie1` and `tie0` are used as tie high and tie low net names, respectively. If these names exist in the design locally in any module, then the global names should be changed. *Default*: `""`
`-updateMode {true | false | auto}`	
	Specifies whether or not to save or restore an OpenAccess design in update mode. If the `-updateMode` parameter is set to `true`, `restoreDesign -cellview` processes parameterized cells (PCells) and other custom objects correctly in the Innovus database. For information about generating/regenerating the PCell cache, refer to the "Preparing the IP Library" section in the Technology Data Preparation chapter of the *Mixed Signal (MS) Interoperability Guide*. `-updateMode true` also ensures that `saveDesign -cellview` updates the Innovus-modified portion of an

OpenAccess database without making changes to PCells or other custom objects.

⚠ In the `setOaxMode -updateMode true` mode, the tool locks the source cellview for the duration of the Innovus session.

The `updateMode` parameter provides the ability to import an OpenAccess database created from Virtuoso that contains objects which are not understood by Innovus. Complete the digital part in Innovus and update only the objects modified by Innovus in the original OpenAccess database. If your design has any of the following objects, they would only be visible (not editable) in Innovus:

- PCells
- Modgen cells
- Fig-groups
- PCell vias
- RODs (Example, Multi-Part Paths, and so on)
- User defined properties on design objects such as nets, shapes (`lxStickyNet`), instances, abstract views, intermediate hierarchical instances, and so on.

You won't be allowed to edit or modify these objects.

On using this parameter, the property on shapes (for example, `lxStickyNet`) and nets created in VLS-XL / GXL would be kept as-is.

In case of designs where parameterized vias are used, Innovus understands these parameters and evaluates them on-the-fly to create an exact shape and orientation of the cuts.

If the `-updateMode` parameter is set to `auto` and the cellview contains objects that are not supported in Innovus, the software internally enables update mode with a message such as follows:

```
INFO: Objects have been found in the cellview requiring updateMode to be enabled so that
there is no loss of semantic information when the cellview is saved.
```

Note that enabling update mode can affect `saveDesign` performance.

Default: `false`

ⓘ The value of `-updateMode` cannot be changed while a design is in memory. If this parameter has been set to `true` before importing an OpenAccess design into Innovus, you cannot convert `-updateMode` to `false` in any new Innovus session.

ⓘ The on-disk OpenAccess cellview is locked between the restore and save steps when `-updateMode` is set to `true`.

ⓘ In `-updateMode auto`, the lock is applied at the time that `oaIn` or `restoreDesign` starts and released at the end of the command if no objects were encountered that required updateMode to be enabled.

`-useVirtuosoColor {true|false}`

	Allows you to display colors and stipples for the design layers (including full custom layers). Using this parameter, Innovus utilizes the same colors and stipples that you would see if you open the design in Virtuoso. *Default*: `false`
`-useVirtuosoBindkey {true|false}`	
	Allows you to use Virtuoso bindkeys. *Default*: `false`
`-viewSubType {VCE | VXL | none}}`	
	Indicates which Virtuoso application should be used for viewing the layout cellviews in the saved OpenAccess database. When set to `VCE`, cellviews are opened in Virtuoso Chip Editor. When set to `VXL`, cellviews are opened in Virtuoso XL. When set to `none`, it indicates that the OpenAccess database can be edited by any editor within Virtuoso platform based on its license availability. *Default*: `VXL`

Examples

- The following command instructs the Innovus software to create the `DEFINE` statements using full paths:
  ```
  setOaxMode -fullPath true
  ```
- The following command cuts rows against placement obstructions, block halos, or power domain fence minimum gaps:
  ```
  setOaxMode -cutRows true
  ```
- The following command resets the `-fullPath` parameter to its default value:
  ```
  setOaxMode -reset -fullPath
  ```
- The following command resets all `setOaxMode` parameters to their default values:
  ```
  setOaxMode -reset
  ```
- The following command searches for the `mydisplay.drf` file irrespective of the value of the `-displayDrfInLibrary` parameter:
  ```
  setOaxMode -displayDrfFile /servers/oastore/mydisplay.drf
  ```
- The following command sequence enables the `saveDesign` command to write out an `inn` file to enable loading the saved database into a new session without needing to know the design library or cell names:
  ```
  setOaxMode -saveRestoreFile true
  saveDesign -cellview "designLib top placed"
  ```

  In addition to saving the cellview `"designLib top placed"`, the tool creates an `inn` file named `placed.inn` in the current working directory. This file contains the command `restoreDesign -cellview "designLib top placed"`
  To load the design cellview that was saved in a new session, use:
  ```
  innovus -init placed.inn
  ```

unlockOaDesign

```
unlockOaDesign
[-help]
lib
cell
view
```

Unlocks the specified OpenAccess design.

A design cannot be opened if `setOaxMode -locking` is set to `true`, and the design is currently locked. You can use the `unlockOaDesign` command to free the lock so that other tools can access and edit the database. You also can use the command to override the lock, if the design is incorrectly locked.

You can use the `unlockOaDesign` command at any time.

Parameters

cell	Specifies the name of the top cell to unlock.
-help	Outputs a brief description that includes type and default information for each `unlockOaDesign` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man unlockOaDesign`.
lib	Specifies the name of the OpenAccess library in which the design was saved.
view	Specifies the name of the cell view to unlock.

Example

- The following command unlocks the view `layout` in the cell `dtmf_chip` in the library `designLib`:
  ```
  unlockOaDesign designLib dtmf_chip layout
  ```

Related Information

- `setOaxMode`

update_oa_lib

```
update_oa_lib
[-help]
lib_name
[-compress_level value]
[-create_cdsinfo_tag]
[-tech_attach_to_reference]
```

Updates the specified OpenAccess library from within Innovus. You can use this command to:

- Convert the specified library to use a tech reference from the attached tech so that the non-parameterized or custom vias can be written to it. Saving non-parameterized vias to OA require write permission to OA tech so that custom viadef entry can be created. If attached technology is read-only and OpenAccess design has non-parameterized vias, you should run `update_oa_lib` with -tech_attach_to_reference command line option before invoking `saveDesign`. The tool is then able to save the design and does not throw an error because it can now make non-parameterized vias entry to local tech in the converted library.
- Add a cdsinifo.tag to legacy libraries created by earlier versions of Innovus.
- Modify the compression level for the library.

If you run the `update_oa_lib` command on a library that is not in attached mode, a warning is displayed. However, the script continues to run. This is useful if you want to make sure that libraries are writable for new vias and the `saveDesign` command does not fail.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `update_oa_lib` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man update_oa_lib`.
`-compress_level` *value*	Sets the compression level of the specified library. New cellviews written to the library follow the specified compression level. However, existing cellviews in the library are not modified. Use the oazip utility to modify the existing cellviews in the library. Valid compression level values range from 0 to 9. A value of 0 indicates that compression is turned off.
`-create_cdsinfo_tag`	Adds a `cdsinfo.tag` file to the specified library.
lib_name	Specifies the name of the library to be updated.
`-tech_attach_to_reference`	Converts the specified library to use a tech reference from the attached tech so that new custom via definitions can be added to the library.

Examples

- The following command sets the compression level of the `lib1` library to 9. However, it does not change the compression of the existing cellviews in the library:
  ```
  update_oa_lib lib1 -compress_level 9
  ```
  The tool displays warning such as the following:
  ```
  Changed library compressLevel from '0 (uncompressed)' to '9'. Cellviews within the library are not affected
  by changing the library's compressLevel. To update the cellviews, use the oazip utility.
  ```
- The following command turns off the compression for any newly created cellviews in `my_lib` library, which previously is at compression level `1`:
  ```
  update_oa_lib my_lib -compress_level 0
  ```

write_lef_library

```
write_lef_library
[-help]
[filename]
[-all_auto_generated_via | -macro_only ]
[-lef_layer_order]
[-macro_only [-no_property]]
[-tech_only | -macro_only]
[-tech_only | -macro_list string]
```

Writes the LEF library data (composed of technology data and macros) that is present in the Innovus database.

The `write_lef_library` command facilitates comparisons between LEF-based input and OpenAccess-based input. LEF allows cases where `VIARULE GENERATE` has `WIDTH` specified for either the top or bottom layer. However, such cases are not supported by the OpenAccess tech. To make the comparison between LEF-based and OpenAccess-based input easier, `write_lef_library` dumps `"WIDTH 0 TO 1000 ;"` for any `VIARULE GENERATE` that does not have WIDTH specified in the original LEF.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `write_lef_library` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_lef_library`.
`fileName`	Specifies the output LEF file name.
`-all_auto_generated_via`	
	Includes all auto generated vias from the `generateVias` command.
`-lef_layer_order`	Writes out only the layers specified in the lefLayerOrder constraint.
`-macro_list` *`string`*	
	Writes the macros specified in the macro list.
`-macro_only`	Writes only the macro data to the LEF file.
`-no_property`	Writes data in the LEF file without any properties. This option can be used only with the `-macro_only` option.
`-tech_only`	Writes only the technology data to the LEF file.

Examples

- The following command writes the technology data into the `tech.lef` file:
  ```
  write_lef_library tech.lef -tech_only
  ```
- You can set the LEF version to 5.7 or 5.8 using `lefDefOutVersion`:
  ```
  set lefDefOutVersion 5.8
  ```

write_oa_techfile

```
write_oa_techfile
[-help]
[fileName]
[-include_rules]
[-process_node coord]
```

Writes out a DFII style ASCII technology file that can be given to the `techLoadDump` executable to create an equivalent OpenAccess technology database.

This command is used to create and verify OpenAccess technology files that match LEF technology files. By default, `write_oa_techfile` writes out only DRC information and no LDRS or VIA information.

The expected flow for new processes is as follows:

1. Read a LEF file into Innovus with `init_design`.
2. Use `write_oa_techfile` to write out the tech (`.tf`) file.
3. Run `techLoadDump` using the `.tf` file.
4. Use `lef2oa -pnrLibDataOnly` to create the LDRS and vias.

For more information, refer to the chapter "Technology File Layer Attributes" of the *Virtuoso Technology Data ASCII Files Reference*.

Parameter

`-help`	Outputs a brief description that includes type and default information for each `write_oa_techfile` parameter. For a detailed description of the command and all of its parameters, use the man command: man `write_oa_techfile`.
`fileName`	Specifies the output ASCII file name.
`-include_rules`	Includes LDRS and VIA information in the output tech file. This option should be used only if the LEF default and NDRs do not utilize fixed vias.
`-process_node` *`coord`*	Specifies a process node value in nm. When specified, `write_oa_techfile` creates a processNode entry in the techfile for processes using the MASK construct. For example, if you specify `-process_node 20` to indicate a 20nm process, the following entry is included in the control() section of the techfile: `processNode(0.020)` If `-process_node` is not specified and the `write_oa_techfile` command detects MASK constructs on any layer, it returns an error.

Examples

- The following set of commands updates an OpenAccess technology file with any missing information from a LEF technology file:

```
#Initialize a design using LEF files
write_lef_library -tech_only lef.lef  #A LEF file in canonical
                                      #sorted order for easy
                                      #comparison with diff
write_oa_techfile lef.tf              #A DFII ASCII tech file
                                      #that can be given to
                                      #techLoadDump executable
#Edit existing OA tech file to add any missing information in
#the lef.tf file
#Initialize a design using the new OA tech. Then:
write_lef_library -tech_only oa.lef #A LEF file in canonical
                                    #order derived from OA tech
#Compare the two LEF files. Any differences need to be fixed
#or explained.
diff lef.lef oa.lef
```

add_connection_to_neighbor_partition

```
add_connection_to_neighbor_partition
[-help]
[-dictFile file_name]
```

Adds a partition pin on the abutted edge of unique abutting partitions to create a 2-partition pin scenario for target pins. This helps to avoid floating pins on abutted edges. The `add_connection_to_neighbor_partition` command targets the following pins:

- Input partition pins with have tie definition and a GNC/UPF to resolve the tie net to a supply
- Floating output partition pins

Note: The target pins may or may not have any load/driver inside the partition.

This command should be used after the pins have been assigned for the target partition and tie cells have been specified using the `setTieHiLoMode -cell` command.

Parameters

`-dictFile` *`file_name`*	Specifies the name of the file in which the TCL dictionary is written. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `add_connection_to_neighbor_partition` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man add_connection_to_neighbor_partition`

Example

- The following command adds partition pins on abutting partitions and reports the number of new partition pins and tie cells in a table.
  `add_connection_to_neighbor_partition`

```
-------------------------------------------------------------------------------------
|    Type     | Total Pins | Pins placed in abutted edge | New partition pins added |
-------------------------------------------------------------------------------------
|   Tie-low   |          4 |                           4 |                        4 |
|   Tie-hi    |          4 |                           4 |                        4 |
| Floating(I) |         16 |                          16 |                        - |
| Floating(O) |         16 |                          16 |                       16 |
-------------------------------------------------------------------------------------
```

addNetToNetGroup

```
addNetToNetGroup
[-help]
netGroupName
-net {netName | netNameList}
```

Adds a net to specified net group that was created with the `createNetGroup` command. A net can be a single net, bus name, or segment of a bus. You can use this command after defining a net group.

Note: If a net is a part of a net group, the net cannot belong to any other net group.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `addNetToNetGroup` parameter. For a detailed description of the command and all of its parameters, use the man command: `man addNetToNetGroup`
netGroupName	Specifies the name of the created net group. *Data_type*: string, required
`-net {`*netName* `|` *netNameList*`}`	
	Specifies the name of an individual net, bus, or segment of a bus. You can use wildcards (*?) with this parameter. *Data_type*: string, required

Examples

- The following command adds net ENOUT to net group bundle1:
  ```
  addNetToNetGroup bundle1 -net ENOUT
  ```
- The following command adds the entire bus cpua to net group bundle2:
  ```
  addNetToNetGroup bundle2 -net cpua
  ```
- The following command adds only bus segments 2 through 10 to net group bundle1:
  ```
  addNetToNetGroup bundle1 -net cpua[2:10]
  ```

-pin {pinName | pinNameList}
```

Adds a module port to specified pin group that was created by `createPinGroup` command. You can use this command after defining a net group.

Note: You can use this command for the top-level also.

Parameters

`-cell cellName`	Specifies the name of a module. This parameter is not required for top-level ports. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `addPinToPinGroup` parameter. For a detailed description of the command and all of its parameters, use the man command: `man addPinToPinGroup`
`-pinGroup pinGroupName`	
	Specifies the name of the created pin group. *Data_type*: string, required
`-pin {pinName | pinNameList}`	
	Specifies the name of a module port. You can specify wildcards (*?) with this parameter. *Data_type*: string, required

Example

- The following command adds the module SH17's port RASN to pin group pin17:
  ```
  addPinToPinGroup -cell SH17 -pinGroup pin17 -pin RASN
  ```
- The following command adds the top-level port ADDER to pin group PIN_GRP_TOP
  ```
  addPinToPinGroup -pinGroup PIN_GRP_TOP -pin ADDER
  ```

alignPtnClone

```
alignPtnClone
[-help]
[ptnName]
[-outFile filename]
[-checkOnly | -snapAllCorners ]
[[-stripeOffset ] | [[-pgHGrid ] [-pgVGrid ] [-pgLayer {layeridList}]
[-updateUserGrid ] [-snapAllCorners ] [-skipFinFETGrid ] [-includeStdCellPinLayers {layeridList}]]  |
[[-symmetryPatternReference string
[-symmetryPatternTarget string [ [-targetOrientation {R0 R90 R180 R270 MX MX90 MY MY90}]
[-targetOrigin {x y}] ]]]] |
[-symmetricOrientation ]]
[-pgLayer {layeridList}
[-pgNet pgNetName | -pgCenterLine float]]
[-pgPitch float [-pgCenterLine float]]
```

Aligns partition clones with the master partition on a power mesh and with routing tracks. You can use this command after specifying a master partition and clone partition(s). This will avoid off-track pins in clones and avoid potential DRC violations due to misalignment of power meshes inside clone.

Note: The power mesh must be regular for `alignPtnClone` to work correctly.

The `alignPtnClone` command detects and highlights any gap or overlap of fence created in an abutted floorplan.

Parameters

`-checkOnly`	Specifies that the design should not be modified. When enabled, it only reports messages. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `alignPtnClone` parameter. For a detailed description of the command and all of its parameters, use the man command: `man alignPtnClone`
`-includeStdCellPinLayers {layeridList}`	Specifies the layer(s) of standard cell pins that should be aligned in addition to the user-specified pin layers. *Data_type*: string, optional
`-outFile filename`	Specifies the name of the output file in which to save the master and clone alignment report with details. **Note:** The `alignPtnClone` command supports tracks with multiple definitions. The `-outFile` parameter reports the details of multi-track definitions. *Data_type*: string, optional
`-pgCenterLine float`	Specifies the center-line of the first virtual symmetric pg stripe (in microns). This option can be repeated. *Data_type*: float, optional
`-pgHGrid`	Provide information about horizontal PG grid. *Data_type*: bool, optional
`-pgLayer {layeridList}`	Specifies layer(s) for the pg stripe. This option can be repeated. *Data_type*: string, optional
`-pgNet pgNetName`	Specifies name of the pg stripe net name. This option can be repeated. *Data_type*: string, optional
`-pgPitch float`	Specifies pitch of the pg stripe net (in microns). This option can be repeated. *Data_type*: float, optional
`-pgVGrid`	Provide information about vertical PG grid. *Data_type*: bool, optional
ptnName	Specifies name of the partition. **Note:** If the partition name is not specified, the command is run on all partitions. *Data_type*: string, optional

`-skipFinFETGrid`	Disables alignment with the FinFet grid. *Data_type*: bool, optional
`-snapAllCorners`	Snaps all corners of master and its clone partition to the user grid. **Note:** The `-snapAllCorners` parameter fixes partition overlaps. *Data_type*: bool, optional
`-stripeOffset`	When specified ensure backward compatibility and and enables the use of obsolete `-snap`, `-track`, `-useUserGrid`, `-skip_row`, and `-layer` parameters **Note:** The `alignPtnClone` command supports advanced node fully abutted designs. It moves the clone partition for aligning with the master with all allowed routing tracks by default. It snaps clones such that the pins are never off grid. Consequently, the `-snap`, `-track`, `-useUserGrid`, `-skip_row`, and `-layer` parameters are obsolete. Even though the use of `snap`, `-track`, `-useUserGrid`, `-skip_row`, and `-layer` parameters is supported in this release using the -`stripeOffset` parameter for backward compatibility, the `-stripeOffset` parameter itself is obsolete and will be removed in a future release. To avoid warnings and to ensure compatibility with future releases, remove the obsolete parameters from your script. *Data_type*: bool, optional
`-symmetricOrientation`	Checks the orientation between each pair of partitions and fixes the symmetry by finding the optimum symmetric orientation of clones. **Note:** If Innovus suggests changing the orientation of a partition, it indicates it as (diff) in the report for quick identification. **Note:** The `-symmetricOrientation` parameter can find orientations based upon nested hierarchy. If the `alignPtnClone` command finds no clone connectivity, it can reports the expected orientations and supports nested designs. *Data_type*: bool, optional
`-symmetryPatternReference` *string*	Specifies the names of the partitions that are used as a reference set to maintain a symmetrical pattern for the other set of clone partitions in the group. **Note:** The first partition in the list is considered as the seed partition from which all the relative locations and orientations are calculated for the rest of the partitions in the list. *Data_type*: string, optional
`-symmetryPatternTarget` *string*	Specifies the names of the partitions that are used as a target set to maintain a symmetrical pattern relative to the reference set of partitions in the group. **Note:** • The number of partitions and their order must be the same as that specified with the `-symmetryPatternReference` parameter. • The current location and orientation of the seed partition is used to relatively move the other partitions in the list. The first partition in the list is considered as the seed partition from which all the relative locations and orientations are calculated for the rest of the partitions in the list. • You can specify master partitions in the target partitions set list. However, master partitions can only have R0 orientation. *Data_type*: string, optional
`-targetOrientation {R0 R90 R180 R270 MX MX90 MY MY90}`	Specifies the new orientation of the seed partition of the target partition set (`-symmetryPatternTarget`). The specified orientation overrides the current orientation of the seed partition and enables you to maintain the relative orientation of the different pairs of clones. **Note:** • The seed partition is the first partition specified with the `-symmetryPatternTarget` parameter from which all the relative locations and orientations are calculated for the rest of the partitions in the list. • The orientation of the master partitions cannot be changed. *Data_type*: enum, optional

`-targetOrigin {x y}`	Specifies the new origin of the seed partition of the target partition set (`-symmetryPatternTarget`). The specified location overrides the current location of the target seed partition.  **Note:** • It does not let the target seed partition go outside the core boundary. • The seed partition is the first partition specified with the `-symmetryPatternTarget` parameter from which all the relative locations and orientations are calculated for the rest of the partitions in the list. *Data_type*: point, optional
`-updateUserGrid`	Updates the user grid with the new values. *Data_type*: bool, optional

Example

- The following command aligns the partition clones with the master partition and displays a report:
  `alignPtnClone`

```
================================================================================
                alignPtnClone Summary
================================================================================
Partition                   | Orientation |   Status   | Moved-by(X) | Moved-by(Y)
================================================================================
MASTER_CLONE(I_MC_1)        |             |    Aligned |             |             |

```

- The following command snaps clones of module `eug` to Master's power grid:
  `alignPtnClone eug`
- The following command aligns with all allowed tracks and automatic detection of pg layers, nets, and pitch of pg grid
  `alignPtnClone eug -pgHGrid -pgVGrid`
- The following command aligns with all tracks and automatic detection of pg nets and pitch of pg grid
  `alignPtnClone eug  -pgHGrid -pgLayer { 2 4 6 } -pgVGrid -pgLayer { 3 5 7}`
- The following command aligns with all tracks and automatic detection of pg pitch of pg grid
  `alignPtnClone eug -pgHGrid -pgLayer { 2 4 6 } -pgNet VSS -pgLayer {4 6} -pgNet VDD -pgVGrid -pgLayer { 3 5 } -pgNet VSS -pgLayer {5 7} -pgNet VDD`
- The following command aligns with all allowed tracks and specified pg grid
  `alignPtnClone eug -pgHGrid -pgLayer { 2 4 6 } -pgNet VSS -pgPitch 1.48 -pgNet VDD -pgPitch 1.28 -pgVGrid -pgLayer { 3 5 7 } -pgNet VSS -pgPitch 1.48 -pgNet VDD -pgPitch 1.28`
- The following command updates the user grid and simulates symmetric PG stripe pattern:
  `alignPtnClone -updateUserGrid -pgVGrid -pgLayer M4 -pgPitch 5.76 -pgCenterLine 0.0 -pgHGrid -pgLayer M5 -pgPitch 46.08 -pgCenterLine 1926.72 -checkOnly`

assembleDesign

```
assembleDesign
[-help]
[-keepPGPinGeometry]
[-keep_block_halo]
[-outFile fileName]
[-skipCells] [-skipComponents] [-skipNets]
[-skipSpecialNets]
{{[-topDir dirname [-mmmcFile mmmcFile] [-cpfFile cpfFile]]
   {[-blockDir dirname [[-fe] | [-fplan]]][-blockData {defFileName netListFileName} | {-fplan|-fe}][-noDefMerge]}}
      | {[-topDesign {topLib topCell topView} [-mmmcFile mmmcFile] [-cpfFile cpfFile]]
        {[-block {blockLib blockCell blockView} | -blockCell blockCell]
   [-allTimingBlocks [-exceptBlocks {list of blocks}] [-reportOnly]]}}}
[-fe | -fplan | -noDefMerge ]
[-keepPinGeometry]
```

Brings back specified block data to the top-level design for chip assembly. The top-level design should instantiate each block as a hard macro whose size matches the design size used for each block when it was implemented. After assembleDesign has completed, the result is a a full-chip design with one or more blocks merged at the location where each block was previously instantiated as a hard macro. You should run this command from the directory with the full chip-level floorplan for the top-down hierarchical flow.

There are two main modes of operation - full and incremental.

- Full mode: When operating in full mode, a session is initiated with the `assembleDesign` command which first loads the top-level design with blocks represented as hard macros then each block is merged within the full-chip context.
- Incremental mode: When operating in incremental mode, a top-level design is loaded prior to calling `assembleDesign` which then merges the contents of one or more blocks.

Notes:

- The `assembleDesign` command supports designs saved in the Innovus database format as well as OpenAccess designs.
- The `assembleDesign` command supports the incremental capability which handles master/clones partitions at different levels of hierarchy and supports nested partitions. The incremental `assembleDesign` capability enables partitions to be brought back in one session, thus, avoiding the need to run multiple sessions for bringing back all the data of a design. You can call the incremental `assembleDesign` for a block multiple times in the same session without having to partition it.
- The `assembleDesign` command supports mixed-origin design. That is, all partitions can have a design origin at the center, lower-left, any location inside the design boundary, or any location outside the design boundary. You can use this command after implementing blocks and top-level designs.
- The `assembleDesign` command preserves Interface Logic Model (ILM) information by automatically bringing back ILMs from block level design to full-chip level design. For DEF data, ILMs can only be brought back if the -blockDir option is specified.
- The `assembleDesign` command supports mixed data types. While specifying partition blocks, you can have different types of data for different partition blocks.
- The `assembleDesign` command supports partitions with flexmodels. It re-assembles partition blocks with flexmodels back to the top-level design.
- The `assembleDesign` command can read design information from the global init_* variables saved in the *.global file.
- The `assembleDesign` command internally calls the `applyGlobalNets` command that applies or restores the global net connectivity rules to the design and creates the necessary connections between instances and global nets. Consequently, the `assembleDesign` command automatically generates a database where the global nets are already connected. This helps to ensure that all instance are correctly tied to PG nets.
- The `assembleDesign` command internally checks color issues and uses the shift-mask functionality to assign correct colors to objects. As a result, at the end of `assembleDesign`, the objects are already given the mask numbers (colorized) and the design has less color violations.
- The `assemble_design` command compares the properties of each block and top and uses a specific resolution for each property.
- The `assembleDesign` command (DEF based) supports multi-threading. It honors the settings of the `setMultiCpuUsage -localCpu` parameter that is used to specify the number of CPUs on the local machine and is required for multi-threading.

  Note: This capability is not supported by the `-fe` based `assembleDesign`.

During `assembleDesign` all rows are cut at the top and only the rows from inside the block are brought at the time of assembly. The `checkPlace` command does not report any false placement violations. Only in cases where partitions are rotated R90 (like vertical rows) are the cells marked as fixed.

A summary report is generated at the end of each `assembleDesign` run which helps in debugging issues. The generated report includes information like the runtime for `assembleDesign`, number of partitions and their instance count.This report is useful in identifying potential issues in the flow.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `assembleDesign` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man assembleDesign`
`-allTimingBlocks`	Enables automatic detection and assembly of blocks with digital content. The `-blockCell` option can be used to manually force blocks to be assembled, and `-ignore_timing_blocks` option can be used to exclude cells from being assembled as it overrides to the default list of blocks to be assembled. *Data_type*: bool, optional
`-block` *blockLib blockCell blockView*	
	Specifies the block-level library, cell, and view names respectively for a design that was saved into an OpenAccess database. This parameter is used when bringing back block data for the partition from an OpenAccess database. **Note:** If you specify more than one block-level design, specify the `-block` option separately for each block. For example: `-block libForOA TDSP_CORE ptnView1 -block libForOA TDSP_ARB ptnView1` *Data_type*: string, optional
`-blockCell` *blockCell*	Specifies the cell name for the block cell. *Data_type*: string, optional
`-blockData` *defFileName netlistName*	
	Specifies the DEF file name and the Verilog netlist file name. Use this parameter if the Verilog netlist file name or the DEF file name is different from the cell or module name. You must provide the full path (absolute or relative) with the file names. This is distinct from using the -blockDir option in that only a DEF file and Verilog netlist are required as opposed to a database saved with the `saveDesign` command. If a design contains multiple instantiations of a block, -blockData only needs to be specified once per master. **Note:** If you specify more than one block-level design, specify the `-blockData` option separately for each block-level DEF file and Verilog netlist file. For example: `-blockData block_a.def block_a.v -blockData block_b.def block_b.v` gzipped files are supported. *Data_type*: string, optional
`-blockDir` *dirname*	Specifies the path to the block-level design(s). This directory should be generated by the `saveDesign -def` command. **Note**: If you specify more than one block-level design, specify the -blockDir option separately for each block-level directory. For example: `-blockDir block_a.enc.dat -blockDir block_b.enc.dat` *Data_type*: string, optional
`-cpfFile` *CPFFile*	Specifies the name of the (Chip Level) CPF file that contains the power intent and timing information. *Data_type*: string, optional
`-exceptBlocks {`*list_of_blocks*`}`	
	Specifies the list of block names to be excluded from being assembled even if they contain digital content. This option only applies to the case where `-allTimingBlocks` is used. If not specified, there is no restriction on the detection and assembly that is automatically determined. *Default*: `""` *Data_type*: string, optional
`-fe`	Specifies that Innovus place-and-route data should be used for `-blockDir` option. **Note**: The `-fe` parameter cannot be used with the `-blockData` parameter because the `-fe` parameter points to data from the Innovus database format whereas the `-blockData` parameter points to data from Verilog netlist and DEF name. *Default*: By default, data from DEF files is used. *Data_type*: bool, optional

`-fplan`	Specifies that only floorplan data should be assembled. When specified it brings back the floorplan changes from a partition block to full-chip level design. It supports un-committed partition(s) and replaces the top level uncommitted partition(s) with updated block floorplan data. **Note:** After `assembleDesign -fplan` command, any signal net at top-level design may be overlapped with other floorplan objects. You may need to reroute or ECO route the design. Additionally, PG net of CHIP, place, and route data may not be brought back. *Data_type*: bool, optional
`-keep_block_halo`	When specified, the `assembleDesign` command preserves the block place and route halo. *Data_type*: bool, optional
`-keepPGPinGeometry`	Retains the partition PG pin geometry. *Data_type*: bool, optional
`-keepPinGeometry`	Specifies that for every partition pin, a DRCFILL metal of the type special route is placed on top of the partition pins. The `-keepPinGeometry` parameter is used for analysis (both RC extraction, and DRC checking). **Note:** If you intend to run incremental routing "flat after `assembleDesign`", then you must either not use this option, or delete the DRCFILL shapes and allow the nanoRoute router to do any repair needed at the pin junctions before incremental routing is done. *Data_type*: bool, optional
`-mmmcFile` *mmmcFile*	Specifies the name of the (Chip Level) MMMC file that is used to supply the MMMC information. Normally, it is a chip level file named *viewDefinition.tcl*. When `assembleDesign` is used to incrementally assemble blocks this option isn't applicable since the timing environment should have already been established when loading the top-level design. *Data_type*: string, optional
`-noDefMerge`	Specifies that the DEF merge capability will be disabled and normal `assembleDesign` will be used. *Data_type*: bool, optional
`-outFile` *fileName*	Specifies name of the output file. *Default*: `./<design>.assembleDesign.rpt` *Data_type*: string, optional
`-reportOnly`	When enabled, the `assembleDesign` command only reports the list of blocks that would be assembled and does not perform actual assembling. **Note:** The `-reportOnly` parameter can only be used in the `assembleDesign` command along with the `-allTimingBlocks` option, to get a list of (and not actually assemble) blocks that would be assembled by a subsequent `assembleDesign -allTimingBlocks` command invocation without the `-reportOnly` option. This list of blocks can be used to include or exclude blocks to be assembled via the `-blockCell` or `-exceptblocks` options. *Data_type*: bool, optional
`-skipCells`	Skips merging standard cells. It does not load the standard cells section from DEF. *Data_type*: bool, optional
`-skipComponents`	Skips merging all components.It does not load the COMPONENT section from DEF. *Data_type*: bool, optional
`-skipNets`	Skips merging signal routes. It does not load the NETS section from DEF. *Data_type*: bool, optional
`-skipSpecialNets`	Skips merging special routes. It does not load the SPECIALNETS section from DEF. *Data_type*: bool, optional
`-topDesign` *topLib topCell topView*	
	Specifies the top-level library, cell, and view names respectively for a design that was saved into an OpenAccess database. This parameter is used when bringing back top-level data from an OpenAccess database. *Data_type*: string, optional

`-topDir` *dirname*	Specifies the path to the top-level design created by `saveDesign -def`. This design directory should contain the Verilog netlist and DEF files. Typically, this directory has the extension .enc.dat *Data_type*: string, optional

Examples

- The following command assembles the design after bringing back information from the top-level cell and two block-level cells. The top-level design data is in the top.enc.dat directory and the block-level data is in the `block_a.enc.dat` and `block_b.enc.dat` directories.
  ```
  assembleDesign -topDir top.enc.dat -blockDir block_a.enc.dat -blockDir block_b.enc.dat
  ```
- The following command assembles a design with the top-level restored from an database which was previously saved with saveDesign -def with block_a instantiated as an abstracted hard macro.
  The contents of block_a are defined by a DEF and Verilog netlist:
  - the DEF file with the name block_a.def
  - the Verilog netlist block_a.v

  ```
  assembleDesign -topDir top.enc.dat -blockData block_a.def block_a.v
  ```
- The following commands load a top-level design then incrementally calls `assembleDesign` to pull in the contents of one hard macro in the design:
  - top.enc.dat is a top-level design saved by saveDesign -def where block_a is represented by an abstract
  - block_a.def and block_a.v represent the physical contents of block_a in DEF and Verilog format
  - `restoreDesign top.enc.dat top`
  - `assembleDesign -blockData block_a.def block_a.v`
- The following command assembles a design that was saved in an OpenAccess database. The design contains two blocks.
  - The library, cell, and view names for the top-level are `libForOA, DTMF,` and `ptnView1` respectively.
  - The library, cell, and view names for the first block are `libForOA, TDSP_CORE,` and `ptnView1` respectively.
  - The library, cell, and view names for the second block are libForOA, TDSP_ARB, and ptnView1 respectively.

  ```
  assembleDesign -topDesign {libForOA DTMF ptnView1} -block {libForOA TDSP_CORE ptnView1} -block {libForOA TDSP_ARB ptnView1}
  ```
- The following command is an example of incremental assemble design capability that can restore master and clones at different levels of hierarchy. Along with assembling nested partitions:
  - Block1 and Block2 are partitions at top level
  - Block1 contains Block3 and Block4
  - Block4 is a clone of Block2

  ```
  restoreDesign topDesign.enc.dat top
  assembleDesign -blockDir Block1.enc.dat -blockDir Block2.enc.dat -blockDir Block3.enc.dat
  ```
- `-mmmcFile` and `-cpfFile` do not work with incremental `assembleDesign` since the timing and power intent is defined during design initialization, however when running assembleDesign to fully initialize the design timing and power intent can be supplied:
  ```
  assembleDesign -topDir top.enc.dat -blockDir block_a.enc.dat -mmmcFile viewDefinition.tcl -cpfFile CPFFile
  ```

assignIoPins

```
assignIoPins
[-help]
[-align]
[-debugPinAll]
[-debugPinFile fileName]
[-improveSI]
[ {-pin { pinNameList } | -pin_file  fileName  | -exclude_pin_file  fileName } [-moveFixedPin ]  [-ignore_group_pins ]]
[-autoBusGroup]
```

Assigns the top I/O pin locations for a block-level design. Set the maximum or minimum pin layers with the `setPinAssignMode -maxLayer` or `-minLayer` parameters. By default, the `assignIoPins` command sets the depth of all partition pins equal to: MINAREA/pin width. This ensures that the minimum area rule is met. However, if any pin-size-related constraints are specified on these pins, the user-specified pin size will have a higher precedence.

Notes:

- The MINAREA/pin width means that the default pin width will be met MAR (minimum area rule) if an area rule of this layer is defined in the technology LEF. An I/O pin width value is based on the following order:
  1. User-specified pin width constraint.
  2. Minimum area rule of the layer if it is available in the technology file.
  3. Default layer width
- When assigning pins, the `assignIoPins` command does not check for violations between placed pins and shapes of objects (such as macros, standard cells, etc) just inside the partition fence (design boundary). This may result in DRV violations if the fence (design boundary) to core distance is zero.
- The `assignIoPins` command honors preferred routing layer attributes as soft constraints during pin assignment and reports the nets that have these attributes. It also honors the *keep out spacing* constraints on pin groups and net groups.
- In bottom-up flow, the `assignIoPins` command promotes both signal and P/G pins from the list of pins promoted by the `setPromotedMacroPin` command.
- The `assignIoPins` command honors net/pin groups that have all nets from multiple buffer chains added in the same group. Such groups can be generated through bus guide flow, feedthrough insertion flow, or can be user created. It places the pins of such nets in order to achieve better pin alignment and improve the QoR.

You can use this command after running placement and early global routing to legalize the I/O pins. However, placement is not a mandatory step for pin assignment. Placement is recommended for better QOR.

Parameters

`-align`	If you specify this option, each top I/O pin will be aligned with one of the instance pins with which it is connected. The instance pin with which the I/O pin is aligned is the one whose distance from its nearest edge is shortest among all the instance pins connected to the top I/O pin. *Default*: If you do not specify this option, the location of the top pin is based on the average of the distance of all instance pins (that are connected to the top I/O pin) from their respective nearest edges. *Data_type*: bool, optional
`-autoBusGroup`	Specifies that the buses will be grouped automatically. **Note:** Internally the createPinGroup command is applied on buses. It is removed automatically after the command execution. *Data_type*: bool, optional

`-debugPinAll`	Specifies that all pins will be debugged. **Note:** The `-debugPinAll` and `-debugPinFile` parameters can be used to write the following information in the log file: • Pin assign mode information • Connectivity information of each partition pin, including pinGroup/netGroup name and NDR name • Available pin slot information on each edge for each layer and pin slot density • PinGuide box and virtual pinGuide box information, master-clone series, feedthru chain and so on. • Reason for failure on the first failed location • For pins with location constraints, if the pin is not placed at the location constraint then the reason is provided in a tabular form. • For placed partition pins, the pin location, layer, edge, spacing and so on are provided. *Data_type*: bool, optional
`-debugPinFile` *fileName*	Specifies the file containing the pin-list for partition or the net that is to be used for debugging. *Data_type*: string, optional
`-exclude_pin_file` *fileName*	Specifies pin-list to be excluded for partition in a file. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `assignIoPins` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man assignIoPins`
`-ignore_group_pins`	Avoid placing the whole group of pins. With this parameter enabled, the `pinGroup` and `netGroup` pins are ignored during selected pin assignment. *Data_type*: bool, optional
`-improveSI`	Avoid signal integrity issues by blocking tracks while placing pins to avoid overlap of wires. With this parameter specified, the `asignIoPins` command does not allow pins to be placed on the tracks in an area which spans a layer higher or lower (on the preferred routing direction) and also on the tracks on the left and right of the placed pin. *Data_type*: bool, optional
`-moveFixedPin`	If you use this parameter, the specified pins with a *`Fixed`* status can also be moved. However, this parameter must be used with the -pin parameter to specify the list of fixed pins to move while assigning io-pins. **Note:** Pins that are not specified but have a *`Fixed`* status are not moved. *Default*: If you do not specify this parameter, the specified pins with a *`Fixed`* status are *not* moved. *Data_type*: bool, optional
`-pin` *pinNameList*	Specifies that only the specified pins should be assigned. **Note:** To move fixed pins while assigning io pins, you must specify the `-moveFixedPin` parameter. *Default* : If you do not specify this parameter, all pins are assigned. *Data_type*: string, optional

`-pin_file` *fileName*	Specifies the pin list for a partition in a file. In the pin file, the pins and nets are specified in the following format: `Partition:` *PtnName/BlockName* *Pin1* *Pin2* .. *PinN* `Partition:` *PtnName/BlockName* *Pin1* *Pin2* .. *PinN* `Nets:` *netA* *netB* .. *netN* **Note:** While specifying the pin list in the pin_file, it is necessary to give the "Partition" keyword followed by the name of the partition or block. If this is not specified, no operations are performed. You can specify multiple partitions in the same pin_file. The pin_file does not support buses or wild cards for pin names. If a pin specified in the list or a partition is not present in the design, a warning is displayed. *Data_type*: string, optional

Example

- The following command assigns all io pins and can also move pins with fixed-status.
  ```
  assignIoPins -moveFixedPin -pin *
  ```
- The following command accept a file *pinLst.txt* that contains the list of pins and assigns io pins.

  ```
  assignPtnPin -pin_file pinLst.txt
  ```

  Where *pinLst.txt* contains:
  ```
  Partition: top
  out1
  out2
  out3
  Partition: A
  in1
  in2
  in3
  Partition: B
  pina
  pinb
  pinc
  ```

  The `assignIoPins` command selects all Io pins under the section `Partition:top`.

assignPtnPin

```
assignPtnPin
[-help]
[-basedOnMasterOnly]
[-blackbox]
[-debugPinAll]
[-debugPinFile fileName]
[-dumpVirtualPinGuide]
[-ignoreAbuttedCheck]
[-improvePinOrder]
[-improveSI]
[-layerPriority {layeridList}]
[-markFixed]
[-printPinMovementStatistics]
[-skipAutoBusBitOrder]
[-skipPlaceExternalUnconnectedPin]
[-unplacedOnly]
[partitionName | {{{-ptn partitionName {-pin {pinName list}}} |
{-pin_file fileName [-exclude_ptn ptnName]} | {-exclude_pin_file ptnName}} [-moveFixedPin ] [ -ignore_group_pins ]}]
[-alignFeedThruPinsOptWithMasterClone ]
[-autoBusGroup ]
[-enforceRoute | -enforceRouteLegal | -enforceFlyline ]
```

Assigns partition pins before the partitions are committed. By default, the assigned pins will be in a Placed status after running this command. You can specify a Fixed status by running this command with the `-markFixed` option. The `assignPtnPin` command does not align pins in the local context thus avoiding mis-aligning in other scenarios. minimizing maximum mis-alignment effects across farsighted net pairs (2-pin nets). For example, in master/clone pin assignment, since the clone pin follows the master's position, the position of the pin on master partition is determined such that pin on clone also gets aligned on clone.

Running the `saveFPlan` command saves the pin assignment in the floorplan to a separate file named `fpFileName.fp.ptnpin`, which is included in main `fpFileName.fp` floorplan file.

By default, the `assignPtnPin` command sets the depth of all partition pins equal to: MINAREA/pin width. This ensures that the minimum area rule is met. However, if any pin-size-related constraints are specified on these pins, the user-specified pin size will have a higher precedence. The `assignPtnPin` command internally calls the `reportUnalignedNets` command to generate the summary report at the command line.

When assigning pins, the `assignPtnPin` command does not check for violations between placed pins and shapes of objects (such as macros, standard cells, etc) just inside the partition fence (design boundary). This may result in DRV violations if the fence (design boundary) to core distance is zero.

You can use this command after specifying the partitions, placing the design, and after running or loaded routing information. If no routing information is available, the Innovus software uses the projected pin assignment. However, placement is not a mandatory step for pin assignment. Placement is recommended for better QOR.

Notes:

- The `assignPtnPin` command honors preferred routing layer attributes as soft constraint during pin assignment and reports the nets that have some attributes assigned to them. It also honors the keep out spacing constraint for a pin group or net group.
- This command only assigns signal pins. Power and ground pins are created during partition. However, this pin optimization honors power stripes and follow pins.
- This command assigns pins for blackboxes as well as regular partitions. If this command is run on a blackbox that has one or more pins with a single LEF port but with multiple shapes within the LEF port, the command will remove these multiple shapes and create a single shape. If this command is run on a blackbox that has one or more pins with multiple LEF ports, the first LEF port will be processed as per the command and the remaining LEF ports will remain unchanged.
- The `assignPtnPin` command performs automatic pin assignment of partitions inside other partitions. It places pins of nested partitions similar to single level partitions.
- In top-down flow, the `assignPtnPin` command only promotes signal pins from the list of pins promoted by the `setPromotedMacroPin` command.
- The `assignPtnPin` command honors net/pin groups that have all nets from multiple buffer chains added in the same group. Such groups can be generated through bus guide flow, feedthrough insertion flow, or can be user created. It places the pins of such nets in order to achieve better pin alignment and improve the QoR.
- The `assignPtnPin` command can place the pins on the partitions that are connected to PG supplies defined in the netlist.

Note: You can use the `check_design -type pin_assign` command to detect the potential problems and correct the design before running `assignPtnPin` command.

Parameters

`-alignFeedThruPinsOptWithMasterClone`	Specifies that the pins should be placed such that they are aligned on different partitions across buffers on master/clone partitions.
	• In symmetric designs, since there is no conflict with master/clone so it aligns the pins of all the path.
	• In non-symmetric designs, it will try to place pins such that master-clone alignment count should not degrade.
	  ◦ It only assigns a feedthru path if there is common alignment zone available between master-clone alignment and feedthru chain alignment.
	  ◦ It assigns pins in common alignment zone for first pins in feedthrough path.
	Data_type: bool, optional

`-autoBusGroup`	Specifies that the buses will be grouped automatically. **Note:** Internally the `createPinGroup` command is applied on buses. It is removed automatically after the command execution. *Data_type*: bool, optional
`-basedOnMasterOnly`	Specifies that for designs that have partition clones, the command should consider only the partition master and use the master assignment for all the clones. *Default*: For designs that have partition clones, this command by default also considers partition clones while assigning pins. *Data_type*: bool, optional
`-blackbox`	Assigns pins of blackboxes. *Data_type*: bool, optional
`-debugPinAll`	Specifies that all pins will be debugged. **Note:** The `-debugPinAll` and `-debugPinFile` parameters can be used to write the following information in the log file: • Pin assign mode information • Connectivity information of each partition pin, including pinGroup/netGroup name and NDR name • Available pin slot information on each edge for each layer and pin slot density • PinGuide box and virtual pinGuide box information, master-clone series, feedthru chain and so on. • Reason for failure on the first failed location • For pins with location constraints, if the pin is not placed at the location constraint then the reason is provided in a tabular form. • For placed partition pins, the pin location, layer, edge, spacing and so on are provided. *Data_type*: bool, optional
`-debugPinFile` *`fileName`*	Specifies the file containing the pin-list for partition or the net that is to be used for debugging. *Data_type*: string, optional
`-dumpVirtualPinGuide`	Writes the virtual pinGuide for netGroup and pinGroup. *Data_type*: bool, optional
`-enforceFlyline`	Specifies that the pin assignment completely follows flylines, without taking into consideration any pin constraints. *Data_type*: bool, optional

`-enforceRoute`	Specifies that the pin assignment completely follows the routing results generated by Early Global Route, without taking into consideration any pin constraints. For example, the following constraints are not considered when the `-enforceRoute` parameter is used: • Constraints related to pin spacing, layer, width, depth, and side • Pin Guide constraints and Pin Group constraints • Constraints specified by the `-pinsOffStrip` parameter of the `assignIoPins` and the `assignPtnPin` commands The `-enforceRoute` parameter can be useful when, for example, you want to compare pin locations based purely on Early Global Route results with pin locations that honor the specified pin constraints. *Data_type*: bool, optional
`-enforceRouteLegal`	Specifies that during pin assignment, the pins are placed close to the routing cross points but at legal locations only. Consequently all the pins are legally placed, even if they may not be on routing cross points always. The `-enforceRouteLegal` parameter ignores the pinGroup, netGroup, and pinGuide constraints. *Data_type*: bool, optional
`-exclude_ptn` *ptnName*	Specifies the list of excluded partition for pin file. *Data_type*: string, optional
`-exclude_pin_file` *fileName*	Specifies pin-list to be excluded for a partition in a file. In the pin file, the pins and nets are specified in the following format: `Partition:` *PtnName/BlockName* *Pin1* *Pin2* .. *PinN* `Partition:` *PtnName/BlockName* *Pin1* *Pin2* .. *PinN* `Nets:` *netA* *netB* .. *netN* *Data_type*: string, optional
`-help`	Outputs a brief description that includes type and default information for each `assignPtnPin` parameter. For a detailed description of the command and all of its parameters, use the man command: `man assignPtnPin`.
`-ignoreAbuttedCheck`	When enabled, the abutted check is ignored during pin assignment. This results in faster pin assignment on abutted designs. *Data_type*: bool, optional
`-ignore_group_pins`	Avoid placing the whole group of pins. With this parameter enabled, the `pinGroup` and `netGroup` pins are ignored during selected pin assignment. **Note:** If all the pins in a group have been individually selected for pin assignment and `-ignore_group_pins` is applied then the pin assignment takes precedence and `-ignore_group_pins` parameter is not honored for this group. Rest of the groups whose pins appear in the selection list continue to be ignored. *Data_type*: bool, optional

`-improvePinOrder`	Reduces flightline crossing during pin alignment. The partition and the blackbox pins are rearranged to be aligned with external connections: • Guided pins are reordered within the pin guide box. • Pins are rearranged at (or close to) their original locations. • Pin ordering is performed independently for each partition edge. The locations of fixed pins, aligned pins or multi-location pins is not changed. Master-clone pins are not reordered. **Note:** `-improvePinOrder` is a post processing step during pin assignment so it can override the pin assignment that is complying with `-maxPinMovementForAlign`. This option should not be used with `-maxPinMovementForAlign`, if you strictly want to control the maximum pin movement for alignment. *Data_type*: bool, optional
`-improveSI`	Avoid signal integrity issues by blocking tracks while placing pins to avoid overlap of wires. With this parameter specified, the `assignPtnPin` command does not allow pins to be placed on the tracks in an area which spans a layer higher or lower (on the preferred routing direction) and also on the tracks on the left and right of the placed pin. *Data_type*: bool, optional
`-layerPriority {`*`layeridList`*`}`	Specifies the metal layer(s) that should be used with priority during pin assignment such that there is an increase in alignment in the prioritized layers. With this parameter specified, there is no degradation in the total unaligned nets of the partition/design. There is an increase in the unaligned number in the prioritized layers and a decrease in the over all pin count in the non-prioritized layers. **Note**: The list of layers to be given priority must be a sunset of the layers selected with `setPinAssignMode -maxLayer -minLayer` parameters. **Note**: In case of conflict in the layer priority between the `assignPtnPi`n command and the `createPinGuide` command on some edges, the `createPinGuide` command priority takes precedence. For example, in the following command: `assignPtnPin -layerPriority {7 6 2 3}` • Most aligned pins are in layers 7 and 3 or 6 and 2 (horizontal / vertical) • Most unaligned pins are also in 7,6,2,3 • Maximum pins are in these layers *Data_type*: string, optional
`-markFixed`	Specifies that all pins will have a *Fixed* status. *Data_type*: bool, optional
`-moveFixedPin`	If you use this parameter, the specified pins with a *Fixed* status can also be moved. **Note:** Pins that are not specified but have a *Fixed* status are not moved. *Default*: The specified pins with a *Fixed* status are not moved. *Data_type*: bool, optional
`-ptn` *`partitionName`*	Specifies the partition names for pin assignment. *Default*: Pins are assigned for all partitions. **Note:** Pin assignment for a selected partition by specifying the *`partitionName`* is obsolete and will be removed in the next major release of the software. The obsolete parameter still works in this release, but to avoid warnings, and to ensure compatibility with future releases, update your scripts to use `-ptn` *`partitionName`* `-pin` *`pinList`* `...` *Data_type*: string, optional

`-pin_file` *fileName*	Specifies the pin list for a partition in a file. In the pin file, the pins and nets are specified in the following format: `Partition:` *PtnName/BlockName* *Pin1* *Pin2* .. *PinN* `Partition:` *PtnName/BlockName* *Pin1* *Pin2* .. *PinN* `Nets:` *netA* *netB* .. *netN* **Note:** While specifying the pin list in the pin_file, it is necessary to give the “Partition” keyword followed by the name of the partition or block. If this is not specified, no operations are performed. You can specify multiple partitions in the same pin_file. The `pin_file` does not support buses or wild cards for pin names. If a pin specified in the list or a partition is not present in the design, a warning is displayed. *Data_type*: string, optional
`-pin pinList ...`	Specifies the list of pins to be assigned in the respective partitions. *Default*: Pins are assigned for all partitions. *Data_type*: string, optional

`-printPinMovementStatistics`	Prints a summary of the deviation (in micrometers) of the final pin locations from the point of intersection of the net and the partition edge. The report on the screen contains the following statistics:
	• Maximum displacement on the X axis. This is the difference in the x-coordinates of the point of intersection of the net and the partition edge, and the point at which the pin is finally assigned.
	• Maximum displacement on the Y axis.
	• Maximum X+Y displacement. The X+Y displacement of a pin is the sum of the displacement of a pin on the X axis and the displacement of the pin in the Y axis. For example, if a pin has moved 10 micrometers on the X axis and 5 micrometers on the Y axis, the X+Y displacement for that pin is 15. Thus, if there are three pins and their X+Y displacements are 5, 23, and 30 respectively, the maximum X+Y displacement is reported as 30.
	• Mean of the X+Y displacement.
	The report appended to the Innovus log file contains the following additional details:
	• Names of the pins that have moved the maximum distances.
	• The coordinates of the point of intersection of the net and the partition edge, and the point at which the pin is finally assigned.
	Here is a sample report displayed on screen.
	`Partition: [tdsp_core]`
	`maximum X = 120.1200 um (Pin: t_data_out[6])`
	`maximum Y = 58.8000 um (Pin: rom_data_in[4])`
	`maximum X+Y = 154.5600 um (Pin: t_data_out[6])`
	`moved from (706.2000, 1025.0800) -> (586.0800, 990.6400)`
	`mean X+Y = 12.5600 um`
	`total pins = 114`
	`pins moved = 75`
	The log file has additional information such as:
	`Pin: int: X Movement: 3.3000 um ; Y Movement: 0.0000. From (701.2500, 1247.6800) -> (697.9500, 1247.6800)`
	Data_type: bool, optional

`-skipAutoBusBitOrder`	Skips automatically placing the bus pins together. *Data_type*: bool, optional
`-skipPlaceExternalUnconnectedPin`	Skips placing partition pins that are not connected outside the partition. *Data_type*: bool, optional
`-unplacedOnly`	Assigns only unplaced pins. *Data_type*: bool, optional

Example

- The following command assigns partition pins of all partitions
  ```
  assignPtnPin
  ```
- The following command assigns partition pins, including those which have fixed status of all partitions and mark them as fixed after assigning them
  ```
  assignPtnPin -markFixed -moveFixedPin
  ```
- The following command accepts a file *`pinLst.txt`* that contains the list of pins to be placed.

  ```
  assignPtnPin -pin_file pinLst.txt
  ```

  Where *`pinLst.txt`* contains:
  ```
  Partition: top
  out1
  out2
  out3
  Partition: A
  in1
  in2
  in3
  Partition: B
  pina
  pinb
  pinc
  ```

  The `assignPtnPin` command, considers all pins of all partitions in the file, except the pins under the section Partition:top.
- The following command ignores the `partition B` mentioned in the pin file pin.list.
  ```
  assignPtnPin -pin_file pinLst.txt -exclude_ptn {B}
  ```

changeBBoxMasterFromR0

```
changeBBoxMasterFromR0
[-help]
black_box_cell
{R90 R180 R270 MX MX90 MY MY90}
new_x_origin
new_y_origin
```

Converts the orientation of the master instance blackboxes from R0 to the specified orientation.

Parameters

black_box_cell	Specifies the name of the balckbox cell. *Data_type*: string, required
-help	Outputs a brief description that includes the type and default information for each `changeBBoxMasterFromRO` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man changeBBoxMasterFromRO`
new_x_origin	Specifies the new origin x-coordinate. *Data_type*: float, required
new_y_origin	Specifies the new origin y-coordinate. *Data_type*: float, required
{R90 R180 R270 MX MX90 MY MY90}	
	Specifies the new orientation value of the cell. The orientation value can be R0, R90, R180, R270, MX, MX90, MY, or MY90. *Data_type*: enum, required

Examples

- The following commands converts the orientation of the master blackboxes CORE_CELL120 to R90.
  `changeBBoxMasterFromR0 CORE_CELL120` {R90}

Related Information

- `assignPtnPin`
- partition

  - Handling of Blackboxes with Non-R0 Orientation

changeBBoxMasterToR0

```
changeBBoxMasterToR0
[-help]
[-checkOnly]
[cellName | {cellNameList}]
```

Converts the orientation of the master instance blackboxes to R0. Partitioning-related commands such as `assignPtnPin`, `partition`, `assembleDesign`, `flattenPartition`, `convertBlackBoxToFence`, and `editPin` work only with those blackboxes whose master instances have an R0 orientation. If the design has master blackboxes whose orientation is non-R0, you can use the `changeBBoxMasterToR0` command to change the orientation of these master blackboxes to R0.

Note: Orientations of corresponding clone instances are also relatively transformed.

Parameters

`-checkOnly`	Specifies that the command will not actually convert the orientation of any master blackbox; it only displays the number of master blackboxes whose orientation would have been changed had the command been run without the `-checkOnly` parameter. *Default:* The orientation of master blackboxes in the design are converted to R0. *Data_type*: bool, optional
cellName | {*cellNameList*}	
	Specifies that cell, or the list of blackbox cells, whose orientation will be converted to R0. *Default:* The orientation of all master blackboxes is converted to R0. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `changeBBoxMasterToR0` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man changeBBoxMasterToR0`

Examples

- The following commands converts the orientation of all master blackboxes that have a non-R0 orientation to R0.
  ```
  changeBBoxMasterToR0
  ```
- The following commands converts the orientation of the master blackboxes CORE_CELL120 and CORE_CELL121 to R0.
  ```
  changeBBoxMasterToR0 {CORE_CELL120 CORE_CELL121}
  ```
- The following command uses the `-checkOnly` parameter. The command, therefore, does not actually convert the orientation of any master blackboxes; it only returns the number of blackboxes whose orientation would have been converted to R0 had the command been run without the `-checkOnly` parameter.
  ```
  changeBBoxMasterToR0 -checkOnly
  ```

checkHierRoute

```
checkHierRoute
[-help]
[-ptn {ptnName | ptnList}]
[-outFile outputFileName]
```

Checks and reports hierarchy violations for nets in the specified partitions.

The following conditions for hierarchy violations are checked:

- Intra-partition nets: All routes of this net should be within the partition boundary.
- Pure-Top nets: All routes of this net should be outside the partition boundary or touch the partition boundary from *outside*.
- Inter-partition nets: At least one route of this net must cross the partition boundary at partition pin. No route should cross the partition boundary at any other point.

Note: You can use this command to check for hierarchy violations before you push down the signal routes with the `partition -pushRoute` command.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `checkHierRoute` parameter. For a detailed description of the command and all of its parameters, use the man command: `man checkHierRoute`.
`-ptn {ptnName | ptnList}`	Report the nets that violate the hierarchy with respect to the specified partition(s). *Default:* The command checks the hierarchy violations for nets on all partitions. *Data_type*: string, optional
`-outFile outputFileName`	Prints the details of net-wise violations in the specified file. *Default:* By default, the name of the file is `hier.rpt`. *Data_type*: string, optional

Examples of hierarchy violation conditions:

The following are examples of hierarchy violation conditions:

- If wires of a inter-partition net, are crossing the partition boundary at a place other than the corresponding pin shape.
- If wires of a inter-partition net, are crossing the partition boundary at multiple places.
- If wires of a pure top net, are crossing over a partition.
- If wires of a intra partition net are going outside the boundary of its partition.

Example

The following command checks the violations for nets on all the partitions in the design. A report of the violations is printed in the `hier.rpt` file.

```
checkHierRoute
```

The output of this command on the display terminal is as follows:

```
------------------------------------------------------------
Summary of hierarchy violating nets with respect to each partition:
Partition: p1: 3 nets (0 intra, 2 inter, 1 top, 0 global)
Partition: p2: 1 nets (0 intra, 1 inter, 0 top, 0 global)
Partition: p3: 2 nets (1 intra, 0 inter, 1 top, 0 global)
Details of hierarchy violating nets reported in: hier.rpt
------------------------------------------------------------
```

The report printed in the `hier.rpt` file is as follows:

```
------------------------------------------------------------

Added the new header as follows:
############################################################
```

```

pin_spacing_constraint pin_spacing_routeBlk pin_width clones logical_pin pin_color unplaced}]
[-report_violating_pin ] [-exclude_ptn fileName]}]
```

Checks the generated partition pins and I/O pins for the following:

- Pins are assigned to the proper metal layer depending on the side of the partition
- Pins are assigned within the range of layers reserved for the partition
- Any particular location on a routing layer has only one pin assigned
- Pins are assigned on the routing track
- Pins have a valid spacing from:
  - routing blockages
  - power pins and ground pins
- Pins have the correct size, status, and type
- Pin assignment follows the minimum area rule
- If the `-minArea` parameter is specified, the command checks for and reports the pins that are:
  - floating from inside (that is, the pins that are connected only to the top level)
  - floating from both inside the partition and at the top level.
- Pins follow the *`keep out spacing`* constraints for a pin group or net group and reports any violations in pin spacing.
- Checks and reports pin violations on clones in a master clone design.

The summary report generated by the command also includes information about feedthrough pins. These reports also provide a summary for all pins of the partition, blackbox, and the top module. However, summary report for pins is only displayed when there are multiple objects. It does not provide such a summed up pin summary report when we use the `checkPinAssignment` command for individual objects. For example, when you use the `-ptn` option, the summary report for all pins is not displayed.

Note:

- The `checkPinAssignment` command honors preferred routing layer attributes as soft constraint during pin assignment and reports violations in pin layers as an error.
- You can use this command after running early global routing and then partitioning with pin assignment.
- If this command is run on a blackbox that has one or more pins with a single LEF port but with multiple shapes within the LEF port, the command will check violations only with respect to the first shape and will ignore all other shapes. If this command is run on a blackbox that has one or more pins with multiple LEF ports, the command will check violations only with respect to the first LEF port and will ignore all other LEF ports.
- The `checkPinAssignment` command supports nested partitions and reports the pin status for pins of nested partitions.
- Each time the `checkPinAssignment` command is run, it automatically refreshes the violations as properties of pins. It clears all violation properties on all pins and populates fresh violation properties on each pin based on the latest `checkPinAssignment` results. These properties are persistent in save/restore DB. You can query results of the pin violations report generated by the `checkPinAssignment` command to automate the flow. For example:
  - To query for all partition pins with depth violation, you can use the following query:
    ```
    get_db [get_db partitions .master -if {.obj_type == hinst}] .local_hpins -if {.vio_depth == 1}
    ```
  - To query for all pins (partition pins, bbox pins and IO pins) with depth violation, you can use the following query:
    ```
    puts [concat \
    ```

```
[get_db ports -if {.vio_depth == 1}] \
[get_db [get_db partitions .master -if {.obj_type == inst}] .pins -if {.vio_depth == 1}] \
[get_db [get_db partitions .master -if {.obj_type == hinst}] .local_hpins -if {.vio_depth == 1}] \
]
```

- To query for all pins in a master partition having pin depth violations, you can use the following query:
  `get_db [get_db partitions .master -if {.obj_type == hinst && .name == "S"}] .local_hpins -if {.vio_depth == 1}`

Parameters

`-help`	Outputs a brief description that includes type and default information for each `checkPinAssignment` parameter. For a detailed description of the command and all of its parameters, use the man command: `man checkPinAssignment`
`-excludeNetFile` *filename*	Specifies the file containing the list of nets that are excluded while checking the pin assignment. *Data_type*: string, optional
`-exclude_ptn` *partitionName*	Specifies the list of excluded partition for pin file. *Data_type*: string, optional
`-exclude_pin_file` *fileName*	Specifies pin-list to be excluded for partition in a file. *Data_type*: string, optional

`-ignore`	Ignores the mentioned list of categories from checking and reporting.
	• `bus_guide`: When specified, the command ignores the violations of bus guide constraints.
	• `net_group`: When specified, the command ignores the ordering and exclusion checks on nets.
	• `pin_abutment`:When specified, the command ignores pin positions for abutted partitions.
	• `pin_depth`: When specified, the command ignores violations of pin depth constraints.
	• `pin_group`: When specified, the command ignores ordering and exclusion checks on pins.
	• `pin_guide`: When specified, the command ignores violations of pin guide constraints.
	• `pin_layer`: When specified, the command ignores violations of pin layer constraints.
	• `pin_min_area`:When specified, the command ignores the pins that are:
	  ◦ floating from inside the partition
	  ◦ floating from both inside the partition and at the top level
	• `pin_on_fence`: When specified, the command ignores whether the pins are on fence or not.
	• `pin_on_track`: When specified, the command ignores pins that are placed on layer tracks.
	• `pin_spacing`: When specified, the command ignores violations of pin spacing constraints.
	• `pin_width`: When specified, the command ignores violations of pin width constraints.
	• `clones`: When specified, the command ignores violations relating to clone pins.
	• `logical_pin`: When specified, the command ignores violations relating to logical pins.
	• `pin_color`: When specified, the command ignores violations relating to pin color.
	• `pin_spacing_constraint`: When specified, the command ignores violations relating to pin spacing constraints.
	• `pin_spacing_routeBlk`: When specified, the command ignores violations relating to pin spacing around routing blockages.
	• `unplaced`: When specified, the command ignores violations relating to unplaced pins.
	Data_type: enum_list, optional

`-outFile` *fileName*	Specifies that in addition to displaying the report on screen, the command should also print the output in the specified file. *Default*: `<design_name>.checkPin.rpt` *Data_type*: string, optional

`-pin {`*`pinName	pinNameList`*`}`	Specifies that the command should be run on the specified pin(s) only. *Data_type*: string, optional

`-pin_file` *`fileName`*	Specifies the pin list for a partition in a file.
	In the pin file, the pins and nets are specified in the following format:
	`Partition:` *`PtnName/BlockName`*
	`Pin1`
	`Pin2`
	`..`
	`PinN`
	`Partition:` *`PtnName/BlockName`*
	`Pin1`
	`Pin2`
	`..`
	`PinN`
	`Nets:`
	`netA`
	`netB`
	`..`
	`netN`
	Note: While specifying the pin list in the pin_file, it is necessary to give the “Partition” keyword followed by the name of the partition or block. If this is not specified, no operations are performed. You can specify multiple partitions in the same pin_file.
	The `pin_file` does not support buses or wild cards for pin names. If a pin specified in the list or a partition is not present in the design, a warning is displayed.
	Data_type: string, optional

`-preCheck`	Checks for the feasibility of pin assignment mainly to catch the reason for unplaced pins in fully abutted design. **Note**: No other `checkPinAssignment` command parameter can be used if `-preCheck` is being used. *Data_type*: bool, optional
`-ptn` *`partitionName`*	Specifies the partition for which the pins will be checked. This parameter is required if the partition is not the top-level module. *Data_type*: string, optional
`-reportSameNetPinAsOverlap`	Reports the pins (connected to same net) placed at the same location and the same layer as overlap violation. *Data_type*: bool, optional
`-report_violating_pin`	Reports all the pins with violations. *Data_type*: bool, optional
`-skipCheck {overlap layer spacingConstraint fixedIoPins multiTermNet masterClone netGroup connection relativeOrientRelation gridTrackAlignment symmetryOffset masterCloneSize alignZone}`	

	Skips checking the category from the list of type of checks. This parameter is used with the `-preCheck` parameter. • `overlap`: When specified, the command skips checking for any partition fences which are overlapping. • `layer`: When specified, the command skips checking for allowed layers on abutted edges of partition. • `spacingConstraint`: When specified, the command skips checking for spacing on abutted edges. • `fixedIoPins`: When specified, the command skips checking if the block pin is placed on an abutted edge with its connected partition. • `multiTermNet`: When specified, the command skips checking for multi partition pin nets in abutted design. • `masterClone`: When specified, the command skips checking for master and clone partitions. • `netGroup`: When specified, the command skips checking the net group ordering check in master and clone. • `connection`: When specified, the command skips checking if symmetric abutted designs have each master-clone pair connected to same pin. • `relativeOrientRelation`: When specified, the command skips checking the clone inside clone orientation. The clone inside a clone should have a relative orientation with its parent which is checked with master/clone inside master. • `gridTrackAlignment`: When specified, the command skips checking for routing track offset in Master-Clone design to avoid off grid pins. • `symmetryOffset`: When specified, the command skips checking if the clone to clone offset (relative distance on abutted edges) is same as in the master to master/clone connection pair. This is required so that the pins in each clone-clone and master-master/clone pair is the same. • `masterCloneSize`: When specified, the command skips checking the master-clone size. This is required to check the number of poly edges of clones with master and check each edge size for any mismatch. • `alignZone`: When specified, the command skips checking for the common alignment zone between master-clone and their connected partitions. *Data_type*: enum_list, optional
topCellName	Specifies the top cell name. *Data_type*: string, optional

Example

- The following command checks violations on pins of partition `tdsp_core` and reports them to file `reportViolation.txt` :

  ```
  checkPinAssignment -ptn tdsp_core -outFile reportViolation.txt
  ```

  The output will look like:

  ```
  Start Checking pins of partition: [tdsp_core]
  Summary report for partition: [tdsp_core]
  Total Pins : 134
  Legally Assigned Pins : 110
  Illegally Assigned Pins : 0
  Unplaced Pins : 0
  Constant/Spl Net Pins : 24
  Internal Pins : 0
  Legally Assigned Feedthru Pins : 0
  Illegally Assigned Feedthru Pins : 0
  End of Summary report
  End Checking pins of partition: [tdsp_core]
  ```

- The following command accepts a file that contains the list of pins for partition A and partition B and checks any violations in pin assignment.

  ```
  checkPinAssignment -ptn {A B} -pin_file pinLst.txt
  ```

clonePtnObj

```
clonePtnObj
[-help]
[-checkOnly]
[-objs {all busGuides}]
[-redo]
[-refHinsts list_of_hinst_names]
[-sync]
[-targetHinsts list_of_hinst_names]
[-undo]
```

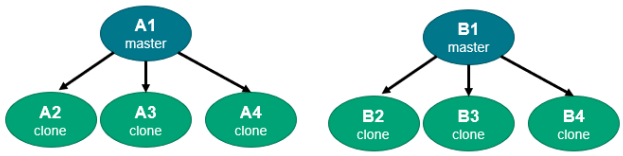
Syncs up the changes made to the specified objects in the master or clone partitions in the design with other hierarchical instances (master and clones) of the same module.

Parameters

`-checkOnly`	When specified, the tool check if the master and clone partitions are out of sync or not. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `clonePtnObj` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man clonePtnObj`
`-objs {all busGuides}`	When specified, the tool does the sync-up of the specified objects. *Data_type*: enum, optional
`-redo`	When specified, the changes made to the object are done again . The master and clone partitions are brought to the next committed sync state. **Note**: Currently this parameter only supports the `busGuides` object type (-objs). **Note**: This parameter is exclusive with the `-refHinsts` and –`targetHinsts` parameter options. *Data_type*: bool, optional
`-refHinsts list_of_hinst_names`	Specifies the name of the master or clone hierarchical instance *from which* the obj data is to be copied. *Default*: All master partitions in the design. *Data_type*: string, optional
`-sync`	When specified, the objects in all master and clone partitions are synced up by looking at the changes in shape in any hierarchical instance of the master and clone partitions. **Note**: Currently this parameter only supports the `busGuides` object type (-objs). **Note**: This parameter is exclusive with the `-refHinsts` and –`targetHinsts` parameter options. *Data_type*: bool, optional

`-targetHinsts` *list_of_hinst_names*	Specifies the name of the master or clone hierarchical instance *to which* the obj data is to be copied. • When a master partition is specified with the `-targetHinsts` parameter, specifying the `-refHinsts` becomes mandatory as a user provided hinst is considered to sync up objects. • When clones partitions are specified with the `-targetHinsts` parameter, specifying the `-refHinsts` is optional as master hierarchical instances are automatically considered (default) to sync-up objects *Default*: All clone partitions in the design. *Data_type*: string, optional
`-undo`	When specified, the changes made to the object are reverted. The master and clone partitions are brought to the last committed sync state. **Note**: Currently this parameter only supports the `busGuides` object type (-objs). **Note**: This parameter is exclusive with the `-refHinsts` and –`targetHinsts` parameter options. *Data_type*: bool, optional

Example



```
Hinst: A1 (master), A2 (clone), A3(clone), A4 (clone)
Hinst: B1 (master), B2 (clone), B3(clone), B4 (clone)
```

- The following commands syncs all clones to their respective master.
  ```
  clonePtnObj
  ```
- The following command syncs the hinsts A2 and A3 (clones) to the master of module A (A1).
  ```
  clonePtnObj -targetHinsts {A2 A3}
  ```
- The following command syncs the hinsts A1 (master) and A3 (clone) to the hinst A2 (clone)
  ```
  clonePtnObj -targetHinsts {A1 A3} -refHinsts {A2}
  ```
- The following command syncs the hinsts A1 (master), A3, B2, B3 (clones) to hinsts A2 (clone) and the master of module B (B1)
  ```
  clonePtnObj -targetHinsts {A1 A3 B2 B3} -refHinsts {A2}
  ```
- The following command checks and reports if the hinsts A1(master) and A3, B2, B3 (clones) are synced to hinst A2 (clone) and the master of module B (B1)
  ```
  clonePtnObj -targetHinsts {A1 A3 B2 B3} -refHinsts {A2} -checkOnly
  ```
- The following command checks and reports if the hinsts A1 (master) and A3, B2, B3 (clones) are synced to hinst A2 (clone) and the master of module B (B1) for bus guides only.
  ```
  clonePtnObj -targetHinsts {A1 A3 B2 B3} -refHinsts {A2} -checkOnly -objs {busGuides}
  ```
- The following command syncs the hinsts A1 (master) and A3, B2, B3 (clones) to hinst A2 (clone) and the master of module B (B1) for bus guides only.
  ```
  clonePtnObj -targetHinsts {A1 A3 B2 B3} -refHinsts {A2} -objs {busGuides}
  ```

commit_pushdown_eco

```
commit_pushdown_eco
[-help]
-eco_object_dir dirName
-post_eco_dir dirName
-pre_eco_dir dirName
[-ptns ptnNameList]
```

Commits ECO for a partition block by applying ECO and generating a database for the block. It applies the previously generated ECO objects, to each partition, in parallel, using EDP (parallel/distributed) framework.

Note: The `commit_pushdown_eco` command also commits the FlexHtree amendment into the partition block. Clock amendments can be restored by using the `create_ccopt_clock_tree_spec` command.

Parameters

`-eco_object_dir dirName`	Specifies the parent directory which contains all partition sub-directories in which ECO object files of partitions are kept. **Note:** The eco object file names are pre-determined to be: *eco_logical.txt* *eco_physical.txt* *eco_net.def.gz* *eco_pin.txt* *Data_type:* string, required
`-help`	Outputs a brief description that includes type and default information for each `commit_pushdown_eco` parameter. For a detailed description of the command and all of its parameters, use the man command: `man commit_pushdown_eco`.
`-post_eco_dir dirName`	Specifies the parent directory in which, after applying the ECOs, the partition databases are to be saved. *Default:* *./post_eco_dir* *Data_type:* string, required
`-pre_eco_dir dirName`	Specifies the latest version of original design, to which ECO objects need to be applied. It contains sub-directories to represent latest version of each partition database. *Data_type:* string, required
`-ptns ptnNameList`	Specifies the list of partition names for which ECO objects are created. *Data_type:* string, optional

comparePinAssignStatistics

```
comparePinAssignStatistics
[-help]
[-ignoreMinWireLength minWireLength]
[-outFile pinQoRCompareFileName]
-reference referenceFileName
-target targetFileName
```

Generates a pin QoR comparison file based on a reference and a target pin QoR file.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `comparePinAssignStatistic` parameter. For a detailed description of the command and all of its parameters, use the man command: `man comparePinAssignStatistic`.
`-ignoreMinWireLength minWireLength`	Specifies the minimum wire length. If reference wire length at a partition pin is less than the *`minWireLength`*, then it is not reported in the output file. *Default*: 60 *Data_type*: string, optional
`-outFile pinQoRCompareFileName`	Specifies an output file for the pin QoR comparison. *Default*: `./qor_compare.txt` *Data_type*: string, optional
`-reference referenceFileName`	Specifies the reference file generated using the `reportPinAssignStatistics` command. For example, the following command generates a reference pin QoR file named `pin_qor_reference.txt`. `reportPinAssignStatistics -outFile pin_qor_reference.txt` *Data_type*: string, required
`-target targetFileName`	Specifies the target file generated using the `reportPinAssignStatistics` command. For example, the following command generates a target pin QoR file named `pin_qor_target.txt`. `reportPinAssignStatistics -outFile pin_qor_target.txt` *Data_type*: string, required

Example

The following command generates a pin QoR comparison file, `pin_qor_compare.txt`:

```
reportPinAssignStatistics -outFile pin_qor_reference.txt
reportPinAssignStatistics -outFile pin_qor_target.txt
comparePinAssignStatistics -reference pin_qor_reference.txt -target pin_qor_target.txt -outFile pin_qor_compare.txt
```

connectMacroFeedthrough

```
connectMacroFeedthrough
[-help]
[-selectNet string | -excludeNet string | -selectMarkedNet]
[-selectInst string | -excludeInst string]
[-ecoFile string | -checkOnly]
[-portMap string]
[-verbose]
[-maxSearchDistance float]
[-searchAllSides]
[-abutment float]
[-abutmentFile string]
[-floatingPortList string]
```

Connects predefined feedthrough pins in custom macros to overlapping nets that have wires crossing over the custom macros, based on the routing information. The feedthrough connectivity details are defined in a mapping file, which is specified through the `-portmap filename` parameter. You can include or exclude specific nets or instances. This command deletes routing only for the modified nets. You can run this command after placing the design and running Early Global Route.

Parameters

`-abutment float`	Specifies the distance that pins on the same track and layer must have from one another so as to be considered as abutted. If two or more pins are considered as abutted, any feedthrough path that passes through one of the pins will pass through the other pin(s) as well. *Default:* If this parameter is not specified, the default value is `1` micron. *Data_type*: float, optional

`-abutmentFile string`	Reports, in the file specified, the list of pins that are considered as abutted. In the file, each feedthrough path is traced from the first input pin to the last input pin. Each path is preceded by the word `Begin` on a new line and followed by the word `End` on a new line.
	Here is the extract from an example file:
	`Begin`
	`Inst [Inst1], Term In [A1] Term Out [X1]`
	`Inst [Inst2], Term In [A2] Term Out [X2]`
	`End`
	In the previous example, the out term `X1` of instance `Inst1` is abutted with the in term `A2` of instance `Inst2`.
	Data_type: string, optional

`-checkOnly`	Specifies that only a report of the messages should be displayed but no changes should be made to the netlist. *Data_type*: bool, optional

`-ecoFile string`	Specifies the name of the ECO file that will contain a report of the changes. You can use this file while performing ECO changes.
	Here is a sample report generated through this parameter:
	`FORMATVERSION 2`
	`ATTACHTERM eco_instance1 inputbuf2[2] testnet`
	`ADDNET FE_FTM_1_testnet`
	`ATTACHTERM eco_instance1 outputbuf2[2] FE_FTM_1_testnet ATTACHTERM i1 A FE_FTM_1_testnet ATTACHTERM eco_instance1 rstb FE_FTM_1_testnet`
	Data_type: string, optional

`-excludeInst string`	Prevents feedthrough buffers from being added for the specified instance. The names of the instances are specified in a file, specified by `fileName`. In the file, you can specify wildcards (*) for the instance names to exclude. *Default:* All instances of the cell types specified in the portmap file are considered. *Data_type*: string, optional

`-excludeNet` *string*	Prevents feedthrough buffers from being added to the specified net. The names of the nets are specified in a file, specified by *fileName*. In the file, you can specify wildcards (*) for the net names to exclude. *Default:* All nets or bus names are considered. *Data_type*: string, optional
`-floatingPortList` *string*	Specifies that the list of unused ports should be saved in the specified file. The file lists the instance name and the pin name for each unused port. After running the `connectMacroFeedthrough` command, the unused ports should be manually tied. You can use this parameter to save the list of the unused ports to a file. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `connectMacroFeedthrough` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man connectMacroFeedthrough`
`-maxSearchDistance` *float*	Specifies the distance in microns from the wire crossing till which the command should search to find a connected feedthrough. **Note:** Specifying a large value for this parameter might have an adverse impact on the Quality of Results (QoR). *Data_type*: float, optional

`-portMap` *string*	Specifies the name of the file that contains the feedthrough connectivity definitions.
	Default: If you do not specify a file name, a file with the name `portmap` in the current directory is used.by default.
	Note: A file with the feethrough connectivity definitions must be available.
	The syntax of the file is as follows:
	`MACRO MacroName`
	`Macro definition section`
	`END MACRO`
	The definition of the macro is provided in the *`Macro definition`* section, which can contain one or more feedthrough sections. The name of the feedthrough section is optional.
	The syntax of the Feedthrough section is as follows:
	`Feedthrough [FeedthroughName]`
	`Pin Section`
	`END FEEDTHROUGH`
	Each Feedthrough section contains one section for the INPUT PIN and one section for the output pin.
	Note: Multi-fanout feedthrough sections are not supported.
	The syntax of the pin section is as follows:
	`PIN PinName`
	`DIRECTION {in | out };`
	`SIDE {left | right | top | bottom};`
	`END PIN`
	If the pin direction is not specified, it is read from the LEF file. If you specify a value for pin direction, ensure that it is consistent with the description in the LEF file.
	Note: The pin direction `inout` is not supported.
	Note: All the predefined macro feedthrough pins should be floating pins.
	Here is an example of a mapping file:
	`MACRO RAMXXX`
	`FEEDTHROUGH feedthrough1`
	`PIN feedthrough1_in`
	`END PIN`
	`PIN feedthrough1_out`
	`END PIN`
	`END FEEDTHROUGH`
	`FEEDTHROUGH feedthrough2`
	`PIN feedthrough2_in`
	`END PIN`
	`PIN feedthrough2_out`
	`END PIN`
	`END FEEDTHROUGH`
	`END MACRO`
	Data_type: string, optional

`-searchAllSides`	Specifies that if the closest available feedthrough pin on the same side cannot be connected, the command should search for the feedthrough pins on other sides as well. When you specify this parameter, it is recommended to limit the distance of the search using the `-maxSearchDistance` option to get good QoR. *Default*: The command searches for a feedthrough whose in and out pins lie *on the same sides* of the macro on which the wires enter and exit the macro. *Data_type*: bool, optional
`-selectInst` *string*	Specifies that the feedthrough buffers should be added only for the specified instances. *Data_type*: string, optional

`-selectMarkedNet`	Specifies that feedthrough buffers should be added only to the nets that are currently selected. *Default:* All nets.are considered. *Data_type*: bool, optional
`-selectNet` *string*	Specifies that the feedthrough buffers should be added only to the specified nets. *Data_type*: string, optional
`-verbose`	Provides additional messages, for example net-specific messages. *Data_type*: bool, optional

Example

The following command connects predefined feedthrough buffers in custom macros for nets that are listed in the file named `NetsToIncludeFile`. The command searches for a distance of 10 microns. The feedthrough connectivity is described in a file named `portmapFileForNets`.

```
connectMacroFeedthrough portMap portmapFileForNets -selectNet NetsToIncludeFile
-maxSearchDistance 10
```

convertBlackBoxToFence

```
convertBlackBoxToFence
[-help]
{-cell cellName | -inst instName}
```

Converts a blackbox to a fence. Once the black box netlist is well defined, use this command to convert the black box back to a regular partition.

Parameters

`-cell cellName`	Specifies the name of a module or submodule that should be converted to a fence. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `convertBlackBoxToFence` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man convertBlackBoxToFence`
`-inst instName`	Specifies the name of the blackbox instance that should be converted to a fence. *Data_type*: string, optional

Example

The following command converts a blackbox, hinst5, to a fence:

```
convertBlackBoxToFence -inst hinst5
```

Related Information

  - Defining Blackboxes

convertFenceToBlackBox

```
convertFenceToBlackBox
[-help]
{-cell cellName | -hinst hinstName}
[-noRebuildTiming]
[-size { x y }]
```

Converts a fence to a blackbox. Use this command before committing partition.

Parameters

`-cell cellName`	Specifies the name of a module or submodule that should be converted to a black box. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `convertFenceToBlackBox` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man convertFenceToBlackBox`
`-hinst hinstName`	Specifies the name of the hierarchical instance that should be converted to a black box. *Data_type*: string, optional
`-noRebuildTiming`	Skips rebuilding the timing graph and re-initializing the top cell information. *Data_type*: bool, optional
`-size {x y}`	Specifies the width and height of the blackbox. *Default:* If you do not specify this parameter, the current fence size is taken as the initial size of the blackbox. *Data_type*: point, optional

Example

The following command converts a fence, cp1A to a blackbox with 12,44 dimensions.

```
convertFenceToBlackBox -cell cp1A -size 12 44
```

Related Information

create_partition_wrapper

```
create_partition_wrapper
[-help]
-partitions partition_names
[-pushdown]
[-wrapper_name wrapper_suffix_string]
```

Creates a wrapper partition that embeds the specified partition cell to preserve its verilog module definition in the netlist. The wrapper partition can be used for making netlist changes without changing the netlist of the embedded (wrapped) cell definition.

The wrapper partition has the same partition definition attributes as the specified partition. The timing constraints (through SDC) and low power information (through UPF) of the wrapper partition is updated with the correct hierarchical pin information. The pin constraints applied on pins of the original partition are mapped to the new wrapper pins.

Note: After the wrapper partition is created using the `create_partition_wrapper` command:

- the original partition ceases to exist (`deletePartition`).
- the fence attributes and pin constraints of the original partition are removed.
- the module pins of the original partition as preserved such that they cannot be altered later.

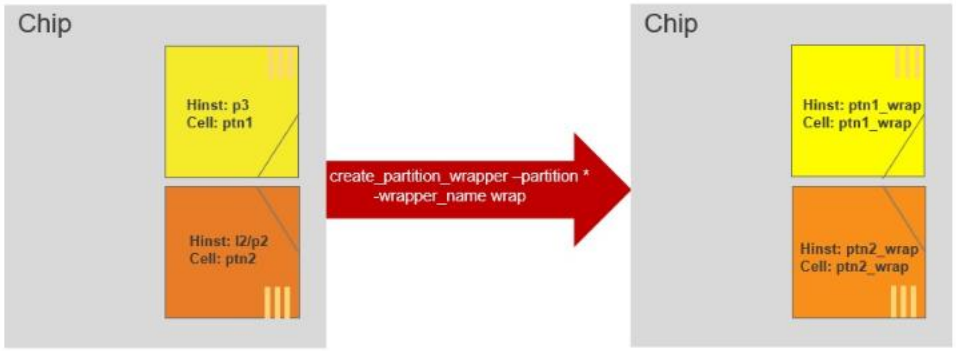
Parameters

`-help`	Outputs a brief description that includes the type and default information for each `create_partition_wrapper` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man create_partition_wrapper`
`-partitions partition_names`	Specifies the name of one or more partitions on which the wrapper is created. **Note:** The partition_wrapper will have the same: • Number, name and locations (If already assigned) of pins • Area, shape, location, orientation *Data_type*: string, optional
`-pushdown`	When enabled, it keeps the partition hinst intact for the wrapper partition. *Data_type*: bool, optional
`-wrapper_name wrapper_suffix_string`	Specifies the suffix that is added to a partition name for creating a partition wrapper. *Default*: <`ptnName`>`_wrapper` *Data_type*: string, optional

Example

The following command creates a wrapper partition with suffix wrap for all the partitions in the design:

```
create_partition_wrapper -partition * -wrapper_name wrap
```



Related Information

- deletePartition
- Partitioning the Design chapter in the *Innovus User Guide*

create_pushdown_eco

```
create_pushdown_eco
[-help]
[-gen_script_only]
[-ptn_net_dir ptnNetDirName]
[-ptns ptnNameList]
{-original_dir originalDirName | -original_tag tagName }
{-pushdown_dir pushdownDirName | -pushdown_tag tagName }
[-eco_object_dir outputDirName | -eco_tag tagName ]
```

Creates logical and physical ECO files that are used to push down ECO objects by comparing two partition databases. It generates logical and physical ECO objects for each partition, in parallel, using EDP (parallel/distributed) framework. The regular/special wire ECO is generated for those nets which are specified via `-ptn_net_dir`.

Note: A FlexHtree amendment file will also be created besides the logical ECO and DEF file.

Parameters

`-eco_object_dir` *outputDirName*	Specifies the directory in which eco objects for each partition will be created. The eco objects are saved in sub-directories, one for each partition. *Default*: `./eco_object_dir` *Data_type*: string, optional
`-eco_tag` *tagName*	Specifies the tag name where ECO file will be saved. *Default*: `eco_object_dir` *Data_type*: string, optional
`-gen_script_only`	Generates a TCL command file but does not execute it. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes type and default information for each `create_pushdown_eco` parameter. For a detailed description of the command and all of its parameters, use the man command: `man create_pushdown_eco`.
`-original_dir` *originalDirName*	Specifies the directory in which the original partition sub-directories are present. *Data_type*: string, optional
`-original_tag` *tagName*	Specifies the tag name where the original partition pnr model is present. *Data_type*: string, optional
`-ptn_net_dir` *ptnNetDirName*	Specifies the directory in which net file for each partition is present. The net file contains the nets for which regular/special wire ECO is generated. **Note**: Specifying `-ptn_net_dir` iis not mandatory for the `create_pushdown_eco` command. If the `-ptn_net_dir` parameter is not specified, then logically modified nets are selected for DEF ECO generation. Otherwise, a union of `-ptn_net_dir` and logically-modified-nets is selected for DEF ECO generation. *Data_type*: string, optional
`-ptns` *ptnNameList*	Specifies the list of partition names for which ECO objects are to be created. *Data_type*: string, optional
`-pushdown_dir` *pushdownDirName*	Specifies the directory in which pushdown (Example, clock tree constructed) version of partition sub-directories are present. These partitions will be compared with respective original partitions, and ECO objects will be generated for each of them. *Data_type*: string, required
`-pushdown_tag` *tagName*	Specifies the tag name of the pnr model that contains the pushed down data (clock or feedthrough). *Data_type*: string, optional

Example

- The following is an example dbTCL script for generating the original database of each partition , generating the pushdown database, and then generating partition pushdown ECO:

```
# load full-chip database;
partition -pushDownSpecialNetAsObs $snets
savePartition -dir $originalDir -def
flattenPartition
# Create push down (say, htree/push_ptn_network) database
push_ptn_network -nets $clk_nets -output_nets_for_wire_distribution nets.txt …
partition -pushDownSpecialNetAsObs $snets -inputNetsForWireDistribution nets.txt
savePartition -dir $htreeBlocksDir -def
# Create ECO by comparing original and pushdown databases
create_pushdown_eco \
-original_dir $originalDir \
 -pushdown_dir $htreeBlocksDir \
 -ptns [concat [dbget top.ptns.master.cell.name] [dbget top.name]] \
-eco_object_dir $ecoObjectDir \
-gen_script_only
```

  The above script generates ECO objects, for each partition, in $ecoObjectDir. ECO is generated only for the partitions specified via –ptns option.
- The following command generates logical and physical ECO objects based on the specified tag names of the pnr model:

```
create_pushdown_eco -original_tag original -pushdown_tag block_with_ft  -eco_tag eco_data
```

createNetGroup

```
createNetGroup
[-help]
[-mixed_signal]
[-spacing  minSpaceInTracks]
[ {[-optimizeOrder ]} | -spreadPin | -compact_area ]
[-excludePin {allLayer | sameLayer | allLayerInGuidedArea} [-keep_out_spacing integer]]
{ [netGroupName [-net netNameList]]}
```

Creates an empty net group. A net group can contain net names, bus names, or segments of a bus. To add nets into the net group, use the `addNetToNetGroup` command. You can use this command after importing the design.

Note: If a net is part of a net group, and you add the same net to another net group, the Innovus software will display a warning, but the net will be added to the second net group too. However, when pin assignment is performed, the net is considered part only of the *first* net group to which it was added – and *not* part of any other net group to which it was subsequently added.

Parameters

`-compact_area`	Specifies that pins in the group are assigned tightly together. By default, pins which are part of a group and associated to a guide can be spread inside the guide based on the area available and alignment to targets. The `compact_area` option, when used, ignores the alignment and available area and forces the pins to the minimum area on guide honoring the minimum spacing constraint and overlooking any alignment to targets.  *Data_type*: bool, optional
`-excludePin {allLayer | sameLayer | allLayerInGuidedArea}`	
	Specifies that pins in the group exclude foreign pins on all layers, same layer, or on all layers in the guided area. • `allLayer`: Specifies that pins in the group exclude foreign pins between grouped pins on all layers. • `sameLayer`: Specifies that pins in the group exclude foreign pins grouped pins on all same layer. • `allLayerInGuidedArea`: Specifies that pins in the group exclude foreign pins in the guide area defined for the group, on all layers. **Note:** If guide is not defined for a group down the flow, `allLayerInGuidedArea` option would be treated like `-excludePin {allLayer}` for the group without guides behavior. *Data_type*: enum, optional
`-help`	Outputs a brief description that includes type and default information for each `createNetGroup` parameter. For a detailed description of the command and all of its parameters, use the man command: `man createNetGroup`.
`-keep_out_spacing integer`	Specifies the minimum spacing between the pins placed outside of the group, in number of tracks or pitch. *Minimum:* 0 *Maximum:* 65535 *Data_type*: int, optional
`-mixed_signal`	Specifies to identify a mixed signal group. *Data_type*: bool, optional

`-net netNameList`	Specifies the name of the net(s). You can use wildcards (`*?`) with this parameter. *Data_type*: string, optional
`netGroupName`	Specifies the name of the created net group name. *Data_type*: string, optional
`-optimizeOrder`	Specifies that pins in the group are reordered to optimize wire length. If this option is not selected, the pin order is exactly as specified in the pin group. *Data_type*: bool, optional
`-spacing minSpaceInTracks`	Specifies the minimum spacing between the pins of the net group. *Default:* The default value is two tracks. *Data_type*: int, optional
`-spreadPin`	Specifies that pins in the group must be distributed evenly. *Data_type*: bool, optional

Example

- The following command creates a net group `bundle1`:
  ```
  createNetGroup bundle1
  ```
- The following command creates a net group `bundle1` and allows re-ordering of the nets definition inside the group:
  ```
  createNetGroup bundle1 -optimizeOrder
  ```

createPinBlkg

```
createPinBlkg
[-help] [-cell cell_name] [-layer {layer_id_list}]
{ -area {x1 y1 x2 y2} | [-edge edge_number [[-offset_start distance] [-offset_end distance]]] |
[-abutted_master_clone_channel_access_only [-feedthru_blockage_file file_name]] }
[ -name blockage_name [ -includePinPatterns {pin_name_pattern_list} | -excludePinPatterns {pin_name_pattern_list} ]]
```

Creates a pin blockage for a module. You can run this command on the top-level module also. You can use this command during partition floorplanning.

Parameters

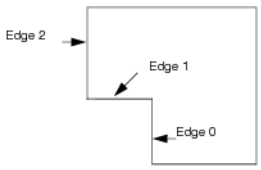
`-abutted_master_clone_channel_access_only`	Creates pin blockages on abutted edges of master-clones that abut to its parent or other master-clones. *Data_type*: bool, optional
`-area x1 y1 x2 y2`	Specifies the lower left x coordinate, lower left y coordinate, upper right x coordinate, and upper right y coordinate respectively of the blockage area. **Note:** The values of *x1, y1, x2, and y2* are relative to the top-level coordinates. *Data_type*: box, optional
`-cell cell_name`	Specifies the module for which the pin blockage will be created. • If `-cell` option is not used, then the blockage applies to top-level pins only. • If `-cell` option is used, then only, the Partition/Blackbox pins will be considered. *Data_type*: string, optional
`-edge edge_number`	Specifies the integer value where edge numbering starts from lower-left corner of a partition clock-wise. Edge `0` is the edge that has the smallest y value. *Data_type*: int, optional
`-excludePinPatterns {pin_name_pattern_list}`	Specifies the pin-list on which the pin-blockage is not applicable. Pins which are specified in this list can be placed in this area legally. **Note**: The `-excludePinPatterns` and `-includePinPatterns` options are mutually exclusive and cannot be used in a single command. Both these options require the use of the `-name` option to specify the name of the partition pin blockage. *Data_type*: string, optional
`-feedthru_blockage_file file_name`	Outputs a file with coordinates of blocked edges for pin assignment transformed into feedthru blockage_file format. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `createPinBlkg` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man createPinBlkg`
`-includePinPatterns {pin_name_pattern_list}`	Specifies the pin-list on which the pin-blockage is applicable. All other pins can be placed in this area legally. **Note**: The `-excludePinPatterns` and `-includePinPatterns` options are mutually exclusive and cannot be used in a single command. Both these options require the use of the `-name` option to specify the name of the partition pin blockage. *Data_type*: string, optional
`-layer {layer_id_list}`	Specifies the metal layer(s) for which pins are not to be created. **Note:** Layers can be specified using the LEF layer names or layer ID numbers. *Default:* If no layer number is specified, all metal layers are blocked. *Data_type*: string, optional

`-name` *`blockage_name`*	Specifies the name of the partition pin blockage. *Default:* By default, the name is `defPtnPinBlkName`. *Data_type*: string, optional
`-offset_end` *`distance`*	Specifies the distance, in microns, from the ending corner of the edge. *Minimum Value:* 0 *Maximum Value:* 65535 *Data_type*: float, optional
`-offset_start` *`distance`*	Specifies the distance, in microns, from the starting corner of the edge. *Minimum Value:* 0 *Maximum Value:* 65535 *Data_type*: float, optional

Examples

- The following command creates a pin blockage named `pinBlkg1` on the edge `0` of layers `Metal5` and `Metal7` for the module `PtnBlock1`.

```
createPinBlkg -edge 0 -name pinBlkg1 -cell PtnBlock1 -layer {Metal5 Metal7}
```



- The following command creates a pin blockage named `pinBlkg2` on layers Metal5 and Metal7 for the module `PtnBlock2`. The blockage area is bounded by the lower-left coordinates `100`, `200` and the upper-right coordinates `300`, `400`.

```
createPinBlkg -area 100 200 300 400 -name pinBlkg2 -cell PtnBlock2 -layer {Metal5 Metal7}
```

- The following command creates a pin blockage named pinBlkg3 that only applies to partition pins that match pattern1 and pattern2. All other partition pins can be placed in this area legally.

```
createPinBlkg -includePinPatterns {*pattern1* *pattern2*} -cell PtnBlock3 -area $area -name pinBlkg3
```

- The following command creates a pin blockage named pinBlkg4 that only applies to all partition pins except those that match pattern1 and pattern2. Only pins that match pattern1 and pattern2 can be placed at this edge legally.

```
createPinBlkg -excludePinPatterns {*pattern1* *pattern2*} -cell PtnBlock4 -edge 0 -name pinBlkg4
```

createPinGroup

```
createPinGroup
[-help]
[-cell string]
[-excludePin {allLayer | sameLayer | allLayerInGuidedArea}]
[-keep_out_spacing integer]
[-spacing integer]
[-width width]
[{[-optimizeOrder ]} | -spreadPin | -compact_area ]
[{pinGroupName [-pin {pinNameList}]} ]
```

Creates a pin group for a partition or for the top-level. Pin groups in conjunction with pin guides are used to guide pin placement when the `assignIoPins` or `assignPtnPin` command is called. A pin group is a first class data object–delete with the `deletePinGroup` command.

Parameters

`-cell string`	Specifies the name of the module or submodule to which the pin group applies. This parameter is not required if the pin group being created is for the top level. *Data_type*: string, optional
`-compact_area`	Specifies that pins in the group are assigned tightly together. By default, pins which are part of a group and associated to a guide can be spread inside the guide based on the area available and alignment to targets. The `compact_area` option, when used, ignores the alignment and available area and forces the pins to the minimum area on guide honoring the minimum spacing constraint and overlooking any alignment to targets.  *Data_type*: bool, optional
`-excludePin {allLayer | sameLayer | allLayerInGuidedArea }`	
	Specifies that pins in the group exclude foreign pins on all layers, same layer, or on all layers in the guided area. • `allLayer`: Specifies that pins in the group exclude foreign pins between grouped pins on all layers. • `sameLayer`: Specifies that pins in the group exclude foreign pins between grouped pins on the same layer. • `allLayerInGuidedArea`: Specifies that pins in the group exclude foreign pins in the guide area defined for the group, on all layers. **Note**: If a guide is not defined for a pin group, `-excludePin allLayerInGuidedArea` option is treated like `-excludePin {allLayer}`. *Data_type*: enum, optional
`-help`	Outputs a brief description that includes type and default information for each `createPinGroup` parameter. For a detailed description of the command and all of its parameters, use the man command: `man createPinGroup`
`-keep_out_spacing integer`	
	Specifies the minimum spacing between the pins named in the pin group and any other pins, in number of tracks. *Minimum*: 0 *Maximum*: 65535 *Data_type*: int, optional

`-optimizeOrder`	Specifies that pins in the group are to be reordered to optimize wire length during pin placement. Otherwise the pin order is exactly as specified in the pin group. *Data_type*: bool, optional
`-pin {pinNameList}`	Specifies the pins to be added to the pin group. Additional pins can be added subsequently with the `addPinToPinGroup` command. *Data_type*: string, optional
pinGroupName	Specifies the name of the pin group. *Data_type*: string, required
`-spacing integer`	Specifies the minimum spacing between the pins of the pin group, in number of tracks. *Default*: Two tracks. *Data_type*: int, optional
`-spreadPin`	Specifies that pins in the group are distributed evenly. *Data_type*: bool, optional
`-width width`	Specifies the pin width, in microns. *Data_type*: float, optional

Example

- The following command creates a pin group PG_A22 for module SH17 and adds the pins pinA22_1 and pinA22_2 to it.
  ```
  createPinGroup PG_A22 -cell SH17 -pin {pinA22_1 pinA22_2}
  ```
- The following command creates a pin group PG_A for module SH17 and adds the pins pinA22_1 and pinA22_2 to it. No other pins are to be placed between pinA22_1 and pinA22_2 in any layer.
  The pins may be reordered to optimize wire length.
  ```
  createPinGroup PG_A22 -cell SH17 -pin {pinA22_1 pinA22_2} -excludePin allLayer -optimizeOrder
  ```
- The following command deletes the pin group PinGroup17 of module SH17:
  ```
  deletePinGroup -cell SH17 -pinGroup PinGroup17
  ```

createPinGuide

```
createPinGuide
[-help]
{[ -area {x1 y1 x2 y2} | [-edge integer [[-offset_start float] [-offset_end float]]][ -layer {layeridList} [-layerPriority ]]}
 [-pin string | -pinGroup string | -net string | -netGroup string | -name string ]
 [-edge integer | -net string | -netGroup string]
 [-cell string | -net string | -netGroup string]
```

Creates a pin guide object. The pin guide restricts the pins associated with the pin guide within the specified area. You can run this command on the top-level module also. You can assign the same pin group or net group to multiple pin guides. Pin guides are generated for buses, nets, net groups, pins, and pin groups. For buses and nets that do not physically connect to the partition, pin guides will not be created. You can use this command during partition floorplanning.

Parameters

`-area x1 y1 x2 y2`	Specifies the coordinates of the pin guide area. • x1: Specifies the lower left x coordinate of the pin guide area. • y1: Specifies the lower left y coordinate of the pin guide area. • x2: Specifies the upper right x coordinate of the pin guide area. • y2: Specifies the upper right y coordinate of the pin guide area. *Data_type*: rect, required
`-cell string`	Specifies the name of the cell. This parameter is not required if you are using the command for a top-level module. *Data_type*: string, optional
`-edge integer`	Specifies the integer value where edge numbering starts from lower-left corner of a partition clock-wise. Edge 0 is the edge that has the smallest y value. *Data_type*: int, optional
`-help`	Outputs a brief description that includes type and default information for each `createPinGuide` parameter. For a detailed description of the command and all of its parameters, use the man command: `man createPinGuide`.
`-layer {layerIdList}`	Specifies the metal layer(s) for the pin guide. *Default*: You must specify the correct pin layer. If you do not specify the pin layer, Innovus will display an error instead of choosing the preferred layer to assign pins like the old behavior. **Note**: Pins will not be assigned on non-preferred layers. However, pins can be assigned on Metal1 layer if the `ptnAssignPinsOnLayerM1` global variable is set to 1. **Note**: Layers can be specified using the LEF layer names or layer ID numbers. *Data_type*: string, optional
`-layerPriority`	Assign pins based on the order of -layer specified by the user. *Data_type*: bool, optional

`-name string`	Specifies the name of the partition pin guide object. If you specify this parameter, the command will automatically detect whether the object is a pin, pin group, net, net group, or bus. In case there are different objects with the same name, the command selects the object with the following precedence: • If a cell name is specified, the command selects the object with the following precedence: a. pin b. pin group c. net d. net group or bus • If a cell name is not specified, the command selects the object with the following precedence: a. net b. net group or bus For example, if the value of objectName is P1, and there is a pin group named P1 as well as a bus named P1, the command will select the pin group named P1. *Data_type*: string, optional
`-net string`	For nets, specifies the name of the net. For buses, specifies the name of the bus or the bus radix. *Data_type*: string, optional
`-netGroup string`	Specifies the name of the net group. *Data_type*: string, optional
`-offset_end float`	Specifies the distance, in microns, from the ending corner of the edge. *Minimum Value*: 0 *Maximum Value*: 65535 *Data_type*: float, optional
`-offset_start float`	Specifies the distance, in microns, from the starting corner of the edge. *Minimum Value*: 0 *Maximum Value*: 65535 *Data_type*: float, optional
`-pin string`	Specifies the name of the pin. *Data_type*: string, optional
`-pinGroup string`	Specifies the name of the pin group. *Default*: By default the name is defRGuideName. *Data_type*: string, optional

Example

- The following command creates a pin guide object for bus addr:
  ```
  createPinGuide -area 2353.8000 7123.000 2653.8000 8298.2000 -name addr
  ```

Related Information

  - Setting Pin Constraints
  - Pin Guides

createPtnCut

```
createPtnCut
[-help]
[-ptn string]
x1 y1 x2 y2
```

Creates a partition rectangular cut from a partition. This object can be created after specifying a module guide to be a partition. Rectangular cuts can only occur on the edge of the partition guide. You can use this command after specifying partition.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `createPtnCut` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man createPtnCut`
x1 y1 x2 y2	Specifies the coordinates of the cut area (*x1 y1 x2 y2*). *Data_type*: rect, required
`-ptn` *string*	Specifies a partition to create a partition cut. If this option is not selected, the command loops through all the partitions an attempts to find the overlapped partition, then creates a partition cut for that partition. *Data_type*: string, optional

Example

The following command creates a partition cut area to modify a rectangular partition:

```
createPtnCut 2353.8000 7123.000 2653.8000 8298.2000
```

Related Information

- Partitioning the Design chapter in the *Innovus User Guide*

createPtnFeedthrough

```
createPtnFeedthrough
[-help]
feedBox
[layerId]
[-name string]
```

Creates a partition routing feedthrough object. The object area keeps pins from being created on the specified metal layer. A dump file with routing obstruction is created for the top level partition (done when saving the partition). You can use this command during partition floorplanning.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `createPtnFeedthrough` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man createPtnFeedthrough`
`feedBox`	Specifies the coordinates *(x1 y1 x2 y2)* of the feedthrough area. *Data_type*: rect, optional
`layerId`	Specifies the metal layer where pins are not to be created. **Note:** If *`layerId`* is not specified then by default feed-through is created on all the partition layers. *Data_type*: int, optional
`-name` *`string`*	Specifies the name of the routing feedthrough. *Data_type*: string, optional

Example

The following command creates a feedthrough object to block pins being generated on layer *Metal5*:

```
createPtnFeedthrough 2353.8000 7123.000 2653.8000 8298.2000 5
```

definePartition

```
 definePartition
[-help]
[-coreSpacing {left right top bottom}]
[-minPitchBottom x]
[-minPitchLeft x]
[-minPitchRight x]
[-minPitchTop x]
[-pinLayerBottom {list_of_layers}]
[-pinLayerLeft {list_of_layers}]
[-pinLayerRight {llist_of_layers}]
[-pinLayerTop {llist_of_layers}]
[-placementHalo {left right top bottom }]
[-railwidth railWidth]
[-reservedLayer {list_of_layers}]
[-routingHalo floatValue]
[-routingHaloBottomLayer integerValue]
[-routingHaloTopLayer integerValue]
[-stdCellHeight x]
{-hinst string | -proto {master_hinst_name_list} | -cell cellName}
[-checkCloneAlignment ]
[-hinst hInstName [-copyFrom refPtnName]]
[-cell cellName [-copyFrom refPtnName]]
```

Defines a new partition corresponding to a hierarchical instance. The `definePartition` command supports nested partitions and can be used to specify partitions inside a partition. While specifying partitions, you can specify the definition in any order. You can use this command after importing the design.

Note: The `definePartition` command does not check for fence constraint on clones and does not align them to the partition with respect to the master. If the clones do not have fence constraint, `definePartition` makes fences for clone modules.

Note: For designs that have backside metal layers, both the backside and frontside layers are accepted. However, the automatic pin assignment flow is not impacted with the support for backside metal layers. It assigns pins on front layers only.

Parameters

`-cell` *cellName*	Specifies the name of the cell for defining a new partition at an instance that has R0 orientation. **Note**: For black-boxes, an instance with non-R0 orientation is chosen if an instance with R0 orientation is not found. *Data_type*: string, optional
`-checkCloneAlignment`	When specified, the `definePartition` command only checks the alignment of the clone with the master partition and reports a mismatch. **Note**: The `definePartition` command does not move the clones. *Data_type*: bool, optional
`-copyFrom` *refPtnName*	Specifies the name of the reference partition from which to copy their properties. While copying the constraints, the shape, orientation, and location are considered: • **Orientation**: The orientation of the partition being defined is copied from the reference partition (*`refPtnName`*). If the reference partition has clones, then the orientation of the master is considered. • **Shape**: The shape of the partition being defined is copied from the reference partition (*`refPtnName`*). • **Location**: The fence location of the partition hinst being defined takes priority. In case the target partition hinst does not have a fence constraint (location), the location information is copied from the reference partition master hinst. This will result in overlapping fences. **Note:** If the `-copyFrom` parameter is being used with the -cell parameter that has multiple Hinsts, then the location of the hinst that has a fence (location) constraint is considered as the master of the partition being defined. *Data_type*: string, optional
`-coreSpacing {left right top bottom}`	

	Specifies the space, in micrometers, between the module boundary and core design area of the partition module on the left, right, top, and bottom sides respectively. The partition pins will be located at the partition instance boundary and the core area. **Note**: These core-to-edge values are always synchronized between the partition and the corresponding power domain as follows: If the specified instance was also earlier defined as a power domain, these values for the partition, by default, will have the same value as the values for the power domain. If you specify different values for the partition, the values for the power domain are updated so that they are the same as the values defined for the partition. Similarly, if a power domain is created (or an existing power domain modified) on the specified instance after the partition is defined, the values set earlier for the partition are updated so that they are the same as the values defined for the power domain. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `definePartition` parameter. For a detailed description of the command and all of its parameters, use the man command: `man definePartition`
`-hinst` *`hInstName`*	Specifies the name of the hierarchical instance. **Note**: None of its ancestors or descendants in the netlist tree can be a partition. *Data_type*: string, optional
`-minPitchBottom` *`x`*	Specifies the pin pitch dimension for the bottom partition side. The default is 2, which places one pin for every two metal tracks. The actual pin pitch depends on the pin's metal layer. The Partition Pin Guide floorplan object will supersede this entry and use the Min. Space entry in the object's Attribute Editor. *Data_type*: int, optional
`-minPitchLeft` *`x`*	Specifies the pin pitch dimension for the left partition side. The default is 2, which places one pin for every two metal tracks. The actual pin pitch depends on the pin's metal layer. The Partition Pin Guide floorplan object will supersede this entry and use the Min. Space entry in the object's Attribute Editor. *Data_type*: int, optional
`-minPitchRight` *`x`*	Specifies the pin pitch dimension for the right partition side. The default is 2, which places one pin for every two metal tracks. The actual pin pitch depends on the pin's metal layer. The Partition Pin Guide floorplan object will supersede this entry and use the Min. Space entry in the object's Attribute Editor. *Data_type*: int, optional
`-minPitchTop` *`x`*	Specifies the pin pitch dimension for the top partition side. The default is 2, which places one pin for every two metal tracks. The actual pin pitch depends on the pin's metal layer. The Partition Pin Guide floorplan object will supersede this entry and use the Min. Space entry in the object's Attribute Editor. *Data_type*: int, optional
`-pinLayerBottom {`*`list_of_layers`*`}`	Specifies the metal layers to use for the partition. The metal layers correspond to the sides of the partition, where the vertical metal layers (for example, Metal2, Metal4, and so on) are for the Top and Bottom sides, and horizontal metal layers (for example, Metal3, Metal5, and so on) are for the Left and Right sides of the partition. Specify this value in integers, for example `-pinLayerBottom {2 4}` **Note**: Only layers in their preferred routing direction are accepted. **Note**: If these option is not supplied, all allowed layers in preferred routing direction will be assumed for that side. **Note:** This pin layer option does not support backside metal layers, it only supports frontside layers. *Default*: All allowed layers in preferred direction. *Data_type*: string, optional

`-pinLayerLeft {list_of_layers}`	Specifies the metal layers to use for the partition. The metal layers correspond to the sides of the partition, where the vertical metal layers (for example, Metal2, Metal4, and so on) are for the Top and Bottom sides, and horizontal metal layers (for example, Metal3, Metal5, and so on) are for the Left and Right sides of the partition. Specify this value in integers, for example `-pinLayerLeft {3 5}` **Note**: Only layers in their preferred routing direction are accepted. **Note**: If these option is not supplied, all allowed layers in preferred routing direction will be assumed for that side. **Note:** This pin layer option does not support backside metal layers, it only supports frontside layers. *Default*: All allowed layers in preferred direction. *Data_type*: string, optional
`-pinLayerRight {list_of_layers}`	Specifies the metal layers to use for the partition. The metal layers correspond to the sides of the partition, where the vertical metal layers (for example, Metal2, Metal4, and so on) are for the Top and Bottom sides, and horizontal metal layers (for example, Metal3, Metal5, and so on) are for the Left and Right sides of the partition. Specify this value in integers, for example `-pinLayerRight {3 5}` **Note**: Only layers in their preferred routing direction are accepted. **Note**: If these option is not supplied, all allowed layers in preferred routing direction will be assumed for that side. **Note:** This pin layer option does not support backside metal layers, it only supports frontside layers. *Default*: All allowed layers in preferred direction. *Data_type*: string, optional
`-pinLayerTop {list_of_layers}`	Specifies the metal layers to use for the partition. The metal layers correspond to the sides of the partition, where the vertical metal layers (for example, Metal2, Metal4, and so on) are for the Top and Bottom sides, and horizontal metal layers (for example, Metal3, Metal5, and so on) are for the Left and Right sides of the partition. Specify this value in integers, for example `-pinLayerTop {2 4}` **Note**: Only layers in their preferred routing direction are accepted. **Note**: If these option is not supplied, all allowed layers in preferred routing direction will be assumed for that side. **Note:** This pin layer option does not support backside metal layers, it only supports frontside layers. *Default*: All allowed layers in preferred direction. *Data_type*: string, optional
`-placementHalo {left right top bottom}`	
	Specifies extra spacing, in micrometers (around the left, bottom, right and top sides respectively) of the partition that should not be used for placement. The placement program will not place standard cells in the area for partition placement. This spacing is called placement halo. At the top-level design, this information is saved as part of the partition section in a floorplan file. This information is also saved in a partition floorplan file when saving partitions. By default, the value is 0 for all the sides. If the hierarchical instance was earlier defined as a power domain, then this field corresponds to the minimum gap parameter of the power domain. **Note**: The minimum gap value of the power domain and the placement halo values of the partition are always synchronized as follows: If the specified instance was also earlier defined as a power domain, the placement halo values for the partition, by default, will have the same value as the minimum gap values for the power domain. If you specify a different value for the partition, the value for the power domain is updated so that it is the same as the value defined for the partition. Similarly, if a power domain is created (or an existing power domain modified) on the specified instance after the partition is defined, the value set earlier for the partition is updated so that it is the same as the value defined for the power domain. **Note**: `placementHalo` created by `definePartition` cannot be honored by `place_design` before partitions have not been committed. *Data_type*: string, optional
`-proto {master_hinst_name_list}`	Specifies the master hierarchical instances list for the prototyping flow. It defines new partitions for the specified hierarchical instances with guide constraints. It is used before `proto_design`, which will convert the physical constraint from guide to fence finally. *Data_type*: string, optional

`-railwidth railWidth`	Specifies the standard cell power rail width, in micrometers. If partition pins are not allowed above power or ground rail width, specify the dimension of the power rail width. If a value of 0.0 is entered (the default), the width from the Technology file will be used. *Data_type*: float, optional
`-reservedLayer {list_of_layers}`	
	Specifies the metal layers that are used for routing in the partition and generating partition pins. Any metal layers that are not specified, usually the top-most metal layers, are allowed to route over the partition. A normal six-metal layer specification is Metal1, Metal2, Metal3, Metal4 and Metal5 specified, and Metal6 unspecified. When saving the partition, the LEF generated for this partition will have routing blockages on their layers so that the top-level router is aware of which metal layers are being used in the partition. **Note:** For designs that have backside metal layers, both the backside and frontside layers are accepted. *Data_type*: string, optional
`-routingHalo floatValue`	
	Specifies routing spacing, in micrometers, around the sides of the partition. A routing halo is honored only by the signal router. The signal router treats routing on the specific routing layers in the routing halo area as very high cost routing. However, perpendicular routing or straight connections to pins are acceptable. The special router does not honor routing halos. To block special routing, use routing blockages instead. You can specify a positive or a negative value for the routing halo. A positive value means that the halo will be outside the partition. A negative value means that the halo will be applicable during block implementation, inside of the partition. The same value is used for all sides of the partition. **Note**: For instance blocks - blackboxes, hard macros or block-level designs - specify the routing halo through the *Floorplan - Edit Floorplan - Edit Halos* form in the GUI or through the `addRoutingHalo` command. Also, for bottom- up hierarchical flow, specify routing halo for a block at the top-level design or at the block-level design through the *Floorplan - Edit Floorplan - Edit Halos* form in the GUI or through the `addRoutingHalo` command. *Data_type*: float, optional
`-routingHaloTopLayer integerValue`	
	Specifies the top partition layer for which routing halo will be created. *Default*: By default, the top layer reserved for the partition is used. *Data_type*: int, optional
`-routingHaloBottomLayer integerValue`	
	Specifies the bottom partition layer for which routing halo will be created. *Default*: By default, the bottom layer reserved for the partition is used. *Data_type*: int, optional
`-stdCellHeight x`	Specifies the standard cell height for the partition. *Default*: The default value is derived from the default technology site and row height. *Data_type*: float, optional

Example

- The following example defines a new partition:

```
definePartition -hinst ctr_inst
-coreSpacing 0.56 0.56 0.0 0.0
-railWidth 0.0
-minPitchLeft 2 -minPitchRight 2
-minPitchTop 2 -minPitchBottom 2
-reservedLayer {1 2 3 4}
-pinLayerTop {2 4} -pinLayerLeft {3} -pinLayerBottom {2 4} -pinLayerRight {3}
-placementHalo 10.0 0.0 0.0 0.0 -routingHalo 10.0
-routingHaloTopLayer 7 -routingHaloBottomLayer 1
```

- The following commands define a nest partition where PTN1 is a parent partition and PTN2 is a child:

```
definePartition -hinst PTN1
definePartition -hinst PTN2
```

or

```
definePartition -hinst PTN2
definePartition -hinst PTN1
```

deleteAllPtnCuts

```
deleteAllPtnCuts
[-help]
```

Deletes all the partition cuts in the floorplan. You can use this command after specifying a partition.

Note: Command `deleteAllPtnCuts` is now obsolete and will be removed in the next major release of the software. This command has been replaced by the `deletePtnCut` command.

Parameters

`-help`	Outputs a brief description of the `deleteAllPtnCuts` command. For a detailed description of the command, use the `man` command: `man deleteAllPtnCuts`

Related Information

- `partition`
- `deletePtnCut`
- `deletePartition`

deleteAllPtnFeedthroughs

```
deleteAllPtnFeedthroughs
[-help]
```

Deletes all the partition feedthrough objects in the floorplan. You can use this command during partition floorplanning.

Parameters

`-help`	Outputs a brief description of the `deleteAllPtnFeedthroughs` command. For a detailed description of the command, use the `man` command: `man deleteAllPtnFeedthroughs`

Example

The following command removes all feedthrough objects from the floorplan:

```
deleteAllPtnFeedthroughs
```

Related Information

deleteNetFromNetGroup

```
deleteNetFromNetGroup
[-help]
netGroupName
-net {netName | netNameList}
```

Removes a net from a net group. You can use this command after importing the design.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `deleteNetFromNetGroup` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man deleteNetFromNetGroup`
`netGroupName`	Specifies the name of the net group. You can use wildcards (`*?`) with this parameter. *Data_type*: string, required
`-net {`*`netName`* `|` *`netNameList`*`}`	Specifies the name of the net(s). You can use wildcards (`*?`) with this parameter. *Data_type*: string, required

Example

The following command removes net `NET1` from net group `NG22`:

```
deleteNetFromNetGroup NG22 NET1
```

Related Information

- `addNetToNetGroup`
- `createNetGroup`
- `deleteNetGroup`

  - Setting Pin Constraints
  - Net Group

deleteNetGroup

```
deleteNetGroup
[-help]
netGroupName
```

Removes a net group that was created earlier.

Note: When you delete a net group, any bus guide associated with the net group also gets deleted.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `deleteNetGroup` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man deleteNetGroup`
`netGroupName`	Specifies the name of the net group. You can use wildcards (`*?`) with this parameter. *Data_type*: string, required

Example

The following command removes netgroup `NG_22`.

```
deleteNetGroup NG_22
```

deletePartition

```
deletePartition
[-help]
{ partition_name | -all | -nested | -non_leaf }
[-undo_tcl_file file_name [-non_leaf ]]
```

Deletes the specified partition.

Note: The Hinst retains the fence property.

Parameters

`-all`	Deletes all partitions. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `deletePartition` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man deletePartition.`
`-nested`	Deletes all nested partitions in the design. *Data_type*: bool, optional
`-non_leaf`	Deletes all non-leaf partitions in the design. **Note:** It saves the information of the deleted partitions in a tcl file, so that the same can be used to restore the deleted partitions. For example, in the diagram below, all the non-leaf partitions (marked in yellow) must be deleted and dumped in a tcl file for restoration purpose later on.  *Data_type*: bool, optional
partition_name	Specifies the name of the partition to delete. *Data_type*: string, optional
`-undo_tcl_file` *file_name*	
	Specifies the file that can be sourced to undo deletion of partitions. With this parameter, the partition definition of the partition being deleted is written to the specified file. Later, if required, this file can be sourced to bring back the partition definition. *Data_type*: string, optional

Example

- The following command deletes the partition `p1`.
  ```
  deletePartition p1
  ```
- The following command writes the partition definition of partition p1 in file ptn.tcl and then deletes it.
  ```
  deletePartition p1 -undo_tcl_file ptn.tcl
  ```

deletePinBlkg

```
deletePinBlkg
[-help]
{-name pinBlkgName | -all}
```

Deletes a pin blockage or all pin blockages.

Parameters

`-all`	Specifies that all pin blockages will be deleted. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `deletePinBlkg` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man deletePinBlkg`
`-name pinBlkgName`	Specifies the name of the pin blockage. You can specify wildcards (?*) with this parameter. *Data_type*: string, optional

Example

The following command deletes the pin blockage `PtnPinBlkg1`:

```
deletePinBlkg -name PtnPinBlkg1
```

Related Information

- `createPinBlkg`

  - Pin Blockage

deletePinFromPinGroup

```
deletePinFromPinGroup
[-help]
[-cell cellName]
-pinGroup pinGroupName
-pin {pinName | pinNameList}
```

Removes a port from a specified pin group.

Parameters

`-cell cellName`	Specifies the name of the module. The module name is not required if the command is run on a top-level module. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `deletePinFromPinGroup` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man deletePinFromPinGroup`
`-pinGroup pinGroupName`	Specifies the name of the pin group that was created. *Data_type*: string, required
`-pin {pinName | pinNameList}`	Specifies the name(s) of the port(s) of the module. *Data_type*: string, required

Example

The following command removes ports `RASN1` and `RASN2` of module `SH17` from pin group `pin17`:

```
deletePinFromPinGroup -cell SH17 -pinGroup pin17 -pin {RASN1 RASN2}
```

Related Information

- `addPinToPinGroup`
- `createPinGroup`
- `deletePinGroup`
- Partitioning the Design chapter in the *Innovus User Guide*
  - Setting Pin Constraints
  - Pin Group

deletePinGroup

```
deletePinGroup
[-help]
[-cell cellName]
-pinGroup pinGroupName
```

Deletes a pin group or all pin groups that were created earlier.

Parameters

`-cell cellName`	Specifies the name of the module. The module name is not required if the command is run on a top-level module. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `deletePinGroup` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man deletePinGroup`
`-pinGroup pinGroupName`	Specifies the name of the pin group that was created. Wildcards accepted. *Data_type*: string, required

Example

- The following command deletes the pin group `PinGroup17` of module `SH17`:
  ```
  deletePinGroup -cell SH17 -pinGroup PinGroup17
  ```
- The follow command deletes all the pin groups of module SH17:
  ```
  deletePinGroup -cell SH17 -pinGroup *
  ```

Related Information

- `createPinGroup`
- `addPinToPinGroup`
- `deletePinFromPinGroup`

  - Pin Group

deletePinGuide

```
deletePinGuide
[-help]
{ -pin pin_name | -pinGroup pin_group_name | -net net_name | -netGroup net_group_name | -name object_name | -all }
[-cell ptn_name | -net net_name | -netGroup net_group_name]
```

Deletes a pin guide object in the floorplan. You can use this command during partition floorplanning.

Parameters

`-all`	Specifies that all pin guides will be deleted. *Data_type*: bool, optional
`-cell` *ptn_name*	Specifies the name of the module. The module name is not required if the command is run on a top-level module. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `deletePinGuide` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man deletePinGuide`
`-name` *object_name*	Specifies the name of the partition pin guide object. If you specify this parameter, the command will automatically detect whether the object is a pin, pin group, net, net group, or bus. In case there are different objects with the same name, the command selects the object with the following precedence: • If a cell name is specified, the command selects the object with the following precedence: 1. pin 2. pin group 3. net 4. net group or bus • If a cell name is not specified, the command selects the object with the following precedence: 1. net 2. net group or bus For example, if the value of *objectName* is `P1`, and there is a pin group named `P1` as well as a bus named `P1`, the command will select the pin group named `P1`. *Data_type*: string, optional
`-net` *net_name*	For nets, specifies the name of the net. For buses, specifies the name of the bus or the bus radix. *Data_type*: string, optional
`-netGroup` *net_group_name*	Specifies the name of the net group. *Data_type*: string, optional
`-pin` *pin_name*	Specifies the name of the pin. *Data_type*: string, optional
`-pinGroup` *pin_group_name*	Specifies the name of the pin group. *Default:* By default the name is `defRGuideName`. *Data_type*: string, optional

Example

The following command deletes a pin guide object named `group_1`:

```
deletePinGuide -name group_1
```

Related Information

- `createPinGuide`
- `selectPtnPinGuide`
- Partitioning the Design chapter in the *Innovus User Guide*

deletePtnCut

```
deletePtnCut
[-help]
{-ptn {ptnName | ptnNameList} | -all}
```

Deletes all the partition cuts.

Parameters

`-all`	Deletes all the partition cuts. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes type and default information for each `deletePtnCut` parameter. For a detailed description of the command and all of its parameters, use the man command: `man deletePtnCut`
`-ptn {ptnName | ptnNameList}`	Specifies the name of the partition, or the list of partitions for which partition cuts are deleted. *Data_type*: string, optional

Example

The following command deletes partition cuts for partition `sheet17`:

```
deletePtnCut -ptn sheet17
```

Related Information

- `partition`
- `deleteAllPtnCuts`
- `deletePartition`
- Partitioning the Design chapter in the *Innovus User Guide*

editPin

```
editPin
[-help]
[-cell cellName | {-hinst hinstName [-refMaster]}]
[-end {x y}]
[-fixedPin]
[-global_location]
[-include_rectilinear_edge]
[-masterCloneAware]
[-offsetEnd value]
[-offsetStart value]
-pin {pinName | pinNameList}
[-pinDepth pinDepthValue]
[-pinWidth pinWidthValue]
[-quiet]
[-skipWrappingPins]
[-snap {TRACK | USERGRID | MGRID}]
[-spreadDirection {clockwise | counterclockwise | both}]
[-start {x y}]
[-use { SIGNAL | CLOCK | ANALOG }]
[{-layer {layerId | layerIdListName} |
 {[-layerH layerId] [-layerV layerId]}}
 [-layer_priority]
 [-assign {x y} |
  -spreadType {START | CENTER | SIDE | EDGE | RANGE} |
  -pattern {fill_track | fill_layer | fill_optimised | fill_diagonal | fill_sinusoidal | fill_checkerboard}]]
[-side sideName | -edge edgeNumber]
[-fixOverlap {0|1} [-honorConstraint {0|1}]]
[-pattern {fill_track | fill_layer | fill_optimised | fill_diagonal | fill_sinusoidal | fill_checkerboard} [-reverse_alternate]]
[-spacing spacingValue [-unit {MICRON | TRACK}]]
```

Modifies properties of pins, such as pin spreading, pin location, pin width and depth, spacing, snap-to location, and status. The `editPin` command provides the equivalent capabilities of the *Pin Editor* form.

Note: The `editPin` command does not support wildcards.

The `editPin` command honors the minimum area rule as follows:

- If neither the `-pinWidth` nor the `-pinDepth` parameters have been specified, the `editPin` command takes the minimum pin width and the minimum area from the LEF file and calculates the pin depth accordingly.
- If only the `-pinWidth` parameter has been specified, the `editPin` command takes the minimum area from the LEF file and calculates the pin depth accordingly.
- If only the `-pinDepth` parameter has been specified, the `editPin` command takes the minimum area from the LEF file and calculates the pin width accordingly.

If both the `-pinWidth` and the `-pinDepth` parameters are specified, the `editPin` command takes these specified values, without enforcing the minimum area rule.

The `editPin` command is clone context aware. The command:

- Looks at routing blockages on clone and honors them while keeping pins of master with `-cell <>`.
- Looks at abutted macro blockages and honors them while keeping pins of master with `-cell <>`.
- Honors route blockage on master.

Note: The value of the parameters of the `editPin` command is not stored across multiple runs of the command – you need to specify the required value with every run of the command.
For example, if you do not specify the `-pinWidth` parameter, the default pin width of the specified layer is used.

Note: The `editPin` command checks and corrects DRC violations and overlapping while placing internal pins. It supports pin placement on Metal 1 and accepts all layers for pin placement by default.

Note: The `editPin` command is used for manual pin assignment in nested partitions. It places pins of nested partitions similar to single level partitions.

Parameters

`-assign {x y}`	Preassigns a pin at the specified location. You can use this parameter with other parameters such as `-snap`, `-fixOverlap` **Note**: -assign {*x y*} considers the local coordinates from the bounding box of the fence.  *Data_type*: point, optional
`-cell cellName`	Specifies the name of the module. If you do not specify a cell name, the command runs on the top-level cell. *Data_type*: string, optional
`-edge edgeNumber`	For rectilinear partitions, specifies the edge along which the pins will be placed. The edge number is an integer. The edg Edge 0 is the edge that has the smallest y value.  To spread pins on multiple rectilinear edges that are on the same side, use the `-side` parameter. For rectangular partitions, you can specify a side with the -side parameter. *Data_type*: int, optional
`-end {x y}`	For pin spreading along a range, specifies the coordinates where pins should end. This parameter is used with the `-spr` *Data_type*: point, optional
`-fixedPin`	A value of 1 sets the pin status to Fixed. *Default*: The pin status is placed. *Data_type*: bool, optional
`-fixOverlap {0 | 1}`	With this parameter on, the `editPin` command tries to resolve pin-overlap with other/nearby objects. The pins are moved *Default*: 1. Resolve pin-overlap is on. **Note**: This parameter applies only when pins are snapped to layer track. *Data_type*: bool, optional

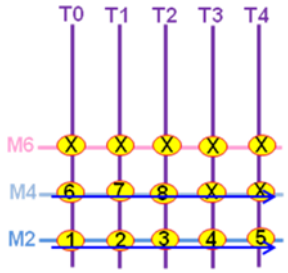
`-global_location`	Specifies that the global location should be considered by the command.
	Note: By default all locations that the `editPin` command considers are coordinates with respect to lower-left corner of pa accept coordinates with respect to the lower-left corner of the design.
	For example, in the following command, the pin will be placed 3u from the lower-left corner of the partition.
	`editPin -cell c -pin cIn -assign 0 3 -layer 2 -side left`
	When you use the `-global_location` parameter, the pin will be placed 3u from the lower-left corner of the design.
	`editPin -cell c -pin cIn -assign 0 3 -layer 2 -side left -global_location`
	Data_type: bool, optional

`-help`	Outputs a brief description that includes type and default information for each `editPin` parameter. For a detailed description of the command and all of its parameters, use the man command: `man editPin`
`-hinst` *hinstName*	Specifies the hinst name, including black box or committed partition and top. *Data_type*: string, optional
`-honorConstraint {0|1}`	Specifies whether user-defined pin constraints should be honored. The following constraints are honored when this parameter is set to on: • pin spacing • pin size • pin-to-corner distance • partition-allowed pin layers. *Default*: 0 (user-defined pin constraints are not honored) *Data_type*: bool, optional
`-include_rectilinear_edge`	Specifies that all the edges coming in the solution space should be included. *Data_type*: bool, optional
`-layer {`*layerId* `|` *layerName*`}`	Specifies the layer on which the pins will be assigned. Layers can be specified using the LEF layer names or layer ID nu **Note**: This parameter is optional but only when `-spreadType` is not specified. **Note:** For designs that have backside metal layers, both the backside and frontside layers are accepted. *Data_type*: bool, optional
`-layerH` *layerId*	Specifies the preferred horizontal layer on which the pins will be assigned. **Note:** For designs that have backside metal layers, both the backside and frontside layers are accepted. *Data_type*: string, optional
`-layerV` *layerId*	Specifies the preferred vertical layer on which the pins will be assigned. **Note:** For designs that have backside metal layers, both the backside and frontside layers are accepted. *Data_type*: string, optional
`-layer_priority`	Specifies that the input layer is given based on its priority. *Data_type*: bool, optional
`-masterCloneAware`	Enables master-clone context awareness for feasibility checking. *Data_type*: bool, optional
`-offsetEnd` *value*	Sets the offset from the end of the edge (in microns) to be considered as the endpoint for placing the pin. **Note**: The `-offsetStart` and `-offsetEnd` options can only be used with the `-edge` option. *Data_type*: float, optional
`-offsetStart` *value*	Sets the offset from the start of the edge (in microns) to be considered as the start point for placing the pin. **Note**: The `-offsetStart` and `-offsetEnd` parameters can only be used with the `-edge` parameter. *Data_type*: float, optional

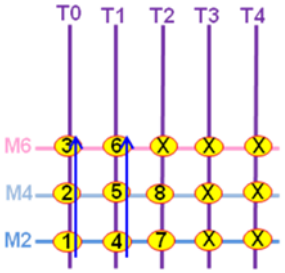
`-pattern {fill_track | fill_layer | fill_optimised | fill_diagonal | fill_sinusoidal | fill_checkerboard}`

Specifies the multi-layer-spread-pattern must be followed by the set of selected pins.

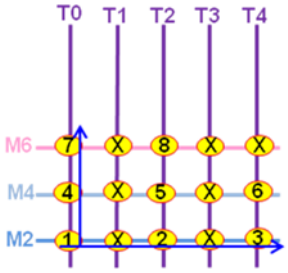
fill_track



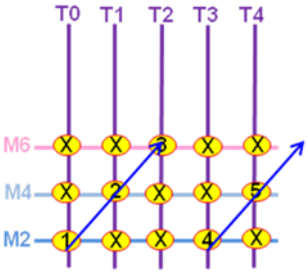
fill_layer



fill_optimised



fill_diagonal



fill_sinusoidal

	 fill_checkerboard `-pin {pinName | pinNameList}`	Specifies the pins, or the list of pins of the specified module on which the command will run. **Note**: The naming convention to identify individual ports is based on the order in which the ports are stored inside the da port1, port2, respectively. For example: VDD.port0, VDD.port1, VDD.port2 *Data_type*: string, required
`-pinDepth pinDepthValue`	Sets the depth of the pin in microns. *Default*: If you do not specify this parameter, the default depth of the specified layer is used. *Data_type:* float, optional
`-pinWidth pinWidthValue`	Sets the width of the pin in microns. *Default*: If you do not specify this parameter, the default width of the specified layer is used. *Data_type:* float, optional
`-quiet`	Specifies that the messages should be suppressed. *Data_type*: bool, optional
`-refMaster`	Specifies that the clone's edge, spreadDirection, and offset are with respect to the master. *Data_type*: bool, optional
`-reverse_alternate`	Specifies that the reverse of the multi-layer-spread-pattern must be followed by the set of selected pins. For example, `fill_track -reverse_alternate`  *Data_type*: bool, optional
`-side sideName`	For rectangular partitions, specifies the side on which the pins will be placed. The values for sideName can be: TOP, BC **Note**: The value INSIDE can only be specified with the `-assign` parameter. For rectilinear partitions, you can also specify an edge with the `-edge` parameter. **Note:** The `setPinAssignMode -pinEditInBatch` parameter does not support the internal pins (where the side is INSIDE). *Data_type*: string, optional

`-skipWrappingPins`	Skips pin wrapping on the adjacent edge or the same edge from the other side. *Data_type*: bool, optional
`-snap {TRACK | USERGRID | MGRID}`	
	Specifies how the pins will be snapped. • `TRACK`: Snaps pins to layer tracks. • `USERGRID`: Snaps pins to the user-defined grid. • `MGRID`: Snaps pins to the manufacturing grid. *Default*: `TRACK` *Data_type*: enum, optional
`-spacing` *spacingValue*	Displays the edge-track-to-edge-track spacing between pins for multi-pin editing. The spacing is either in micrometers o placed on every track with no empty tracks between them. Default: The spacing is set automatically. *Data_type*: string, optional
`-spreadDirection {clockwise | counterclockwise | both}`	
	Specifies the direction in which the pins are spread. You can specify: • `clockwise`: Sets the pins in the clockwise direction. • `counterclockwise`: Sets the pins in the counter clockwise direction. • `both`: Sets the pins by looking for the closest legal location to the desired location in both directions. *Default*: clockwise *Data_type*: enum, optional
`-spreadType {START | CENTER | SIDE | EDGE | RANGE}`	
	Specifies how to spread pins along a block's edge. • `START`: Uses the coordinates of the first pin specified with the `-pin` parameter as the starting point (anchor) for spreadir parameter. • `CENTER`: If a single pin is specified with the `-pin` parameter, the pin will be placed at the center of the specified edge/sic points such that the center pin(s) of the group are placed at the center of the specified edge or side. • `SIDE`: If you specify a side with the `-side` parameter and specify the `-spreadType SIDE` parameter, the pins are spread and from bottom to top. • `EDGE`: If you specify an edge with the `-edge` parameter and specify the `-spreadType EDGE` parameter, the pins are sprea points. • `RANGE`: Spreads pins evenly along the block edge between points you specify with `-start {x y}` and `-end {x y}` para Editor determines the appropriate spacing. **Note:** For rectilinear partitions, if the start and/or end points are not on the specified side, the start and/or end points are s *Data_type*: enum, optional
`-start {x y}`	For pin spreading along a range, specifies the coordinates where pins should start. This parameter is used with the `-spr` *Data_type*: point, optional
`-unit {MICRON | TRACK}`	Specifies the unit in microns or in tracks. This parameter applies only to the unit of the -spacing parameter. *Default*: `Micron` *Data_type*: enum, optional
`-use {SIGNAL | CLOCK | ANALOG}`	
	Specifies the +USE property of the partition pin. *Data_type*: stringl, optional

Example

The following command modifies the pins as specified here:

- the command runs on the module DTMF_CORE_INST1
- the command runs on all pins whose name starts with DTMF_CORE_INST1_OUTPIN
- the pins are spread on the edge number 2
- the USE property is set to CLOCK
- the pins are spread between the coordinates (17 23) and (117 123)
- the pins are assigned on the layer Metal3
- the pin status is set to Fixed
- the pins are snapped to layer tracks
- the unit is in tracks
- the spacing between pins for multi-editing is set to 2 tracks
- the pin depth is set to 10 microns.

  Note: The `-unit` parameter is set to TRACK but that does not affect the unit of pin depth.
- the pins are moved to the nearest acceptable location as the `-fixOverlap` parameter is set to 1. However, the `-overlapConstraints` parameter is not specified.

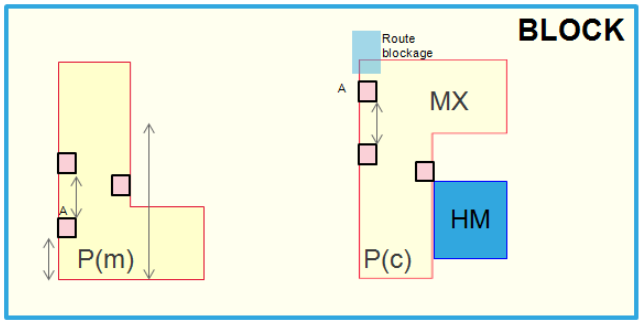
```
editPin
-cell DTMF_CORE_INST1
-pin {DTMF_CORE_INST1_OUTPIN}
-spreadType RANGE
-edge 2
-layer Metal3
-use CLOCK
-fixOverlap 1
-snap TRACK
-pinDepth 10
-start {17 23}
-end {117 23}
-spacing 2
-unit TRACK
-fixedPin 1
```

- The `editPin` command looks at routing blockages on clone and honors them. In the figure below, the following command would not start pins on master from Y=0 as there is a route blockage on clone at desired location.

  ```
  editPin -hinst p(m) -spreadType start -start 0 0 -edge 0 -layer 2 -pin A*
  ```

  Also, the following command would not start pins on master from Y=10 as there is a macro with obstruction on clone at desired location.

  ```
  editPin -hinst p(m) -assign 10 5 -edge 2 -layer 2 -pin B -spreadDirection {both}
  ```



- The following commands are used to edit pins in the batch mode:

  ```
  setPinAssignMode -pinEditInBatch true
  ```

```
editPin -hinst p(m) -spreadType start -start 0 0 -edge 0 -layer 2 -pin A*
...
...
editPin -hinst p(m) -assign 10 5 -edge 2 -layer 2 -pin B -spreadDirection {both}
setPinAssignMode -pinEditInBatch false
```

fix_feedthru_assign

```
fix_feedthru_assign
[-help]
-buffer string
[-delete_feed]
```

Fixes the assign statements that are associated with partitions by replacing them with the specified buffer. This helps to minimize the number of buffers that are added to the design when assign statements are deleted.

The `fix_feedthru_assign` command enables selective replacement of assign statements with real buffers.

Parameters

`-buffer` *`string`*	Specifies the buffer to be used for replacing assign statements. *Data_type*: string, required
`-delete_feed`	Removes input-output(s) assigns from within the partition module. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `fix_feedthru_assign` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man fix_feedthru_assign`

Example

The following command replaces the assign statements associated with partitions with the specified buffer.

```
fix_feedthru_assign -buffer abc
```

Related Information

- `remove_assigns`
- `insertPtnFeedthrough`
- Partitioning the Design chapter in the *Innovus User Guide*

flattenCoverCell

```
flattenCoverCell
[-help]
[-inst {instanceName | instanceNameList}]
```

Dissolves and flattens any instance whose master has class `COVER`, but no subclass `BUMP`. You can use this command after loading a DEF file (after the defIn command).

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `flattenCoverCell` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man flattenCoverCell`
`-inst {instanceName | instanceNameList}`	
	Specifies the instance, or a list of instances, to be flattened. If you are specifying a list, separate the instance names with a space. *Default*: If you do not specify this parameter, all instances whose masters have class `COVER` are flattened. *Data_type*: string, optional

Examples

- The following command flattens the cover cells named `coverCell1` and `coverCell2`
  ```
  flattenCoverCell -inst {coverCell1 coverCell2}
  ```
- The following command flattens *all* cover cells
  ```
  flattenCoverCell
  ```

Related Information

- `defIn`
- Partitioning the Design chapter in the *Innovus User Guide*

flattenPartition

```
flattenPartition
[-help]
[partition_name]
[-bringBackRow]
[-keepPinGeometry]
[-noUninheritPhysical]
```

Uncommits (flattens) the partition back to normal module status. This command should also be used to unassign blackbox pins *after* the blackbox is committed. To unassign blackbox pins *before* the blackbox is committed, use the `setPtnPinStatus` command. This command unassigns partition pins as well. To bring back row information for a partition, use the `-bringBackRow` parameter. If the partition rows are non-integer-multiple-height rows or are not aligned with the top-level rows, the `flattenPartition` command will automatically create a power domain associated with the partition. The power domain will have the following characteristics:

- The timing library will the same as that for the top level.
- If a global net connection is defined in the partition block, the power domain will have the same global net connection. Otherwise the global net connection for the power domain will be set to the top-level net connection.
- The minimum gap values will be the same as the placement halo values for the partition.

The recommended use model for bringing back non-integer-multiple height rows or unaligned rows is as follows.

Top-down flow:

1. Create a power domain at full chip-level design.
2. Specify the same hierarchical instance as the partition

Bottom-up flow:

1. Create a power domain at top-level design.
2. Assign the instance block as a member of the power domain created in step 1.

The `flattenPartition` command supports partitions with FlexModels. It restores back FlexModel information if the committed partition has a FlexModel netlist.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `flattenPartition` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man flattenPartition`
`-bringBackRow`	Specifies that partition row information should be brought back for cases where: • the partition is not a power domain and row information in partition is different from top-level design, *and* • after uncommiting the partition, the rows of the partition space are not aligned with the top-level rows When you use this parameter, a power domain is created for the partition. *Default:* If you do not specify this parameter, the row information is *not* brought back in such cases. *Data_type*: bool, optional
`-keepPinGeometry`	Specifies that for every partition pin, a DRCFILL metal of the type special route is placed on top of the partition pins. *Data_type*: bool, optional
`-noUninheritPhysical`	Specifies that physical only cell instances are removed during `flattenPartition`. *Data_type*: bool, optional
partitionName	Specifies the name(s) of the partition(s). You can specify any number of partitions. *Data_type*: string, optional

Example

The following command uncommits the partition status of partitions `sheet17` and `sheet25`:

```
flattenPartition sheet17 sheet25
```

get_ptn_fplan_mode

```
get_ptn_fplan_mode
[-help]
[-export]
[-import]
[-quiet]
[-nonDefault]
```

Retrieves information about the option values set using the `set_ptn_fplan_mode` command.

Parameters

`-export`	Retrieves the value of data that `saveParititon -fplan` will write. An empty list means default objects are written. *Default:* `special_route` (default data + special route is always saved) *Data_type:* enums={macro special_route pin_constraint}_list
`-help`	Outputs a brief description that includes the type and default information for each `get_ptn_fplan_mode` parameter. For a detailed description of the command and all of its parameters, use the man command: `man get_ptn_fplan_mode`
`-import`	Retrieves the value of data that `assembleDesign -fplan` will bring back. An empty list means default objects are brought back. *Default:* By default, `-import` brings only defaults objects *Data_type:* enums={macro special_route pin_constraint}_list
`-nonDefault`	Displays the current non-default settings.
`-quiet`	Displays the current settings for the specified parameters in Tcl list format only.

Example

The following command reports the value for the `-export` parameter set using the `set_ptn_fplan_mode` command.

```
get_ptn_fplan_mode -export
```

Related Information

- `set_ptn_fplan_mode`

getBlackBoxArea

```
getBlackBoxArea
[-help]
-cell cellName
[-stdCellArea]
[-macroArea]
[-cellUtil]
```

Retrieves the standard cell area, macro area, and cell utilization value for the specified blackbox. If only the blackbox cell name is specified, the command reports the total blackbox area.

Note: You can use this command to report the black box area only if you had specified the blackbox using the `specifyBlackBox` command with the `-gateArea` parameter.

Parameters

`-cell cellName`	Specifies the name of the blackbox cell. *Data_type*: string, required
`-cellUtil`	Reports the standard cell utilization value for the blackbox. The standard cell utilization is calculated as follows: `standard cell area / (blackbox area - total macro area)` This parameter cannot be used if the blackbox was specified based on the total area or the gate count. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `getBlackBoxArea` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man getBlackBoxArea`
`-macroArea`	Reports the area of the macros included in the blackbox area. This parameter cannot be used if the blackbox was specified based on the total area or the gate count. *Data_type*: bool, optional
`-stdCellArea`	Reports the area of the standard cell included in the blackbox area. This parameter cannot be used if the blackbox was specified based on the total area or the gate count. *Data_type*: bool, optional

Examples

- The following command retrieves the total blackbox area for the blackbox `bbox_inst1`:
  ```
  getBlackBoxArea -cell bbox_inst1
  ```
- The following command retrieves the standard cell area, macro area, and cell utilization value for the blackbox `bbox_inst2`:
  ```
  getBlackBoxArea -cell bbox_inst2 -stdCellArea -macroArea -cellUtil
  ```

Related Information

- `specifyBlackBox`

getClonePtnOrient

```
getClonePtnOrient
[-help]
hinst
```

Retrieves the orientation information of the specified partition clone. You can use this command after using the `setClonePtnOrient` command.

Parameters

`-help`	Outputs a brief description of the `getClonePtnOrient` command. For a detailed description of the command, use the `man` command: `man getClonePtnOrient`
hinst	Specifies the name of the partition clone whose orientation information has to be retrieved. This can be an hierarchical instance name of a partition or an instance name of a black box. **Note:** The hinst argument should be registered as a hinst and not as a string to support DPO usage. *Data_type*: (hinst), required

Example

The following command retrieves the the orientation information for the partition clone `TDSP_ARB_C1`:

```
getClonePtnOrient TDSP_ARB_C1
```

Related Topics

- `setClonePtnOrient`

getPinAssignMode

```
getPinAssignMode
[-help]
[-advance_node_rule_support]
[-allow_unconnected_in_abutted_edge]
[-allowNonNdrNetPinsOnNdrTracks]
[-block_boundary_macro_distance]
[-force_abutment_with_fixed]
[-insidePinSearchDistance]
[-max_distance_pairing]
[-maxChannelWidthAsAbutted]
[-pinEditInBatch]
[-pinOffStripe]
[-pinToStripeDistance]
[-pinToViaDistanceNonPrefDirection]
[-pinToViaDistancePrefDirection]
[-promotedMacroMaxLayer]
[-promotedMacroMinLayer]
[-restrict_boundary_macro_distance]
[-strict_abutment]
[-quiet]
```

Returns information about the specified `setPinAssignMode` parameter in the Innovus log file and the console. The following information is returned:

- Parameter name
- Current value
- Type (Boolean, string, and so on)
- Whether the current value was set by user

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `getPinAssignMode` parameter. For a detailed description of the command and all of its parameters, use the man command: `man getPinAssignMode`
`-parameter_names`	Displays information for the specified parameters. You can specify one or more parameters. See `setPinAssignMode` for descriptions of the parameters you can specify.
`-quiet`	Displays the current settings for the specified parameters in Tcl list format only.

Examples

- The following command returns the current settings for the `setPinAssignMode` parameters:

  ```
  getPinAssignMode
  ```

  The software returns the following information:

  ```
  -advanced_node_rule_support true # bool, default=true
  -allow_unconnected_in_abutted_edge true # bool, default=true
  -allowNonNdrNetPinsOnNdrTracks true # bool, default=true
  -block_boundary_macro_distance 3 # float, default=3, min=0, max=100
  -force_abutment_with_fixed true # bool, default=true
  -max_distance_pairing 50 # float, default=50, min=0, max=10000
  -maxChannelWidthAsAbutted 3 # float, default=3, min=0, max=400
  -pinEditInBatch false # bool, default=false
  -pinOffStripe none # enums={below all none}, default=none
  -pinToStripeDistance {} # string, default=""
  -pinToViaDistanceNonPrefDirection {} # string, default=""
  -pinToViaDistancePrefDirection {} # string, default=""
  -promotedMacroMaxLayer 31 # string, default=31
  -promotedMacroMinLayer 31 # string, default=31
  -restrict_boundary_macro_distance 30 # float, default=30, min=0, max=100
  -strict_abutment true # bool, default=true
  ```

getPinConstraint

```
getPinConstraint
[-help]
[-dictFile string]
[[-global | -cell cell_name]
[-global | -pin pin_name_list]]
```

Retrieves information about the constraints set for a partition pin or an I/O pin using the `setPinConstraint` command. It displays the information in a tabular format output report that includes constraints from other sources (top/bottom preferred layer and NDR-rule from `setAttibute`, reserved layer for partition, pin/net-group /guide constraints presence)) and segregates between user-defined, default, and lef values.

Parameters

`-cell` *cell_name*	Specifies the name of the module. The module name is not required if the command is run on a top-level module. You can use *Data_type*: string, optional
`-dictFile` *string*	Writes the output of the command in the specified text file (in dictionary format). *Data_type*: string, optional
`-global`	Specifies to get global constraints. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `getPinConstraint` parameter. For a detailed use the `man` command: `man getPinConstraint`
`-pin` *pin_name_list*	Specifies the name of the partition pin. You can use wildcards (`*?`) with this parameter. *Data_type*: string, optional

Example

- The following command prints all the constraints set for the specified module.

```
getPinConstraint -cell dtmf_chip
```

The following result is displayed on the screen:

```
Default Global Values:
----------------------
Minimum pin-to-pin track spacing : 2
Pin to corner distance : 5

Template from tech LEF
------------------------------
| Layer | width | depth |
------------------------------
| 2 | 0.2800 | 0.2800 |
| 3 | 0.2800 | 0.2800 |
| 4 | 0.2800 | 0.2800 |
| 5 | 0.2800 | 0.2800 |
| 6 | 0.4400 | 0.4400 |
------------------------------

Global Constraint:
-------------------

Constraint on partition dtmf_chip :
-----------------------
Partition reserved layers { 1 2 3 4 5 6 7 }
--------------------------
| Side | allowed layer |
--------------------------
| top | 2 4 6 |
| left | 3 5 |
| bottom | 2 4 6 |
| right | 3 5 |
--------------------------
```

Related Information

- setPinConstraint
- unsetPinConstraint
- Partitioning the Design chapter in the *Innovus User Guide*
  - Setting Pin Constraints

getPtnPinStatus

```
getPtnPinStatus
[-help]
[-cell cellName]
[-pin {pinName | pinNameList}]
```

Retrieves the pin status that was defined with the `setPtnPinStatus` command.

Parameters

`-cell cellName`	Specifies the name of the partition. You can use wildcards (`*?`) with this parameter. *Data_type*: string, optional
`-help`	Outputs a brief description that includes type and default information for each `getPtnPinStatus` parameter. For a detailed description of the command and all of its parameters, use the man command: `man getPtnPinStatus`.
`-pin pinName | pinNameList`	
	Specifies the name of the pin(s) of the partition. You can use wildcards (`*?`) with this parameter. *Default:* If the pin name is not specified, the command is run on all pins. *Data_type*: string, optional

Example

The following command tells the status of pin `DATA` of partition `EUG`:

```
getPtnPinStatus -pin DATA -cell EUG
```

Related Information

- `setPtnPinStatus`
- Partitioning the Design chapter in the *Innovus User Guide*

handlePtnAreaIo

```
handlePtnAreaIo
[-insertBuffer bufferName | -noInsertBuffer]
[-top extension]
[-bottom extension]
[-left extension]
[-right extension]
[-selectedCell]
[-pinOnBoundary]
```

Specifies the name of the buffer to be used for feedthrough insertion in a flip chip design. Use this command before partitioning the flip chip design.

Parameters

`-bottom extension`	Specifies how far, in microns, to expand the Area I/O cell box in the bottom direction when determining the size of the placement and routing obstructions to be pushed down. *Data_type*: int, optional
`-insertBuffer bufferName`	
	Specifies either the name of the buffer, or that there are no buffers to be inserted. *Default*: `-noInsertBuffer` *Data_type*: string, optional
`-left extension`	Specifies how far, in microns, to expand the Area I/O cell box in the left direction when determining the size of the placement and routing obstructions to be pushed down. *Data_type*: int, optional
`-noInsertBuffer`	Specifies that no buffers are to be inserted. *Data_type*: bool, optional
`-pinOnBoundary`	Specifies the internal pin created to be placed at the intersection of the hole punch (placement obstruction) and the space reserved for the partition. If it is not specified, the default is that the internal pin is placed directly on top of the area I/O cell. *Data_type*: bool, optional
`-right extension`	Specifies how far, in microns, to expand the Area I/O cell box in the right direction when determining the size of the placement and routing obstructions to be pushed down. *Data_type*: int, optional
`-selectedCell`	Specifies hole punches for all currently selected cells that overlap partitions if they are Area I/O cells. If you do not specify this parameter, the command specifies hole punches for all Area I/O cells that overlap partitions. *Data_type*: bool, optional
`-top extension`	Specifies how far, in microns, to expand the Area I/O cell box in the top direction when determining the size of the placement and routing obstructions to be pushed down. *Data_type*: int, optional

Related Information

- Partitioning the Design chapter in the *Innovus User Guide*

hier_clock_route

```
hier_clock_route
[-help]
-dir ptnParentDirName
-ptn_net_dir ptnNetDirName
[-ptns ptnNameList]
```

Runs `globalDetailRoute` on the nets specified in the net file (*<ptnName>*`.net` file) provided for each of the specified partitions, in parallel, using EDP (parallel/distributed) framework.

Note:

Before running the `hier_clock_route` command if you have a requirement to set any custom preferences or callbacks (For example,VIA preferences, routing layers preference etc), or perform any other operation, a file with name *`hier_clock_route_global_detail_route.tcl`* must be created in current run directory.

The *`hier_clock_route_global_detail_route.tcl`* file must have a procedure defined like below:

```
proc ::hier_clock_route_pre_global_detail_route {ptnName} {
Puts "called ::hier_clock_route_pre_global_detail_route $ptnName"
<body: operations/settings to be written in tcl format>
. . . .
}

proc ::hier_clock_route_post_global_detail_route {ptnName} {
Puts "called ::hier_clock_route_post_global_detail_route $ptnName"
<body: operations/settings to be written in tcl format>
. . . .
}
```

For example,

```
proc ::hier_clock_route_pre_global_detail_route {ptnName} {
Puts "called ::hier_clock_route_pre_global_detail_route $ptnName"
set bot_layer 6
set top_layer 9
setDesignMode -bottomRoutingLayer $bot_layer
setDesignMode -topRoutingLayer $top_layer
setGenerateViaMode -reset
setGenerateViaMode -ndr_only true
}

proc ::hier_clock_route_post_global_detail_route {ptnName} {
Puts "called ::hier_clock_route_post_global_detail_route $ptnName"
setGenerateViaMode -reset
}
```

Parameters

`-dir` *`ptnParentDirName`*	Specifies the directory in which partition databases are present. *Data_type*: string, required
`-help`	Outputs a brief description that includes the type and default information for each `hier_clock_route` parameter. For a detailed description of the command and all of its parameters, use the man command: `man hier_clock_route`
`-ptn_net_dir` *`ptnNetDirName`*	Specifies the directory in which net file for each partition is present. The net file contains the nets to be routed. *Data_type*: string, required
`-ptns` *`ptnNameList`*	Specifies the list of partition names. *Data_type*: string, optional

Example

The following command routes the nets specified in the net files (./nets/tdsp_core.txt and ./nets/controller.txt), within the ./nets partition net directory, provided for each of the specified partitions (tdsp_core and controller)

```
hier_clock_route -dir ./ptns -ptn_net_dir ./nets -ptns {tdsp_core controller}
```

where,

- ./ptns directory contains partitions, tdsp_core and controller.
- ./nets/tdsp_core.txt contains net names: N1, N2, N3
- ./nets/controller.txt contains net names: N4, N5

The result of this command is equivalent to the following tcl code:

```
 foreach ptnName $ptnNameList {
       cd $ptnParentDir/$ptnName
       restoreDesign . $ptnName
       # select nets specified in $ptnNetDir/$ptnName.net
       # set routeGuide, if found in $ptnNetDir/$ptnName.rgf
       # source user-defined-procs for global detail route
       if {[file exists ${current_run_dir}/hier_clock_route_global_detail_route.tcl]} {
            source ${current_run_dir}/hier_clock_route_global_detail_route.tcl
       }
       # invoke call back : pre global detail route
       if {[info procs ::hier_clock_route_pre_global_detail_route] != {}} {
           ::hier_clock_route_pre_global_detail_route $ptnName
       }

       # run globalNanoRoute on the selected nets
       setNanoRouteMode -route_selected_net_only true
       globalDetailRoute
       setNanoRouteMode -route_selected_net_only false

       # invoke call back : post global detail route
       if {[info procs ::hier_clock_route_post_global_detail_route] != {}} {
           ::hier_clock_route_post_global_detail_route $ptnName
       }

       # write def file
       defOut -routing $ptnName.def.gz
       }
```

Related Information

- globalDetailRoute
- Partitioning the Design chapter in the *Innovus User Guide*

hiliteFeedthroughNets

```
hiliteFeedthroughNets
[-help]
fileName
[netNameList ]
```

Highlights all nets for which feedthrough buffers were inserted with the `insertPtnFeedthrough` command. The highlighted feedthrough path consists of the nets, the terms that the nets connect to, and the instances that contain those terms.
Note: For the `hiliteFeedthroughNets` to work, the `insertPtnFeedthrough` command must be run with the `-netMapping` parameter. The net mapping file generated with the `insertPtnFeedthrough -netMapping` parameter is used by the `hiliteFeedthroughNets` command to highlight the feedthrough nets.

To dehighlight the feedthrough nets, run the `dehighlight` command.

Note: It displays a warning message when used for a design with nested partitions and generates results based on single level partitions.

Parameters

fileName	Specifies the net mapping file that was generated with the `insertPtnFeedthrough -netMapping` parameter. *Data_type*: string, required
`-help`	Outputs a brief description that includes the type and default information for each `hiliteFeedthroughNets` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man hiliteFeedthroughNets`
netNameList	Specifies the name of the net(s) whose feedthrough path should be highlighted. *Default:* The feedthrough paths of all nets specified in the net mapping file are highlighted. *Data_type*: string, optional

Examples

- The following command highlights all feedthrough nets specified in the net mapping file `nmpFile1`.
  ```
  hiliteFeedthroughNets nmpFile1
  ```
- The following command highlights all feedthrough nets that are specified in the net mapping file nmpFile1 whose name begins with `feedthruNet_core`.
  ```
  hiliteFeedthroughNets nmpFile1 feedthruNet_core*
  ```

[[-checkOnly ] | [[-ecoFile fileName] [-netMapping fileName]] ] [-topoFile topologyFileName ] [-noBuffer ]
```

Inserts feedthrough buffers into the partitions, changing the original netlist, to avoid routing a net over a block area. ECO placement runs automatically with this command. The buffer supplied during design import is taken as default. For Alternately, you can specify a buffer with the `-bufCell` parameter or specify the `-noBuffer` parameter to generate an ASSIGN statement in the netlist. You can use this command after the floorplanning steps for a partitioned design.

The `insertPtnFeedthrough` command can detect if the design has power domains. This way, appropriate buffers which are inserted into power domains will automatically be derived based on power domain library binding. An error message is reported if no regular buffer is found for an *Always On* power domain in the feedthrough path. Both placement and route based feedthrough insertions can support *Always On* and switchable power domains.

You can save the feedthrough buffer topology tree information in a file by using the `-saveTopoFile` parameter. You can later use the `-topoFile` parameter to replicate feedthrough buffer insertions for an ECO netlist by specifying the file that has the topology tree information. You can also manually create a topology file to guide feedthrough insertion for specific nets.

Notes:

- The `insertPtnFeedthrough` command by default derives the feedthrough topology using a shortest-path algorithm, which is based on the placement results.
- The `insertPtnFeedthrough` command by default considers a design to be channel-less, having no channel available for routing. Therefore all nets are candidates for feedthrough insertion.
  The default behavior assumes a true channel-less design - that is, the possibility of routing through channels is considered minimal. It does not consider routing congestion, routing blockages, route guides, pin guides, and bus guides. If these considerations are required, use the `-routeBased` parameter to derive the feedthrough topology based on the routing results.
- Feedthroughs are inserted in nets that connect to floating ports. Floating ports are hierarchical ports that are not connected to any logic inside the module.
- The `insertPtnFeedthrough` command removes nets that are inserted with feedthrough buffers from any net groups to which they belong. After running this command you should, therefore, update the net groups that contain feedthrough nets.
- If a pin guide exists for a net for which feedthrough buffers are inserted, the pin guide information is updated.
- The `insertPtnFeedthrough` command will handle designs with master/clone partitions automatically. However, it may create infeasible pin solution for channel-less designs with fully abutted partitions.
- The `insertPtnFeedthrough` command supports nested partitions. For inserting feedthrough buffers into nested partitions, the `insertPtnFeedthrough` command, first, automatically deletes the parent partitions and keeps only the bottom-most partition. It then does a single-level feedthrough insertion and then automatically restores the parent partitions and brings the nested partition definition back as it is. In nested designs, the `insertPtnFeedthrough` command only puts buffers and ports in the bottom most level of partitions.
- The `insertPtnFeedthrough` command prints a summary of all messages issued for nets in the log file.
- A feedthrough always uses a low power compatible buffer/AO-buffer. If it cannot use a low power complaint cell, then the default buffer (specified with the `-bufCell` parameter) is used, and the buffer name is prefixed with “MSV_INVALID”.

Parameters

`-allLowercase`	Specifies all lowercase characters for the inserted feedthrough buffer and feedthrough net names. *Data_type*: bool, optional
`-autoSelectNetsByCongestion`	Specifies that the critical nets in congested channels will be identified automatically. These critical nets are routed flat so that later they can be feedthrough over partition(s) to reduce congestion, while other remaining nets are routed by honoring fences. Once the routing is done, feedthroughs are inserted based on the routing result. *Data_type*: bool, optional
`-autoSelectNetsBySlack`	Specifies that the critical nets in the design will be identified automatically. These critical nets are routed flat so that later on they can be feedthrough over partition(s) to improve timing while other remaining nets are routed by honoring fences. Once the routing is done, feedthroughs are inserted based on the routing result. *Data_type*: bool, optional
`-blockageFile` *fileName*	Specifies a file that contains the coordinates of line segments that are considered as blockages for placement based feedthrough insertion. **Note:** The blockages must be defined as lines that do not overlap with partitions or macros. These blockage lines are supported only with automatic feedthrough insertion or placement based feedthrough insertion. The following is the format of the blockage file: *x1 y1 x2 y2* *x1 y1 x2 y2* *...* *xn yn xm ym* The blockage lines are specified as coordinates of a box, however, the boxes should be of zero width or height. *Data_type*: string, optional
`-blockedEdgesFile` *fileName*	Specifies a file that contains the names of the partitions followed by the edge numbers for the partition which are considered as blocked for the purpose of `insertPtnFeedthrough` command. *Data_type*: string, optional
`-bufCell {`*cellName* `|` *cellNameList*`}`	
	Specifies the name of the feedthrough buffer cell type. **Note:** You can specify multiple buffer cells with MSV designs. The first buffer will be used for the default power domain. *Data_type*: string, optional
`-checkOnly`	Specifies that the feedthrough buffers are *not* inserted. This parameter is useful when you want to know how the `insertPtnFeedthrough` command will affect the design. A summary information will be printed. You can specify this parameter along with the `-saveTopoFile` parameter. This will save the feedthrough topology information. *Data_type*: bool, optional
`-doubleBuffer`	Adds a buffer close to the feedthrough input pin and adds a buffer close to the feedthrough output pin. *Data_type*: bool, optional
`-ecoFile` *fileName*	Specifies the file for logging ECO directives. This parameter cannot be used with the `-checkOnly` parameter. *Data_type*: string, optional
`-excludeNet` *fileName*	Specifies a file that contains net names to be excluded from being a feedthrough net for a partition. *Data_type*: string, optional
`-excludePtnList {`*partitionName* `|` *partitionList*`}`	
	Specifies that feedthrough buffers should not be added to the specified partitions. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `insertPtnFeedthrough` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man insertPtnFeedthrough`
`-instPrefix` *instancePrefix*	Specifies a prefix for the newly created instances. The prefix that you specify will be used instead of the default prefix. *Data_type*: string, optional

`-netMapping` *fileName*	Generates a file that maps the original net name to the new net name created for the feedthrough buffers. **Note:** You must specify this parameter if you later want to run the `hiliteFeedthroughNets` command to highlight the feedthrough paths of the nets. *Data_type*: string, optional
`-netPrefix` *netPrefix*	Specifies a prefix for the newly created nets. The prefix that you specify will be used instead of the default prefix. *Data_type*: string, optional
`-noBuffer`	Generates an `ASSIGN` statement in the netlist instead of inserting a buffer. *Data_type*: bool, optional
`-repeatedSymmetricAbuttedFPlan`	This option is relevant to master clone designs. It is to be used for the floorplans which have repeated components arranged in a symmetric fashion with a data flow going from the top to each component independently. **Note**: If the design has nested partitions, it will delete all the partitions which are parents. It will hold more partitions within them, perform its operation and restore the parent partitions once finished. *Data_type*: bool, optional
`-reuseBuffer {true | false | 0 | 1}`	
	Reuses inserted buffers across multiple instantiation of a module within one run. This option should only be used for designs that have master and clone partitions. *Default*: `true` *Data_type*: enum, optional
`-routeBased`	Derives the feedthrough topology based on the routing results. *Data_type*: bool, optional
`-routeBasedStrict`	Derives the feedthrough topology based on the routing results and follows each criss-cross. In comparison to the `-routeBased` parameter, the `-routeBasedStrict` option inserts more number of buffers depending on the routing cross-overs and also supports special routes. It can insert buffers on intra-partition net, if the routing crosses outside the boundary. However, such a net needs to be handled via selected feedthrough insertion and not default selection. The `-routeBasedStrict` parameter places the pins at each of the routing cross-point. **Note:** You can use the `showPtnWireX` command to get `[design_name].nets_not_crossing_mc.txt` for a selection of nets on which to use this option. *Data_type*: bool, optional
`-saveTopoFile` *fileName*	Saves a file with feedthrough buffer topology tree information from an existing floorplan. *Data_type*: string, optional
`-selectMarkedNet`	Specifies that feedthrough buffers should be inserted on the nets that are currently selected in the GUI. *Data_type*: bool, optional
`-selectNet` *fileName*	Specifies a file that contains net names to be feedthrough nets for a partition and inserted feedthrough buffers. *Data_type*: bool, optional
`-topoFile` *topologyFileName*	Specifies the file that has the topology tree information. This information is used to create feedthrough buffers for the netlist. If you use the `-topoFile` parameter, only those nets that are specified in the topology file are considered for feedthrough buffer insertion. If a net does not exist in the design, it should not be in the topology file. For example, if ECO changes remove a net, that net should be removed from the topology file. **Note:** Hierarchical bus names are not supported in the Innovus software. Therefore, you cannot use hierarchical bus names in the topology file. **Note:** The names of the feedthrough nets, buffers, and ports created might change in the different runs of the command. Only the feedthrough path (the partitions through which the net will pass) will always remain the same across the different runs of the command. *Data_type*: string, optional
`-useShortName`	Specifies the abbreviation of inserted feedthrough net names so that the net names do not extend too long for multiple runs. *Data_type*: bool, optional

`-verbose`	Specifies that net-specific information is included in the logs. *Default:* Only the summary information is included in the logs. *Data_type*: bool, optional

Examples

- The following command generates a file, `K_ABC.topo`, with the feedthrough buffer topology tree information:
  ```
  insertPtnFeedthrough -saveTopofile K_ABC.topo -netMapping abcfile
  ```

  The following is the generated topology file:

  ```
  ##############################################################
  #  Generated by:      Cadence Innovus
  #  OS:                Linux x86_64(Host ID nofcnl040)
  #  Generated on:      Mon Jan 21 12:34:59 2015
  #  Design:            test
  #  Command:           insertPtnFeedthrough -saveTopoFile K_ABC.topo ...
  ##############################################################
  version 1.0;
  net K_ABC_NET
  hinst-hinst p4 p8;
  hinst-hinst p4 p7;
  end net
  ```
- The following command specifies that topology tree information from the `topology_info` file should be used to generate feedthrough buffer insertions:
  ```
  insertPtnFeedthrough -topofile topology_info
  ```

legalizePin

```
legalizePin
[-help]
[-auto_pairing]
[-ignore {pin_spacing pin_spacing_constraint pin_spacing_routeBlk pin_width pin_depth pin_layer pin_min_area pin_on_track pin_abutment
pin_non_nbr_abutment clones pin_color}
[-internalPin]
[-keepLayer]
[-keepOrder]
[-moveFixedPin]
[-pin {pinName | pinNameList}]
[-ptn ptnName]
[-snapToBoundary]
[-verbose]
[-ptn ptnName | {-pin_file fileName [-exclude_ptn ptnName]}]
[-pin_file fileName  | -exclude_pin_file fileName]
```

Moves a pin from its existing location. It moves the pins in the following cases:

- The pin overlaps with any other object or pin. The objects considered are:The pin violates pin-to-pin spacing constraints
    - stripes
    - vias
    - feedthrough buffers
    - routing blockages
    - pin blockages
- The pin is on a non-preferred layer, a non-reserved layer, or the Metal1 layer
- The pin is not on the routing track
- The pin does not honor corner mask settings

The pin is assigned to the nearest legal location.

Note: If this command is run on a blackbox that has one or more pins with a single LEF port but with multiple shapes within the LEF port, the command will remove these multiple shapes and create a single shape. If this command is run on a blackbox that has one or more pins with multiple LEF ports, the first LEF port will be processed as per the command and the remaining LEF ports will remain unchanged.

The `legalizePin` command supports nested partitions and corrects the pin position of illegal pins across hierarchies. It gives a warning if the first level pin is placed in second level partition or vice versa and legalizes them to the nearest track. It also supports pin overlapping across N levels for overlapping partition boundaries.

The `legalizePin` command honors net weights and accordingly legalizes pins. For example, if there are 2 or 3 pins that can be put into a slot, the `legalizePin` command automatically looks at the net weight of these pins and assigns the slot according the net weight priority.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `legalizePin` parameter. For a detailed description of the command and all of its parameters, use the man command: `man legalizePin`
`-auto_pairing`	Automatically calculates the channel width or distance between pins in a design which will be considered for pairing. *Data_type*: bool, optional
`-exclude_ptn ptnName`	Specifies the list of excluded partition for pin file. *Data_type*: string, optional
`-exclude_pin_file fileName`	
	Specifies pin-list to be excluded for partition in a file. *Data_type*: string, optional
`-ignore {pin_spacing pin_spacing_constraint pin_spacing_routeBlk pin_width pin_depth pin_layer pin_min_area pin_on_track pin_abutment pin_non_nbr_abutment clones pin_color}`	

	Legalizes by taking the category(ies) of ignore types into account. *Data_type*: (enum)+, optional
`-internalPin`	Legalizes internal pins by moving them to the closest track on the preferred routing layer. *Data_type*: bool, optional
`-keepLayer`	Maintains the pin layer while legalizing the pins. If the pin is on a layer that is not on the allowed partition layer list then an error is reported and the pin is not legalized. *Data_type*: bool, optional
`-keepOrder`	Maintains the pin order while legalizing pins irrespective of the layers. Initially, the pins are legalized within the range of original pin locations. However, if the legalizePin `-keepOrder` command is unable to find a legal location, `legalizePin` will try to find a valid location that is outside the original range and give warning message. If `legalizePin` fails to find a valid location, it reports an error. **Note**: The option is only applicable for pins on the fence. It does not apply to internal pins. *Data_type*: bool, optional
`-moveFixedPin`	If you use this parameter, the specified pins with a Fixed status can also be moved. **Note**: Pins that are not specified but have a Fixed status are not moved. *Default*: If you do not specify this option, the specified pins with a Fixed status are not moved. *Data_type*: bool, optional
`-ptn` *ptnName*	Specifies the partition for which the pins will be checked. This parameter is required if the partition is not the top-level module. **Note**: The `legalizePin` command can also resolve I/O pins from overlapping power stripes. In this case, ptnName specifies the block-level design name. *Data_type*: string, optional
`-pin {`*pinName* `|` *pinNameList*`}`	
	Specifies that the command should be run on the specified pin(s) only. *Data_type*: string, optional

`-pin_file` *fileName*	Specifies the pin list for a partition in a file. In the pin file, the pins and nets are specified in the following format:
	`Partition: PtnName/BlockName`
	Pin1
	Pin2
	`..`
	`Partition: PtnName/BlockName`
	Pin1
	Pin2
	`..`
	`Nets:`
	netA
	netB
	`..`
	Note: While specifying the pin list in the pin_file, it is necessary to give the “Partition” keyword followed by the name of the partition or block. If this is not specified, no operations are performed. You can specify multiple partitions in the same pin_file.
	The `pin_file` does not support buses or wild cards for pin names. If a pin specified in the list or a partition is not present in the design, a warning is displayed.
	Data_type: string, optional

`-snapToBoundary`	Snaps internal partition pins to the boundary and legalizes them. **Note**: The `-snapToBoundary` parameter does not work with `-internalPin` as both work on internal pins and their results are different. *Data_type*: bool, optional
`-verbose`	Reports all the existing pin violations. *Data_type*: bool, optional

Example

The following command legalizes pins in same the metal as they were present and moves fixed pins if they are placed illegally:

```
legalizePin -keepLayer -moveFixedPin
```

The following command accepts a file that contains the list of pins for partition A and partition B and legalizes them.

```
legalizePin -ptn {A B} -pin_file pinLst.txt
```

where, the *pinList.txt*

```
Partition: top
out1
out2
out3
Partition: A
in1
in2
in3
Partition: B
pina
pinb
pinc
```

loadBlackBoxNetlist

```
loadBlackBoxNetlist
[-help]
netlist
```

Loads a netlist for a black box. You can use this command to incrementally load an updated netlist for a blackbox. You can use this command before converting a blackbox to a fence.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `loadBlackBoxNetList` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man loadBlackBoxNetList`
`netlist`	Specifies the netlist name. The netlist can contain more than one black box netlist, but it should not contain any non-blackbox netlist. *Data_type*: string, required

Example

The following command loads the netlist `netlist_v1`.

```
loadBlackBoxNetlist netlist_v1
```

Related Information

- `convertBlackBoxToFence`
- `convertFenceToBlackBox`

  - Blackbox Flow

loadPtnPin

```
loadPtnPin
[-help]
[-report string]
[-snapModifiedToBoundary]
{-ptnName string | -all}
{-file string | -def string}
```

Loads either a partition floorplan file (from a saved partition design session) or a DEF file, and then displays the preassigned I/O pins for the partition. This command must be run for each partition in the design. You can use this command on a partition design after loading the top level floorplan and after running/loading placement and early global route data. Use `unloadPtnPin` to remove the preassigned I/O pins.

Note: The `loadPtnPin` command can load partition files that are saved using the `saveFPlan` command.

Parameters

`-all`	Specifies that pin positions for all the partitions should be loaded. *Data_type*: bool, optional
`-def string`	Specifies the full pathname of the partition def file. **Note:** You can specify a DEF file in the gzip format (with the .gz extension) also. *Data_type*: string, optional
`-file string`	Specifies the full path name of the partition floorplan file. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `loadPtnPin` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man loadPtnPin`
`-ptnName string`	Specifies the name of the partition. *Data_type*: string, optional
`-report string`	Specifies the optional report filename that contains any pins deleted or newly added. *Data_type*: string, optional
`-snapModifiedToBoundary`	Snaps pins to the modified partition boundary. The pin is unplaced if it cannot be snapped to edge at same location in same direction. If the existing pin is off-grid, the `loadPtnPin` command does not snap it to the track and you need to run the `legalizePin` command to snap the pin to the track. *Data_type*: bool, optional

Example

The following command loads pin information from file `EUG.fp.ptn` for partition `EUG`

```
loadPtnPin -ptnName EUG -file EUG.fp.ptn
```

merge_hierarchical_def

```
merge_hierarchical_def
[-help]
defFiles <...>
[-add_blockage]
[-delete_blockages_over_partition_macro]
[-incremental_ilm_def]
[-ignore_drcfill]
[-rdl_def string]
[-rdl_orientation orientation]  [-rdl_placement {x y}]
[-secondary {{suffix def_file_list}...}]
[-skipNets]
[-skip_filler]
[-skip_pg]
[-skip_routing {[pg|signal] [regular|special] [high_layer_routing]}]
[-to_layer routing_layer_name]
[-top_scope]
[-topcell_orientation orientation]
[-topcell_placement {x y}]
[-transform_file string]
[-use_top_def_die_area]
```

Merges DEF data from various blocks to a single chip database. The `merge_hierarchical_def` command provides the following features:

- Takes the TOP DEF file and a set of block DEF files and merges them into a single chip database.
- The Verilog files for each of the blocks, and TOP, need to be loaded up front .
- The block and TOP Verilog files (or their DEF files) can be specified in any order. However, if there are empty Verilog module stubs of blocks in some of the parent Verilog files, ensure that the parent Verilog files are specified prior to the child Verilog files.
- There is no need to specify the LEF files for the blocks.
- During the course of this command, TOP rows will be cut around the block boundary, and all block rows will be brought back as is.
- Partition definitions are created for each of the assembled block as per the DIE AREA statement in the block DEF.
- The wire at the block boundaries will be stitched with the electrically connected net's wires at the TOP.
- All orientations of blocks are supported for assembly. Repeated blocks are also supported. Non-R0 master is also supported.

Parameters

`-add_blockage`	Specifies that the netlist is a reduced one and converts the undefined instances into blockages. *Data_type*: bool, optional
defFiles <...>	Specifies DEF files to be merged. *Data_type*: list, required
`-delete_blockages_over_partition_macro`	
	Deletes top design placement and routing blockages overlapping partitions. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `merge_hierarchical_def` parameter. For a detailed description of the command and all of its parameters, use the man command: `man merge_hierarchical_def`
`-ignore_drcfill`	Ignores the special routing with DRCFILL shape attribute. *Data_type*: bool, optional

`-incremental_ilm_def`	Incrementally flattens the ILM def. *Data_type*: bool, optional
`-rdl_def` *string*	Specifies RDL def file. *Data_type*: string, optional
`-rdl_orientation` *orientation*	Specifies orientation for RDL def. *Data_type*: enum, optional
`-rdl_placement {`*x y*`}`	Specifies offset of RDL def. *Data_type*: point, optional
`-secondary {{`*suffix def_file_list*`}...}`	
	Specifies the secondary DEF file(s) to load. *Data_type*: string, optional
`-skip_filler`	Skips merging filler and decap cells. *Data_type*: bool, optional
`-skip_pg`	Skips merging routing on pg nets. *Data_type*: bool, optional
`-skipNets`	Skips merging signal nets section. *Data_type*: bool, optional
`-skip_routing {[pg|signal] [regular|special] [high_layer_routing]}...`	
	Skips merging routing based on the settings specified. This setting can be any combination of the three optional keywords from the following set: • `[pg|signal]`: Specifies the type of the net on which the routing to be skipped. pg – pg net, signal – signal net, both if not specified. • `[regular|special]`: Specifies the type of routing to be skipped. regular – regular routing, special – special routing, both if not specified. • `[high_layer_routing]`: Specifies that only the routing on high layers to be skipped, where the layers are calculated automatically. If not specified, the routing on all layers are skipped. The layers can be specified with `-to_layer` option. In that case, the routing on the layers from top to the specified layer are skipped. **Note:** You must specify the `-to_layer` parameter explicitly if `high_layer_routing` is specified for `-skip_routing`. Otherwise, `high_layer_routing` has no effect. *Data_type*: string, optional
`-to_layer` *routing_layer_name*	Skips the routing of layers from top to the specified layer (inclusive) when the `high_layer_routing` option is specified for the `-skip_routing` parameter. *Data_type*: (layer), optional
`-top_scope`	Merges routing only on top scope nets. *Data_type*: bool, optional
`-topcell_orientation` *orientation*	

	Specifies orientation for topcell. *Data_type*: enum, optional
`-topcell_placement {x y}`	Specifies placement for topcell. *Data_type*: point, optional
`-transform_file string`	Specifies the name of the transform file that contains the final x and y offsets, orientation in the top-level of each LEF block that got replaced by DEF, and the block's origin. *Data_type*: string, optional
`-use_top_def_die_area`	Enables the use of TOP DEF DIE AREA. *Data_type*: bool, optional

Example

- The following command merges DEF data from `top.def.gz` and `blockA.def.gz` to a single chip database.

```
merge_hierarchical_def top.def.gz blockA.def.gz
```

Related Information

- Partitioning the Design chapter in the *Innovus User Guide*

partition

```
partition
[-help]
[partitionName {list}]
[-addPinForPGWireLayersInDistance {{layer_name1 distance1} {layer_name2 distance2}}]
[-inputNetsForWireDistribution filename]
[-noTopPushDown]
[-noViaCutSpace]
[-pgPushDownHonorUPF]
[-pushDownHonorInsidePinForSpecialNet]
[-pushDownNonPGSpecialNet]
[-pushDownSelectedPGWiresAsRouteBlockage]
[-pushDownSpecialNetAsObs {SNet list}]
[-skipRouteBlockagesOutsidePartition]
[-tcf]
[-pinCutSpace]
[-noInheritPhysical]
[-pushRoute]
[-pushdownAllBumps | -pushDownSelectedPGBump]
```

Converts the specified module fences to be partitions, pushes down the physical cells or power routing information to the partition level design(s), and duplicates strips in the partition that overlap with the partition boundary at their original widths. You can use this command after specifying the partition(s).

Notes:

- While bringing back mis-aligned rows to top-level design, the `partition` command automatically detects mis-aligned rows and pushes down the row information as it is to the top-level design.
- To assign signal pins for the partitions, use the `assignPtnPin` command.
- This command should be used in combination with the `assignPtnPin` command. Cadence recommends not mixing these version 4.2 pin commands with previous (version 4.1 or earlier) pin commands in the design flow.
- While handling metal fills, the `partition` command removes the metal-fill shapes that cross the partition boundary. It pushes down only those fill-shapes that are inside the partition boundary and are on the metal-layers owned by the partition.
- In top-down flow, the partition command only promotes P/G pins from the list of pins promoted by the `setPromotedMacroPin` command.
- The `partition` command supports partitions with flexmodels and structured data paths.
- The `partition` command pushes down the route blockage layer even when the layer type is master-slice. It creates routing blockages for master-slice layers, in the "OBS" section of LEF (from macro/IP/PADs), that are overlapping partition fences. With this feature:
  - The shape of the routing blockage is the same as the overlapping shape of the layer, in the "OBS" section.
  - The routing blockage is given a “pushdown” property, so that it is not brought back in `assembleDesign`.
  - The union of overlapping shapes of layers in “OBS” section is taken for master and clones.
- The `partition` command automatically saves all the bus guide constraints with associated net groups. This enables bus routing at block level as per chip level constraints.
- The `partition` command automatically saves all the cell padding information to each partition block data. This information is saved in partitioned block .fp file.
- The `partition` command inherits all the attributes assigned to a net for block implementation flow. Preserving these attributes allows the Early Global Router and the NanoRoute Router to route the nets following specific requirements.
- The `partition` command now preserves all the pin shapes of nets.

Parameters

`-addPinForPGWireLayersInDistance {{layer_name1 distance1} {layer_name2 distance2}}`

	Specifies the layers and distance to consider for creating pins on PG stripes that lie in the specified distance range from the partition boundary. **Note:** Some designs shorten the PG stripes to avoid stripes of different net/voltages in different abutted partition abutting together and creating a short. In such wire shapes, the `partition` command does not create any pins by default since the PG stripes do not touch the partition boundary. However, you can use the `-addPinForPGWireLayersInDistance` parameter to create PG pins during block implementation for wire shapes that lie in the specified distance range from the partition boundary. The `-addPinForPGWireLayersInDistance` parameter identifies the PG wires for the specified layers in the given proximity (in preferred direction of route) of the partition boundary to create pin shapes on them.  For example, the following command creates pins on PG stripes on layers M10-M13 that are within a distance of 5 um from the partition boundary. `partition -addPinForPGLayersInDistance {{M10 5} {M11 5} {M12 5}}` *Data_type:* string, optional
`-help`	Outputs a brief description that includes type and default information for each `partition` parameter. For a detailed description of the command and all of its parameters, use the `man` command: man partition.
`-inputNetsForWireDistribution` *filename*	
	Specifies the file containing the net names to use for wire distribution. *Data_type:* string, optional
`-noInheritPhysical`	Specifies that physical only (filler) cells are not pushed down into the partition; they remain at the top level. *Data_type:* bool, optional
`-noTopPushDown`	Specifies that top-level power routing is not pushed down from top-level design to partition blocks on layers not reserved for partition. Nothing is pushed down on layers reserved for top design. *Data_type:* bool, optional

`-noViaCutSpace`	Specifies that there are no cuts in the obstructions around vias. You can use this parameter when you want to ensure that the top-level routing can connect the vias without using the space between the vias and the corresponding cover blockages. *Data_type:* bool, optional
partitionName ...	Specifies the partition names to be committed. *Data_type:* string, optional
`-pgPushDownHonorUPF`	When enabled, the UPF information is pushed down to partitions. *Data_type:* bool, optional
`-pinCutSpace`	Specifies that there are cuts in the obstructions around pins. *Default:* By default, there are no cuts in the obstructions around pins so that the top-level routing can connect the pins without using the space between the pins and the corresponding cover blockages. *Data_type:* bool, optional
`-pushRoute`	Pushes down signal routes when the design is partitioned. **Note:** All the wires of a hierarchy-violating net are discarded, in case even a single wire of that net has a hierarchy violation. *Data_type:* bool, optional
`-pushdownAllBumps`	Specifies that all the PG bumps should be pushed down into the partition. *Data_type:* bool, optional
`-pushDownHonorInsidePinForSpecialNet`	

Preserves wire segments till partition pins at the top level while wire segments beyond partition pins are still pushdown as it is. With this option enabled, Innovus automatically detects the list of nets with inside pin having a fixed status over the partition and all top- level nets crossing the partition boundary. The pure top level nets along with wire segments of nets connected to partition pins are replaced by route blockages in block data and the actual wire segments are retained at the top level.

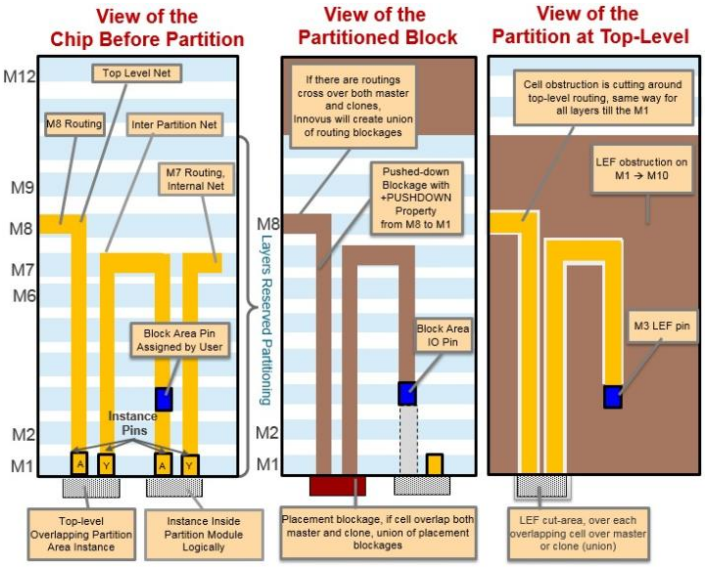
At the top-level:

- All wires till the partition pin (with fixed status) are kept. For pure top nets, all wires are kept.
- LEF obstructions are cut out for preserved wires segments.
- LEF shape against overlapping top instances are cut out.

At the block level:

- Routing blockages till the partition pin for wires that were retained at top level are created.
- All wires segments after the partition pin are retained.
- Placement blockages are created for top instances overlapping partition fence area.

Note: Before using this option, ensure that partition area pins – of the corresponding net – must be FIXED.



Data_type: bool, optional

`-pushDownNonPGSpecialNet`	Specifies that the non PG special nets should also be pushed down into the partition. *Data_type:* bool, optional
`-pushDownSelectedPGBump`	Specifies that only the selected PG bumps should be pushed down into the partition. The bumps which are not selected come as route blockage. *Data_type:* bool, optional
`-pushDownSelectedPGWiresAsRouteBlockage`	
	Pushes down selected PG routes as route blockages into the partition. This parameter enables you to select the wire segments that you want to keep at the top-level design. These non-pushed down wires must be special PG Routes.  *Data_type:* bool, optional
`-pushDownSpecialNetAsObs {`*`SNet list`*`}`	
	Specifies a list of special nets, which will be pushed down as routing blockages. It supports all types of special nets including power/ground nets. You can use wildcards while specifying the net name. *Data_type:* string, optional
`-skipRouteBlockagesOutsidePartition`	Skips pushing of objects which are close to partition fence. *Data_type:* bool, optional
`-tcf`	Enables tcf writing for the block. **Note:** A TCF file is used to store power related information of the nets in the design by keeping their toggle count related data. With the `-tcf` parameter enabled, the `partition` command generates tcf related data of partition blocks. This data can be later saved using the `savePartition` command into their respective directories. *Data_type:* bool, optional

Example

- The following command converts fences to partition data and pushes down route crossing over fence `EUG` inside the partition boundary:
  ```
  partition EUG -pushRoute
  ```
- PG is Metal7, Metal8
  Partition is defined with reserved layer Metal6

  The following command copies PG from top to block for all the PG layers:
  ```
  Partition ptnName
  ```

  The following command cuts PG from top to block for PG layers reserved for partitions. For layers above the reserved layer, PG is not pushed down to ptn.
  ```
  partition ptnName -noTopPushDown
  ```
  If reserved layer is Metal7 then Metal7 PG is cut at top and pushed down and Metal8 PG will not be pushed down.

partitionPushSpecialWires

```
partitionPushSpecialWires
[-help]
[-checkOnly]
[-nets list_of_net_names]
```

Creates Verilog ports (connections) in partitions for nets whose special wires overlap a partition, so that the special wire of the net gets pushed down when the `partition` command is used.

Note: For pushdown of special wires in master and clone partitions, it checks for the symmetry of the special wire shapes. For symmetrical shapes only, the `partitionPushSpecialWires` command creates one port in the Verilog module and establishes a logical connection between the new port and the net of special wire over all master and clone hinsts (reuse of logical port in master and clones).

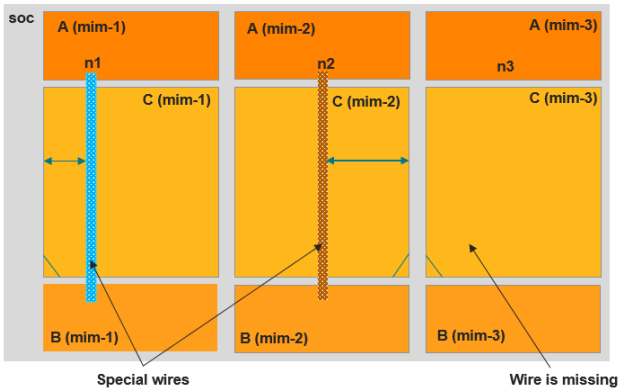
Note: If the original net was connected to a partition port of type inout, then an inout port is created inside the overlapping partition else only an input port is created.

Parameters

`-checkOnly`	When specified, the tool checks if the selected nets special-wires are symmetric over all hints of overlapping master clone cells or not. In master and clone partitions, it checks for the symmetry of nets and reports asymmetrical nets. When the `-checkOnly` parameter is not specified, the tool check the nets specified and creates logical ports only on valid nets. Data_type: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `partitionPushSpecialWires` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man partitionPushSpecialWires`
`-nets list_of_net_names`	Specifies the list of nets (Verilog nets) which have special wires to be pushed into blocks. *Data_type*: string, required

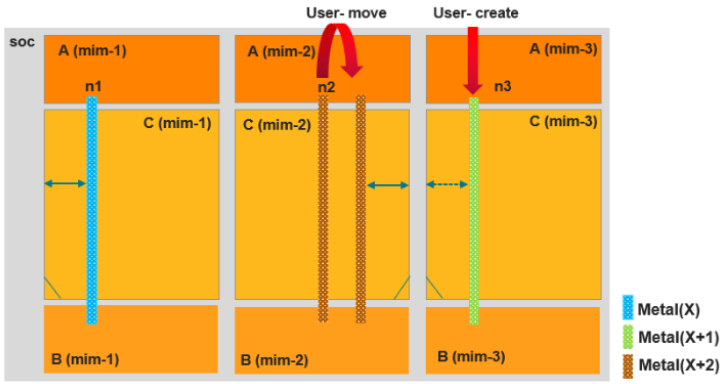
Example

- The following command checks the special wires of specified Verilog nets n1 and creates ports on valid nets.
  ```
  partitionPushSpecialWires -nets {n1}
  ```
- The following command checks if the special-wires of the specified nets are symmetric over all hints of overlapping master clone cells or not.
  ```
  partitionPushSpecialWires -nets {n1 n2} -checkOnly
  ```



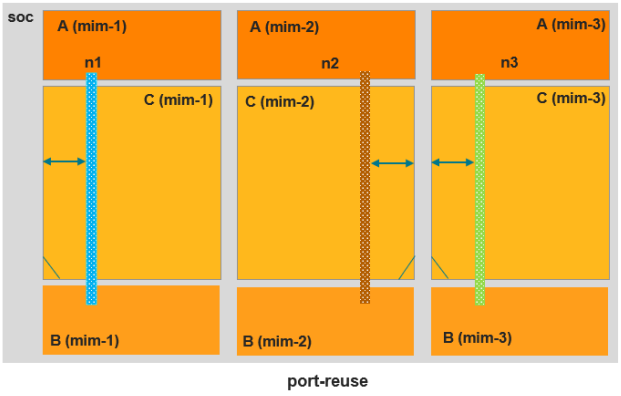
```
Report: C (mim-1) net n1 box missing in C mim-2
Report: C (mim-1) net n1 box missing in C mim-3
Report: C (mim-2) net n2 box missing in C mim-1
Report: C (mim-2) net n2 box missing in C mim-3
```

For pushdown, you must fix the wire asymmetry.



After the symmetry is fixed, the following command pushes down symmetrical nets:

```
partitionPushSpecialWires -nets {n1 n2}
```



```
Report: user Net n1, n2 and derived nets n3 pushdown, with one logical port
```

Related Information

pinAlignment

```
pinAlignment
[-help]
[-ignore_ref_pin_shape]
[-markFixed]
[-moveFixedPin]
[-keepLayer | -newLayer layer]
[-legalizePin ]
[-noSnap]
[-pinNames pinList]
[-ptnInst ptnName]
[-refObj refObjName]
[-refType {partition_pin hinst}]
[-verbose]
```

Aligns pins between blocks on their facing edges. By default, this command snaps pins to the routing grid. You can use this command after partitioning floorplanning.

Notes:

- Specified pins will not be aligned if they do not have the reference connections on the reference block, or if the reference pins are not assigned prior to running this command.
- If this command is run on a blackbox that has one or more pins with a single LEF port but with multiple shapes within the LEF port, the command will remove these multiple shapes and create a single shape. If this command is run on a blackbox that has one or more pins with multiple LEF ports, the first LEF port will be processed as per the command and the remaining LEF ports will remain unchanged.
- This command supports Multi Level Hierarchical Flow.

The pin alignment priority is as follows:

- If you specify the `-refObj` and the `-ptnInst` parameters but not the `-pinNames` parameter, the `pinAlignment` command aligns *all* pins of specified instances that are connected to the referenced object.
- If you specify the `-refObj` parameter but not the `-ptnInst` and the `-pinNames` parameter, the `pinAlignment` command aligns *all* pins of all partitions that are connected to the referenced object.
- If you specify the `-refObj`, `-ptnInst`, and the `-pinNames` parameters, the `pinAlignment` command tries to align *all* possible pins that can be aligned.
- If you do not specify the `-refObj` parameter, the following order of priority will be used for aligning partition pins that have multiple connections:
    - Hard macro pins
    - I/O pads or pins
    - Partition pins
    - Standard cell pins

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `pinAlignment` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man pinAlignment`
`-ignore_ref_pin_shape`	Specifies that the aligned pin will ignore matching of shape with the reference pin. *Data_type*: bool, optional
`-keepLayer |`	Specifies whether to keep the current pin layer. *Default*: If you do not specify this option, the new pin layer will be the same as the referenced layer to reduce wire routing. *Data_type*: bool, optional
`-legalizePin`	Specifies that the `legalizePin` command should run automatically after the `pinAlignment` command. *Data_type*: bool, optional
`-markFixed`	Specifies that the pins that are moved by this command will have a *Fixed* status. *Default*: By default, the pins moved by this command have a *Placed* status. *Data_type*: bool, optional
`-moveFixedPin`	Specifies that the pins with a *Fixed* status can also be moved. *Data_type*: bool, optional
`-newLayer` *layer*	Specifies a new pin layer. **Note:** Layers can be specified using the LEF layer names or layer ID numbers. *Data_type*: string, optional
`-noSnap`	Disables pins from being snapped to the routing grid. *Data_type*: bool, optional
`-pinNames` *pinList*	Specifies the pin(s) to be aligned between the facing edges of the target block and reference block. You can use wildcards (`*?`) with this parameter. If you specify more than one pin, you must enclose them in curly braces. *Data_type*: string, optional
`-ptnInst` *ptnName*	Specifies the target instance where its pins will be aligned to the pins of the specified instance. *Data_type*: string, optional
`-refObj` *refObjectName*	Specifies the reference object where the specified pins of the target block will be aligned to the pins of the reference object. The reference object can be a standard cell, an I/O pin, an I/O pad, a macro, or all I/O pins in the design by specifying the top cell as the reference object. Now the `pinAlignment` command can also take uncommitted ptn as the reference object. **Note:** You can also use wildcard (* or ?) for specifying the reference object names. *Data_type*: string, optional
`-refType {partition_pin hinst}`	Specifies the type of reference objects to consider. You can specify partition pins or hinsts. *Data_type*: enum, optional
`-verbose`	Generates intermediate messages. *Data_type*: bool, optional

Examples

- The following command aligns `A0` and `A1` pins of `p1` to the reference pins of `blockA`:

  ```
  pinAlignment -refObj blockA -ptnInst p1 -pinNames {A0 A1}
  ```

- Assume the following netlist:

  ```
  module testcase (in1, in2, in3);
  input in1, in2, in3;
  ```

```
wire net;
a i_a(.in1(in1), .in2(in2), .in3(in3), .out1(net));
BUFX1 i0(.A(net));
endmodule

module a(in1, in2, in3, out1);
input in1, in2, in3;
output out1;
endmodule
```

The following command aligns pins `in1`, `in2`, and `in3` on partition `i_a`:

```
pinAlignment -refObj testcase -ptnInst i_a
```

```
  Moving pin [in1] of partition [a] connected to pin [in1] of top cell [testcase] to ALIGNED location ( 0.000 21.000 Metal3).
  Moving pin [in2] of partition [a] connected to pin [in2] of top cell [testcase] to ALIGNED location ( 0.000 38.920 Metal5).
  Moving pin [in3] of partition [a] connected to pin [in3] of top cell [testcase] to ALIGNED location ( 0.000 57.960 Metal3).
  Aligned 3 pin(s) of the partition [a] successfully.
```

Note: Only 3 of the 4 partition pins are moved because pin `out1` is connected to a nearby instance rather than a top-level IO pin.

pinAnalysis

```
pinAnalysis
[-help]
[-checkLegality]
[-outFile fileName]
[-noHtml]
```

Reports certain Quality of Results (QoR) metrics for pin assignment. The `pinAnalysis` command deletes the existing routes, reroutes the design ensuring that the routes pass through partition pins, and reports pin assignment QoR metrics. You can run this command after assigning partition pins.

Notes:

- The `pinAnalysis` command creates new routes. The original routes are not retained.
- The `pinAnalysis` command reroutes the design using `setRouteMode -earlyGlobalRoutePartitionHonorPin`. This command thus takes at least as much time as running Early Global Route.
- In addition to displaying the report on screen, the command also generates the report in an HTML file named `pinAnalysis.html`.
- This command is not supported by Multi Level Hierarchical Flow. It displays a warning message when used for a design with nested partitions and generates results based on single level partitions.

Parameters

`-checkLegality`	Checks the legality of pin assignment (similar to the `checkPinAssignment` command) and prints a summary report of the results. The legality details for every partition are available through hyperlinks that are provided in the HTML report file. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `pinAnalysis` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man pinAnalysis`
`-noHtml`	Specifies that HTML report file should not be created. *Data_type*: bool, optional
`-outFile` *fileName*	In addition to displaying the report on screen, prints the report to the specified file. *Data_type*: string, optional

Example

The following command checks the legality of pin assignment, displays the QoR report for pin assignment on the screen, and also prints the QoR report to a file named `pinAnalysisMetricReport`

```
pinAnalysis -checkLegality -outFile pinAnalysisMetricReport
```

place_cells_at_center_for_feedthrus

```
place_cells_at_center_for_feedthrus
[-help]
[-insts list_of_selected_insts]
```

Places all the instances corresponding to a given partition at its center to facilitate feed-through insertion in the flow during the floorplanning stage. It quickly changes the design status to “placed” by placing all unplaced cells in the middle of the partition, so that feedthrough can be run.

Note: It places all the cells on the same location (overlapping).

Note: It can handle rectilinear partition fences and nested designs.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `place_cells_at_center_for_feedthrus` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man place_cells_at_center_for_feedthrus`
`-insts list_of_selected_insts`	Specifies the name of the instances that will be placed at the center of the partition. You can use wildcards (*?) with this parameter. For example, the following command places all unplaced cells that have ECO in their name to the center of the partition: `place_cells_at_center_for_feedthrus -insts *ECO*` *Data_type*: string, optional

Example

The following command changes the design status to “placed” by placing all unplaced cells in the middle of the partition, so that feedthrough can be run.

```
place_cells_at_center_for_feedthrus
```

Related Information

place_partition_clone

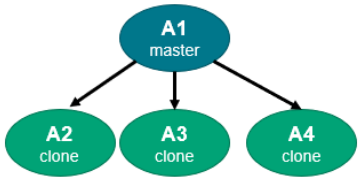
```
place_partition_clone
[-help]
-hinst partition_clone_hinst_name
-location {x y}
[-orient {R0 R180 MX MY}]
[-skip_sync]
[-sync_objs {placeBlockage routeBlockage pinBlockage macros fences}]
```

Places the clones, set their orientation and syncs up the data with other hierarchical instances (master and clones) of the same module.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `place_partition_clone` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man place_partition_clone`
`-hinst partition_clone_hinst_name`	Specifies the name of partition clone hierarchical instance. *Data_type*: string, required
`-location {x y}`	Specifies location of the clone partition. *Data_type*: point, required
`-orient {R0 R180 MX MY}`	Specifies orientation of the clone partition. The orientation can be one of the following: `R0, R180, MX, and MY` *Data_type*: enum, optional
`-skip_sync`	When specified, the tool skips the sync-up of reference hinst (`-hinst`) objects with other hinsts of the same module. *Data_type*: bool, optional
`-sync_objs {placeBlockage routeBlockage pinBlockage macros fences}`	When specified, the tool does the sync-up of the specified objects from reference hinst with other hinsts of same module. The objects that can be synced up include placeBlockage, routeBlockage, pinBlockage, macros, and fences. *Data_type*: string, optional

Example



```
Hinst: A1 (master), A2 (clone), A3(clone), A4 (clone)
```

- The following commands places the clone A2 at location 2,5. If partition block has FP/def/route objs/data present, the command will sync the data from A2 to all other hinsts (A1 (master), A3 , A4 (clones)).
  ```
  place_partition_clones -hinst A2 -location {2 5}
  ```
- The following commands places the clone A3 at location 12,15 and changes the orientation to R180 (if not already R180). If partition block has FP/def/route objs/data present, the command will sync the data from A3 to all other hinsts (A1 (master), A2 , A4 (clones))
  ```
  place_partition_clones -hinst A3 -location {12 15} -orient R180
  ```
- The following commands places the master A1 at location 22,25. If partition block has FP/def/route objs/data present, the command will sync the data from A1 to all other hinsts (A2, A3, A4 (clones)).

```
place_partition_clones -hinst A1 -location {22 25}
```

- The following commands places the master A1 at location 22,25. If partition block has FP/def/route objs/data present, the command will not sync any data to other hinsts.

  ```
  place_partition_clones -hinst A1 -location {22 25} -skip_sync
  ```

- The following commands places the clone A3 at location 12,15 and changes the orientation to R180 (if not already R180). If partition block has FP/def/route objs/data present, the command will not sync any data to other hinsts.

  ```
  place_partition_clones -hinst A3 -location {12 15} -orient R180 -skip_sync
  ```

- The following commands places the clone A3 at location 12,15 and changes the orientation to R180 (if not already R180). If partition block has FP/def/route objs/data present, the command will sync the bus-guide data from A3 to all other hinsts (A1 (master), A2 , A4 (clones)).

  ```
  place_partition_clones -hinst A3 -location {12 15} -orient R180 -sync_obj {bus_guide}
  ```

Related Information

push_ptn_network

```
push_ptn_network
[-help]
[-exclude_ptn_list ptnNameList]
[-filter string]
[-inst_prefix instPrefixName]
[-logical_only]
[-net_prefix netPrefixName]
[-output_logical_only_nets string]
[-output_nets_for_wire_distribution string]
[-ptn_net_dir fileName]
{-nets netNameList | -file fileName | -buf_only | -insts instNameList }
[-check_only [-output fileName]]
```

Pushes down a network (std cells and connected wires) logically and physically into overlapping partitions. The `push_ptn_network` command:

- Logically pushes down a set of nets into overlapping partitions by doing all the necessary logical port creations.
- Physically pushes down the special wires of the nets into overlapping partitions and does all the necessary partition pin creations. The pushed wires look exactly the same as the original wires.
- Creates Verilog assign statements wherever required to ensure that the pushed logic is logically equivalent to the original logic.

Notes:

- The `push_ptn_network` command does not support designs with master and clone partitions. In such scenarios, only masters will be seen and the overlapping wires and logic will be pushed down into masters only.
- The `push_ptn_network` command takes care of new nets connected at top level nets automatically post committing partitions.
- The `push_ptn_network` command supports partially routed nets. It does not require the wires of a net to be DRC/LVS clean. Wires need not connect to the instance-pin of a driver or loads. Even if a wire is in the 5u radius of a source-instance-pin or a sink-instance-pin, the tool considers the net for pushdown.

Parameters

`-buf_only`	Specifies that only all buffers, and their connected nets, will be considered for pushed down. *Data_type*: bool, required
`-check_only`	Informs which nets are going to be pushed down. *Data_type*: bool, optional
`-exclude_ptn_list` *ptnNameList*	Specifies that the instances/nets within the specified partition(s) will not be pushed down. *Data_type*: string, optional
`-file` *fileName*	Specifies the name of the file containing the list of net names to be considered for push down. *Data_type*: string, required
`-filter` *string*	Specifies that only instances/nets whose name matches this specified regular expression will be pushed down. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `push_ptn_network` parameter. For a detailed description of the command and all of its parameters, use the man command: `man push_ptn_network`
`-inst_prefix` *instPrefixName*	Specifies a custom prefix for instances that are pushed down. *Data_type*: string, optional
`-insts` *instNameList*	Specifies that all instances, and their connected nets, will be considered for pushed down. **Note:** The `push_ptn_network` command accepts instances names with backspace '\' in them. *Data_type*: string, required
`-logical_only`	Logically pushes down network into overlapping partitions. *Data_type*: bool, optional
`-net_prefix` *netPrefixName*	Specifies a custom prefix for nets that are pushed down. *Data_type*: string, optional
`-nets` *netNameList*	Specifies that list of net names, and their connected instances, will be considered for pushed down. **Note:** The `push_ptn_network` command accepts nets names with backspace '\' in them. *Data_type*: string, required
`-output` *fileName*	Specifies a file name in which net names, to be pushed down, will be mentioned. This parameter is used with `-check_only`. *Data_type*: string, optional
`-output_logical_only_nets` *string*	
	Specifies a file name in which net names are mentioned. This parameter is used with `-logical_only`. *Data_type*: string, optional
`-output_nets_for_wire_distribution` *string*	
	Outputs the user-specified nets so that they can be used later during the `partition` command. *Data_type*: string, optional
`-ptn_net_dir` *fileName*	Specifies the directory that consists of the names of the pushed nets corresponding to each partition. *Data_type*: string, optional

Example

- The following command consider nets n1, n2 and n3 for push down.
  ```
  push_ptn_network -nets {n1 n2 n3}
  ```
- The following command generates a file, push_down_nets.txt, containing the names of nets that would have been considered for push down.
  ```
  push_ptn_network -nets [dbGet -e top.nets.name] -check_only -output push_down_nets.txt
  ```
- The following command generates a file, push_down_nets.txt, containing the names of nets (connected to the specified instances)that would be considered for push down.
  ```
  push_ptn_network -insts [dbGet -e top.insts.name] -check_only -output push_down_nets.txt
  ```
- The following command considers all buffers for push down.
  ```
  push_ptn_network -buf_only
  ```
- The following command considers all buffers and their connected nets for push down which have their hierarchical name (TCL) regexp matching to KK.*.
  ```
  push_ptn_network -buf_only -filter KK.*
  ```
- The following command considers all buffers and their connected nets for push down. The pushed down buffers will have their base names starting with II_
  ```
  push_ptn_network -buf_only -inst_prefix II
  ```
- `The following command` considers all buffers and their connected nets for push down. The pushed down buffers will have their base names starting with II_, and the pushed down nets will have their base names starting with NN_.`push_ptn_network -buf_only -inst_prefix II -net_prefix NN`

recreatePtnCellBlockage

```
recreatePtnCellBlockage
[-help]
[ptnName]
[-noPinCutSpace | -hasPinCutSpace]
[-noViaCutSpace | -hasViaCutSpace]
```

Recreates cell blockage for a specified partition, or all partitions. This reflects incremental changes, such as pin movement. You can use this command after editing the pin in a partition with the Pin Editor, or using the `editPin` command, to move pins in the partition.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `recreatePtnCellBlockage` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man recreatePtnCellBlockage`
ptnName	Specifies the partition to recreate the cell blockage. *Default*: All partitions *Data_type*: string, optional
`-noPinCutSpace`	Specifies that no cut space will be created for pins in the partition cell blockage. **Note:** Blockages are always cut for power pins. *Data_type*: bool, optional
`-hasPinCutSpace`	Specifies that cut space will be created for pins in the partition cell blockage. **Note:** This is the default. *Data_type*: bool, optional
`-noViaCutSpace`	Specifies that no cut space will be created for vias in the partition cell blockage. *Data_type*: bool, optional
`-hasViaCutSpace`	Specifies that cut space will be created for vias in the partition cell blockage. **Note:** This is the default. *Data_type*: bool, optional

Example

- The following command recreates pin blockages for partition `EUG`:

  ```
  recreatePtnCellBlockage EUG
  ```

Related Information

- `editPin`
- Partitioning the Design chapter in the *Innovus User Guide*

report_partitions

```
report_partitions
[-help]
[topCell]
```

Reports the partitions and clones in a correct tree like format.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `report_partitions` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man report_partitions`
topCell	Specifies the top cell to print its cell partition tree. *Data_type*: string, optional

Example

The following command prints the partitions and clones in the design in a tree like format.

```
report_partitions
```

```
Format: partitionName, MasterOrClone, Orient, PartitionOrBlackBox (CommittedOrUncommited, Level, BottomUpLevel, In/Active): InstOrHInstName

reportPinAssignStatistics

```
reportPinAssignStatistics
[-help]
[-maxFanOut fanOutCount]
[-maxRegisterFanOut registerFanOutCount]
[-outFile pinQoRFileName]
[-hinst hinstNameList | -ptn ptnNameList]
```

Generates the pin QoR data for a specified partition(s).

Note:

- If a net is not routed, then, manhattan distance between source-sink pairs is be used to replace corresponding wire-length distance.
- For floating pins (from outside) of a partition,the pin is always assumed to be within the timing cone box.
- Pin QoR statistics is not generated for blackbox partitions

Parameters

`-help`	Outputs a brief description that includes type and default information for each `reportPinAssignStatistic` parameter. For a detailed description of the command and all of its parameters, use the man command: `man reportPinAssignStatistic`.
`-hinst hinstNameList`	Generates the pin QoR metrics for all pins of the specified hierarchical instance name or list of instance names. *Default*: All partition and clone hierarchical instances. *Data_type*: string, optional
`-maxFanOut fanOutCount`	Specifies the maximum fanout count. The QoR report is not generated for a pin if the number of instances in its timing cone fanout exceeds this maximum fanout count, *Default*: 1000 *Data_type*: string, optional
`-maxRegisterFanOut registerFanOutCount`	
	Specifies the maximum register fanout count. The QoR report is not generated for a pin if the number of registers in its timing cone fanout exceeds this maximum fanout count. *Default*: 50 *Data_type*: string, optional
`-outFile pinQoRFileName`	Specifies an output report file for the pin QoR data. *Default*: `./pin_qor.txt` *Data_type*: string, optional
`-ptn ptnNameList`	Generates the pin QoR metrics for all pins of the partition or list of partitions. *Default*: All partition and clones. *Data_type*: string, optional

Example

- The following command creates a `pin_qor.txt` report file:
  ```
  reportPinAssignStatistics
  ```
- The following command generates a reference pin QoR file named `pin_qor_reference.txt`.
  ```
  reportPinAssignStatistics -outFile pin_qor_reference.txt
  ```
- The following command generates a target pin QoR file named `pin_qor_target.txt`.
  ```
  reportPinAssignStatistics -outFile pin_qor_target.txt
  ```

reportTwoPinChain

```
reportTwoPinChain
[-help]
[-reset  |
[[-output fileName] [-through string]
[-noOverwrite ]
[-showAll ]
[-strict ]
[-tolerance value]]]
```

Reports two pin chains for nets, instterms, and hinstterms. This command can traverse through buffers, inverters, and assign-statements and report the complete two pin chain. You can specify any element of the chain to get the same results. The `reportTwoPinChain` command is used after pin assignment to analyse results and debug issues especially in cases where the expectation to align all partition pins across a two-pin chain is not met.

Parameter

`-help`	Outputs a brief description that includes type and default information for each `reportTwoPinChain` parameter. For a detailed description of the command and all of its parameters, use the man command: `man reportTwoPinChain`
`-noOverwrite`	When specified the report continues to display the previous 2-pin-chains also. *Default*: false *Data_type*: bool, optional
`-output fileName`	Specifies the file in which the 2-pin nets are traced and dumped. *Default*: stdout *Data_type*: string, optional
`-reset`	Removes GUI markers and GUI objects, created during previous invocations. No two pin chain reporting. *Default*: false *Data_type*: bool, optional
`-showAll`	Displays the intermediate instances of the chain also. *Default*: false *Data_type*: bool, optional
`-strict`	Strictly displays only pure two pin chains even at module port connections. *Default*: false *Data_type*: bool, optional
`-through string`	Specifies the list of names of net, instterms, hinstterms for which 2-pin chains are traced and dumped. *Data_type*: string, optional
`-tolerance value`	Specifies the tolerance range. This specified difference in ordinates treated as still aligned. *Default*: 1.0 microns *Data_type*: float, optional

Example

- In the following diagram P1, P2, W3/P3 are partitions and W3 is a non-partition verilog module.
  It shows a pure two pin connection where red and green pins aligned together in one chain.

  The following command reports this two pin chain passing through p2/I1/Y:
  ```
  reportTwoPinChain -through p2/I1/Y
  ```

- The following command reports the two pin chains passing through `DTMF_INST/TDSP_CORE_INST/port_pad_data_out[13]`:
  ```
  reportTwoPinChain -through DTMF_INST/TDSP_CORE_INST/port_pad_data_out[13]
  ```

  ```
  Report:
  2-pin-chain through: DTMF_INST/TDSP_CORE_INST/port_pad_data_out[13] ...
  chain terminator: other pin of buffer is multi-fanout
  net: DTMF_INST/TDSP_CORE_INST/port_data_in[13]

reportUnalignedNets

```
reportUnalignedNets
[-help]
[-alignDistance distance]
[-alignFeedThruPins]
[-considerMacroPinWithinDistance distance]
[-ignoreLength length]
[-noHighlight]
[-reportAllWithinChannelWidth width]
[-rptFile filename]
[-statistics]
[-steinerBox]
[-verbose]
[[ -ptnToPtn {aligned unaligned layerMismatch samePtn nonNbr multiFanout all unplaced none} ]
[ -topToPtn {aligned unaligned layerMismatch samePtn nonNbr multiFanout all unplaced none} ]]
[-pin_file filename | -exclude_pin_file filename]
```

Reports the names of the nets where the pins are not aligned. It reports the nets in the following cases:

- nets that have two pins on two different partitions and/or clones and are not connected to top level hard-macro, standard cell, or I/O.
- nets that have two pins that are connected to the same partition.
- nets that have one pin connected to top level hard-macro, standard cell, or I/O and the other pin connected to a partition or a clone.

Notes:

- The nets reported by this command are also highlighted in the artwork window.
- The `assignPtnPin` command internally calls the `reportUnalignedNets` command to generate the summary report at the command line.
- The `reportUnalignedNets` command measures the average misalignment with standard deviation for multi-partition nets.
- The `reportUnalignedNets` command detects and reports pins that are placed on non-facing edges.

Parameters

`-alignDistance` *distance*	Specifies the distance, in microns, up to which the pins are assumed to be aligned. With this parameter specified, the `reportUnalignedNets` command assumes that the pins are aligned within the specified distance even though they are not physically aligned. *Data_type*: float, optional
`-alignFeedThruPins`	Reports the deviation of partition pins from chain's source-target box. *Data_type*: bool, optional
`-considerMacroPinWithinDistance` *distance*	Reports nets connected to macro-pin which are within specified distance from nearest partition boundary. *Default*: 3 microns *Data_type*: float, optional

`-exclude_pin_file` *filename*	Specifies the pin list to be excluded for a partition in a file. In the pin file, the pins and nets are specified in the following format: `Partition:` *PtnName/BlockName* *Pin1* *Pin2* .. *PinN* `Partition:` *PtnName/BlockName* *Pin1* *Pin2* .. *PinN* `Nets:` *netA* *netB* .. *netN* **Note:** While specifying the pin list in the pin_file, it is necessary to give the “Partition” keyword followed by the name of the partition or block. If this is not specified, no operations are performed. You can specify multiple partitions in the same pin_file. The pin_file does not support buses or wild cards for pin names. If a pin specified in the list or a partition is not present in the design, a warning is displayed. *Data_type*: string, optional
`-help`	Outputs a brief description that includes type and default information for each `reportUnalignedNets` command parameter. For a detailed description of the command and all of its parameters, use the man command: `man reportUnalignedNets`
`-ignoreLength` *length*	Specifies the length, in microns. It ignores the nets from checking unalignment whose length is greater the specified length value. *Default*: 5000 These ignored nets will be reported in the ignored category in the output report file. *Data_type*: float, optional
`-steinerBox`	Report the deviation of partition pins from the connectivity box of the partition. *Data_type*: bool, optional
`-noHighlight`	Disables the highlight capability. *Data_type*: bool, optional
`-rptFile` *fileName*	Specifies an output report file. **Note**: Default name for report file is `<designName>_unaligned.rpt` *Data_type*: string, optional
`-ptnToPtn {aligned | unaligned | layermismatch | sameptn |nonnbr | multifanout | all | unplaced | none}`	

	Reports nets that have two pins on two different partitions and/or clones and are not connected to top level hard-macro, standard cell, or I/O. • `aligned`: Reports nets that have aligned pins. • `all`: Reports all categories of unaligned pins. • `layermismatch`: Reports nets that have pins at an aligned location but different layers. • `multiFanout`: Reports nets that have multiple fanouts • `none`: Disables reporting of nets. • `nonnbr`: Reports nets that have two pins on two different partitions that are not adjacent. • `sameptn`: Reports nets that have two pins that are connected to the same partition. • `unaligned`: Reports nets that have unaligned pins. • `unplaced`: Reports nets that have unplaced pins. *Data_type*: (enum)+, optional
`-pin_file` *filename*	Specifies the pin list for a partition in a file. In the pin file, the pins and nets are specified in the following format: `Partition:` *PtnName/BlockName* *Pin1* *Pin2* .. *PinN* `Partition:` *PtnName/BlockName* *Pin1* *Pin2* .. *PinN* `Nets:` *netA* *netB* .. *netN* **Note:** While specifying the pin list in the pin_file, it is necessary to give the “Partition” keyword followed by the name of the partition or block. If this is not specified, no operations are performed. You can specify multiple partitions in the same pin_file. The pin_file does not support buses or wild cards for pin names. If a pin specified in the list or a partition is not present in the design, a warning is displayed. *Data_type*: string, optional
`-reportAllWithinChannelWidth` *width*	Reports all the unaligned nets within the specified channel width even if the `-ignoreLength` parameter has been specified. *Data_type*: float, optional
`-statistics`	Reports average misalignment with standard deviation and layer difference count for aligned, layer mismatched, and unaligned ptnToPtn 2-pin nets of partitions. It is also used for reporting pin QOR. *Data_type*: bool, optional
`-topToPtn {aligned | unaligned | layermismatch | sameptn |nonnbr | multifanout | all | unplaced | none}`	

	Reports nets that have one pin connected to top level hard-macro, standard cell, or I/O and the other pin connected to a partition or a clone. • `aligned`: Reports nets that have aligned pins. • `all`: Reports all categories of unaligned pins. • `layerMismatch`: Reports nets that have pins at an aligned location but different layers. • `multiFanout`: Reports nets that have multiple fanouts • `none`: Disables reporting of nets. • `nonNbr`: Reports nets that have two pins on two different partitions that are not adjacent. • `samePtn`: Reports nets that have two pins that are connected to the same partition. • `unaligned`: Reports nets that have unaligned pins. • `unplaced`: Reports nets that have unplaced pins. *Data_type*: (enum)+, optional
`-verbose`	Reports all categories in log file. By default, this parameter is not enabled and only the nets that have unaligned pins are reported in the log file. **Note**: There will be no change in the report file with use of verbose parameter. *Data_type*: bool, optional

The following are some of the attributes specified in the output report file to report the names of nets where the pins are not aligned:

- `layer mismatch`: Specifies nets that have pins at an aligned location but different layers.
- `non-neighbor`: Specifies nets that have two pins on two different partitions that are not adjacent.
- `ptnToPtn`: Specifies nets that have two pins on two different partitions and/or clones.
- `topToPtn`: Specifies nets that have one pin connected to top level hard-macro, standard cell, or I/O and the other pin connected to a partition or a clone.
- `unAligned`: Specifies nets that have unaligned pins.

Example

The following command reports all nets which are placed in a channel equal to or narrower than 7.5 microns irrespective of the `-ignoreLength` parameter.

```
reportUnalignedNets -ptnToPtn unaligned -rptFile a -ignoreLength 10.0 -reportAllWithinChannelWidth 7.5
```

The following command creates an a.out report file:

```
reportUnalignedNets rptFile a.out -noHighlight -ptnToPtn all -topToPtn all
```

A summary of the reported unaligned nets displays on the Innovus console and in the Innovus log file.
The following is a sample of the resulting a.out report file.

```

resizeBlackBox

```
resizeBlackBox
blackBoxName
[-help]
[-width width]
[-height height]
[-aspectRatio ratio]
```

Resizes a blackbox.

Parameters

`-aspectRatio` *ratio*	Specifies the new aspect ratio, which is height divided by width, with the blackbox area constant. *Data_type*: float, optional
blackBoxName	Specifies the name of the blackbox. *Data_type*: string, required
`-height` *height*	Specifies the new height in user units. *Data_type*: float, optional
`-help`	Outputs a brief description that includes the type and default information for each `resizeBlackBox` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man resizeBlackBox`
`-width` *width*	Specifies the new width in user units. *Data_type*: float, optional

Examples

- The following command resizes the height of `blackbox1` to 600.5 µm. The width remains the same dimension.
  ```
  resizeBlackBox blackbox1 -height 600.5
  ```
- The following command resizes the height of `blackbox2` to be twice as long as its width. The area remains the same.
  ```
  resizeBlackBox blackbox2 -aspectRatio 2
  ```

saveBlackBox

```
saveBlackBox
[-help]
{instName | -all}
[-5.6]
[-lefFile string]
```

Creates a blackbox LEF file containing the pin definitions and obstructions.

Note: The `savePartition` command also automatically saves this file, among others.

Parameters

`-5.6`	Specifies the LEF file format version. *Data_type*: bool, optional
`-all`	Specifies all blackbox instances. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `saveBlackBox` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man saveBlackBox`
instName	Specifies the name of the blackbox instance. You can use wildcards (`*?`) with this parameter. *Data_type*: string, optional
`-lefFile` *string*	Specifies the LEF filename. If you do not specify a name, the default is *cellTypeName*`.lef`. *Data_type*: string, optional

Example

The following command creates a LEF file containing the pin definitions and obstructions for all blackbox instances that start with the letter `A` to a LEF file named `BBox.lef`:

```
saveBlackBox A* -lefFile BBox.lef
```

savePartition

```
savePartition
[-help]
[ partitionName  { list }]
[-fplan]
[-noStdCells]
[-noTrialRoute]
[-verilog]
[ [-dir  dirName ]
[ {[-noFPlan | {[-noNetlist] [-savePlacement]}]
[-def [-savePlacement]]
[-defNoCutRow]
[-ptnSite]
[-module_model_tag tag_name]
[-topLevelNoPtnModule]} |
{[-ptnLib  ptnLibName ][-ptnView  ptnViewName ][-topView  topViewName ]}]]
```

Saves the partition information to the current directory or a specified directory. This command is run after running the `partition` command to generate timing budget files and stamp model files.

Notes:

- The `savePartition` command does not write GNC rules in the partition floorplan file for multiple-supply voltage (MSV) designs.The Common Power Format (CPF) file contains this information.
- The `savePartition` command supports partitions with FlexModels. If there are FlexModels at the top-level, then the saved top-level netlist contains FlexModels. If there are no FlexModels outside partitions, then the top-level netlist will be the original full netlist. Similarly, if a partition has FlexModels, then its partition netlist will contain flexmodes.
- The `savePartition` command saves a file with the hierarchy information into the top-level design directory for a FlexModel design with nested partitions. This hierarchy information is used by the `replace_proto_model` command. When the `replace_proto_model` command replaces the FlexModel netlist back to the original full netlist after the `savePartition` command, the hierarchy information for the nested partitions is automatically available.
- The `savePartition` command saves the design information to the global init_* variables in the *.global file.
- The `savePartition` command supports multi-threading. This reduces the run time for huge designs by saving individual blocks in parallel.
- The `savePartition` command saves mmmc data without timing information for partitions for which timing budgets are not derived.
- The `savePartition` command automatically saves all the bus guide constraints with associated net groups. This enables bus routing at block level as per chip level constraints.
- The `savePartition` command automatically saves all the cell padding information to each partition block data. This information is saved in partitioned block .fp file.
- The `savePartition` command inherits all the attributes assigned to a net for block implementation flow. Preserving these attributes allows the Early Global Router and the NanoRoute Router to route the nets following specific requirements.
- The `savePartition` command writes out an additional DEF file for each block with its scan information in the `<partition_name>.scandef.gz` format.
- The `savePartition` command saves an additional file in each parent directory in the <design_name>.pg.gz format to support for PG-file in hierarchical flow. The `assembleDesign` command loads this file when it is run with the `-fe` mode.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `savePartition` parameter. For a detailed description of the command and all of its parameters, use the man command: `man savePartition`
`-def`	Writes out the DEF format files for the design. *Data_type*: bool, optional
`-defNoCutRow`	Specifies that, when row information is written to the DEF file, the rows are not cut against placement obstructions, block halos, or power domain fence minimum gaps. *Data_type*: bool, optional

`-dir dirName`	The directory name that will contain the partition information/files. *Data_type*: string, optional
`-fplan`	Writes out incremental floorplan by pushing down floorplan changes from a full chip level design to a partition block. This option allows you to run `savePartition` for a uncommitted partition without running the `partition` command. For committed partition `savePartition -fplan` reports an error. The `savePartition -fplan -dir` command honors blackboxes and saves limited floorplan information for blackboxes in the previously saved data created by the `savePartition -dir` command.. **Note:** After `savePartition -fplan` command, a non-committed partition still remains uncommitted. *Data_type*: bool, optional
`-module_model_tag tag_name`	Specifies the module model tag to be used for saving the partition. This creates pnr and lef module models for each partition block. For top-level design, this also creates a pnr module model. **Note:** This parameter is part of the Integrated Hierarchical Database (iHDB) flow. Before using this parameter, you must set the default central directory name (`set_module_model -default_dir default_model_data_directory`) where the module models data will be saved/loaded. **Note:** These block-level and top-level pnr models should be used for implementing the block-level and top-level designs, respectively. For example, if design dtmf has the ptn_wrapper partition and the default global data directory is /myproject/DATA. With `savePartition -module_model_tag init`, a pnr model will be created for top-level design in the following directory: `myproject/DATA/dtmf/init/pnr`. For partition ptn_wrapper, a pnr and lef models will be created in the `/myproject/DATA/ptn_wrapper/init/pnr` and `/myproject/DATA/ptn_wrapper/init/lef` directories. *Data_type*: string, optional
`-noFPlan`	Saves partitions without generating a floorplan file for the partitioned design. *Data_type*: bool, optional
`-noNetlist`	Saves partitions without generating a netlist file for the partitioned design. *Data_type*: bool, optional
`-noStdCells`	When you specify this option, standard cells are not written in the DEF file. *Data_type*: bool, optional
`-noTrialRoute`	When you specify this option, routed wires are not written in the DEF file. *Data_type*: bool, optional
partitionName list	Specifies the names of each partition to be saved. *Data_type*: string, optional
`-ptnLib ptnLibName`	Specifies an OpenAccess database library directory where the top-level design and the block-level design for all the partitions will be saved. This parameter is used when saving the partition into an OpenAccess database. **Note:** For OpenAccess data, you can save the specified partitions using the `partitionName` parameter. However, if the specified partition is a top-level design then all committed partitions must be saved just like no partition names are specified to avoid unbound references in OpenAccess. *Data_type*: string, optional
`-ptnSite`	Outputs sites for partitions in the LEF file. *Data_type*: bool, optional

`-ptnView` *ptnViewName*	Specifies the view name for the top and the partition views. This parameter is used when saving the partition into an OpenAccess database. *Default:* The default value of the view is layout **Note:** • If `-ptnView` is specified, but not `-ptnLib`, then the current design lib is used. You do not have to use the `savePartition` command to create a special library to hold the partition data. You can create the partition data into the same design library that holds the full-flat version of the design. In this case, cellviews will be overwritten if they already exist. • If `-ptnView` is specified, but not `-topView`, then all cell views created with the `savePartition` command will have the `ptnViewName` appended to the top cell's cellview. In order to prevent overwriting the top cell's cellview if the name already exists, use the `-topView` option to specify a different view name than the one used for the rest of the partitions being created by the `savePartition` command. • If `-dir` is specified, but `-ptnView` is not, then the `savePartition` command would be in the non-OA mode. If `-dir` and `-ptnView` are specified then the `dir` is created, but instead of putting design data into it, only the `cds.lib` is added to the directories created. *Data_type*: string, optional
`-savePlacement`	When used with the `-def` parameter, specifies that the unplaced standard cells should also be saved to the DEF file. This is equivalent to the `-unplaced` parameter of the `defOut` command. When used with the `-pdef` parameter, specifies that the placed standard cells should also be saved to the PDEF file. *Data_type*: bool, optional
`-topLevelNoPtnModule`	Suppresses stub verilog modules for partitions in the top-level partition netlist. *Data_type*: bool, optional
`-topView` *topViewName*	Specifies view name for top design. *Data_type*: string, optional
`-verilog`	Writes out an ASCII Verilog file to the saved partition directory. The netlist is always stored as a binary file, so this Verilog file is not used by `restoreDesign`. It is sometimes useful to save the Verilog in addition to the other saved files to make it possible to send the Verilog directly to other tools, or to open it in an editor for debugging. Otherwise, you need to load the design into Innovus, and call `saveNetlist` to see the Verilog file. *Data_type*: bool, optional

Example

- The following command saves the partition information/files in a directory `try3` hierarchically for each of the three partitions:

  ```
  savePartition -dir try3 TOPCHIP_SP sheet17 sheet25 sheet7
  ```

- The following command saves the partition information/files in the OpenAccess database format.
  The information for the top and the block level designs (all blocks) will be written in the `libForOA` directory view with the name `ptnView1`.
  It saves partitions without generating a floorplan file or a net list for the partitioned design. It also does not write the standard cells or trialRoute wires in the DEF file.

  ```
  savePartition -ptnLib libForOA -ptnView ptnView1 -noFPlan -noNetlist -noStdCells -noTrialRoute
  ```

savePtnPin

```
savePtnPin
[-help]
{-ptn partitionName | -all | -design | -selected}
fileName
```

Saves the pin assignment information for one or more partitions. You can subsequently load the saved pin assignment information with the `loadPtnPin` command. The `savePtnPin` command also saves the pin assignment information for blackboxes.

Parameters

`-all`	Specifies that pin assignment information will be saved for all partitions, including the top-level design. *Default*: By default, the `savePtnPin` command saves the pin assignment information for all partitions. *Data_type*: bool, optional
`-design`	Specifies that pin assignment information will be saved only for the top-level design. *Data_type*: bool, optional
`fileName`	Specifies the name of the file in which the partition pin assignment information will be saved. *Data_type*: string, required
`-help`	Outputs a brief description that includes the type and default information for each `savePtnPin` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man savePtnPin`
`-ptn` *`partitionName`*	Specifies the name of the partition for which the pin assignment information is to be saved. *Data_type*: string, optional
`-selected`	Specifies that the pin assignment information will be saved for all the selected pins of the partitions, including the top-level design. *Data_type*: bool, optional

Example

The following command saves the pin assignment information for the partition named `tdsp_block` into a file named `tdsp_block_pin_info`.

```
savePtnPin -ptn tdsp_block tdsp_block_pin_info
```

selectPtnPinGuide

```
selectPtnPinGuide
[-help]
x1 y1 x2 y2
pinGuideName
metalLayer
minSpace
[pinGroupCell]
```

Selects a partition pin guide and highlights it in the design display window.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `selectPtnPinGuide` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man selectPtnPinGuide`
`x1 y1 x2 y2`	Specifies the coordinates of the pin guide (x1 y1 x2 y2). *Data_type*: box, required
`metalLayer`	Specifies the layer on which the pin guide resides. *Data_type*: string, required
`minSpace`	Specifies the minimum pin spacing for the pin guide. *Data_type*: int, required
`pinGroupCell`	Specifies the cell name if the pin guide is associated with a cell pin group. *Data_type*: string, optional
`pinGuideName`	Specifies the name of the pin guide. *Data_type*: string, required

set_ptn_fplan_mode

```
set_ptn_fplan_mode
[-help]
[-reset]
[-export {macro | special_route | pin_constraint}}]
[-import {macro | special_route | pin_constraint}}]
```

Sets what floorplan objects will be written-out and/or read back in. The `set_ptn_fplan_mode` command allows you to specify which objects should be written out during `savePartition -fplan` or read back in during `assembleDesign -fplan`.

Parameters

`-export {macro | special_route | pin_constraint}`	
	Specifies the objects to be exported. This is used by `savePartition -fplan` command to save the data to the fp file. Using the `-export` option, you can choose from saving `macro` and/or not saving `special_route` data. *Default:* `special_route` (default data + special route is always saved) *Data_type:* enums={macro special_route pin_constraint}_list
`-help`	Outputs a brief description that includes the type and default information for each `set_ptn_fplan_mode` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_ptn_fplan_mode`
`-import {macro | special_route | pin_constraint}`	
	Specifies the objects to be imported. This is used by `assembleDesign -fplan` command to load the data from the fp file. Using the `-import` option, you can choose from bringing `macro` and/or `special_route` data. *Default:* By default, `-import` brings only defaults objects *Data_type:* enums={macro special_route pin_constraint}_list
`-reset`	Restores all parameters modified using `set_ptn_fplan_mode` to their default settings. The `-reset` parameter must be the first parameter specified. If you specify -reset by itself, the software resets all `set_ptn_fplan_mode` parameters to their default values. If you specify parameters after `-reset`, the software resets only those parameters to their default values. Any values that do not already match the default value and are reset will be reported.

Example

- The following command will save only macro information.
  ```
  set_ptn_fplan_mode -export {macro}
  ```
- The following command will reset the value to its default value.
  ```
  set_ptn_fplan_mode -export -reset
  ```

setClonePtnOrient

```
setClonePtnOrient
[-help]
name
{R0 R90 R180 R270 MX MX90 MY MY90}
```

Changes the orientation of the specified partition clone.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `setClonePtnOrient` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setClonePtnOrient`.
name	Specifies the name of the partition clone whose orientation has to be changed. *Data_type*: (hinst), required
`{R0 R90 R180 R270 MX MX90 MY MY90}`	Specifies the orientation. The orientation can be one of the following: • `R0` • `MY` • `MX` • `R180` • `MX90` • `R90` • `R270` • `MY90` *Data_type*: enum, required

Example

The following command sets the orientation of the partition clone name `TDSP_ARB_C1 to R270:`

```
setClonePtnOrient TDSP_ARB_C1 R270
```

Related Information

- `getClonePtnOrient`
- Partitioning the Design chapter in the *Innovus User Guide*
  - Changing Partition Clone Orientation

setPinAssignMode

```
setPinAssignMode
[-help]
[-reset]
[-advanced_node_rule_support {true | false}]
[-allow_unconnected_in_abutted_edge {true | false}]
[-allowNonNdrNetPinsOnNdrTracks {true | false}]
[-block_boundary_macro_distance distance]
[-force_abutment_with_fixed {true | false}]
[-insidePinSearchDistance {nrTracks}]
[-max_distance_pairing distance]
[-maxChannelWidthAsAbutted channelWidthInMicrons]
[-pinEditInBatch {true | false}]
[-pinOffStripe {below | all | none}]
[-pinToStripeDistance {listOfLayerDistanceValuePair}]
[-pinToViaDistanceNonPrefDirection {listOfLayerDistanceValuePair}]
[-pinToViaDistancePrefDirection {listOfLayerDistanceValuePair}]
[-promotedMacroMaxLayer layerName]
[-promotedMacroMinLayer layerName]
[-restrict_boundary_macro_distance distance ]
[-strict_abutment {true | false}]
```

Sets the global parameters of the partition or block pin assignment feature. Parameters specified with the `setPinAssignMode` command are then used whenever you run the pin related commands. Use the `getPinAssignMode` command to return the current settings for the `setPinAssignMode` command. You can use this command before assigning pins.

Note: You can use the `-topRoutingLayer` and `-bottomRoutingLayer` parameters of the `setDesignMode` to specify the maximum and minimum layers, respectively, for routing, partition, or block pin assignment.

Note: To control the pin assignment layers, you can use the `setPinConstraint` command. The `setPinConstraint` command sets the constraints for partition pins or I/O pins. The constraints can be applied on three different levels: global pin constraints, cell specific pin constraints, and pin specific constraints. If no pin specific constraints exist, then the cell level constraints are applied. If cell specific pin constraints are not defined, then global constraints are applied.

Parameters

`-advanced_node_rule_support {true | false}`	
	A `true` value specifies that 20nm (and below) as well as DPT LEF rules will be respected (if present in LEF technology file) for determining and resolving any DRC violations, during all pin assignment related commands. *Default*: `true` *Data_type*: bool
`-allow_unconnected_in_abutted_edge {true | false}`	
	A `true` value specifies that unconnected partition pins can be placed in abutted edges. *Default*: `true` *Data_type*: bool
`-allowNonNdrNetPinsOnNdrTracks {true | false}`	
	A `true` value allows general pins to be placed on NDR tracks (if available). Alternatively, if the value is set to false, the NDR-track rule is followed strictly and the net pins are placed on matching NDR tracks only. *Default*: `true` *Data_type*: bool
`-block_boundary_macro_distance distance`	

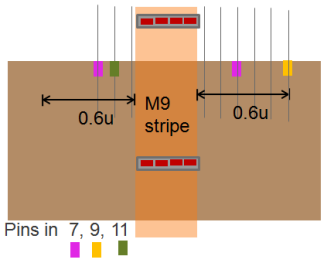
	Blocks automatic pin assignment from putting pins, on the part of the partition boundary facing the block, where the channel width between the partition boundary and the block is less than the value specified. For channel width below the specified value, it blocks pins on the boundary facing this channel. *Minimum*: 0 *Maximum*: 100 *Default*: 3 *Data_type*: float
`-help`	Outputs a brief description that includes the type and default information for each `setPinAssignMode` parameter. For a detailed description of the command and all of its parameters, use the man command: man setPinAssignMode
`-force_abutment_with_fixed {true|false}`	
	Specifies that for the connected pin of fixed abutted pins, ignore soft constraints check. Some partitions in abutted design have preassigned pins with 1-track spacing and marked as fixed. As the design is abutted, there is no other legal location for such pins. Also, the automatic pin assignment has default spacing of two tracks. As a result, all pins connecting to these reference pins with one spacing are not assigned and lot of pins are left unassigned. When the `-force_abutment_with_fixed` is enabled, track spacing violations are ignored. As a result, assigns the corresponding pins opposite to the prefixed pins while maintaining abutment of pins. *Default*: true *Data_type*: bool
`-insidePinSearchDistance {`*`nrTracks`*`}`	Controls the search distance for legalizing the internal pins. *Minimum*: 1 *Maximum*: 100 *Default*: 10 *Data_type*: int
`-max_distance_pairing` *`distance`*	Ignores moving corresponding connected pins of 2-pin-connection nets where distance (in microns) between the pins is equal or greater than distance specified. You can avoid moving the corresponding pin for any channel width (routing bends are acceptable in channels) by using the distance value for the `-max_distance_paring` parameter as 0. *Minimum*: 0 *Maximum*: 10000 *Default*: 50 *Data_type*: float
`-maxChannelWidthAsAbutted` *`channelWidthInMicrons`*	
	Specifies that all channels with width less than or equal to the specified width will be considered as abutted and abutment rules will be applied on them. **Notes:** • The `assignPtnPin`, `assignIoPins`, and the `legalizePin` commands do not place non-neighbor pins in the thin channels considered abutted. • The `checkPinAssignment` command reports an abutment violation in case a non-neighboring pin is placed in the thin channel (abutted). The `-preCheck` option of the `checkPinAssignment` command that checks for the feasibility of pin assignment, also treats these thin channels as abutted. *Minimum*: 0 *Maximum*: 400 *Default*: 3 *Data_type*: float

`-pinEditInBatch {true | false}`	Enables pin-editing in batch mode. **Note**: Once the interactive pin assignment is complete, it is important to set the mode to false. This can be done using the `setPinAssignMode -pinEditInBatch false` command. *Default*: `false` *Data_type*: bool
`-pinOffStripe {below | all | none}`	Prevents the generation of pins on metal layers with respect to the power and ground stripe. • `below`: Prevents the generation of pins on metal layers below the power and ground stripes. • `all`: Prevents the generation of pins on all metal layers, above and below the power and ground stripes. • `none`: Allows the generation of overlapping pins on all metal layers. *Default*: none *Data_type*: enums={below all none}
`-pinToStripeDistance {listOfLayerDistanceValuePair}`	
	Specifies the distance (in microns) from pin to stripe. It is layer specific. *Default*: "" *Data_type*: string
`-pinToViaDistanceNonPrefDirection {listOfLayerDistanceValuePair}`	
	Specifies the distance (in microns) from pin to via-stack. It is layer specific. *Default*: "" *Data_type*: string
`-pinToViaDistancePrefDirection {listOfLayerDistanceValuePair}`	
	Specifies the distance (in microns) from pin to via-stack from the partition fence boundary. It is layer specific. *Default*: "" *Data_type*: string
`-promotedMacroMaxLayer layerName`	Specifies the maximum metal layer name for promoting macro pins. *Default*: 31 *Data_type*: string
`-promotedMacroMinLayer layerName`	Specifies the minimum metal layer name for promoting macro pins. *Default*: 31 *Data_type*: string
`-reset`	Restores all parameters modified using `setPinAssignMode` to their default settings. The `-reset` parameter must be the first parameter specified. If you specify -reset by itself, the software resets all `setPinAssignMode` parameters to their default values. If you specify parameters after `-reset`, the software resets only those parameters to their default values. Any values that do not already match the default value and are reset will be reported.
`-restrict_boundary_macro_distance distance`	
	Blocks automatic pin assignment, from putting pins on the part of the partition boundary facing the block, in the places where the channel width between the partition boundary and the block is less than the specified value. For the channel width below the specified value, allowed layers and the channel length/width will be considered to allow a suitable number of pins on the boundary facing this channel. *Minimum*: 0 *Maximum*: 100 *Default*: 30 *Data_type*: float

`-strict_abutment {true | false}`	Controls abutted check for non-neighbour 2-pin and multi-partition pins. *Default*: true *Data_type*: bool

Examples

- The following command prevents the generation of pins below power and ground strips:
  ```
  setPinAssignMode -pinOffStripe below
  ```
- The following command resets all setPinAssignMode parameters to their default values:
  ```
  setPinAssignMode -reset
  ```
- The following command will leave .6u of space between Metal9 stripe and Metal9 pins, and leave 1u of space between Metal11 stripe and Metal11 signal pin
  ```
  setPinAssignMode -pinToStripeDistance {{9 .6} {11 1}}
  ```



- For preferred direction pins, the following commands will:
  - Leave .1u of space between Metal2, Metal4, Metal6 stack via to pins in same layer, and leave .3u of space between Metal9 stacked via and corresponding signal pin, on left/right edges
  - Leave .1u of space between Metal3, Metal5, Metal7 stack via to pins in same layer, and leave .3u of space between M9 stacked via and corresponding signal pin, on top/bottom edges

  ```
  setPinAssignMode -pinToViaDistancePrefDirection {{2 .1} {3 .1} {4 .1} {5 .1} {6 .1} {7 .1} {8 .3} {9 .3}}
  ```
- For any pins in non preferred direction, the following commands will:
  - Leave .2u of space between Metal2, Metal4, Metal6 stack via to pins in same layer, and leave .4u of space between M9 stacked via and corresponding signal pin, on top/bottom edges
  - Leave .2u of space between Metal3, Metal5, Metal7 stack via to pins in same layer, and leave .4u of space between M9 stacked via and corresponding signal pin, on left/right edges

  ```
  -pinToViaDistanceNonPrefDirection {{2 .2} {3 .2} {4 .2} {5 .2} {6 .2} {7 .2} {8 .4} {9 .4}}
  ```

  Note: In the following picture, N stands for non-preferred and P stands for preferred.

setPinConstraint

```
setPinConstraint
[-help]
{[-global | -cell cell_name | -matchEarlyGlobalRoute ]
 [-global | -pin pin_name_list| -area {x1 y1 x2 y2} | -side side_name | -matchEarlyGlobalRoute ]
 [-global | -layer {layer_id_or_name_list} | -loc {x y z}]
 [-global | -loc {x y z} | -edge edge_numbers | -corner corner_number]
 [[-pin pin_name_list [-loc {x y z}] [-edge edge_nmbers]] |
 [[-loc {x y z}] [-edge edge_numbers]] |
 [-corner_to_pin_distance pin_distance [-corner corner_number]]]
 [{-pin pin_name_list | -pinTemplate {layer_id_or_name_list}}
 [-use_min_width_as_depth | -depth depth] [-width width]]
 [[-layer {layer_id_or_name_list} [-side side_names]] |
[-pinTemplate {layer_id_or_name_list} [-use_min_width_as_depth ]]]
[-spacing spacing [-area {x1 y1 x2 y2}] [-side side_names]]}
[-depth depth [-special_wire ]]
```

Sets the constraints for partition pins or an I/O pins. You can use this command before assigning pins. The constraints can be applied on three different levels:

- Global pin constraint
- Cell specific pin constraint
- Pin specific constraint

If no pin specific constraints exist, then the cell level constraints are applied. If cell specific pin constraints are not defined, then global constraints are applied.

Note: To retrieve the pin constraints specified using the `setPinConstraint` command, use the `getPinConstraint` command. To remove the constraints for a partition pin, use the `unsetPinConstraint` command.

Parameters

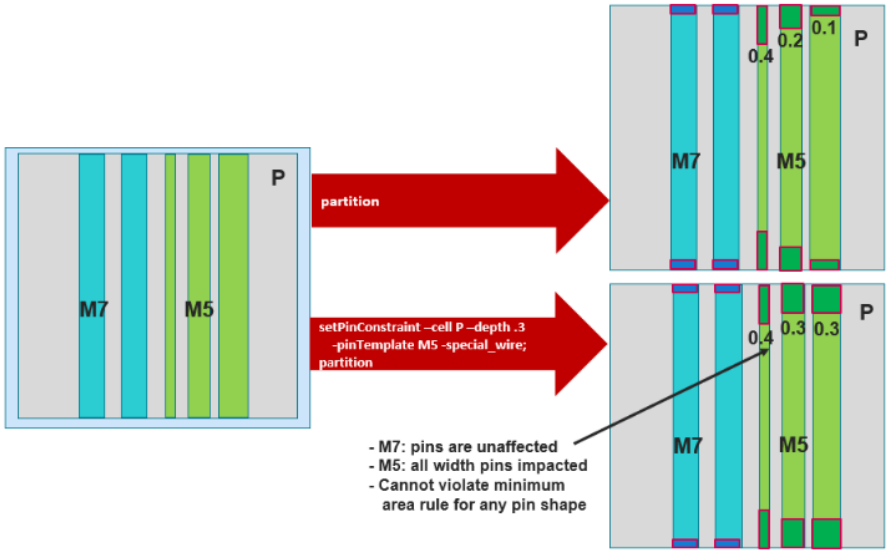
`-area {x1 y1 x2 y2}`	Specifies an area overlapping with partition where spacing constraint. *Data_type*: rect, optional
`-cell cell_name`	Specifies the name of the module. The module name is not required if the command is run on a top-level module. You can use wildcards (*?) with this parameter. *Data_type*: string, optional
`-corner corner_number`	Specifies the corner of the partition block. *Data_type*: int, optional
`-corner_to_pin_distance pin_distance`	
	Specifies the corner to pin distance in tracks. *Data_type*: int, optional
`-depth depth`	Specifies the pin depth in microns. *Data_type*: float, optional
`-edge edge_numbers`	Specifies the integer value where edge numbering starts from lower-left corner of a partition clock-wise. Edge `0` is the edge that has the smallest y value.  You can set multiple sides in the `-edge` option. This allows you to set multiple sides in a rectilinear design. *Data_type*: string, optional

`-global`	Specifies that the global constraints for spacing, width, and depth to be honored. **Note:** If no pin specific constraints exist, then the cell level constraints are applied. If cell specific pin constraints are not defined, then global constraints are applied. For example, the following command specifies that the global constraints are to be honored. `setPinConstraint -global -spacing 2 -width 2 -pinTemplate { 2 3 4 }` *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `setPinConstraint` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setPinConstraint`
`-layer {layer_id_or_name_list}`	
	Specifies the metal layers for the partition pin. If you specify multiple layers, separate the layer names with a space. In this case, the command will constrain the pin to one of the specified layers. **Notes:** • This parameter does not restrict the pin to a location on the layer. If you want to restrict a pin on a particular location on a particular layer, use the `-loc` parameter instead. • The `-layer` parameter cannot be used with the `-loc` parameter. • The `-layer` parameter cannot be used with the `-spacing` parameter. • Layers can be specified using the LEF layer names or layer ID numbers. *Data_type*: string, optional
`-loc {x y z}`	Specifies the x and y locations and z layer ID number of the partition pin. The x and locations are calculated with respect to the distance in microns from the lower left corner of the module. The layer number specified should be a preferred layer. Otherwise, the command will move the pin to a preferred layer. For example, `-loc {10 12 7}` specifies that the pin should be constrained to a location 10 microns on the x axis and 12 microns on the y axis from the lower left corner of the partition. on layer `Metal7`. **Notes:** • If the pin location as per the specified x and y locations is not on a track, the pin is snapped to the nearest track on the specified layer. • If you specify this parameter, the assigned pins have a *Placed* status. • The `-loc` parameter cannot be used with the `-layer` parameter. *Data_type*: string, optional
`-matchEarlyGlobalRoute`	When specified, it changes the pin constraints to make them compliant with `earlyGlobalRoute` and does the following for every partition: • Allows all layers from `setDesignMode -topRoutingLayer` to `-bottomRoutingLayer`. • Sets pin spacing as 1 **Note:** The changes in pin constraints impact the output of the pin assignment commands - `assignPtnPin`, `assignIoPins`, and `editPin`. *Data_type*: bool, optional
`-pin pin_name_list`	Specifies the name of the partition pin. You can use wildcards (`*?`) with this parameter. *Data_type*: string, optional
`-pinTemplate {layer_id_or_name_list}`	
	Specifies the metal layers for the width, depth, and spacing constraints at global level and cell level *Data_type*: string, optional
`-side side_name`	Specifies name of the side. Valid values are { N S E W } or { L B T R } or all. *Data_type*: string, optional

`-spacing spacing`	Specifies the minimum spacing between pins in pin pitch value, that is, the distance between tracks. For example, if you specify a value of `2`, the minimum pin spacing will be equal to the distance between track 1 and track 3.  *Data_type*: int, optional
`-special_wire`	Specifies the depth constraint to be set and honored for special wire pins. When `-special_wire` parameter is specified with the `-depth`, `-cell` and `-pinTemplate` parameters, it enables the depth on desired layers of specified cells to be honored for special wire pins by the `partition` command only. *Data_type*: bool, optional
`-use_min_width_as_depth`	Minimum width should be used as the pin depth. *Data_type*: bool, optional
`-width width`	Specifies the pin width in microns. *Data_type*: float, optional

Example

- The following command specifies a width of 10 micrometers for all partition pins in the partition `sheet14`. These pins will be placed either on layer 2 or on layer 4.
  ```
  setPinConstraint -cell sheet14 -pin * -layer {Metal2 Metal4}
  ```
- The following commands set the pin width and depth of layer `Metal2` for partition cell `ALU` to 0.4 and 0.6 respectively.
  ```
  setPinConstraint -cell ALU -layer Metal2 -width 0.4
  setPinConstraint -cell ALU -layer Metal2 -depth 0.6
  ```
- The following commands set the pin width of pin pGroup1 to 0.3 and pin depth of pin pGroup1 to default.
  ```
  setPinConstraint -cell ALU -pin pGroup1 -width 0.3
  setPinConstraint -cell ALU -pin pGroup1 -depth default
  ```
  With this example, all the pins of pGroup1 will have the width 0.3 and the default depth.
- The following commands set the minimum pin spacing for top and bottom edge of partition cell ALU to 1 track.
  ```
  setPinConstraint -cell ALU -edge T -spacing 1
  setPinConstraint -cell ALU -edge B -spacing 1
  ```
- The following command sets minimum pin spacing for all edges of partition cell TDSP to 3 tracks
  ```
  setPinConstraint -cell TDSP -all -spacing 3
  ```
- The following command sets the sides, T and B, of layer 3 and 5 of partition cell ptn4
  ```
  setPinConstraint -cell ptn4 -layer {3 5} -side {T B}
  ```
- The following command sets the edges, 2 and 0, of partition cell ptn4
  ```
  setPinConstraint -cell ptn4 -pin * -edge {2 0}
  ```
- The following commands sets the pin depth of layer `M5` for partition cell `P` to 0.3 using the `-special_wire` parameter so that it is honored only by the `partition` command.
  ```
  setPinConstraint -cell P -depth .3 -pinTemplate M5 -special_wire;
  partition
  ```



Related Information

setPromotedMacroPin

```
setPromotedMacroPin
[-help]
{-reset  | -reportOnlyFile fileName.tcl |
 {[-insts {instName | instNameList}]
  [-pins {pinName | pinNameList}]
  [-layers {layerId | layerIdList}]
  [-override ]
  [-abuttedToBoundaryOnly ]}}
```

Selects or marks signal and/or PG pin shapes to be promoted later on. You can use this command before assigning pins.

Note: The `setPromotedMacroPin` command should be called after specifying the maximum and minimum metal layer names for promoting macro pins using the `setPinAssignMode -promotedMacroMaxLayer maxLayer and -promotedMacroMinLayer minLayer` parameters, respectively.

Parameters

`-abuttedToBoundaryOnly`	Specifies that all macro pin shapes that are abutted to the partition boundary will be selected for promotion. The `-pins` parameter can also be used to select abutted pins . **Note:** You can use the `-maxChannelWidthAsAbutted` parameter of the `setPinAssignMode` command to enable thin channels in the design to be considered as abutted partitions in the pin assignment flow. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `setPromotedMacroPin` parameter. For a detailed description of the command and all of its parameters, use the man command: `man setPromotedMacroPin`
`-insts {instName | instNameList}`	
	Specifies the name of instances. You can also use wildcard (* or ?) for specifying the instance names. This parameter is optional. If `-insts` is not specified, all BLOCK, PAD, and AREAIO macros are selected. This is similar to specifying `-insts *` *Data_type*: string, optional
`-layers {layerId | layerIdList}`	
	Specifies the metal layer(s) of the macro pins. This parameter is optional. If `-layers` is not specified, all pin layers between `setPinAssignMode -promotedMinLayer` and `setPinAssignMode -promotedMaxLayer` range are selected. *Data_type*: string, optional
`-override`	Specifies to override specific option(s) where previous settings of these options will be removed and be replaced by new specified value(s). For example, specifying `setPromotedMacroPin -layers {} -override` means no layer is promoted from now on. **Note:** All `setPromotedMacroPin` commands are incremental with no conflict resolution, unless the `-override` option is used. *Data_type*: bool, optional
`-pins {pinName | pinNameList}`	Specifies the name of macro pins. You can also use wildcard (* or ?) for specifying the pin names. This parameter is optional. If `-insts` is not specified, all signal and P/G pins are selected. This is similar to specifying `-pins *` *Data_type*: string, optional
`-reportOnlyFile fileName.tcl`	Writes out all `setPromotedMacroPin` settings in memory into an output TCL file. *Data_type*: string, optional
`-reset`	Resets all or specified promoted pin selections. *Data_type*: bool, optional

Examples

- The following command promotes the top most layer pins of selected macros

```
setPinAssignMode -promotedMacroMinLayer 4 -promotedMacroMaxLayer 8
setPromotedMacroPin -reset
setPromotedMacroPin -insts {A B} -pins * -layers {7 8}
setPromotedMacroPin -insts B -pins X -layers 8 -override
setPromotedMacroPin -insts C -layers 5 -abuttedToBoundaryOnly
setPromotedMacroPin -insts C -layers {8}
setPromotedMacroPin -insts C -pins D[*] -layers {} -override
setPromotedMacroPin -insts D -pins OUT
setPromotedMacroPin -insts D -pins CLK -abuttedToBoundaryOnly
assignIoPins
```

	A/CLK	A/VDD	B/X	B/VSS	C/D[*]	C/GND	D/CLK	D/OUT
M8	v	v	v	v	x	v		v
M7	v	v	x	v	x	x	v	v
M6		x	x	x		x	x	
M5		x		x	x	x		
M4				x		x

setPtnPinStatus

```
setPtnPinStatus
[-help]
[-selectedPinStatus {fixed | placed | cover}]
[-pin {pinName | pinNameList}]
[-status {fixed | placed | unplaced | cover}]
{[-pin {pinName | pinNameList} -status{fixed | placed | unplaced | cover} [-cell partitionName]] }
```

Sets the pin status for a pin of a partition as fixed, placed, cover, or unplaced. The `setPtnPinStatus` command operates, like a lot of other pin commands, on the top cell in addition to on partitions. If the top cell name is specified, or if `setPtnPinStatus` receives a "*" as its first argument, the IO pin status is modified. You can use this command any time after assigning pins.

Note:

- Use this command to unassign blackbox pins before the blackbox is committed. To unassign blackbox pins after the blackbox is committed, use the `flattenPartition` command instead.
- If this command is run on a blackbox that has one or more pins with a single LEF port but with multiple shapes within the LEF port, the command will remove these multiple shapes and create a single shape. If this command is run on a blackbox that has one or more pins with multiple LEF ports, the first LEF port will be processed as per the command and the remaining LEF ports will remain unchanged.

Parameters

`-cell` *partitionName*	Specifies the name of the partition. You can use wildcards (*?) with this parameter. *Data_type*: string, optional
`-help`	Outputs a brief description that includes type and default information for each `setPtnPinStatus` parameter. For a detailed description of the command and all of its parameters, use the man command: `man setPtnPinStatus`.
`-pin` *pinName* | *pinNameList*	
	Specifies the name of the pin(s) of the partition. You can use wildcards (*?) with this parameter. *Data_type*: string, optional
`-selectedPinStatus {fixed | placed | cover}`	
	Selects pins with only specified status. This options enables the `setPtnPinStatus` command to change the status of selected pins based on their present status and not just the names. • `fixed`: Selects pins with fixed status. • `placed`: Selects pins with placed status. • `cover`: Selects pins with cover status. *Data_type*: enum, optional
`-status {fixed | placed | unplaced | cover}`	
	Specifies the status of the pin. • `Fixed`: Fixed pin status specifies the pin's location, orientation, and that it's location cannot be moved by automatic tools, but can be moved by interactive commands. **Note**: Fixed pins can be moved by automatic pin assignment commands by using the `-moveFixed` parameter. • `Placed`: Placed pin status specifies the pin's location, orientation, and that it's location is fixed, but can be moved during automatic layout. • `Unplaced`: Unplaced pin status specifies that the pin does not have a location. • `cover`: Cover pin status specifies the pin's location, orientation, and that it is a part of the cover macro. A cover pin cannot be moved by automatic tools or by interactive commands. *Data_type*: enum, optional

Example

The following command marks all partition pins to fixed:

```
setPtnPinStatus -cell * -pin * -status fixed
```

Related Information

- `getPtnPinStatus`
- `flattenPartition`
- Partitioning the Design chapter in the *Innovus User Guide*

setPtnPinUSE

```
setPtnPinUSE
[-help]
ptnName
pinName
pinUse
```

Allows you to change the `USE` property of a partition pin.

Note: A partition pin can also be an I/O pin if the partition is a top-level cell.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `setPtnPinUSE` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setPtnPinUse`
ptnName	Specifies the name of the partition, blackbox or top-level cell name. *Data_type*: string, required
pinName	Specifies the pin name. *Data_type*: string, required
pinUse	The choices represent `USE` properties, SIGNAL | CLOCK | ANALOG, that you can change with this command. *Data_type*: string, required

Example

- The following command sets the `USE` property of pin `A` in partition `PTN1` to `CLOCK`:

  ```
  setPtnPinUSE PTN1 A CLOCK
  ```

- The following command sets the USE property for pin scan_clk to CLOCK:

  Original DEF:

  ```
  - scan_clk + NET scan_clk + DIRECTION INPUT + USE SIGNAL ;
  ```

  Run `setPtnPinUse` to change USE to CLOCK:

  ```
  setPtnPinUSE [dbGet top.name] scan_clk CLOCK
  ```

  DEF after change:

  ```
  - scan_clk + NET scan_clk + DIRECTION INPUT + USE CLOCK ;
  ```

Related Information

- Partitioning the Design chapter in the *Innovus User Guide*

showPtnWireX

```
showPtnWireX
[-help]
[ptnName]
[-outfile fileName]
[-excludeNet exNetFileName]
[-excludeClock]
[-excludeTri]
[-excludeHighFan nrFan]
[-allNets]
[-delta]
```

Displays and writes a file of wires that physically cross over partitions. You can use this command after routing the design.

Note: The `showPtnWireX` command supports designs with nested partitions.

Parameters

`-allNets`	Reports nets that cross partitions that also connect to the ports of partitions. If this parameter is not specified, only nets that cross the partitions are reported. *Data_type*: bool, optional
`-delta`	Reports the total segment length of the wires crossing the block in the X and Y directions. *Data_type*: bool, optional
`-excludeClock`	Excludes clock nets from the wire crossing information. *Data_type*: bool, optional
`-excludeHighFan` *nrFan*	Excludes nets with fanouts over nrFan from the display. *Data_type*: int, optional
`-excludeNet` *exNetFileName*	Specifies the filename that contains nets to be excluded from the display. *Data_type*: string, optional
`-excludeTri`	Excludes all tristate nets from the display. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `showPtnWireX` parameter. For a detailed description of the command and all of its parameters, use the man command: `man showPtnWireX`
`-outfile` *fileName*	Specifies the name of the output file of wire crossing information. *Default*: If you do not specify this parameter, the detailed information is output to the ptnName.wireCrossing file, where ptnName is the name of the partition. For master clone designs, three output files are created. These files can be used by the `insertPtnFeedthrough` command for path based feedthrough insertions in master and clone designs. For example, when you specify, `ShowPtnWireX -outFile abc` The following files are generated: • abc.mc_connected_nets.txt: For all nets connected to master/clone partitions. • abc.mc_crossing_nets.txt: For all nets with wires over master/clone partitions (but not in the above file) and not intra partition nets. • abc.non_mc.txt: For all remaining nets which are not in above files and are not intra partition nets. **Note**: The default output file, abc.wireCrossing, is now only valid for non master/clone designs and has no significance for master and clone designs. **Note**: It is not recommended to use the `insertPtnFeedthrough -routeBased` option for the nets in abc.mc_connected_nets.txt and abc.mc_crossing_nets.txt. *Data_type*: string, optional
ptnName	Specifies the name of the partition to show wire crossing. If you choose this option with other options, it must be the first specified when running this command. *Default*: If you do not specify this parameter, it will show all partition wire crossings. *Data_type*: string, optional

Example

The following command displays the routes crossing over partition, sheet17, and outputs the detail information into file, sheet17.crossing:

```
showPtnWireX sheet17 -outfile sheet17.crossing
```

The wire crossing report section lists the nets, their wire lengths, in micrometers, and the shape of the wire in relation to the partition.
For example, the following report segment is for a partition module named `sheet17`:

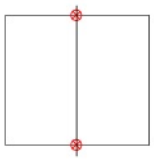
```
#########################################################
# Nets that cross partition module sheet17
# Box (335 335) (833 567)
```

```
# Format: Net <netName> <wireLength> <shape>
##########################################################

Net A 65 I
Net B 80 L
Net C 1050 T
Net D 132 X
...
```

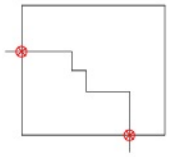
The first net in the report, A, has a wire length of 65 micrometers in an `I' shape, which indicates that the net crosses the partition on opposite sides, as follows:

```
Net A 65 I
```



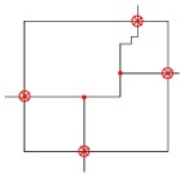
The second net in the report, B, has a wire length of 80 micrometers in an `L' shape, which indicates that the net crosses the partition on adjacent sides, as follows:

```
Net B 80 L
```



The third net in the report, C, has a wire length of 105 micrometers in an `T' shape, which indicates that the net crosses the partition on three sides, as follows:

```
Net C 105 T
```



The fourth net in the report, D, has a wire length of 132.30 micrometers in an `X' shape, which indicates that the net crosses the partition on all four sides, as follows:

```
Net D 132 X
```

[-routingHaloBottomLayer integer ]
[-noRebuildTiming]
[ -cell string| -masterInst string]
{-size { x y } | -area float | -gateCount string
   | {-gateArea float [-cellUtil float ]
[ -includeMacroArea {0 | 1}
{-macroArea float | -macroList { macroName [ count ]}}]}}
[{-area float | -gateCount string }
[-minWidth float | -minHeight float
| -fixedWidth float | -fixedHeight float ]]
[-minWidth float | -minHeight float
| -fixedWidth float | -fixedHeight float |-aspectRatioRange { min max }]
[-aspectRatio float |-aspectRatioRange { min max }]
```

Converts a hard macro into a blackbox. It is also used for specifying an instance to be the master of multiplying instantiated blackboxes. You can use this command after importing the design.

Note: You can convert a hard macro into a blackbox; however, Cadence does not recommend this because it will not update the blockage definitions when you change the blackbox size.

Note: For designs that have backside metal layers, both the backside and frontside layers are accepted. However, the automatic pin assignment flow is not impacted with the support for backside metal layers. It assigns pins on front layers only.

Parameters

`-area float`	Specifies the total area in square micrometers. If you specify the block size area, the default for the created block aspect ratio is 1. *Data_type*: float, optional
`-aspectRatio float`	Specifies the aspect ratio value. This value combined with the area information determines the width and height. *Data_type*: float, optional
`-aspectRatioRange {min max}`	Sets the minimum and maximum values for the aspect ratio range. This value combined with the specified related area information enables the blackbox to be reshaped while maintaining the current area. *Data_type*: point, optional
`-cell string`	Specifies the name of the cell. *Data_type*: string, optional
`-cellUtil float`	Specifies the cell utilization. This value is used to derive the area of the blackbox, which is calculated using the following formula: `Blackbox area = (standard cell area / cell utilization) + macro area` *Default*: The default value of cell utilization is `1` (100%). *Data_type*: float, optional

`-coreSpacing {left right top bottom}`	Specifies the space, in micrometers, between the module boundary and core design area of the module on the left, right, top, and bottom sides respectively. The partition pins will be located at the partition instance boundary and the core area. *Data_type*: string, optional
`-fixedHeight float`	Specifies the fixed height of the module. *Data_type*: float, optional
`-fixedWidth float`	Specifies the fixed width of the module. *Data_type*: float, optional
`-gateArea float`	Specifies the gate area. If the value of the `-includeMacroArea` parameter is `0`, the gate area is equal to the standard cell area. If the value of the `-includeMacroArea` parameter is `1`, the gate area also includes the macro area. *Data_type*: float, optional
`-gateCount string`	Specifies a gate count value. The total cell area is equal to the specified gate count multiplied by the specified area per gate. • *`count`:* Specifies the gate count value. • *`areaPerGate`:* Specifies an area per gate value in square micrometers. To get the cell area, this value is multiplied by the specified gate count. • *`utilization Value`:* Specifies the cell utilization. This value derives the area that is reserved for routing. The final block size is equal to the total cell area plus the routing area. *Default*: The default value is 0.7 (70%) *Data_type*: string, optional
`-help`	Outputs a brief description that includes type and default information for each `specifyBlackBox` parameter. For a detailed description of the command and all of its parameters, use the man command: `man specifyBlackBox`
`-includeMacroArea {0 | 1}`	A value of `0` specifies that the gate area does not include the macro area specified through the `-macroArea` or the `-macroList` parameter. A value of `1` specifies that the gate area includes the macro area specified through the `-macroArea` or the `-macroList` parameters. *Default:* The default value is `0`. *Data_type*: enum, optional

`-macroArea float`	Specifies the total area of the macro(s) in square microns.
	• If the value of the `-includeMacroArea` parameter is set to 0:
	`Total blackbox area = (gate area / cell utilization value) + macro area`
	• If the value of the `-includeMacroArea` parameter is set to 1:
	`Total blackbox area = ((gate area - macro area) / cell utilization value) + macro area`
	Data_type: float, optional

`-macroList {macroName [count ]}`	Specifies the name of the hard macro whose area will be included while calculating the total gate area. The `macroName` argument specifies the name of the macro, and the `count` argument specifies the number of times the macro is referenced. Thus, by specifying a value for count, you avoid repeating the macro names for macros that are referenced multiple times.
	• If the value of the `-includeMacroArea` parameter is set to 0:
	`Total blackbox area = (gate area / cell utilization value) + macro area`
	• If the value of the `-includeMacroArea` parameter is set to 1:
	`Total blackbox area = ((gate area - macro area) / cell utilization value) + macro area`
	Default: The default value of *`count`* is `1`.
	Data_type: string, optional

`-masterInst string`	Specifies the name of the master blackbox. *Data_type*: string, optional
`-minHeight float`	Specifies the minimum height of the specified module. *Data_type*: float, optional

`-minPitchLeft` *integer* `-minPitchRight` *integer* `-minPitchTop` *integer* `-minPitchBottom` *integer*	Specifies the pin pitch dimension for the *Left*, *Right*, *Top*, and *Bottom* blackbox sides. The default is 2, which places one pin for every two metal tracks. The actual pin pitch depends on the pin's metal layer. *Data_type*: int, optional
`-minWidth` *float*	Specifies the minimum height of the specified module. *Data_type*: float, optional
`-pinLayerLeft {`*list_of_layers*`}` `-pinLayerRight {`*list_of_layers*`} -pinLayerTop {`*list_of_layers*`} -pinLayerBottom {`*list_of_layers*`}`	
	Specifies the metal layers to use for the blackbox. The metal layers correspond to the sides of the blackbox, where the vertical metal layers (for example, *Metal2, Metal4*, and so on) are for the Top and Bottom sides, and horizontal metal layers (for example, `Metal3, Metal5`, and so on) are for the Left and Right sides of the blackbox. Specify this value in integers, for example `-pinLayerTop {2 4}`. *Data_type*: string, optional
`-placementHalo {left right top bottom}`	Specifies extra spacing, in micrometers around the sides (left, bottom, right and top respectively) of the blackbox that should not be used for placement. At the top-level design, this information is saved as part of the partition section in a floorplan file. This information is also saved in a partition floorplan file when saving partitions. By default, the value is 0 for all the sides. *Data_type*: string, optional
`-reservedLayer {`*list_of_layers*`}`	Specifies the metal layers that are used for routing in the partition and generating partition pins. Any metal layers that are not specified, usually the top-most metal layers, are allowed to route over the partition. A normal six-metal layer specification is Metal1, Metal2, Metal3, Metal4 and Metal5 specified, and Metal6 unspecified. When saving the partition, the LEF generated for this partition will have routing blockages on their layers so that the top-level router is aware of which metal layers are being used in the partition. *Data_type*: string, optional
`-routingHalo` *float*	Specifies routing spacing, in micrometers, around the sides of the blackbox. You can specify a positive or a negative value for the routing halo. A positive value means that the halo will be outside the blackbox. A negative value means that the halo will be applicable during block implementation, inside of the blackbox. The same value is used for all sides of the blackbox. *Data_type*: float, optional
`-routingHaloBottomLayer` *integer*	Specifies the bottom partition layer for which routing halo will be created. *Default*: By default, the bottom layer reserved for the partition is used. *Data_type*: int, optional
`-routingHaloTopLayer` *integer*	Specifies the top partition layer for which routing halo will be created. *Default*: By default, the top layer reserved for the partition is used. *Data_type*: int, optional
`-size x y`	Specifies fixed width and height of a specified module, in micrometers. *Data_type*: point, optional
`-noRebuildTiming`	Skips re-building the time graph and re-initializing the top cell information in order to improve the run time of the blackbox specification for designs with a large number of blackboxes. **Note:** Since the timing graph only needs to build for the last blackbox, you must specify the final `specifyBlackBox` command without this parameter. For example, if your design has three blackboxes, the first two `specifyBlackBox` commands should be specified with the `-noRebuildTiming` parameter while the last `specifyBlackBox` command should be specified without this parameter. *Data_type*: bool, optional

Examples

- The following command converts the hard macro `hn246` into a black box. The gate area is specified as 100000 square microns and the specified macro area is 220 square microns. The cell utilization value is not specified, and so the default value of 1 is used. The `-includeMacroArea` parameter is not specified and so the default value of 0 is used.
  When the `-includeMacroArea` parameter is 0, the blackbox area is calculated using the formula:
  ```
  Total blackbox area = (gate area / cell utilization value) + macro area
  ```
  The total black box area in this case is, therefore, (100000 / 1) + 220 that is 100220 square microns.
  ```
  specifyBlackBox -cell hn246 -gateArea 100000 -macroArea 220
  ```
- The following command is similar to the command in the previous example, except that the value of `-includeMacroArea parameter` is set to 1 and the value of the `-cellUtil` parameter is set to `.7`
  When the `-includeMacroArea` parameter is set to 1, the blackbox area is calculated using the formula
  ```
  Total blackbox area = ((gate area - macro area)/cell utilization value) + macro area
  ```
  The total blackbox area in this case is, therefore, ((100000 -220) /.7 + 220) that is 142762.86 square microns.
  ```
  specifyBlackBox -cell hn246 -gateArea 100000 -includeMacroArea 1 -macroArea 220 -cellUtil 0.7
  ```
- The following command converts the macro `hn246` into a blackbox and specifies that the areas of macros `macro_2A` and `macro_2B` should be added while calculating the blackbox area. The macro named `macro_2A` is included four times and the macro named `macro_2B` is included three times.
  ```
  specifyBlackBox -cell hn246 -gateArea 100000 -macroList macro_2A 4 macro_2B 3
  ```

specifyPartition

```
specifyPartition
[-help]
partitionSpecFileName
[-noEqualizePtnHInst]
```

Loads the partition specification file. The partition specification file is created from the *Specify Partition* form. You can use this command after importing the design.

Note: You can create partitions inside power domains as well.

Note: Command `specifyPartition` is now obsolete and will be removed in the next major release of the software. This command has been replaced by the `definePartition` command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `specifyPartition` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man specifyPartition`
`-noEqualizePtnHInst`	Disables the snapping capability of the clone partitions to the power grid, such that clones do not necessarily have the same row structure and pattern as their master. *Data_type*: bool, optional
partitionSpecFileName	Specifies the file containing the partition specification. *Data_type*: string, required

Example

The following command loads the partition specification file `app1.ptn` and updates the Floorplan view:

```
specifyPartition app1_p.ptn
```

Related Information

- `definePartition`
- `partition`

undo_uniquify_partition

```
undo_uniquify_partition
[-help]
-hinst hierarchical_instance_name
[-preserve_routes]
```

Brings back the recursion of cells in a netlist and restores the master and clone association.

Note: The `uniquify_partition` command is used to remove the master and clone association by uniquifying the netlist.

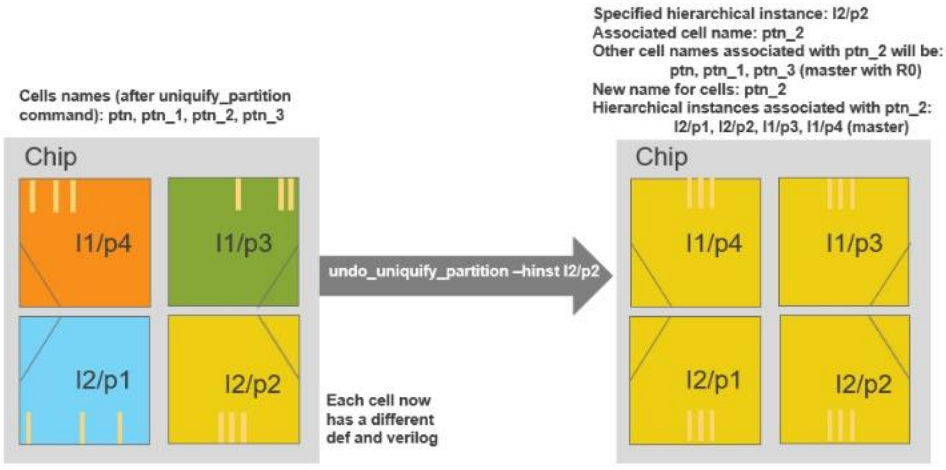
Parameters

`-help`	Outputs a brief description that includes the type and default information for each `undo_uniquify_partition` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man undo_uniquify_partition`
`-hinst hierarchical_instance_name`	Specifies name of the hierarchical instance that is used to bring back the recursion of cells in a netlist and restore the master and clone association. Based of the selected hierarchical instance, its cell (module) is identified. All other occurrences of the identified cell with the same naming format (`cellname_<number>`) are then renamed to the identified cell name. That means all instances will have the same cell name and definition again, thereby restoring the master and clone relationship. **Note:** • You can specify any hierarchical instance with the `undo_uniquify_partition` command. • Any hierarchical instance with R0 orientation can become a master. • The name of the cells will change to the name of the cell of the specified hierarchical instance. • The netlist and def of the cell of the hierarchical instance name specified with the `undo_uniquify_partition` command will be copied in all hierarchical instances. *Data_type*: string, optional
`-preserve_routes`	Preserves the routes during `undo_uniquify_partition`. *Data_type*: bool, optional

Example

The following command brings back the master and clone association for the cell name associated with `I2/p2`:

```
undo_uniquify_partition -hinst I2/p2
```



Related Information

- uniquify_partition
- Partitioning the Design chapter in the *Innovus User Guide*

uniquify_partition

```
uniquify_partition
[-help]
-hinst hierarchical_instance_name
```

Removes the master and clone association by uniquifying the cells (module) in the netlist.

Note: You can use the `undo_uniquify_partition` command to remove the uniquification and bring back the master and clone association.

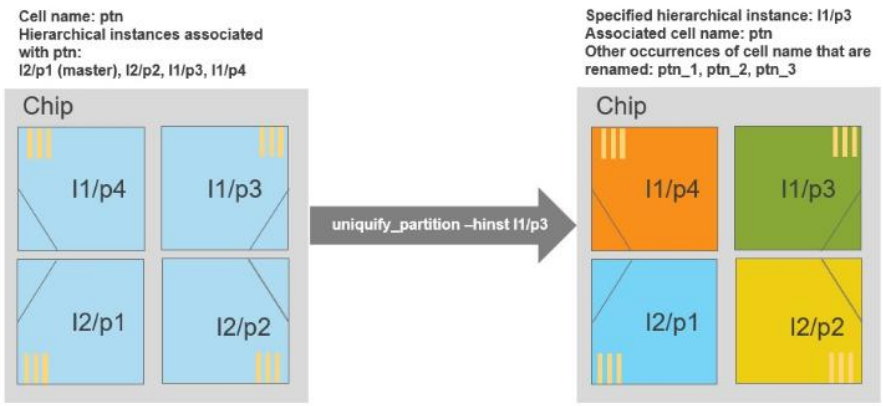
Parameters

`-help`	Outputs a brief description that includes the type and default information for each `uniquify_partition` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man uniquify_partition`
`-hinst hierarchical_instance_name`	Specifies the name of the hierarchical instance to uniquify. Based of the specified hierarchical instance, its cell (module) is identified. All other occurrences of the identified cell are renamed by adding the `_<number>` suffix (for example `cellname_<number>`) in order to uniquify the cell. **Note:** • You can specify any hierarchical instance with the `uniquify_partition` command. It does not necessarily have to be a master. • The `uniquify_partition` command preserves the orientation of the hierarchical instances. • The `uniquify_partition` command preserves the pin location of the hierarchical instances. • A new cell name is created for each hierarchical instance. *Data_type*: string, required

Example

The following command identifies the cell associated with `I1/p3` and then renames all other occurrences of the cell in order to remove the master and clone association.

```
uniquify_partition -hinst I1/p3
```



Related Information

- `undo_uniquify_partition`
- Partitioning the Design chapter in the *Innovus User Guide*

unloadPtnPin

```
unloadPtnPin
[-help]
-ptnName partitionName
{-file floorplanFileName }
```

Removes the loading of partition pins by the `loadPtnPin` command. This is used to remove the preassignment of pins that were previously reassigned by the loading.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `unloadPtnPin` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man unloadPtnPin`
`-file floorplanFileName`	Specifies the full pathname of the partition floorplan file. *Data_type*: string, optional
`-ptnName partitionName`	Specifies the name of the partition. *Data_type*: string, required

Example

The following command unloads pin positions for partition `EUG` from file `EUG.fp.ptn`:

```
unloadPtnPin -ptnName EUG -file EUG.fp.ptn
```

Related Information

- `loadPtnPin`
- Partitioning the Design chapter in the *Innovus User Guide*
  - Assigning Partition and Blackbox Pins

unsetPinConstraint

```
unsetPinConstraint
[-help]
{[-global | -cell cell_name | -all_user ]
[-global | -pin pin_name_list | -area {x1 y1 x2 y2} | -all_area | -side side_names]
[-global | -layer ] [-global | -loc | -edge | -corner corner_number]
[[-pin pin_name_list [-loc ] [-edge ]] |
[-corner_to_pin_distance [-corner corner_number]]]
[{-pin pin_name_list | -pinTemplate {layer_id_or_name_list}} -width ]
[{-pin pin_name_list | -pinTemplate {layer_id_or_name_list}} -depth ]
[[-layer [-side side_names]] | -pinTemplate {layer_id_or_name_list}]
[-spacing [-area {x1 y1 x2 y2}]
[-all_area ] [-side side_names]] }
[-depth [-special_wire ]] [-all_user ]
```

Removes the constraints for a partition pin. You can use this command after setting the pin's constraints with the `setPinConstraint` command.

Parameters

`-all_area`	Specifies that spacing constraints on all areas should be removed. *Data_type*: bool, optional
`-all_user`	Specifies that all user specified constraints should be removed from all levels (`-global`, `-cell`, and `-pin` level). *Data_type*: bool, optional
`-area {x1 y1 x2 y2}`	Specifies that the area overlapping with partition for which the spacing constraints have been specified should be removed. *Data_type*: box, optional
`-cell cell_name`	Specifies the name of the cell (partition). The cell name is not required if the command is run on a top-level cell. *Data_type*: string, optional
`-corner corner_number`	Specifies the corner of the partition block. *Data_type*: int, optional
`-corner_to_pin_distance`	
	Specifies that the corner to pin distance constraints should be removed. *Data_type*: bool, optional
`-depth`	Specifies the pin depth related constraints should be removed. *Data_type*: bool, optional
`-edge`	Specifies that edge-related constraints should be removed. *Data_type*: bool, optional
`-global`	Specifies to reset global constraints. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `unsetPinConstraint` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man unsetPinConstraint`
`-layer`	Specifies that the layer-related constraints should be removed. *Data_type*: bool, optional
`-loc`	Specifies that the location-related constraints should be removed. *Data_type*: bool, optional
`-pin pin_name_list`	Specifies the name of the partition pin. You can use wildcards (`*?`) with this parameter. *Data_type*: string, optional
`-side side_name`	Specifies name of the side. Valid values are { N S E W } or { L B T R } or all. *Data_type*: string, optional
`-spacing`	Specifies that the spacing-related constraints should be removed. *Data_type*: bool, optional
`-special_wire`	Specifies that the depth constraint that is honored for special wire pins by the `partition` command should be removed. *Data_type*: bool, optional
`-pinTemplate { layer_id_or_name_list }`	
	Specifies the metal layers for the width and depth constraints at global level and cell level. *Data_type*: string, optional
`-width width`	Specifies that the pin width related constraints should be removed. *Data_type*: bool, optional

Example

- The following command removes the spacing- and layer-related constraints for all partition pins in the partition `sheet14`.
  ```
  unsetPinConstraint sheet14 -pin * -layer -spacing
  ```
- The following command removes all constraints on globals.
  ```
  unsetPinConstraint -global
  ```
- The following command removes all constraints on all cells.
  ```
  unsetPinConstraint -cell *
  ```
- The following command removes all constraints on all pins.
  ```
  unsetPinConstraint -cell * -pin *
  ```
- The following command removes all constraints on cells, pins, and globals.
  ```
  unsetPinConstraint -all_user
  ```

unspecifyBlackBox

```
unspecifyBlackBox
[-help]
{-cell cellName | -all}
[-keepPtn]
```

Unspecifies or deletes a blackbox and converts it to a module if the blackbox was originally defined as a module, or a block if the blackbox has a cdump or LEF macro definition. You can use this command after importing the design.

Note: You cannot delete a blackbox of an undefined module or cell.

Parameters

`-all`	Selects all blackboxes for deletion. *Data_type*: bool, optional
`-cell cellname`	Selects an individual blackbox for deletion. You can use wildcards (`*?`) with this parameter. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `unspecifyBlackBox` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man unspecifyBlackBox`
`-keepPtn`	Preserves the partition information. You should only use this option if the blackbox is placed inside the core area and is defined as a module in the netlist. *Data_type*: bool, optional

Example

- The following command deletes all blackboxes that begin with the letter A-some of which are inside the core area, and some which are outside the core area and converts them to either a fence or `module`.

  ```
  unspecifyBlackBox -cell A*
  ```

Related Information

- `specifyBlackBox`
- Partitioning the Design chapter in the *Innovus User Guide*

write_generalized_feedthru_paths

```
write_generalized_feedthru_paths
[-help]
[-dont_generalize_reverse_paths]
[-dont_generalize_sub_paths]
[-topological_out_file file_name]
-use_topological_file file_name
```

Automatically derives feedthrough topological paths from the user specified paths to cover all the chain connectivity probabilities in a master and clone hinst scenario. It reads an input topological file, in version 0.5 and creates the version 2.0 topological file.

Note: For the given set of master-clone hinst connectivity, based on floorplan, multiple user defined paths may be required for other same set hinst master and clones. The `write_generalized_feedthru_paths` command can automatically choose correct path for individual master and clone hinst, based on matching connectivity and floorplan, from the set of paths provided by the user.

Parameters

`-dont_generalize_reverse_paths`	
	When enabled, the generalization algorithm does not generalize reverse chain paths. *Data_type*: bool, optional
`-dont_generalize_sub_paths`	
	When enabled, the generalization algorithm does not generalize sub-paths. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `write_generalized_feedthru_paths` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_generalized_feedthru_paths`
`-topological_out_file file_name`	
	Specifies the name of the output topo 2.0 file that contains all paths for all master and clone chain. **Note:** This file should be used as an input file for the `insertPtnFeedthrough` command. *Default:* path.topo *Data_type*: string, optional
`-use_topological_file file_name`	
	Specifies the user specified feedthrough path guidance file. The input topological file with new version 0.5 format contains a path for one master and clone chain to derive path of all master and clone chains. **Note:** You can use the *Path Guidance GUI* form (*Partition - Feedthough Ports - Path Guidance)* to generate the topological file with new version 0.5 format. *Data_type*: string, required

Example

- The following command reads the topology file “a.topo” in version 0.5 and creates the version 2.0 topological file “path.topo”:

  ```
  write_generalized_feedthru_paths  -use_topological_file a.topo
  ```

- The following command reads the topological file “a.topo” in version 0.5 and creates the version 2.0 topological file “new.topo”:

  ```
  write_generalized_feedthru_paths  -use_topological_file a.topo -topological_out_file new.topo
  ```

Related Information

- `insertPtnFeedthrough`
- Partitioning the Design chapter in the *Innovus User Guide*

changeCurrentDesign

```
changeCurrentDesign
[-help]
[ptnName]
```

Changes the partition view. It helps you to switch between different block cells and get back to the top cell.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `changeCurrentDesign` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man changeCurrentDesign`
ptnName	Specifies name of the partition to set as top cell. **Note:** If no partition name is specified, then you are taken to the top cell of the current design. *Data_type*: string, optional

Examples

- The following commands changes sets `tdsp_top` as the top cell.
  ```
  changeCurrentDesign tdsp_top
  ```

Related Information

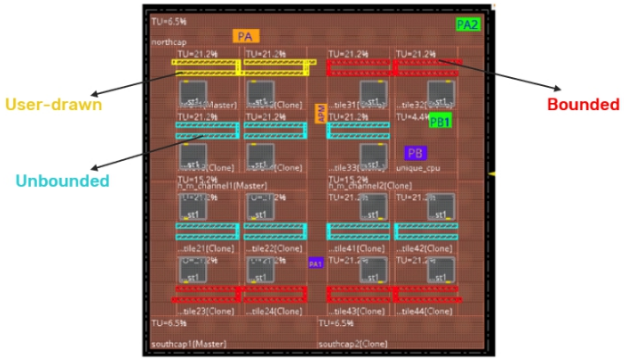
- Change Partition View chapter in the *Innovus Menu Reference*
- Partitioning the Design chapter in the *Innovus User Guide*

highlightSyncObj

```
highlightSyncObj
[-help]
[-obj {all busGuides}]
```

Adds highlight color on sync objects during master-clone-aware bus guide operations. The colors used for highlighting are based on different color schema categories – user-drawn, bounded, or unbounded. These categories are derived from the last sync command (`clonePtnObj -sync` or `setFPlanMode -autoSyncMasterClone busGuides`) used. This command makes it easy to distinguish between different bus guide objects in the design.

- User-drawn bus guides are highlighted in yellow.
- Bounded bus guides are highlighted in red. Nets in bounded bus guides can be determined during sync operation. If either (or both) the source or driver partition is a master-clone, the tool can determine the equivalent net during sync (in master clone chains).
  For example: Consider A1-B1-C1 and A2-B2-C2 chains where A/B/C1 A/B/C2 are master clones. A1/2 pin k is connected to net n1 (in A1) and n2 (in A2). As we can easily determine n1 and n2 in the chains, this is a case of bounded bus guides.
- Unbounded bus guides are highlighted in blue. Nets in unbounded bus guides cannot be determined during sync operation. If both source or driver partition are unique or (special case master and clone but their equivalent pin is floating), the tool cannot determine the net during sync (in master and clone chains).
  For example: Consider UA1-B1-UC1 and UA2-B2-UC2 chains where B1 and B2 are master clones. UA1/UC1/UA2/UC2 are all unique but UA1/UA2 pin may be different. Here since we cannot determine equivalent nets of chains, this is a case of unbounded bus guides.



Parameters

`-help`	Outputs a brief description that includes the type and default information for each `highlightSyncObj` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man highlightSyncObj`
`-obj {all busGuides}`	Specifies the object to be highlighted. *Data_type*: enum_list, optional

Example

- The following command highlights busguides based on different color schema categories:
  `highlightSyncObj -obj busGuides`

Related Information

- Partitioning the Design chapter in the *Innovus User Guide*

createBusNetGroup

```
createBusNetGroup
[-help]
[-considerClone]
[-createBusSinkGroup]
[-dontCommit]
[-file string]
[-ignoreBusSize integer]
[-ignoreConnectivity]
[-ignoreMultiPartitionPinNet]
[-netGroupOptionsList string]
[-overwrite]
[-prefix string]
[-reverseOrder]
[-useShortName]
[-bus string | -all ]
[-forTopOnly | -forPartitionOnly ]
[-includeMacro | -forPartitionOnly ]
[-checkOnly | {[-bus string] [-all ]} ]
```

Creates a net group for buses.

Parameters

`-all`	Creates a net group connected to the design partition for all the buses. **Note:** This parameter is mutually exclusive with the `-bus` parameter. *Data_type*: bool, optional
`-bus string`	Creates a net group connected to different partitions of the specified bus only. **Note:** This parameter is mutually exclusive with the `-all` parameter. *Data_type*: string, optional
`-checkOnly`	Checks and reports all the buses present in the design. *Data_type*: bool, optional
`-considerClone`	Creates a net group for buses connected to clones. *Data_type*: bool, optional
`-createBusSinkGroup`	Creates BusSinkGroup instead of a net group. *Data_type*: bool, optional
`-dontCommit`	Creates nets groups and stores the info in a file instead of creating in the DB. *Data_type*: bool, optional
`-file string`	Specifies the name of the file in which the defined groups are stored. *Data_type*: string, optional
`-forPartitionOnly`	Specifies that the net groups should be connected to partitions only. *Data_type*: bool, optional
`-forTopOnly`	Specifies that the net groups should be connected to the Top only. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `createBusNetGroup` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man createBusNetGroup`
`-ignoreBusSize integer`	Specifies that the buses smaller than the specified size should be ignored. *Data_type*: int, optional

`-ignoreConnectivity`	Specifies that the partition connectivity should be ignored and the net groups should be created for the whole bus. *Data_type*: bool, optional
`-ignoreMultiPartitionPinNet`	Specifies that the buses connected to multiple partitions/clones should be ignored. *Data_type*: bool, optional
`-includeMacro`	Specifies that bus net group being created should have a connection with macros. *Data_type*: bool, optional
`-netGroupOptionsList` *string*	Specifies attributes (like optimizeOrder, spread etc.) that can be added to the bus net group. *Data_type*: string, optional
`-overwrite`	Overwrites the already created net group be deleting the current net group element from an earlier association. *Data_type*: bool, optional
`-prefix` *string*	Specifies a prefix for the bus net group. *Data_type*: string, optional
`-reverseOrder`	When specified, the bus order of the buses in the net group is reversed. *Data_type*: bool, optional
`-useShortName`	When specified, a short name is applied to the bus net group. *Data_type*: bool, optional

Related Information

- Partitioning the Design chapter in the *Innovus User Guide*

check_bus_guides

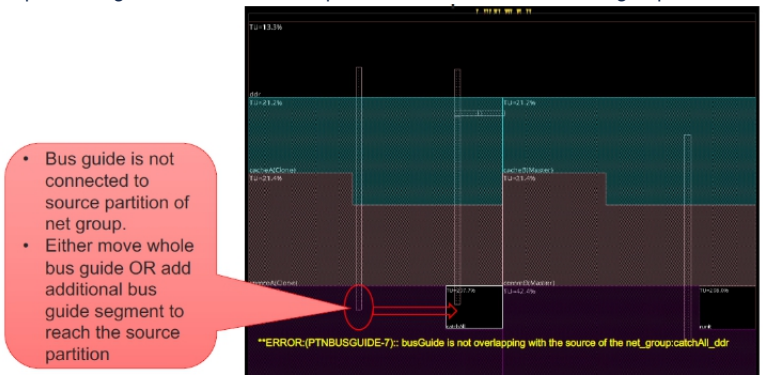
```
check_bus_guides
[-help]
[-net_groups list_of_net_groups]
[-outFile file_name]
```

Checks bus guides for violations during master-clone-aware net group implementation flow. It checks for the consistency of net groups and bus guides by performing the following:

- Bus-guide physical checks:
  - Reports over-drawn bus guides.

  - Reports under-drawn bus guides (bus guide does not reach the sink of net group).

  - Reports bus guide that do not overlap/connect with the source of net group.



- Checks the net-group consistency and reports non-homogeneous nets in a net group.

Note: The `check_bus_guides` command does not support nested designs yet.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `check_bus_guides` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man check_bus_guides`
`-net_groups` *`list_of_net_groups`*	Specifies the net groups whose bus guides are to be checked. *Default* : *. Example: # -net_groups {ng1 ng2 ng3-*} (string, optional) *Data_type*: string, optional
`-outFile` *`file_name`*	Specifies the name of the file where the bus guide violation log is stored. *Default:* `checkBg.rpt` *Data_type*: string, optional

Example

- The following command checks the bus guides for violations.
  ```
  check_bus_guides
  ```
- The following command checks the bus guides of net groups ng1, ng2, and ng3 for violations.
  ```
  check_bus_guides -net_groups {ng1 ng2 ng3}
  ```

Related Information

- Partitioning the Design chapter in the *Innovus User Guide*

write_net_groups_topo

```
write_net_groups_topo
[-help]
[-net_groups list_of_net_groups]
[-outFile file_name]
```

Creates a topological file (used by the `insertPtnFeedthrough` command) for nets of the net group associated with a bus guide. The topology of nets for feedthrough is derived from the shape of the bus guide. All the partitions that the bus guide shape overlaps with, become a node in the topological path.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `write_net_groups_topo` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_net_groups_topo`
`-net_groups` *list_of_net_groups*	Specifies the net groups to be added in topo file. *Default: *.* For example, the following command specifies that the ng1, ng2, and ng3 netgroups must be added to the topo file. `write_net_groups_topo -net_groups {ng1 ng2 ng3-*}` *Data_type*: string, optional
`-outFile` *file_name*	Writes the bus guide violation log to the specified file. *Default:* `bus_guided.topo.v2` *Data_type*: string, optional

Example

- The following command writes the net group information to a topology file.
  ```
  write_net_groups_topo
  ```

add_decomp_filler

```
add_decomp_filler
[-help]
-bottom_edge_endcap {cell_name}
-core_column_cell {cell_name}
-core_row_cell {cell_name_list}
[-offsetx offset_in_microns]
[-offsety offset_in_microns]
[-power_domain power_domain_name]
[-prefix prefix_name]
-stepx step_in_microns
-stepy step_in_microns
-top_edge_endcap {cell_name}
-vertical_edge_endcap {cell_name}
```

Inserts breaker cells to divide the chip into several small parts. This reduces the run time of coloring while manufacturing the chip.

This command is run after `floorPlan` and before `addEndCap`.

Parameters

`-bottom_edge_endcap {cell_name}`	Specifies the CA-break end cap cell for rows, to make bottom_edge of endcap face core.
`-core_column_cell {cell_name}`	Specifies the CA-break filler cell for inserting into columns.
`-core_row_cell {cell_name_list}`	Specifies a list of CA-break filler cells inserted horizontally in the core rows.
`-help`	Outputs a brief description that includes type and default information for each `add_decomp_filler` parameter. For a detailed description of the command and all of its parameters, use the man command: `man add_decomp_filler`.
`-offsetx offset_in_microns`	Specifies the offset added to the first step in the horizontal direction.
`-offsety offset_in_microns`	Specifies the offset added to the first step in the vertical direction.
`-power_domain power_domain_name`	Specifies the power domain for which CA-break filler cells are to be inserted. **Note**: If the `-power_domain` option is used, the offset value is applied to the specified power domain. However, if the -power domain is not specified, the offset value is applied to all available power domains. To use different offset value for a specific power domain, you first need to delete the CA fillers from the power domain if it is already filled and then reinsert CA filler to the power domain with the target offset value.
`-prefix prefix_name`	Specifies the prefix for decomp cells. If this option is specified, the user-specified prefix is applied to all inserted decomp fillers, else the default prefix name is used.
`-stepx step_in_microns`	Specifies the decomposition step in horizontal direction.
`-stepy step_in_microns`	Specifies the decomposition step in vertical direction.
`-top_edge_endcap {cell_name}`	Specifies CA-break end cap cell for rows, to make top_edge of endcap face core.
`-vertical_edge_endcap {cell_name}`	Specifies CA-break end cap cell inserted at the left and right edges as end caps.

Example

The code below shows the usage of the `add_decomp_filler` command.

```
add_decomp_filler
-core_row_cell {CA_ROW2 CA_ROW3} -core_column_cell {CA_COL2}
-top_edge_endcap CA_TE -bottom_edge_endcap CA_BE
-vertical_edge_endcap CA_LRE
-stepx 500 -stepy 500
```

Below is the graphical representation of the above example:

add_gate_array_filler

```
add_gate_array_filler
[-help]
[-allow_shift_distance x y]
[-area x1 y1 x2 y2]
[-cell_orientation {R0|MX|MY|R180}]
[-offsetx offset_in_microns]
[-offsety offset_in_microns]
[-powerDomain powerDomainName]
[-prefix prefixName]
{-cell cellName -stepx step_in_microns -stepy step_in_microns}
```

Inserts GA filler cells with regular pattern during the pre-place stage.

The GA filler cells created by this command are marked as physical-only cells. This means that the `isPhysOnly` attribute of these GA filler cells is set to `true`. This is a prerequisite for the `ecoPlace -useGAFillerCells` command to map the unplaced ECO cells to the added GA filler cells, in case of a GA filler-based post-mask ECO.

Parameters

`-allow_shift_distance x y`	Specifies the distance between the new and the original position in the x and y directions. If you do not specify `-allow_shift_distance`, the GA filler will be removed if it is added at original location with a violation. If `-allow_shift_distance` is specified, the GA can be shifted to avoid violation. If a GA filler cannot be added at the original location because of the violation, it will be moved to the left side, right side, upside, or downside of the original location to ensure that there is no violation. The next filler keeps the step value with the original position of the moved filler.
`-area x1 y1 x2 y2`	Specifies the area in which GA fillers are to be inserted. If no area is specified, GA fillers will be inserted for the complete core area.
`-cell cellName`	Specifies the name of the filler cell to be used.
`-cell_orientation {R0|MX|MY|R180}`	Specifies all legal orientations of GFILL instances.
`-offsetx offset_in_microns`	Specifies the offset, in microns, from the origin in the horizontal direction. If the `-area` parameter is specified, the origin is (x1, y1) of the box defined by `-area`. If `-area` is not specified the origin is (0,0).
`-offsety offset_in_microns`	Specifies the offset, in microns, from the origin in the vertical direction. If the `-area` parameter is specified, the origin is (x1, y1) of the box defined by `-area`. If `-area` is not specified the origin is (0,0).
`-powerDomain powerDomainName`	Specifies the power domain for which fillers are to be inserted.
`-prefix prefixName`	Specifies the prefix for the inserted GA filler cells.
`-stepx step_in_microns`	Specifies the distance between GA fillers in the horizontal direction.
`-stepy step_in_microns`	Specifies the distance between GA fillers in the vertical direction

Examples

- The following command adds GA fillers of type `GAFILL4` with spacing in horizontal and vertical direction of 20 microns. The first GAFILL4 will be placed at (10, 0).

  ```
  add_gate_array_filler -cell GAFILL4 -stepx 20 -stepy 20 -offsetx 10
  ```

- The following command adds GA fillers of type `GAFILL4` with regular spacing 20 and start location (0, 0).

  ```
  add_gate_array_filler -cell GAFILL4 -stepx 20 -stepy 20
  ```

- The following command adds GA fillers of type `GAFILL4` with vertical and horizontal spacing of 10 microns in the area defined by coordinates 100 100 500 500.

  ```
  add_gate_array_filler -area 100 100 500 500 -cell GAFILL4 -stepx 10 -stepy 10
  ```

- ecoPlace

add_tap_walls

```
add_tap_walls
[-help]
[-bottom]
-cell cellName
[-layer layer_name]
[-left]
[-orientation {R0 MX MY R180}]
[-pitch distance]
[-prefix prefix]
[-range lx ux|ly uy]
[-right]
[-top]
[-y_flip_side {left right both}]
```

Adds tap walls to the assigned left, right, top, and/or bottom side of a block.

Parameters

`-bottom`	Specifies the add tap-wall cell on the bottom side.
`-cell cellName`	Specifies the name of the cell to insert.
`-help`	Outputs a brief description that includes type and default information for each `add_tap_walls` parameter. For a detailed description of the command and all of its parameters, use the man command: `man add_tap_walls`.
`-layer layer_name`	Specifies the layer name to check rule.
`-left`	Specifies the add tap-wall cell on the left side.
`-orientation {R0 MX MY R180}`	Specifies orientation of the added tap-wall cells.
`-pitch distance`	Specifies the distance from the center of one tap-wall cell to the center of the following wall-tap cell.
`-prefix prefix`	Specifies the prefix of tap-wall cells to inserted.
`-range lx ux|ly uy`	Specifies the {lx, ux} or {ly uy} as the start or end point at the user given side.
`-right`	Specifies the add tap-wall cell on the right side.
`-top`	Specifies the add tap-wall cell on the top side.
`-y_flip_side {left right both}`	Specifies the orientation of the added tap-wall cells. Defines whether flipping tap walls located at certain side in the Y direction if site symmetry allows it. By default, both left and right side tap walls are R0 or MX. If -y_flip_side is set to left, the left side tap walls would be MY or R180. If it is set to both, both left and right side tap walls would be MY or R180.

addEndCap

```
addEndCap
[-help]
[-area llx lly urx ury]
[-coreBoundaryOnly]
[-powerDomain powerDomainName]
[-prefix prefixName]
```

Adds physical-only end cap cells at the ends of the site rows. A single-height cap cell is required at the end of each row. For deep N-well technology, the command can be used to insert row-caps to isolate p-well from top and bottom. Use `setEndCapMode` to specify the row-cap cells. For deep N-well technology, `addEndCap` also gets the end cap list from LEF if the end cap cell is specified with the following MACRO CLASS, but user definition has higher priority than LEF specification.

```
[CLASS ENDCAP {
| TOPEDGE | BOTTOMEDGE | LEFTEDGE | RIGHTEDGE
| LEFTTOPEDGE | RIGHTTOPEDGE
| LEFTBOTTOMEDGE | RIGHTBOTTOMEDGE
| LEFTTOPCORNER | RIGHTTOPCORNER
| LEFTBOTTOMCORNER | RIGHTBOTTOMCORNER}
} ]
```

Note: `addEndCap` is always called after floorplan is done and before `addWellTap`.

Note: End cap insertion honors core boundary, power domain boundary, placement blockage, fixed macro, and fixed macro halo

To delete the end cap cells, use the `deleteFiller` command.

Parameters

`-area llx lly urx ury`	Specifies the coordinates of the bounding box, in microns. By default, the core box that encloses all core rows is used.
`-coreBoundaryOnly`	Specifies that end-cap cells are placed only within the core boundary. This ensures that end-cap cells do not get placed at locations where site rows are obstructed by blockages.
`-help`	Outputs a brief description that includes type and default information for each `addEndCap` parameter. For a detailed description of the command and all of its parameters, use the man command: `man addEndCap`.
`-powerDomain powerDomainName`	Specifies the power domain in which the end-cap cells are inserted. This identifies the area where to place the end-cap cells and connect to the correct power and ground nets.
`-prefix prefixName`	Specifies the prefix for the placed instances. The generated name for the instance uses this prefix as `prefix_uniqueString`. *Prefix Default:* `ENDCAP` ⓘ Do not use an underscore at the end of the prefix name.

Note: If the given leftEdge cell is the same as the rightEdge cell, and the cell and site symmetries allow it, the postCap instances will be flipped in the Y direction.

Examples

- The following command preplaces cell `abc` at the beginning of each site row of the design, and cell `xyz` at the end of each site row of the design in `R0` orientation, and adds the prefix `PwrCap` for the placed instances.

  ```
  setEndCapMode -leftEdge abc -rightEdge xyz; addEndCap -prefix PwrCap
  ```

- The following command deletes all physical-only cells with the prefix `PwrCap`. As a result, all cells created in the previous example are deleted from the design.

  ```
  deleteFiller -prefix PwrCap
  ```

- The following command preplaces cell `abc` at the beginning and end of each site row of the design and, if site symmetry allows, flips the post-cap cell in Y direction. Thus, for N-oriented rows, placed pre-cap cell is in N orientation, and post-cap cell is in FN orientation.

  ```
  setEndCapMode -leftEdge abc -rightEdge abc; addEndCap -prefix PwrCap
  ```

- The following command, in which the pre-cap cell is the same as the post-cap cell, places pre-cap cells in FN orientation and post-cap cells in N orientation in N-oriented rows, if site symmetry allows:

  ```
  setEndCapMode -leftEdge abc -rightEdge abc -flipY; addEndCap -prefix PwrCap
  ```

- The following command flips both the pre-cap and post-cap cell in Y direction. This preplaces both cells `abc` and `xyz` in FN orientation in N-oriented rows:

  ```
  setEndCapMode -leftEdge abc -rightEdge xyz -flipY; addEndCap -prefix PwrCap
  ```

addFiller

```
addFiller
[-area  x1   y1   x2   y2 ]
[-cell { filler_cell_list }]
[-createRows {true | false}]
[-diffCellViol {true|false}]
[-check_signal_drc {true | false}]
[-ecoMode {true | false}]
[-fitGap]
[-fixDRC]
[-fix_horizontal_max_length_violation]
[-fix_vertical_max_length_violation]
[-honorPrerouteAsObs {true | false}]
[-markFixed]
[-merge {true | false}]
[-minHole {true | false}]
[-powerDomain powerDomainName ]
[-prefix prefixName]
[-prevent_vertical_stack_max_length_violation]
[-util targetUtilization ]
[-viaEnclosure {true | false}]
```

Inserts filler cell instances in the gaps between standard cell instances. Filler cells provide continuity for the VDD/VSS power rail, as well as for n-wells. In most cases, use this command after placement and before detailed routing. If the design is routed, this command also does DRC checks of the filler cells added to the wires in the design. It does not check adjacent cells. This process ensures that this command is fast enough to be used many times in the design flow.

Note: Before using `addFiller`, run the `globalNetConnect` command to provide global-net-connection rules for supply pins of the added fillers. Without these rules, the built-in design-rule checks of `addFiller` will not be accurate.

To resolve adjacent cell DRC violations created by the insertion of filler cells, run the `verify_drc` command to mark these violations. Then, use the `addFiller` command again with the `-fixDRC` parameter to replace the filler cells that caused the violations.

Note: This command resolves only filler-related violations; it cannot resolve net-based violations. To repair net-based violations, reroute the violated nets.

The `addFiller` command recognizes up to eight implant layers and attempts to honor implant layer width and spacing rules within each implant layer. If it does not find the correct filler cell to add to an implant layer, it tries to add "no-implant" filler cells. If it cannot add the "no-implant" cells, it inserts a filler cell that is large enough that it does not violate the minimum width rule of the relevant implant layer.

Use the `deleteFiller` command to remove the added filler cell instances.

Note: This command supports multithreading.

Some `addFiller` parameters can also be specified with `setFillerMode`. However, the parameters you specify with `addFiller` apply to the current `addFiller` run only, and supersede the parameters set by `setFillerMode`. For more information, see `setFillerMode` .

Parameters

`-area` *x1y1x2y2*	Adds filler cells to the specified area. If the area is not defined properly, does not add filler cells. Normally, designs are placed before filler cells are added. However, If you use this parameter and the design is not placed, you get a warning, and the command adds fillers in the specified area. **Note**: You can specify this parameter with `addFiller` only, and not with `setFillerMode`. • Specifies the area's lower left point on the x axis. • Specifies the area's lower left point on the y axis. • Specifies the area's upper right point on the x axis. • Specifies the area's upper right point on the y axis.
`-cell` *filler_cell_list*	Specifies the list of filler cells to add. Separate filler cell names with spaces and enclose the list with quotation marks (") or curly braces ({}). **Note**: Cells specified by this parameter override the list of cells provided by the `-core` parameter of `setFillerMode`.
`-createRows {true | false}`	Controls whether `addFiller` creates rows in the floorplan if a cell's site does not have rows. Specify false for this parameter to prevent `addFiller` from creating the rows. *Default*: `true`
`-diffCellViol {true|false}`	Checks violations between different cell types. *Default*: `false` **Note**: Using this feature will increase the runtime of `addFiller`.
`-check_signal_drc {true | false}`	Controls postroute DRC violation checking against existing net routing, without considering adjacent cell DRC violations. This parameter does not disable regular placement checks. *Default*: `true` In 16.10, addFiller has been enhanced with DRC. This flow would fill gaps as much as possible even with DRC, and will give the violation report and marker for easy debug. Also, the `-add_fillers_with_drc` option has been added to the `setFillerMode` command to call second addFiller without DRC checking. If filler cells are added after routing, the software checks for DRC violations between regular nets and the filler cells. When the inserted filler violates the existing routing, addFiller tries to use other filler cells to replace the violating one. If it fails to fill the gap without violation, it will insert a violated filler in the second pass and give the violation report and marker for easy debug when `-add_fillers_with_drc` is turned on.

`-ecoMode {true | false}`	Controls whether the software resolves overlaps of standard cells with fillers by removing the overlapping fillers, and inserting new fillers in any existing or newly created gaps due to partial overlaps in eco flow. If this parameter is used after routing, the command also resolves DRC violations of filler geometries of all fillers with regular wires. *Default*: `false`
`-fitGap`	Fills a gap between cells by adding a combination of cells, instead of by adding the single largest cell that fits, if doing so avoids leaving an unfilled single-width gap.
`-fixDRC`	Corrects DRC violations reported by `verify_drc` between filler cells and adjacent standard cells. **Note**: The `addFiller` command resolves only filler-related violations--it cannot resolve net-based violations. To repair net-based violations, reroute the violated nets. Use this parameter in subsequent runs of the `addFiller` command, after adding filler cells and checking for violations with `verify_drc`. The command replaces filler cells that cause DRC violations with fillers that do not cause violations. If it cannot replace a violating filler cell without causing another violation, it leaves a gap. **Note**: You can specify this parameter with `addFiller` only, and not with `setFillerMode`.
`-fix_horizontal_max_length_violation`	Fixes the horizontal max-length violation.
`-fix_vertical_max_length_violation`	Fixes the vertical stack max-length violation.
`-honorPrerouteAsObs {true | false}`	Instructs `addFiller` to honor the setting of `setPlaceMode -place_detail_preroute_as_obs`. That is, when this parameter is `true`, `addFiller` treats preroutes on metal layers where filler cells have geometries as obstructions, and ignores preroutes on other layers. In most cases, this means that `addFiller` treats preroutes on metal1 as obstructions and ignores preroutes on other metal layers. For example, if `setPlaceMode -place_detail_preroute_as_obs` is set to metal1 and metal2, and all the filler cell geometries are on metal1, `addFiller` treats metal1 preroutes as obstructions but not metal2 preroutes. *Default*: `false` `addFiller` ignores `setPlaceMode -place_detail_preroute_as_obs` and inserts fillers in all legal sites.
`-markFixed`	Places newly added filler cells in FIXED status in the Innovus database. **Note**: You can specify this parameter with `addFiller` only, and not with `setFillerMode`.

`-merge {true | false}`	When checking for spacing violations, merges same-net geometries to determine width-dependent spacing. If the LEF file contains width-dependent rules, this parameter causes `addFiller` to have the following behavior: • If you specify true, the command merges overlapping same-net objects to create a large rectangle. • If you specify false, the command uses the shape of the object from the database. *Default*: `false`
`-minHole {true | false}`	Calls `verify_drc` to check for minimum hole violations before adding filler cells and repairs the violations when `addFiller` runs. *Default*: `false`
`-powerDomain` *powerDomainName*	Specifies the power domain in which to add filler cells. *Default*: If this parameter is not specified, and a list of filler cells is specified with the `-cell` parameter, the `addFiller` command tries to add fillers to all power domains. **Note**: You can specify this parameter with `addFiller` only, and not with `setFillerMode`.
`-prefix` *prefixName*	Specifies the prefix for the placed instances. *Default*: `FILLER`
`-prevent_vertical_stack_max_length_violation`	Adds a repair endcap cell to cut the vertical stack of endcap cells to prevent its vertical max-length violation.
`-util` *targetUtilization*	Specifies the percent of free space remaining after placement to fill with given filler cell instances. Use `-util` to add gate-array core filler cells to use later in the design flow, along with gate-array core cells, for metal-only mask changes. **Note**: You can specify this parameter with `addFiller` only, and not with `setFillerMode`. *Range*: More than `0.0` (`0%`) and equal to or less than `1.0` (`100%`) *Default*: `1.0`
`[-viaEnclosure {true | false}]`	Calls `verify_drc` to check for via enclosure violations before adding filler cells and repairs the violations when `addFiller` runs. *Default*: `false`

Examples

- The following command inserts filler cell instances for cells `FILL64`, `FILL16`, `FILL4`, `FILL2`, and `FILL1`:

  ```
  addFiller -cell FILL64 FILL16 FILL4 FILL2 FILL1 -prefix FILLER
  ```

- The following commands show the use of the `-util` parameter to set the utilization of `GACORE` filler cells to 50 percent:

  ```
  # Place the design
  place_design
  ```

```
# Now fill with GACORE cells up to 50% of remaining space
# area utilization
addFiller -cell {gcore16 gcore8 gcore4} -prefix GACORE -util 0.5
# Now fill with the standard filler cells
addFiller -cell {fill8 fill4 fill2 fill} -prefix FILLER
# Continue with routing
```

- The following command enable postRoute DRC checking for min hole violations and via enclosure violations:
  ```
  addFiller -cell FILL16 FILL8 FILL4 FILL2 -check_signal_drc true -minHole true -viaEnclosure true
  ```

- setPlaceMode

addFillerGap

```
addFillerGap
minGap
[-effort {none | low | medium | high}]
[-radius micron]
```

Moves placed standard cell instances to create gaps so that filler cells can be added. Tries to move cells to create a gap of the specified size. If enough space is not available, moves cells until they touch each other. If a gap already exists, and it is larger than the specified size, the command does not move cells to make it smaller.

By default, this command deletes all routing, because the routing is no longer valid due to the movement of the cells. To override this behavior, specify the following command:

```
setPlaceMode -place_detail_preserve_routing true
```

This command has the following limitations:

- It does not moved `FIXED` cells.
- It does not guarantee to that all gaps will be larger than the specified minimum gap size.

Use this command after placement and before routing.

Parameters

minGap	Specifies the minimum-size gap in which a filler cell can be added. Unit is micron.
`-effort {none | low| medium | high}`	Specifies the effort the command needs to spend for honoring the given gap constraint. • `none` effort specifies that no standard cell is moved for honoring the giving gap constraint. • `low` effort specifies that only single height standard cells can be moved within the same row. • `medium` effort specifies that only single height standard cells can be moved across the rows. • `high` effort specifies that the standard cells can be moved across rows, and double height standard cells can be moved within the same row. *Default*: `low`
`-radius` *micron*	Specifies the searching radius when solving the minimum filler gap. Default: 16

Example

The following command moves standard cells within a row to create gaps of at least two microns between the cells:

```
addFillerGap 0.168
```

Related Topics

- `setPlaceMode`

addMimCap

```
addMimCap
[-help]
-cell cellName
[-orient orientation]
[-prefix prefixName]
[{-stepX step_in_microns -stepY step_in_microns}
[-area {x1 y1 x2 y2}]][{-area {x1 y1 x2 y2} | -loc {x y}}] [-loc {x y} | -offset {x y}]
```

Adds Metal-Insulator-Metal (MIM) cap cell(s) into the design. This command is used before placing the standard cells.

Parameters

`-area x1 y1 x2 y2`	Specifies the area in which MIM caps are to be inserted. If no area is specifies, MIM caps will be inserted in the complete core area. This option must be used in conjunction with -`stepX` and `-step`Y and is mutually exclusive with `-loc`.
`-cell` *cellName*	Specifies the name of the MIM cap cell.
`-help`	Outputs a brief description that includes type and default information for each `addMimCap` parameter. For a detailed description of the command and all of its parameters, use the man command: `man addMimCap`.
`-loc {x y}`	Inserts MIM cap cell at the specified location.
`-offset {x y}`	Specifies the offset in microns from the origin, in horizontal and vertical directions. If the `-area` parameter is specified, the origin is (x1, y1) of the box defined by `-area`. If `-area` is not specified, the origin is (0,0). This option must be used in conjunction with -`stepX` and `-step`Y and is mutually exclusive with `-loc`.
`-orient` *orientation*	Specifies the orientation for the inserted MIM cap cell(s). *Default*: `R0`
`-prefix` *prefixName*	Specifies the prefix for the inserted MIM cap cells.
`-stepX` *step_in_microns*	Specifies the distance between MIM cap cells in the horizontal direction. This option must be used together with `-stepY` and is mutually exclusive with `-loc`.
`-stepY` *step_in_microns*	Specifies the distance between MIM cap cells in the vertical direction. This option must be used together with `-stepX` and is mutually exclusive with `-loc`.

Examples

- The following command inserts the MIM cap cells of type `mim_cell1` to a specific area, with a custom offset, orientation, and step:
  ```
  addMimCap -cell mim_cell1 -orient R0 -stepX 34.56 -stepY 34.56 -offset { 9.317 8.336 } -area 20 20 100 100
  ```

addSpareInstance

```
addSpareInstance
[-help]
[-async netName:terminalList [netName:terminalList … ]
[-clock netName]
-file fileName
[-fix_placed_insts {TRUE|FALSE}]
[-hier moduleName | -powerDomain domainName [-submodule submoduleName]]
[-prefix prefix]
[-tie {0 | 1}]
```

Specifies a file that lists spare cells to add to the netlist. You can use this command before or after standard cell placement.

- If you use this command before placement, the `place_design` command distributes and places the added instances without including them in spare modules. It adds the instances to the top level of the design by default.
- If you use this command after placement, the software places the added instances without creating spare modules or disturbing the existing placement. The distribution of the cells is dependent upon the number of instantiations of each cell type.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `addSpareInstance` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man addSpareInstance`.
`-async` *`netName:terminalList`*	Specifies which net(s) to tie off the async pin(s). Default: async pins will be tied to the logical zero net.
`-clock` *`netName`*	Specifies the clock net that is tied to the clock pins.
`-file` *`fileName`*	Specifies a text file that lists the spare cells, and the number of each, to add to the netlist. The file has the following format: "*`cellName number`*" Begin each line of a comment with a number sign (`#`).
`-fix_placed_insts {TRUE|FALSE}`	Specifies not to move the existing placed instances to find location for newly added spare instances.
`-hier` *`moduleName`*	Specifies the name of the module to which spares will be added.
`-powerDomain` *`domainName`*	Specifies the name of the power domain to which spares will be added.
`-prefix` *`prefix`*	Specifies a prefix for the names of the newly added cells. *Default:* `FE_spare`
`-submodule` *`submoduleName`*	Specifies the name of the module created for spares.
`-tie {0 | 1}`	Specifies the logical net to which the cells are connected. *Default:* `1`

Example

The following command adds instances of the cells specified in `spare_file` and ties them to logical net `0`. It ties the clock pins to `sysclk`:

```
addSpareInstance -file spare_file -tie 0 -clock sysclk
```

`spare_file` contains the following:

```
DFFNSRX2T1T10   1
INVX4T1T10      2
NOR2X2T1T10     2
```

The following command adds instances of the cells specified in spare.txt.It ties the async pin RN to net VDD:

```
addSpareInstance -file spare.txt -async VDD:RN
```

`spare.txt` contains the following:

```
SDFFRHQXL 5
```

addWellTap

```
addWellTap

Adds physical-only well-tap cells. Well-tap cells are physical-only filler cells that are required by some technology libraries to limit resistance between power or ground connections and wells of the substrate. Well-tap cells are placed in a preplaced status.

- To delete well-tap cells, use the `deleteFiller` command.
- To verify well-tap placement, generate markers for violations caused by well-tap cells, and create a violation report, use the `verifyWellTap` command.

`addWellTap` treats the endcap cell as a tap function cell when `set_well_tap_mode -tap_function_cells` is set.

Parameters

`-area x1y1x2y2`	Specifies the coordinates of the bounding box, in microns. By default, the core box that encloses all core rows is used. • *x1:* Specifies the area's lower left point on the x axis. • *y1:* Specifies the area's lower left point on the y axis. • *x2:* Specifies the area's upper right point on the x axis. • *y2:* Specifies the area's upper right point on the y axis.
`-avoidAbutment`	Specifies whether the inserted taps should avoid horizontal and vertical abutment.
`-block_boundary_only {true | false}`	Specifies whether to insert termination tap cells only for well tap columns on the block boundary. Default is false, termination cells are inserted on both core boundary row and block boundary row. **Note:** This parameter works only when inserting termination cells.
`-bottom_termination_cell cell_list`	Specifies the list of termination cells to be used at the bottom.

`-cell` *cellName*	Specifies the name of the cell in the technology library to use as a well-tap. The cell should be of class type CORE.
`-cellInterval` *microns*	Specifies the maximum distance from the center of one well-tap cell to the center of the following well-tap cell in the same row. If well-tap cells cannot be placed at this location due to a placement blockage, the software searches for a legal location: first, towards the previous well-tap cell, and then farther away.
`-channel_offset` *offset_value*	Specifies the offset value between taps and blockage in channel. *Minimum*: 0 *Maximum*: 1.79769313486232e+308
`-check_channel`	Inserts well taps inside channel.
`-checkerBoard`	Places the well-tap cells in a checkered pattern, that is, with every other row offset by one-half gap. In rows where a one-half offset gap is not available in the row above or below, the tap-cell is inserted at one-half gap in the row in question.Thus, for a simple floorplan, the first and last rows will have well-taps at one-half gap only, while all other rows will have the full gap. When a floorplan has hard blocks or placement blockages, the rows above and below the block (or blockage) will also have well-taps at one-half gap. **Note:** When this parameter is specified, `-skipRow` is ignored.
`-column_cell tap_column_cell_list`	Specifies the list of well tap columns that need to be terminated. This parameter must be specified for termination tap cell insertion.
`-fixCutCell`	Fixes all the instances which belong to the `wellCutCell` list.
`-fixedGap`	Ensures that the specified gap is always maintained. That is, the software does not search for a legal location if it cannot place well-tap cells at the specified `-cellInterval`. Instead, it goes on to place well-tap cells at the next position. You can modify the gap by using the `-pitch` and `-pitchOffset` parameters.
`-help`	Outputs a brief description that includes type and default information for each `addWellTap` parameter. For a detailed description of the command and all of its parameters, use the man command: `man addWellTap`.
`-incremental` *list_of_cells*	Checks whether any instances of the cells specified in the *list_of_cells* are within 0.45 times the `-cellInterval` from the next well-tap cell in the same row. If so, does not add well-tap cells at that location.
`-inRowOffset` *microns*	Specifies the offset, in microns, of the first well-tap cell from the start of the site row. *Default*: `0` (first cell on beginning of row is the starting point).
`-insert_cells` *list_of_cells*	Inserts mixed well-taps, and supports the LUP layer and boundary layer rules.
`-pitch` *microns*	Used with the `-fixedGap` parameter to give the software added flexibility to place well-tap cells if it is unable to place a cell at the specified location. If you specify this parameter, the software first tries to fit the well-tap cells in the locations specified by `-cellInterval`, or forced by `-fixedGap`; if it cannot do so, it adds well tap cells at the closest location allowed by this parameter.

`-pitchOffset` *microns*	Used with the `-fixedGap` and `-pitch` parameters to give the software greater flexibility. If you specify this parameter, the software first tries to fit the well-tap cells in the locations specified by `-cellInterval`, or forced by `-fixedGap`; if it cannot do so, it adds well tap cells at the closest location allowed by this parameter.
`-powerDomain` *powerDomainName*	Specifies the power domain in which the well-tap cells are inserted. This is the area where the well-tap cells are placed and connected to the correct power and ground nets.
`-prefix` *prefixName*	Specifies the prefix for the placed well-tap cells. The software adds an underscore and a unique string to the prefix, in the following format: `prefix_`*`uniqueString`*. *Prefix Default:* `WELLTAP` ⓘ Do not include an underscore when you specify a prefix.
`-siteOffset` *number_of_sites*	Specifies an offset value, in number of sites, so that the vertical taps are aware of.
`-skipRow` *number*	Specifies the number of rows to skip between two rows of an identical pattern. **Note:** If you specify `-checkerBoard`, this parameter is ignored. *Default*: `0` (No rows are skipped, so well-tap cells are added in the same pattern to every row)
`-startRowNum` *number*	Specifies the row number starting from the from bottom or left side of the design on which the well-tap cells must be placed. *Default*: 1 (first row from the bottom is the starting point)
`-termination_cell` *termination_cell_list*	Specifies the list of cells that can be used as termination taps. `addWellTap` selects the best fit termination cells from this list and inserts them at the top and bottom of well tap column segment. The existing non-termination well taps are deleted as needed. If the well tap columns have already been terminated with a valid termination cell, the existing termination cell are kept in the incremental run and no changes are made. **Note:** It is recommended that well tap columns are added before termination cell insertion. **Note:** This parameter must be specified for termination tap cell insertion.
`-top_termination_cell` *cell_list*	Specifies the list of termination cells to be used at the top.
`-vertical_boundary_spacing` *spacing_with_well_tap*	Specifies vertical boundary spacing with well tap. `addWellTap` will recognize all vertical boundaries and keep center of tap cells to these boundaries equal to or less than the specified distance when inserting. *Minimum*: -1 *Maximum*: 1.79769313486232e+308
`-wellCutCell` list_of_well_cut_cells	Specifies the list of cells with the well cuts. The `addWellTap -incremental` flow treats cells specified in this list as placement blockage because they cut the row and fix the latch up violations within them.

Examples

- The following command places instances of well-tap cell `xyz` on every row in the design. Instances in the same row are at least 22.50 µm but no more than 50 µm apart. Each instance name is prefixed with `welltap_`.

  ```
  addWellTap -cell xyz -prefix welltap -cellInterval 50
  ```

- The following commands place instances of well-tap cell `xyz` in a checkered pattern. The first instance in the odd row numbers (`1`, `3`, `5`, and so on) is placed at `0` (zero) offset. The first instance in even row numbers (2, 4, 6, and so on) is placed at 50 µm offset. Instances in the same row are at least 45 µm but no more than 100 µm apart. Instances on the odd rows are named `wtap_odd_1`, `wtap_odd_2`, and so on. Instances on the even rows are named `wtap_even_1`, `wtap_even_2`, and so on.

  ```
  addWellTap -cell xyz -prefix wtap_odd -cellInterval 100 -skipRow 1
  addWellTap -cell xyz -prefix wtap_even -cellInterval 100 -skipRow 1 \
      -startRowNum 2 -inRowOffset 50
  ```

- The following command places instances of well-tap cell `WTAP` on every row in the design.Before placing the instances, the software checks for cells named `WTAP` and `PSO1`, and if it finds any within the minimum gap (that is, 21.68 µm from the nearest well-tap cell in that row) it does not place any instances in that area.

  ```
  addWellTap -cell WTAP -incremental "WTAP PSO1"
  ```

- In the following commands, cell TAP is specified as general well tap and TAP_TERMINATION is specified as termination well tap. TAP cells and tap columns are inserted first, followed by TAP_TERMINATION cells as termination cells at the top and bottom of each TAP column.

  ```
  addWellTap -cell TAP -cellInterval 28

  addWellTap -termination_cell TAP_TERMINATION -column_cell TAP
  ```

- The following command places well tap cell `xyz` on both boundary layer region and dense layer region with different rules.

  ```
  addWellTap -insert_cells { { xyz rule 22.5 boundary_layer B1 boundary_rule 5 } { xyz dense_layer D1 dense_rule 8
  }}
  ```

change_IB_cell_site_name

```
change_IB_cell_site_name
[-help]
[-NF site_name]
[-NNF site_name]
[-PF site_name]
[-PPF site_name]
[-new site_name]
[-original site_name]
[-vertical]
```

Change sites for the cells whose site definitions do not match the site definitions used by Innovus. This is applicable only for specific nodes.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `change_IB_cell_site_name` parameter. For a detailed description of the command and all of its parameters, use the man command: `man change_IB_cell_site_name`
`-NF site_name`	Specifies the site name of the N-filler cell.
`-NNF site_name`	Specifies site name of NN-filler cell.
`-PF site_name`	Specifies the site name of the P-filler cell.
`-PPF site_name`	Specifies site name of PP-filler cell.
`-new site_name`	Specifies the new site name of the IB cell
`-original site_name`	Specifies the original site name of the IB cell.
`-vertical`	Is IB transform.

check_base_layer_density

```
  check_base_layer_density
[-help]
[-layer layerName]
[-site_parameter sitePara]
```

Checks the CPODE density by the defined pattern.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `check_base_layer_density` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man check_base_layer_density`.
`-layer layerName`	Specifies the layer name for the base layer density check.
`-site_parameter sitePara`	Specifies the site parameter of the CPODE layer. The site parameters of the CPODE layer include: • `shape_num`: Number of the CPODE shape • `site_num`: Number of the site in row. • `step`: Number of stepping The tool checks the CPODE number of consecutive `site_num` sites by every `step` steps. The CPODE number should be less than the defined `shape_num`. Otherwise, the tool will give a violation.

Example

- In the following example, the command checks the CPODE in the number of consecutive 3 sites by every 1 step. The CPODE number should less than 4.

```
check_base_layer_density -site_parameter  {4 4 1}  -layer  CPODE

Number of CPODE:3

Number of site in row:3

Number of stepping:1
```

- In the following example, the command checks the CPODE number of consecutive 2 sites by every 1 step. The CPODE number should less than 4.

```
check_base_layer_density -site_parameter  {5 4 1} -layer  CPODE

Number of CPODE:5

Number of site in row:4

Number of stepping:1
```

check_library

```
  check_library
[-help]
[-place [-cell cell_name|-all_lib_cell][-legal_frequency ] [-file fileName] ]
```

Checks the problematic cells that cause issues such as bad geometries for DRC and bad pin access for routing. You can specify a library cell or a partition cell. It also performs checks for the multi-height cell legal frequency. The report is dumped into an output file.

Parameters

`-all_lib_cell`	Specifies to check all library cells.
`-cell cell_name`	Specifies the cell to check.
`-file fileName`	Specifies the name of the output file.
`-help`	Outputs a brief description that includes type and default information for each `check_library` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man check_library`.
`-legal_frequency`	Specifies to check multi-height cell legal frequency
`-place`	Specifies to do library checking for placement.

Example

- The following command checks the `buf01` cell:

```
check_library -place -cell buf01

Estimated cell power/ground rail width = 0.021 um

*info: running library checker ...

*info: total 1 cell checked.

*reporting cell (buf01) ...

reporting cell drc : "legal"

reporting cell pin access : "legal"

reporting cell symmetry : cell (buf01) has lef symmetry X Y

reporting cell pin alignment : "legal"

reporting cell legal frequency ...
cell (buf01) legalization frequency: one legal location out of every 1.25 sites
```

checkFiller

```
checkFiller
[-help]
[-area llx lly urx ury]
[-file fileName]
[-horizontal_max_length]
[-powerDomain power_domain_name]
[-vertical_stack_max_length]
[-reportGap microns | -adjacentFiller1]
```

Checks for locations that are missing filler cells, after adding the cells with the addFiller command. Optionally, generates a report with details on sites that are missing filler cells. It also does the static check, and reports the CPODE Group Spacing violation if the distance of the two CPODE groups is less than $value. The distance of the two groups should be greater than or equal to $value.

If you run this command without any parameters, it reports the total number of sites in the core area that are missing filler cells.

Parameters

`-adjacentFiller1`	Checks for locations that are filled with adjacent one-site-width fillers. With this parameter, `checkFiller` flags any one-site-width filler placed next to each other as a violation. To enable this parameter, you must first specify a one-site-width filler by using the following command: `setFillerMode -core fillerCellList`
`-area {llx lly urx ury}`	Specifies a bounding box for the area in which to check for missing filler cells. *Default:* Entire core area
`-file fileName`	Writes the output of the `checkFiller` command to the specified file.
`-horizontal_max_length`	Checks if the horizontal stack length violates max limit.
`-help`	Outputs a brief description that includes type and default information for each `checkFiller` parameter. For a detailed description of the command and all of its parameters, use the man command: `man checkFiller`.
`-powerDomain power_domain_name`	Checks for missing filler cells in the specified power domain. The software checks for missing filler cells in all power domains if you do not specify this parameter.
`-reportGap microns`	Checks only for gaps of the specified size--ignores any other gap, whether larger or smaller.
`-vertical_stack_max_length`	Checks if the vertical stack length violates the max limit.

Examples

The following command checks the entire core area after running `addFiller` and reports the number of sites that are missing filler cells:

```
checkFiller
```

The software reports the following:

```
*INFO: Total number of gaps found: 85
```

The following command checks within the specified bounding box at coordinates {0 0 100 100} and reports the number of sites that have a gap of exactly 0.14 microns:

```
checkFiller -reportGap 0.14 -area {0 0 100 100}
```

The software reports the following:

```
*INFO: Total number of 0.140 microns width gap found: 3
```

Related Information

- addFiller
- setFillerMode

checkPlace

```
checkPlace
[violationReportFileName]
[-clearMarker]
[-honorPrerouteForFiller]
[-ignoreFillerInUtil]
[-ignoreOutOfCore]
[-inst list_of_instances]
[-ioPinBlockage]
[-macroBlockage]
[-noCheckPinAccess]
[-noHardFence]
[-noHalo]
[-noPreplaced]
[-selectedOnly]
```

Checks `FIXED` and `PLACED` cells for violations, adds violation markers to the design display area, and generates a violation report. Use the Violation Browser to see the violation markers.

This command considers preplaced instances and macros as `FIXED`.

Note: The utilization value reported by `checkPlace` and the density value reported by `timeDesign` might differ because `checkPlace` considers padding when calculating utilization but `timeDesign` does not consider padding when calculating density.

You can delete padding by running the `deleteAllCellPad` command before running `checkPlace`.

Note: If `setPlaceMode -place_detail_legalization_inst_gap` is defined, `checkPlace` will report the gaps that violate the specified spacing.

The `checkPlace` command checks for the following violations:

- Implant max cover length. If this violation is detected, GUI adds markers for every instance. As per this violation rule the implant shapes cannot be fully covered horizontally by neighbor shapes on both top and bottom opposite sides. If checkPlace detects the violation, GUI adds markers for every instance
- Region and fence violations (Instances placed outside their region or fence)
- Out of core area violations (Instances placed partly or wholly outside the core area)
- Not placed on placement grid (Standard cells not on the placement grid, or blocks not on the manufacturing grid). If the design is using the FinFET technology, checkPlace will also check if standard cells and blocks are not aligned on the FinFET grid and report violations.
- Row orientation violations (Instances whose orientation is illegal for their row; may short power to ground)
- Tech site violations (Instances placed on tech sites not matching their cells and instances that do not have rows for their tech sites)
- Overlapping with other instance (Placed instances that overlap with other instances)
- Pin access violations (Instances with at least one signal pin that does not have routing access due to pre-wires)
- Orientation violations (Instances whose orientation is not legal based on its cell symmetry rules)
- Routing/placement blockage violations in the core area (Instances placed in an obstruction created by pre-wires or routing blockage)
  The command does not check fixed macros.
- Site orientation violations (Instances whose orientation does not match the tech site orientation)
- Not of fence violations (Instances placed inside a fence to which it does not belong)

- Instance padding violations if `setPlaceMode -place_detail_honor_inst_pad` is set to `true`.
- Standard cells' power-pin connection

In addition to checking for violations, the command reports the following:

- Number of placed instances in the design
- Number of unplaced macros in the design
- Placement density, in terms of used sites over available sites
- Default power domain density

Parameters

`-noCheckPinAccess`	Specifies whether to check for pin access violations.
`-clearMarker`	Removes the violation markers from a previous `checkPlace` run, without rerunning `checkPlace`.
`-honorPrerouteForFiller`	Checks for placement blockage violations on physical instances placed under preroutes or specified by `setPlaceMode -place_detail_preroute_as_obs`. By default, `checkPlace` does not treat filler cells placed under preroutes as violations, even though they are placement/routing blockages; however, it does treat standard cells placed under preroutes as violations.
`-ignoreFillerInUtil`	Ignores filler cells in calculating utilization.
`-ignoreOutOfCore`	Skips instances outside the core design area.
`-inst` *`list_of_instances`*	Specifies the list of instances to check.
`-ioPinBlockage`	Instructs legalization routines to treat top-level I/O pins as fixed metal obstructions while placing standard cell instances at the block level. There is a minor run-time penalty with this parameter, so it is not turned on by default.
`-macroBlockage`	Checks for overlap between hard macro and macro-only blockage and reports macro blockage violation. By default, macro-only blockage is ignored for both hard macro and standard cell. With this setting, it is treated as a placement obstruction for macros.
`-noHalo`	Skips block halos. Uses the place-and-route boundary for the placement overlap check.
`-noHardFence`	Ignores fence and region placement constraints.
`-noPreplaced`	Does not check fixed instances. When this parameter is specified, `checkPlace` treats fixed instances as placement blockages.
`-selectedOnly`	Specifies to check only the selected instances legality.
`violationReportFileName`	Specifies the report file. If you do not specify this parameter, the command displays a summary report. The report file is more detailed than the summary report, and lists every instance with a violation.It contains details on the violations along with a Tcl procedure to select instances based on the violation type.

Note: If a design is loaded where a macro is fixed in an orientation that is not supported according to its LEF, running `checkPlace` changes the orientation and the position of the macro, even if the `-noPreplaced` option is specified. Here is an example:

Cell positions before checkPlace:

```
FPFEL0_SLM/fpicl/fpiclmsc/ThermRemote_FP_1: {544.32 648}
FPFEL0_SLM/fpicl/fpiclmsc/ThermRemote_FP_2: {544.32 669.6}

< CMD> checkPlace
**WARN: (ENCDB-1266): Both given orientation and original orientation not legal,
FPFEL0_SLM/fpicl/fpiclmsc/ThermRemote_FP_1 changes to orientation R0
**WARN: (ENCDB-1266): Both given orientation and original orientation not legal,
FPFEL0_SLM/fpicl/fpiclmsc/ThermRemote_FP_2 changes to orientation R0
Design has 3 cells with cell padding or block halo.
Begin checking placement ... (start mem=690.9M, init mem=714.5M)
*info: Placed = 1098
*info: Unplaced = 0
Placement Density:0.00%(0/407468)
Finished checkPlace (cpu: total=0:00:07.6, vio checks=0:00:00.0; mem=696.2M)
```

Cell positions after checkPlace:

```
FPFEL0_SLM/fpicl/fpiclmsc/ThermRemote_FP_1: {544.446 648}
FPFEL0_SLM/fpicl/fpiclmsc/ThermRemote_FP_2: {544.446 669.6}
```

If few instances are getting overlapped, the report will clearly specifies the violation type and list all the instances. Here is an example:

```
#########################################################

## Total instances with placement violations: 5

#########################################################

## Insts placed overlapping with other insts (5) ##

#########################################################

### 4 (Preplaced) Overlapping with other instance>

set pchkOverlapFixedList [list \

clearScanDisplay

```
clearScanDisplay
[-help]
[chain_name]
```

Removes scan chains from the display.

Parameters

chain_name	Specifies the scan chain to remove from the display. *Default:* Removes all scan chains from the display.

Related Information

- Placing the Design chapter in the *Innovus User Guide*
  - Optimizing and Reordering Scan Chains

clearSpareCellDisplay

```
clearSpareCellDisplay
```

Removes spare cell instances from the display.

Parameters

None

clonePlace

```
  clonePlace
[-help]
[-clone_list cloneinstance(s)orientation(s)]
[-master_inst instance name]
```

Places all clone instances with relative location and relative orientation according to the master partition instances. Adjusts instance orientation based on the clone orientation. Use this command after running `place_design`.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `clonePlace`. For a detailed description of the command and all of its parameters, use the man command: `man clonePlace`
`-clone_list` *`cloneinstance(s)orientation`*	Specifies clone instances with relative location.
`-master_inst` *`instance name`*	Specifies the master partition instance.

Related Information

- `place_design`

congRepair

```
congRepair
-help
-area llx lly urx ury
```

Relieves the congestion of the design. This command performs incremental placement based on early global route congestion results and improves the congestion hot spots by spreading out the cells. It is mostly used after `place_design`, but sometimes it can be used after pre CTS optimization as well. Since this command tends to move many cells around, it should not be run after post CTS optimization.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `congRepair` . For a detailed description of the command and all of its parameters, use the man command: `man congRepair`
`-area` *`llx lly urx ury`*	Specifies the area in which `congRepair` will run. • *`llx:`* Specifies the area's lower left x coordinate. • *`lly:`* Specifies the area's lower left y coordinate. • *`urx:`* Specifies the area's upper right x coordinate. • *`ury:`* Specifies the area's upper right y coordinate. **Note**: If you do not specify this option, `congRepair` will run on the complete design.

Related Information

create_inst_space_group

```
create_inst_space_group
[-help]
groupName
-inst listOfInstances
{[{[ -spacing_y Distance] [-spacing_x Distance]} [-checking_box {all|cross_only}]] | [-spacing_radial Distance]}
```

Creates space group for instances with a specific vertical or horizontal-distance constraint.

The `create_inst_space_group` information can be saved in DB.

Parameters

`-checking_box {all cross_only}`	Checks all area or the intersection area from `-spacing_x` and `-spacing_y`. • `cross_only`: Checks the intersection area of -`spacing_x` and -`spacing_y`. If any instance violates both -`spacing_x` and -`spacing_y`, it is marked as a violation. • `all`: Checks all area covered by `spacing_x` and `spacing_y`. If any instance violates -`spacing_x` or -`spacing_y`, it is marked as a violation. The constrained box is ended by core/blockage/power domain/hard macro/row boundary. *Default*: `cross_only`
groupName	Specifies the name of the group.
`-help`	Outputs a brief description that includes type and default information for each `create_inst_space_group` parameter. For a detailed description of the command and all of its parameters, use the man command: `man create_inst_space_group`.
`-inst` *listOfInstances*	Specifies all instances that belong to the same space group by name.
`-spacing_radial` *Distance*	Specifies the radial distance, in microns.
`-spacing_x` *Distance*	Specifies the distance, in microns, between each specific instance in the X direction.
`-spacing_y` *Distance*	Specifies the distance, in microns, between each specific instance in the Y direction.

createGAFillerGroup

```
createGAFillerGroup
[-help]
-ga_cells gaCellList
-ga_fillers gaFillerCellList
-group groupName
```

It creates gate array filler groups for the post-mask `ecoPlace` flow. When a filler group is created, `ecoPlace -place_detail_use_GA_filler_groups true` can only place the GA cells at the GA filler location that is included in the same filler group.

This command can be used multiple times to define several gate array groups for `ecoPlace`. If one filler group name is defined many times, the last one will be kept.

Parameters

`-ga_cells gaCellList`	Specifies the list of GA cells. The * wildcard is supported to specify the cell list.
`-ga_fillers gaFillerCellList`	Specifies the list of GA filler cells. **Note**: One GA cell or GA filler cell cannot be defined in two groups, otherwise it will give error.
`-group groupName`	Specifies the group name.

Example

The following commands show the flow for GA Filler groups:

```
innovus> createGAFillerGroup -ga_cells <GA_cell_list> -ga_fillers <GA_filler_list> -group <group>
innovus> ecoPlace -place_detail_use_GA_filler_groups true
```

Related Information

- `deleteGAFillerGroup`
- `ecoPlace`

createPipelineBusGuide

```
createPipelineBusGuide
[-help]
[-netGroup netGroupNames]
[-widthFactor value]
[-layer id1:id2]
[-report fileName]
[-spacing value {-report filename}]
```

Generates bus-guide for the pipeline netgroup. The bus-guide is used to guide the router for expected path. It can be used in the analysis flow or after the pipeline flops are inserted in the netlist.

Note: The bus-guide width is scalable by the width factor. Default width factor is 1.0. The bus width equals to the (width factor) x (the largest pitch of given routing layers) x (the number of bus bits) + 1 extra pitch. The extra pitch is added to account for the possibility that bus-guides do not line up exactly with the routing grid.

Parameters

`-netGroup netGroupNames`	Specifies the netgroup name(s) that the bus-guide is created for. Default: `""`
`-widthFactor value`	Specifies the width factor of bus-guide. Default: `1.0`
`-layer id1:id2`	Specifies the layer(s) to use for the generated bus-guide. It can be a single layer or layer range. Default: `all`
`-report fileName`	Specifies the analysis report file name. Default: `<filename>.rpt`
`-spacing float`	Specifies the maximum space between flops. Default: `""`

Example

- The following command writes out a report file 'busguide.rpt' which tells the total estimated length of bus (in microns), the number of stages that will be needed (based on the given spacing of 200 um), and location of each stage of PFFs for all net groups on all routing layers.
  ```
  createPipelineBusGuide -spacing 200 -report busguide.rpt
  ```
- The following command create bus-guide for net group 'NG1' on routing layers 2, 3, and 4. The bus-guide width is 2 times the default width.
  ```
  createPipelineBusGuide -netGroup NG1 -widthFactor 2.0 -layer 2:4
  ```

Related Information

- createPipelineNetGroup
- deletePipelineNetGroup
- modifyPipelineNetGroup

createPipelineNetGroup

```
createPipelineNetGroup
[-help]
netGroupName
[-endReserve reserveDistanceInMicrons]
[-endTerm termList]
[-inst instNameListOrRegularExp]
[-net listOfNetnamesOrRegularExp]
[-startReserve reserveDistanceInMicrons]
[-startTerm termList]
```

Creates Net Groups for Pipeline Flip-Flop (PFF) Placement and Reporting. This command can be used for analysis before the flops exist in the netlist; or it can be used post flop insertion to add a new net group.

Parameters

`-endReserve reserveDistanceInMicrons`	Specifies a distance value from the end points on block boundary to the internal connection inside the block, which is accounted for in each stage distance value. The unit is in micron.
`-endTerm termList`	Specifies the end points of net groups.
`netGroupName`	Specifies the name of the net group.
`-inst instNameListOrRegularExp`	Creates net group of all nets connected to the given instances. All the instances must be flip-flops or latches. All the nets attached to the D and Q pins are put into the PFF net group.
`-net listOfNetNamesOrRegularExp`	Creates net group of all given nets.
`-startReserve reserveDistanceInMicrons`	Specifies a distance budget from internal connections inside block to the start point of the PFF net. This value is added to the first stage distance when calculating equidistant spacing for each stage. The unit is in micron.
`-startTerm termList`	Creates net group of all data nets between the given end points. The PFF-chain is traced from the startTerm, through D and Q terminals of PFF(s) until an endTerm is matched.

Example

- The following command creates a net group named `netGroup1' for Pipeline Flip-Flop (PFF) of all data nets between `blockA/DATA_OUT*` and `blockB/DATA_IN*`:

  ```
  createPipelineNetGroup netGroup1 -startTerm blockA/DATA_OUT* -endTerm blockB/DATA_IN*
  ```

- The following command creates a net group named `netGroup2` for all nets connected with all instance names that begin with `PIPELINE_INST/in`:

  ```
  createPipelineNetGroup NetGroup2 -inst PIPELINE_INST/in*
  ```

- The following command creates a net group named `netGroup3` for all net names that begin with `SUM_P4`.

  ```
  createPipelineNetGroup NetGroup3 -net SUM_P4*
  ```

Related Information

- deletePipelineNetGroup
- modifyPipelineNetGroup

createSpareModule

```
createSpareModule
[-help]
-moduleName moduleName
-cell {cellName [number] [cellName [number] ] …}
[-clock netName]
[-reset netName:pinName [pinName] …]
[-tie {tieCellName [tieCellname] } ]
[-tieLo {pinList | *} ]
[-useCellAsPrefix]
```

Creates a spare module made up of the specified cells.

Parameters

`-cell cellName {[number] [cellName [number] ]}`	Specifies the names of the cells, and the number of each, to add to the spare module. If you do not specify the number of cells to add, the `setTieHiLoMode -maxFanOut` parameter controls the number of cells.
`-clock netName`	Specifies a clock net to connect to the clock pins of the instances in the spare module.
`-help`	Outputs a brief description that includes type and default information for each `createSpareModule` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man createSpareModule`.
`-moduleName moduleName`	Specifies a name for the spare module.
`-reset netName:pinName [pinName]`	Specifies a net and the pins to connect to the reset pins of sequential spare cells in the spare module. If you do not specify this parameter, these reset pins are not connected.
`-tie tieCellName [tieCellName]`	Specifies tie-high and tie-low cells to add to the spare module. The software recognizes whether the pins are high or low.
`-tieLo {pinList | *}`	Specifies the pins to connect to the specified tie-low cell. Pins not specified here will be connected to `1'b1` or the tie-high cell. If no tie-low cells are specified with the `-tie` parameter, it connects the pins to `1'b0`. Use the following format for the pin list: • *pinList*: {*cellName*:*pin*} … • `*` : Specify the pin name and it could be *.
`-useCellAsPrefix`	Adds the master cell name as a prefix to the name of gates that are instantiated inside the module. The software adds `spr_gate_n` as a prefix by default; when you specify `-useCellAsPrefix`, it prepends the master cell name to the default prefix.

Examples

- The following command creates spare module `mod1` with cells `cellA`, `cellB`, and `tiehi4`:

  ```
  createSpareModule -cell {cellA cellB} -tie tiehi4 -moduleName mod1
  ```

- The following command creates spare module `mod1` with the following gates: `and_spr_gate_1`, `and_spr_gate_2`, `nand_spr_gate_1`, `nor_spr_gate_1`:

  ```
  createSpareModule -cell {and 2 nand nor} -moduleName mod1 -useCellAsPrefix
  ```

Related Information

- `deleteSpareModule`
- `placeSpareModule`

delete_cell_stack_area

```
delete_cell_stack_area
[-help]
[-cell cell_name]
[-group group_name]
```

Deletes the cell stack area definition.

Parameters

`-cell cell_name`	Specifies the cell(s) for which the cell stack area definition needs to be deleted.
`-group group_name`	Specifies the group(s) for which the cell stack area definition needs to be deleted.
`-help`	Outputs a brief description that includes type and default information for each `delete_cell_stack_area` parameter. For a detailed description of the command and all of its parameters, use the man command: `man delete_cell_stack_area`

Related Information

- `report_cell_stack_area`
- `specify_cell_stack_area`

delete_cell_stack_group

```
delete_cell_stack_group
[-help]
[-name group_name]
```

Deletes cell stack group definition.

Parameters

`-name group_name`	Specifies the group(s) for which the cell stack group definition is to be deleted.
`-help`	Outputs a brief description that includes type and default information for each `delete_cell_stack_group` parameter. For a detailed description of the command and all of its parameters, use the man command: `man delete_cell_stack_group`

Related Information

- `report_cell_stack_group`
- `specify_cell_stack_group`

delete_cell_virtual_align

```
delete_cell_virtual_align
[-help]
[-cell cells]
```

Deletes the cells that need to be virtually aligned.

Parameters

-cell *cells*	Specifies the lib cells that require virtual alignment.
-help	Outputs a brief description that includes type and default information for each `delete_cell_virtual_align` parameter. For a detailed description of the command and all of its parameters, use the man command: `man delete_cell_virtual_align`

Related Information

- `report_cell_virtual_align`
- `specify_cell_virtual_align`

delete_inst_space_group

```
delete_inst_space_group
[-help]
groupName
```

Deletes instance space group by a specific group name.

Parameters

groupName	Specifies the name of the group.
-help	Outputs a brief description that includes type and default information for each `delete_inst_space_group` parameter. For a detailed description of the command and all of its parameters, use the man command: `man delete_inst_space_group`.

Related Topics

- `create_inst_space_group`
- `report_inst_space_group`

delete_pg_keepout

```
delete_pg_keepout
[-help]
{-cell lib_cell_name | -inst instance_name | -all }
[-layer layer_name | -layerId layer_id]
```

Deletes PG keep out boxes in design for user defined objects.

Parameters

`-all`	Removes all PG keepout boxes in design.
`-cell` *`lib_cell_name`*	Specifies the lib cell to remove the PG keepout box applied to the specified cell.
`-help`	Outputs a brief description that includes type and default information for each `delete_pg_keepout` parameter. For a detailed description of the command and all of its parameters, use the man command: `man delete_pg_keepout`
`-inst` *`instance_name`*	Specifies the instance to remove the PG keepout box applied to the specified instance.
`-layer` *`layer_name`*	Specifies the names of the layers to delete the PG keepout box applied on the specified metal layers.
`-layerId` *`layer_id`*	Specifies the layer IDs to delete the PG keepout box applied on the specified metal layer.

Related Information

- `report_pg_keepout`
- `specify_pg_keepout`

deleteAllCellPad

`deleteAllCellPad`

Removes placement padding specified by `specifyCellPad` for all cells. If you run this command before running `checkPlace`, `checkPlace` does not consider the cell padding when calculating effective utilization.

Parameters

None

Examples

The following set of commands specifies the cell padding for `HDSDFRSPQ1` and `HDSDFRSPQ2`, and then deletes all padding by using `deleteAllCellPad`:

```
specifyCellPad HDSDFRSPQ1 2
specifyCellPad HDSDFRSPQ2 2
deleteAllCellPad
```

Related Information

- `checkPlace`
- `specifyCellPad`
- Placing the Design chapter in the *Innovus User Guide*
    - Adding Padding

deleteAllScanCells

```
deleteAllScanCells
[-help]
```

Unassigns all assigned scan cells. This command can be called after importing the design if there are scan cell specifications in library; or else it can be used after the `specifyScanCell` command.

Parameters

None

Example

The following set of commands deletes all scan cells after loading design:

```
restoreDesign init.enc.dat top
deleteAllScanCells
```

Related Information

- Placing the Design chapter in the *Innovus User Guide*
    - Optimizing and Reordering Scan Chains

deleteCellEdgeSpacing

```
deleteCellEdgeSpacing
[-help]
edgeType1
edgeType2
```

Deletes the spacing rule between two edge types. The edge types specified must be predefined.

Note: This command only deletes the cell edge constraint specified by Tcl and does not delete the edge spacing defined in LEF.

Parameters

edgeType1	Specifies edge type1 for edge spacing.
edgeType1	Specifies edge type2 for edge spacing.
-help	Outputs a brief description that includes type and default information for each `deleteCellEdgeSpacing` parameter. For a detailed description of the command and all of its parameters, use the man command: `man deleteCellEdgeSpacing`.

Related Information

- `report_cell_edge_spacing`
- `specifyCellEdgeSpacing`

deleteCellEdgeType

```
deleteCellEdgeType
[-help]
-cell cellName
-edgeType edgeType
```

Deletes the cell edge type constraint of the specified cell.

Parameters

`-cell cellName`	Specifies cell name to remove constraint.
`-edgeType edgeType`	Specifies the name of edge type to be removed.
`-help`	Outputs a brief description that includes type and default information for each `deleteCellEdgeType` parameter. For a detailed description of the command and all of its parameters, use the man command: `man deleteCellEdgeType`.

Related Information

- `report_cell_edge_type`
- `specifyCellEdgeType`

deleteCellPad

```
deleteCellPad
[-help]
cellNames
```

Deletes the padding for a cell or list of cells. If a regular expression or a list of cells is provided, this command returns the number of cells for which the padding was deleted.

Parameters

cellNames	Specifies the cell name for which padding has to be deleted. The cell name can be a regular expression, or a list of cell names or expressions.
-help	Outputs a brief description that includes type and default information for each `deleteCellPad` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man deleteCellPad`.

Examples

- The following command deletes padding for the cells with prefix `FF_SCAN`:
  ```
  deleteCellPad FF_SCAN*
  ```
- The following command deletes padding for all cells that have names starting with `BUF`, `INV`, and `DLY`. If a matched cell name does not have padding information, it is ignored without any message.
  ```
  deleteCellPad {BUF* INV* DLY*}
  ```
- The following command deletes padding for cell `FF_SCAN1` and cell `FF_SCAN2`:
  ```
  deleteCellPad {FF_SCAN1 FF_SCAN2}
  ```

Related Information

- `reportCellPad`
- `specifyCellPad`

deleteFiller

```
deleteFiller
[-cell fillerCellList]
[-area {llx lly urx ury}]
[-inst instanceName]
[-prefix prefix]
[-keepFixed]
```

Removes physical cell instances, such as filler cells, end-cap cells, and well-tap cells, from standard cell rows. This command can be called if there are filler cells, end-cap cells, or well-tap cells added in the design.

⚠ Physical cells should not be removed with the `<Delete>` key. If you delete a cell using the `<Delete>` key, the cell will become unplaced. The cell will not be displayed in the layout, but it will still be part of the design. You should remove a physical cell using the `deleteFiller` command.

ⓘ Some `deleteFiller` parameters can also be specified with `setFillerMode`. However, the parameters you specify with `deleteFiller` apply to the current `deleteFiller` run only, and supersede parameters set by `setFillerMode`. For more information, see `setFillerMode`.

Parameters

`-area {llx lly urx ury}`	Specifies the bounding box within which the filler cells are deleted. The argument type is a box, in microns. **Note:** Only those filler cells that are completely contained within the area will be deleted. the command does not delete filler cells that cross the area boundary.
`-cell` *`fillerCellList`*	Specifies a cell name or list of cells to delete. Separate cell names with spaces. **Note:** Cells specified by this parameter override the list of cells provided by the `-core` parameter of `setFillerMode`.
`-keepFixed`	Controls the command to keep the End-cap and Well-tap cells that are marked FIXED. By default, those cells will be deleted if this option is not specified. Deletes End-cap and Well-tap cells by default, though they are marked as `FIXED`. *Default:* `true`
`-prefix` *`prefix`*	Specifies the prefix of the cell instances to delete. For example, to delete all filler cell instances with the prefix `FILL`, type the following command: `deleteFiller -prefix FILL` The software will remove all physical instances whose name starts with `FILL`, including instances named `FILL_1`, `FILLTEMP_1`, and so on. Default: `FILLER`
`-inst` *`instanceName`*	Specifies the instance of the cell to delete. You can use wildcards (`*?`) with this parameter. **Note:** You can specify this parameter with this command or with `addFiller`, and not with `setFillerMode`.

Examples

- The following command deletes all physical-only cells from the design:
  ```
  deleteFiller -cell xyz
  ```
- The following command deletes only the `xyz` cells whose instance names have a `wtap_even` prefix. If well-tap cells in even rows have a `wtap_even` prefix and well-tap cells in odd rows have a different prefix, the cells in rows `2`, `4`, `6`, and so on are deleted.
  ```
  deleteFiller -cell xyz -prefix wtap_even
  ```
- The following command deletes all added cell instances with the prefix instance name `FILLER`:
  ```
  deleteFiller -prefix FILLER
  ```
- The following command deletes all instances of filler cell `FILL2`, end-cap `ecp17`, and well-tap `wtp5`:
  ```
  deleteFiller -cell FILL2 ecp17 wtp5
  ```
- The following command deletes all instances of given the spacer cells from the design:
  ```
  deleteFiller -cell FILL64 FILL32 Fill8 FILL16 FILL2 FILL1
  ```
- The following command deletes all well-tap and end-cap cell instances from the design:
  ```
  deleteFiller -cell WELLTAP PRECAP POSTCAP
  ```
- The following command deletes all physical cells with prefix `WELLTAP` in the specified bounding box of {0 0 300 300} except those cells with `FIXED` status:
  ```
  deleteFiller -prefix WELLTAP -area {0 0 300 300} -keepFixed
  ```
- The following command deletes all physical cells with prefix WELLTAP in the specified bounding box of `{0 0 300 300}`, except those cells with `FIXED` status:
  ```
  deleteFiller -prefix WELLTAP -area {0 0 300 300} -keepFixed
  ```

Related Information

- `addFiller`
- `setFillerMode`

deleteGAFillerGroup

```
deleteGAFillerGroup
[-help]
groupName
```

Deletes the gate array filler groups created by `createGAFillerGroup`.

Parameters

groupName	Specifies the name of the group to be deleted. The * wildcard is supported.

Related Information

- `createGAFillerGroup`
- `ecoPlace`

deleteInstPad

```
deleteInstPad
[ instName | -all]
-suppress
```

Deletes the padding for the specified instances, or all instance-based padding, in the design.

Parameters

instName	Deletes the padding on the specified instance.
-all	Deletes all instance-based padding.
-suppress	Suppresses verbose messages. The option is of type boolean and is optional.

Examples

- The following command deletes padding for all instances in the design:
  ```
  deleteInstPad -all
  ```

  It outputs following:

  ```
  ...

  Delete Padding for Instant [U27312].

  Delete Padding for Instant [U27313].

  Delete Padding for Instant [U27314].

  Delete Padding for Instant [U27315].

  16432
  ```

- The following command deletes padding for one instances named `U27316`:
  ```
  deleteInstPad U27316
  ```

  It outputs following:

  ```
  Delete Padding for Instant [U27316].
  ```

Note: `deleteInstPad` deletes padding for either all instances or single instance. Wildcard is not supported yet.

Related Information

- `reportInstPad`
- `specifyInstPad`
- Placing the Design chapter in the *Innovus User Guide*

- Adding Padding

deleteMimCap

```
deleteMimCap
[-help]
[{[-cell cellName] [-prefix prefixName]} [-area llx lly urx ury]]
```

Deletes the mim caps from the design based on cell type or prefix. This command can be used after `addMimCap`.

Parameters

`-area llx lly urx ury`	Deletes only the Mim caps that are in the specified box. The `-cell` or `-prefix` options are required when this option is specified.
`-cell cellType`	Deletes the mim caps by cell type.
`-help`	Outputs a brief description that includes type and default information for each `deleteMimCap` parameter. For a detailed description of the command and all of its parameters, use the man command: `man deleteMimCap`.
`-prefix prefixName`	Deletes the mim caps by prefix.

Examples

- The following command deletes the mim cap cell `mim_cell1`:

  ```
  deleteMimCap -cell mim_cell1
  ```

Related Information

- `addMimCap`

deletePipelineNetGroup

```
deletePipelineNetGroup
[-help]
netGroupName
```

Deletes pipeline net groups including the subgroups created inside the net groups.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `deletePipelineNetGroup` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man deletePipelineNetGroup`.
`netGroupName`	Specifies the name of the net group.

Example

- The following command deletes a net group named `` `netGroup1' ``:

  ```
  deletePipelineNetGroup netGroup1
  ```

Related Information

- `createPipelineNetGroup`
- `modifyPipelineNetGroup`
- `reportPipeline`

deleteScanCell

```
deleteScanCell
[-help]
[cellName]
```

Removes the scan cell specification from a library cell. This command can be called after importing design if there are scan cell specifications in library; or else it can be used after `specifyScanCell`.

Parameters

cellName	Specifies the cell from which to remove the scan specification.

Example

The following command removes the scan specification from the cell named `FF_SCAN`:

```
deleteScanCell FF_SCAN
```

Related Information

- `reportScanCell`
- `specifyScanCell`
- Placing the Design chapter in the *Innovus User Guide*
  - Optimizing and Reordering Scan Chains

deleteScanChain

```
deleteScanChain
[-help]
[chainName]
```

Removes a scan chain specification from the design. Use this command if there is scan chain specified or traced.

When you are debugging a new scan chain specification, it is useful to delete all scan chains and start over.

Parameters

chainName	Specifies the name of the scan chain to remove from the design. If you do not specify a scan chain name, the command deletes all scan chains.

Example

The following commands load the scan information from a DEF file, remove the scan chain ABC, and output the scan information to a DEF file:

```
defIn -scanChain
deleteScanChain ABC
defOut -scanChain
```

Related Information

- defIn
- defOut
- displayScanChain
- specifyScanChain
- report_scan_chain
- Placing the Design chapter in the *Innovus User Guide*
  - Optimizing and Reordering Scan Chains

deleteScanChainPartition

```
deleteScanChainPartition
[-help]
{-all | -partition partitionName1 partitionName2 ...}
```

Deletes scan chain partitions. The partitions are used to group scan chains so elements in compatible scan chains can be swapped. The scan chains are then reordered on a per-chain basis.

Specify scan chain partitions with the following command: `specifyScanChainPartition`.

Parameters

`-all`	Deletes all partitions from compatible groups.
`-partition partitionName1 partitionName2 …`	Specifies the partitions to delete.

Example

The following command deletes partition `clk1Domain`:

```
deleteScanChainPartition clk1Domain
```

Related Topics

- `reportScanChainPartition`
- `specifyScanChainPartition`
- Placing the Design chapter in the *Innovus User Guide*
    - Optimizing and Reordering Scan Chains

deleteSpareModule

```
deleteSpareModule hInst Name
```

Deletes the instantiation of a created spare module and all the spare instances under the hinst.

Parameters

hInstName	Specifies the instantiation to delete.

Example

The following code shows the creation of the spare module SPGM, placement of the module and its instances in the design, and deletion of the hInst of "SPGM_spr_1":

```
#create a spare module
createSpareModule -moduleName SPGM -cell {DFFNSRX2 INVX4 \ NOR2X2} -clock sysclk

#instantiation the spare module and place them in the design
placeSpareModule -moduleName SPGM -channel -minWidth 4.7 -maxWidth 10 \ -minLength 11 -stepx 10 -stepy 10 -util 0.6

#delete one instantiation of the spare module
deleteSpareModule top/SPGM_spr_1
```

Related Information

- createSpareModule
- placeSpareModule
- Placing the Design chapter in the *Innovus User Guide*
  - Placing Spare Cells and Spare Modules

displayScanChain

```
displayScanChain
[-help]
[chain_name]
```

Displays a scan chain. You must load the scan information, place the design, and view the design in the Placement view. Use this command after scan chains are traced.

Parameters

chain_name	Specifies the scan chain. *Default:* If you do not specify this parameter, the software displays all scan chains.

Examples

- The following command displays all scan chains in the design:
  ```
  displayScanChain
  ```
- The following command displays the scan chain whose name is `chain0`.
  ```
  displayScanChain chain0
  ```

Related Information

- `defIn`
- `defOut`
- `specifyScanChain`
- `report_scan_chain`
- Placing the Design chapter in the *Innovus User Guide*
  - Optimizing and Reordering Scan Chains

displaySpareCell

`displaySpareCell`

Displays the results of placing the spare instances. You must specify the spare cell types or spare instances before placing the design.

Parameters

None

Examples

The following set of commands displays all spare instances defined by the `specifySpareGate` command:

```
specifySpareGate -cell ADDFXLT1T10
place_design
displaySpareCell
```

Related Information

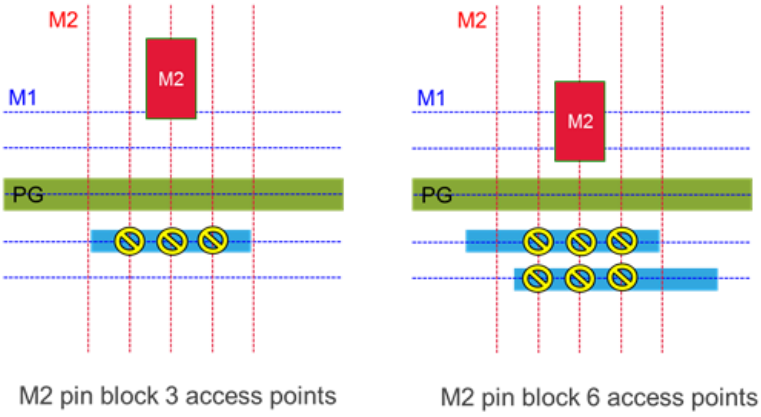
- `place_design`
- `specifySpareGate`

generate_vertical_cell_edge_constraint

```
generate_vertical_cell_edge_constraint
[-help]
{-file tclFile | -updateDB }
[[-check_m2_only ] | [-check_m2_to_m1_only ]]
```

Generates the bottom and top cell edge constraints for 10nm libraries to avoid vertical cell abutment that may cause pin access issue on M1 and M2. The vertical M2 fat PIN or OBS has impact on the abutted cell when it is near to the top and bottom boundaries. It can cause DRC violations between M2 PIN/OBS, block some of the M1 pin access points in the abutted cell, and make router hard to access those M1 PINs.

The following graphic show an example of how fat M2 Pin/OBS may block 3 or 6 access points.



The `generate_vertical_cell_edge_constraint` command generates vertical cell edge constraints based on the cell libraries and LEF rules. Placer is aware of these constraints and avoids the bad placement patterns.

Parameters

`-check_m2_only`	Checks M2 to M2 pins only in abutted 2 cells when generating cell edge constraints.
`-check_m2_to_m1_only`	Checks M2 to M1 pins only in abutted 2 cells when generating cell edge constraints.
`-help`	Outputs a brief description that includes type and default information for each `generate_vertical_cell_edge_constraint` parameter. For a detailed description of the command and all of its parameters, use the man command: `man generate_vertical_cell_edge_constraint`.
`-file tclFile`	Specifies file name to output vertical tcl constraint.
`-updateDB`	Updates the constraints to DB.

Note:

- You must specify `-file` or `-updateDB`.
- The `-file` option is for the debug mode, and you need to source the tcl file to let placer know about the constraints.
- The `-updated` option is for the standard flow usage. It reads the constraints automatically.

get_well_tap_mode

```
 get_well_tap_mode
[-help]
[-avoidAbutment]
[-block_boundary_only]
[-bottom_tap_cell]
[-bottom_termination_cell]
[-cell]
[-channel_offset]
[-check_channel]
[-column_cell]
[-inRowOffset]
[-insert_cells]
[-rule]
[-siteOffset]
[-tap_function_cells]
[-tap_termination_alignment]
[-termination_align]
[-termination_cell]
[-top_tap_cell]
[-top_termination_cell]
[-vertical_boundary_spacing]
[-well_cut_cell]
[-quiet]
[-nonDefault]
```

Returns the information about `set_well_tap_mode` parameters in the Innovus log file and in the Innovus console. Returns the following information:

- Parameter name
- Current value
- Type (Boolean, string, and so on)
- Whether the current value was set by user

If you do not specify a parameter, the software displays values for all of the `set_well_tap_mode` mode parameters.

Related Information

- `set_well_tap_mode`

getDensityMapMode

```
getDensityMapMode
[-gridInMicron]
[-gridInRow]
[-ignoreBlock]
[-ignoreFiller]
[-quiet]
[-threshold]
```

Returns the information about `setDensityMapMode` parameters in the Innovus log file and in the Innovus console. Returns the following information.

- Parameter name
- Current value
- Type (Boolean, string, and so on)
- Source of current value (default, user)

If you do not specify a parameter, the software displays values for all of the `setDensityMapMode` mode parameters.

Related Information

- `setDensityMapMode`
- Placing the Design chapter in *Innovus User Guide*.

getEndCapMode

```
getEndCapMode
[-help]

Returns the information about `setEndCapMode` parameters in the Innovus log file and in the Innovus console. Returns the following information:

- Parameter name
- Current value
- Type (Boolean, string, and so on)
- Source of current value (default, user)

If you do not specify a parameter, the software displays values for all of the `setEndCapMode` mode parameters.

Related Information

[-quiet]
```

Returns the information about `setFillerMode` parameters in the Innovus log file and in the Innovus console. Returns the following information.

- Parameter name
- Current value
- Type (Boolean, string, and so on)
- Whether the current value was set by user

If you do not specify a parameter, the software displays values for all of the `setFillerMode` mode parameters.

Parameters

parameter_names	Returns information for the specified parameters. You can specify one or more parameters. See `setFillerMode` for parameter descriptions.
`-quiet`	Returns the current settings for the specified parameters in Tcl list format only. If you specify `-quiet` without any parameters, the software returns the current settings of all `setFillerMode` parameters in Tcl list format.

Examples

- The following command returns the current setting of the `setFillerMode -core` in the Tcl list format:

  ```
  getFillerMode -core -quiet
  ```

  The software returns the following information:

  ```
  {}
  ```

- The following command returns the current settings for the `-core` and `-corePrefixFILLER`:

  ```
  getFillerMode -core -corePrefix
  ```

  The software returns the following information:

  ```
  -core {} # string, default=""

  -corePrefix FILLER # string, default="",user setting

  {core {}} {corePrefix FILLER}
  ```

- The following command returns the current settings for `setFillerMode-core` and `-corePrefix` in Tcl list format:

  ```
  getFillerMode -core -corePrefix -quiet
  ```

  The software returns the following information:

  ```
  {core {}} {corePrefix FILLER}
  ```

- The following command returns the current settings for all `setFillerMode` parameters in Tcl list format:

  ```
  getFillerMode -quiet
  ```

  The software returns the following information:

  ```
  {add_fillers_with_drc true} {avoid_abutment_patterns {}} {check_signal_drc true} {core {}} {corePrefix {}}
  {createRows true} {diffCellViol false} {distribute_implant_evenly false} {ecoMode false} {fitGap true}
  {honorPrerouteAsObs false} {horizontal_exception_cell {}} {horizontal_max_length 0} {horizontal_repair_cell {}}
  {keepFixed false} {preserveUserOrder false} {scheme locationFirst} {swap_cell {}} {vertical_stack_exception_cell
  {}} {vertical_stack_left_edge_exception_cell {}} {vertical_stack_max_length 0} {vertical_stack_repair_cell {}}
  {vertical_stack_repair_edge ""} {vertical_stack_right_edge_exception_cell {}} {y_flip_type {}}
  ```

Displays the information about `setPlaceMode` parameters in the Innovus log file and in the Innovus console. Displays the following information:

- Parameter name
- Current value
- Type (Boolean, string, and so on)
- Whether the current value was set by user

If you do not specify a parameter, the Innovus software displays values for all of the `setPlaceMode` mode parameters.

Parameters

parameter_names	Returns information for the specified parameters. You can specify one or more parameters. See `setPlaceMode` for description of parameters.
`-quiet`	Returns the current settings for the specified parameters in Tcl list format only. If you specify `-quiet` without any parameters, the software returns the current settings of all `setPlaceMode` parameters in Tcl list format.

Examples

- The following command returns the current setting for the `-place_global_place_io_pins` parameter in Tcl list format:

  ```
  getPlaceMode -place_global_place_io_pins -quiet
  ```

  The software returns the following information:

  ```
  false
  ```

- The following command returns the current settings for the `-place_global_place_io_pins` and -place_global_solver_effort parameters:
  getPlaceMode -place_global_place_io_pins -place_global_solver_effort

  The software returns the following information:

  ```
  -place_global_place_io_pins           # enums={false true}, default=false
  -place_global_solver_effort high        # enums={medium high}, default=high
  ```

```
{-place_global_place_io_pins false} {place_global_solver_effort high}
```

- The following command returns the current settings for all `setPlaceMode` parameters in Tcl list format:

  ```
  getPlaceMode -quiet
  ```

  The software returns the following information:

  {place_design_floorplan_mode false} {place_design_refine_place true} {place_detail_allow_border_pin_abut false} {place_detail_check_cut_spacing false} {place_detail_check_route false} {place_detail_color_aware_legal false} {place_detail_context_aware_legal all} {place_detail_eco_max_distance 0} {place_detail_eco_priority_insts placed} {place_detail_fixed_shifter false} {place_detail_hard_fence true} {place_detail_honor_inst_pad false} {place_detail_io_pin_blockage false} {place_detail_legalization_inst_gap 0} {place_detail_max_shifter_column_depth 9999} {place_detail_max_shifter_depth 9999} {place_detail_max_shifter_row_depth 9999} {place_detail_no_filler_without_implant false} {place_detail_pad_fixed_insts false} {place_detail_preroute_as_obs {}} {place_detail_preserve_routing false} {place_detail_remove_affected_routing false} {place_detail_swap_eeq_cells false} {place_detail_use_check_drc false} {place_detail_use_GA_filler_groups false} {place_detail_use_no_diffusion_one_site_filler false} {place_detail_wire_length_opt_effort medium} {place_global_auto_blockage_in_channel none} {place_global_clock_gate_aware true} {place_global_clock_power_driven false} {place_global_cong_effort auto} {place_global_enable_distributed_place false} {place_global_group_flop_to_macro false} {place_global_group_flop_to_macro_level 1} {place_global_group_flop_to_macro_list {}} {place_global_ignore_scan true} {place_global_ignore_spare false} {place_global_max_density -1} {place_global_module_aware_spare false} {place_global_module_padding {}} {place_global_place_io_pins false} {place_global_reorder_scan true} {place_global_soft_guide_strength low} {place_global_solver_effort high} {place_global_timing_effort medium} {place_global_uniform_density false} {place_opt_post_place_tcl {}}

getScanReorderMode

```
getScanReorderMode
[-addScanPortPrefix]
[-allowSwapping]
[-clkAware]
[-compLogic {true | false}]
[-enable_for_partition]
[-keepPDPorts]
[-keepPort]
[-preferH]
[-preferV]
[-scanEffort]
[-skipMode]
[-quiet]
```

Returns the information about `setScanReorderMode` parameters in the Innovus log file and in the Innovus console. Returns the following information:

- Parameter name
- Current value
- Type (Boolean, string, and so on)
- Source of current value (default, user)

If you do not specify a parameter, the Innovus software returns values for all of the `setScanReorderMode` mode parameters.

Parameters

parameter_names	Returns information for the specified parameter. You can specify one or more parameters. See `setScanReorderMode` parameter descriptions.
`-quiet`	Returns the current settings for the specified parameters in Tcl list format only. If you specify `-quiet` without any parameters, the software returns the current settings of all `setScanReorderMode` parameters in Tcl list format.

Examples

- The following command returns the current setting for the `-keepPDPorts` parameter in Tcl list format:

  ```
  getScanReorderMode -keepPDPorts -quiet
  ```

  The software returns the following information:

  ```
  false
  ```

- The following command returns the current settings for the `-keepPDPorts` and `-preferH` parameters:

  ```
  getScanReorderMode -keepPDPorts -preferH
  ```

  The software returns the following information:

  ```
  -keepPDPorts false # bool, default=false
  ```

```
-preferH false # bool, default=false

{keepPDPorts false} {preferH false}
```

- The following command returns the current settings for the `-keepPDPorts` and `-preferH` parameters in Tcl list format:

  ```
  getScanReorderMode -keepPDPorts -preferH -quiet
  ```

  The software returns the following information:

  ```
  {keepPDPorts false} {preferH false}
  ```

- The following command returns the current settings for all `setScanReorderMode` parameters in Tcl list format:

  ```
  getScanReorderMode -quiet
  ```

  The software returns the following information:

  ```
  {allowSwapping false} {clkAware false} {keepPDPorts true} {keepPort (false)} {preferH false} {preferV false}
  {scanEffort medium} {skipMode skipNone}
  ```

modifyPipelineNetGroup

```
modifyPipelineNetGroup
netGroupName
[{-inst instNameListOrRegularExp |
      -startTerm termList -endTerm termList |
      -net listOfNetnamesOrRegularExp }]
[-startReserve distInMicrons] [-endReserve distInMicrons]
```

Modifies the existing net group attributes or converts an existing net group added during floorplanning to be of type pipeline. This command can be used if there are existing pipe line net groups in the design.

Parameters

`-endReserve` *ReserveDistanceInMicrons*	Specifies a distance value from the end points on block boundary to the internal connection inside the block that needs to be added to the last stage distance, to achieve equidistant spacing. The unit is in micron.
`-inst` *instNameListOrRegularExp*	Modifies net group to add all nets connected to the given instances. The instances must all be flip-flops or latches. All the nets attached to the D and Q pins are put into the PFF net group.
`-net` *listOfNetNamesOrRegularExp*	Creates net group of all given nets.
`-startReserve` *ReserveDistanceInMicrons*	Specifies a distance budget from internal connections inside block to the start point of the PFF net. This value is added to the first stage distance when calculating equidistant spacing for each stage. The unit is in micron.
`-startTerm` *termList*	Modifies net group to add all data nets between the given end points. The PFF-chain is traced from the startTerm, through D and Q terminals of PFF(s) until an endTerm is matched.
`-endTerm` *termList*	Modifies net group to add all data nets between the given end points. The PFF-chain is traced from the startTerm, through D and Q terminals of PFF(s) until an endTerm is matched.
`netGroupName`	Specifies the name of net group.

Example

The following command modifies the existing net group named `netGroup1` between `blockA/DATA_OUT*` and `blockB/DATA_IN*` with a budget distance 10 microns from internal connections inside the blockA to the start point of `DATA_OUT*` :

```
modifyPipelineNetGroup netGroup1 -startTerm blockA/DATA_OUT* -endTerm blockB/DATA_IN* -startReserve 10
```

Related Information

pack_align_macros

```
pack_align_macros
[-help]
```

Pushes macros (or pack of macros) to core corners and marks them fixed.

The `pack_align_macros` command executes the following two steps:

- Aligns macros of the same size (initially placed together) on the entire design.
- Pushes macros (or pack of macros) to core corners and marks them fixed.

The `pack_align_macros` command honors the following rules of `set_macro_place_constraint`.

- Min space to macro
- Min space to core
- Forbidden space to macro
- Forbidden space to core
- Avoid abut macro edge with pins
- Macro corner keepout

Figure 1: Macros before running `pack_align_macros`

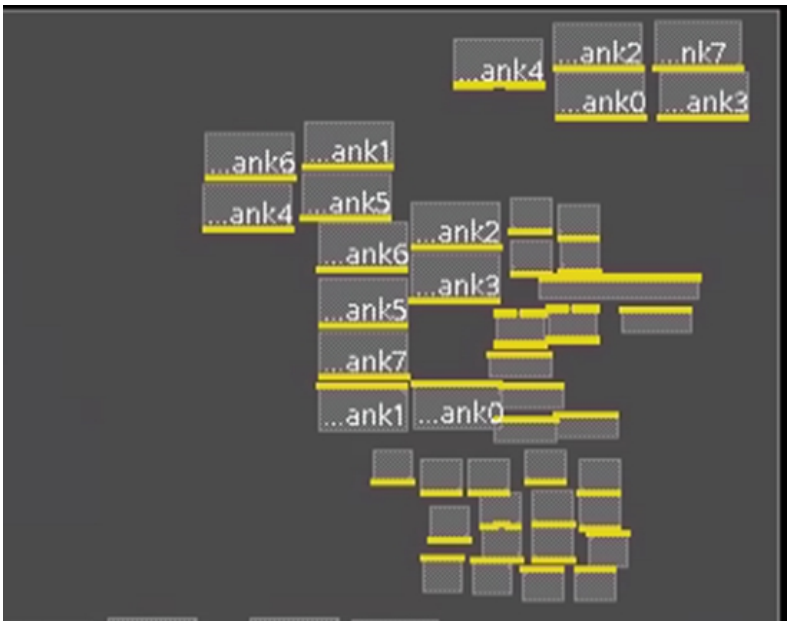

Figure 2: Macros aligned after running `pack_align_macros`

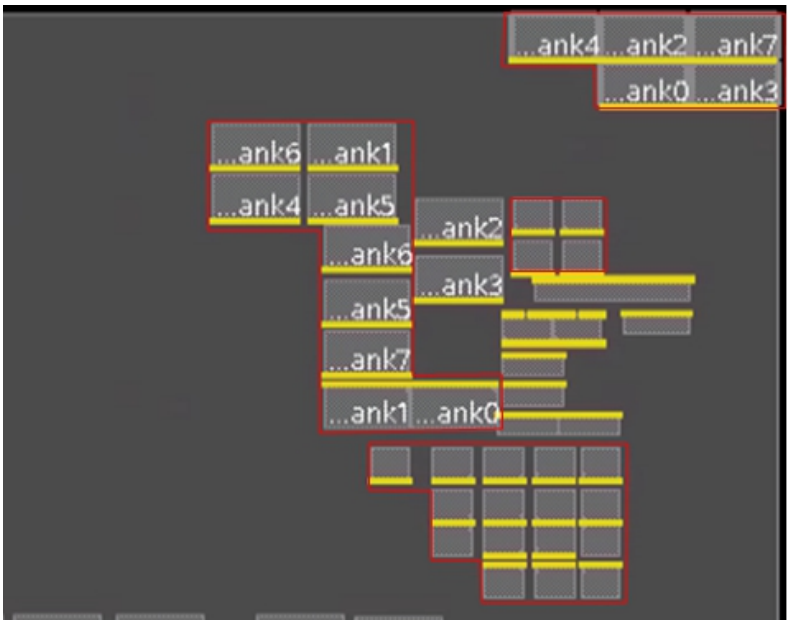
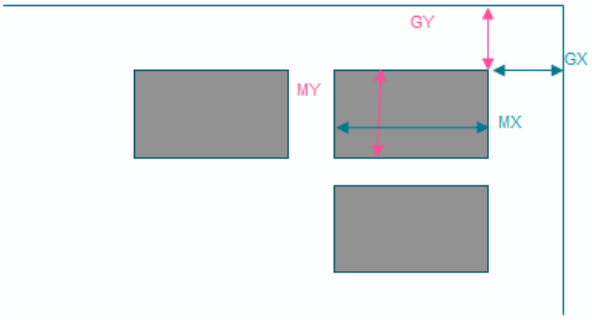


The Figure 1 and Figure 2 show a design before and after running the `pack_align_macros`, respectively. The Figure 2 shows that the push till the core corner takes place when the gap between the core corner and the corner of the nearest macro satisfies the following condition:
GY <= MY And GX <= MX



Parameters

None

place_connected

```
place_connected
[-help]
-attractor macro/IO list
[-fixed]
[-move_fixed]
[-placed]
{-level integer  | -sequential all_connected | direct_connected | -stop_points instance_name | -before_points
instance_name | -instance_pin instance/pin}
[{ -stop_points instance_name | -key_cell cell_name }]
[{ -instance_pin instance/pin | -key_cell cell_name }]
[{ -attractor_pin pin_list } [-instance_pin instance/pin ]]
```

Places the specified standard cells close to the specified attractor with legal location. The attractor can be IOs, hard macros, fixed standard cell. The recommended flow is to run this command before `place_design`.

Parameters

`-help`	Outputs a brief description that includes type and default information for each place_connected parameter.
`-attractor` *`macro/IO list`*	Specifies target hard macros, IOs, or fixed standard cell for attracting standard cells. Wildcards are supported. Tool processes attractors in list one by one. If there are instances shared by different attractors, the locations of shared instances are determined by the later one. In that case, the placement result may vary with different order of objects in list.
`-attractor_pin` *`pin_list`*	Places only standard cells connected with specified pins of attractors close to attractor. Wildcards are supported. Without this setting, standard cells connected with all pins of attractors are pulled.
`-before_points` *`instance_name`*	The attractor stops attracting before these instances.
`-fixed`	Sets the placement status as fixed.
`-instance_pin` *`instance/pin`*	Pulls all instances, instance pins, and IO pins specified in the list close to the attractor. This option requires only full instance pin name. Wildcards are not supported. Option `-attractor_pin` needs to be used with this option.
`-key_cell` *`cell_name`*	Places specified type of cells close to attractors, as well as other logics between the key cell and attractor. Wildcards are supported. Without this setting, all standard cells connected with attractors are pulled.
`-level` *`integer`*	Pulls all instances within certain logic level of connections to the attractor close to attractors. This option is mutually exclusive with -sequential, and user must specify one of them.
`-move_fixed`	Specifies that instances with the fixed status can also be moved close to the attractor.
`-placed`	Specifies instances being placed is in “placed” status. By default, the pulled cells are marked as “softfixed”.
`-sequential` *`all_connected`* | *`direct_connected`*	Pulls sequential cells connected with the attractor close to the attractor. `all_connected`: attracts all sequential cells from/to attractor; combinational logics between the sequential instance and attractor are attracted as well. `direct_connected`: attracts sequential cells directly connected with attractor.
`-stop_points` *`instance_name`*	Pulls all instances connected between the attractor and the specified stop point close to attractors. This option requires full instance name or instance pin name. Wildcards are supported.

Examples

- The following command places all instances directly connected with all pins of `RAM1` close to `RAM1`.

  ```
  place_connected -attractor RAM1 -level 1
  ```

- The following command pulls all sequential cells from `RAM1` and all combinational cells between `RAM1` and the sequential cells close to `RAM1`.

  ```
  place_connected -attractor RAM1 -sequential all_connected
  ```

- Only the sequential cells from “IN*” pins of `RAM1` and their combinational logics are caught to be placed nearby `RAM1`.

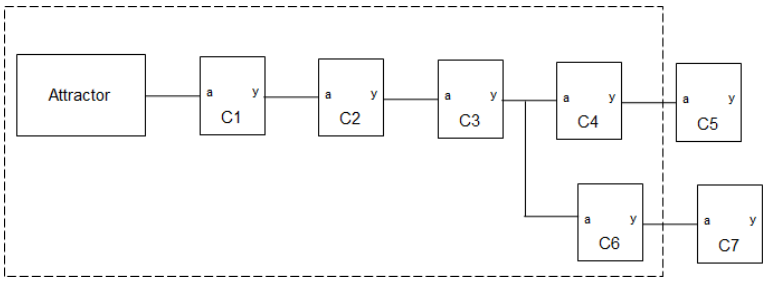
  ```
  place_connected -attractor RAM1 -sequential all_connected -attractor_pin IN*
  ```

- The following command picks out instances that are `"BUF1X"` cell type and directly connected with `RAM1`, and places them close to `RAM1` with `"placed"` status.

  ```
  place_connected -attractor RAM1 -level1 -key_cell BUF1X -placed
  ```

- The following command places instances, C1, C2, C3, C4, C6, close to the attractor RAM1.

  ```
  place_connected -attractor RAM1 -before_points {C5 C7}
  ```



Related Information

- `place_design`

place_design

```
place_design
[-help]
[-concurrent_macros]
[-incremental]
[-noPrePlaceOpt]
[-sdp]
```

Places standard cells based on the global settings for placement, RC extraction, timing analysis, and early global routing. It also relieves the congestion and reorders the scan cells. Also performs the following operations:

- Pre-placement optimization
- Scan tracing and scan reordering
- Placement optimization during the placement process
- Incremental placement on an already placed design

By default, `place_design` performs timing-driven placement with scan reordering, except during prototyping, when it runs in non-timing-driven mode. To change this behavior, run `setPlaceMode` with the following parameters prior to running `place_design`:

- `-place_global_reorder_scan false`
- `-place_global_timing_effort false`

Or, in prototyping mode:

- `-place_design_floorplan_mode`

If there are no timing constraints, `place_design` assumes non-timing-driven mode.

Note: This command supports multiple-CPU processing. For information, see "Multiple-CPU Processing Commands" and "Accelerating the Design Process by Using Multiple-CPU Processing".

Notes:

- The `get_metric` command can be used with the `place_design` command to retrieve metrics.
- The `place_design` command:
- Supports multithreading
- Honors the `set_proto_mode -place_effort` setting
- Honors instance padding constraint as a hard rule if `setPlaceMode -place_detail_honor_inst_pad` is set to `true`.
- Honors settings for the following commands with the exceptions noted in the table below:

Command	Exceptions/Notes
`setAnalysisMode`	• Does not honor `-checkType hold`. If you specify `-checkType` hold, issues a warning and assumes `-checkType setup` mode. • Does not honor `-clockPropagation sdcControl`. If you specify `-clockPropagation sdcControl`, assumes `-clockPropagation forcedIdeal`. • Does not honor `-clkSrcPath true`. If you specify `-clkSrcPath true`, assumes `-clkSrcPath false`.
`setExtractRCMode`	Does not honor `-detail`. If you specify `-detail`, issues a warning and assumes `-default` mode.

setOptMode	All parameters honored
setPlaceMode	If you specify -place_global_clock_gate_aware, you must specify a clock specification file before running place_design.
setScanReorderMode	You must specify scan chain information or import a scan DEF file or the software issues a warning message and skips scan reordering.
setRouteMode	All parameters honored

Parameters

-help	Outputs a brief description that includes type and default information for each place_design parameter. For a detailed description of the command and all of its parameters, use the man command: man place_design.

-concurrent_macros	When this option is enabled, place_design will do concurrent timing driven placement of macros and standard cells. By default, the place_design -concurrent_macros command does not call the refine_macro_place command to legalize the macros. It is recommended to check the "brut" mixed placer result before invoking the refine_macro_place command. When the place_design -concurrent_macros command is run, it sets the value of setPlaceMode -place_opt_run_global_place to seed.
	Flow usage is as follows:
	`place_design -concurrent_macros`
	`saveDesign macroPlace.enc`
	`…`
	`refine_macro_place`
	`saveDesign macroRefine.enc`
	`place_opt_design`
	⚠ **Note:** When the -place_global_place_io_pins parameter of the setPlaceMode command is set to true, the place_design -concurrent_macros command places the placed and unplaced I/O pins in the mixed placer flow and optimize their locations to reduce wire length and congestion.
	This support is a limited-access feature in this release. It is enabled by a variable specified using the setLimitedAccessFeature command. To use this feature, contact your Cadence representative to explain your usage requirements, and make sure this feature meets your needs before deploying it widely.

-incremental	Runs placement incrementally. This parameter works only when the design is already placed. **Note:** Using this parameter defaults to -noPrePlaceOpt.
-noPrePlaceOpt	Disables pre-place optimization during the placement run. By default, the command removes all cells with the specified buffer footprint (same as with the deleteBufferTree command), except when using the -incremental parameter.
-sdp	Enables SDP-aware (Structured Data Path) placement.

Command Order

Use the `place_design` command after performing general floorplanning, including macro placement, regioning (if applicable), and power planning on the design. The design could be in the unplaced state, or in a state that the existing placement is to be replaced.

- To run timing-driven placement (the default), make sure the timing constraints are loaded in the design.
- To run scan reorder (the default), specify the scan chain or import the scan DEF data before running this command.

Examples

- The following commands perform non-timing-driven placement:

  ```
  setPlaceMode -place_global_timing_effort false
  place_design
  ```

- The following commands disable scan chain reordering:

  ```
  setPlaceMode -place_global_reorder_scan false
  place_design
  ```

- The following command disables the pre-placed buffer tree removal:

  ```
  place_design -noPrePlaceOpt
  ```

- After the design is placed, the following command performs incremental placement, and disables the pre-placed buffer tree removal:

  ```
  place_design -incremental
  ```

place_opt_design

```
place_opt_design
[-help]
[-expanded_views]
[-incremental]
[-incremental_timing]
[-num_paths number_of_paths]
[-out_dir outputDirectory]
[-predict_prects]
[-prefix outputFileName]
[-timing_debug_report]
```

Executes pre-CTS flow with both placement and pre-CTS optimization.

Earlier, users had to perform the following two steps to do placement and preCTS optimization:

1. `place_design`
2. `optDesign -preCTS`

With `place_opt_design`, users need to run only a single command to do placement and preCTS optimization.

The `place_opt_design` command provides better integration between placement and optimization to achieve faster runtime and better PPA.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `place_opt_design` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man place_opt_design`.
`-expanded_views`	Prints timing information for each active view at the end of the command restoring all pruned views if absent.

`-incremental`	Specifies `place_opt_design` to be run in the incremental mode. In the incremental mode `place_opt_design` incrementally improves the existing placement based on the critical timing paths and congestion. The command then re-optimizes the netlist based on the new placement. The optimization in incremental `place_opt_design` does DRV fixing, WNS, and TNS optimization. The input to `place_opt_design -incremental` can be either a partial placement or full placement with placement violations, and the output is a legal placement as `place_detail` is called at the end. This can be used if you want to further improve the congestion and timing QoR or if there is a minor floorplan change and this by default, congestion-driven, and timing-driven. It also honors density screens and floorplan constraints. If you run `place_opt_design` and notice some areas of congestion, you can introduce density screens and run `place_opt_design -incremental`. As `place_opt_design -incremental` honors density screens, it would spread out some of the cells, reducing congestion in that area. In contrast, `place_detail` would not do this as it only works on the hard placement violations such as cell overlaps, while density screens is a "soft" constraint. There is no scan-reordering done in `place_opt_design -incremental`. **Note**: Early clock flow mode `place_opt_design -incremental` reuses the existing early clock flow clock tree without any logical or physical modification and makes adjustments only to useful skew using virtual delays. It is also essential to note that the CCOpt clock tree spec must not be deleted between the original and incremental `place_opt_design` steps, just like it must not be done between `place_opt_design` and `ccopt_design`, otherwise any useful skew will be lost.
`-incremental_timing`	In the `incremental_timing` mode, `place_opt_design` does incremental DRV and timing optimization. In this mode, `place_opt_design` incrementally optimizes the critical timing path. Also, the optimization in incremental timing `place_opt_design` does DRV fixing, WNS, and TNS optimization.
`-num_paths` *`number_of_paths`*	Specifies the number of paths reported in the timing report. By default, all timing paths are reported.
`-out_dir` *`outputDirectory`*	Specifies the output directory in which the timing/drv reports will be saved.
`-predict_prects`	Performs optimization specific to physical synthesis exchange.
`-prefix` *`outputFileName`*	Specifies the file name prefix for the timing/drv reports that are generated at the end of `place_opt_design`.
`-timing_debug_report`	When specified, generates a machine-readable timing debug report after completing placement and preCTS optimization. This report is used for debugging timing results using the timing debug feature in Innovus. **Note**: You can specify the number of paths to be reported using the `-num_paths` parameter.

placeInstance

```
placeInstance
[-help]
instance_name
location
[orientation]
[{-fixed | -placed | -softFixed}]
```

Places a leaf instance in the core box. Instance is snapped to the site whose lower left corner is nearest to the location specified. If the location specified is outside of the core box, then the instance is snapped to site whose lower left corner is nearest to the location specified. Instance is not checked for legality–it can overlap other boxes, either placed or fixed, and it can be placed within placement blockages. If no orientation is specified, or if an illegal orientation is specified, `placeInstance` will orient the instance with the default orientation of the site in which the instance is being placed. You can check the legality of the placed instance by the `checkPlace` command.

Note: If you place a master instance blackbox to non-R0 orientation, the new non-R0 orientation will be converted to R0 orientation.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `placeInstance` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man placeInstance`.
`instance_name`	Specifies the leaf instance name.
`location`	Specifies x and y coordinates of new origin. • *`x`*: Specifies the lower-left x coordinate of the instance on the x axis. • *`y`*: Specifies the lower-left y coordinate of the instance on the y axis.
`orientation`	Specifies the orientation of the instance. Specify one of the following values: `R0, R90, R180, R270, MX, MX90, MY,` or `MY90`. *`Default`*: `R0`
`-fixed | -placed | -softFixed`	Specifies that the cell being placed is in the `fixed`, `placed`, or `softFixed` status. *`Default`*: `-fixed`

Example

- The following command places the instance `SH22/I40` with mirrored through Y axis orientation at location `1500.3, 980.3` in the floorplan. The instance SH22/I40 is fixed by default and the placement program will not move this instance later:
  ```
  placeInstance SH22/I40 1500.3 980.3 MY
  ```
- The following command places the instance SH22/I51 with default `R0` orientation at location 398.7, 1480.2 in the floorplan. The instance SH22/I52 has 'placed' status and it can be moved during optimization, clock synthesis, or refinePlace:
  ```
  placeInstance SH22/I51 398.7 1480.2 -placed
  ```

placeJtag

```
placeJtag
[-help]
-nrRow nrRow
[-nrRowTop nrRowTop]
[-nrRowBottom nrRowBottom]
[-nrRowLeft nrRowLeft]
[-nrRowRight nrRowRight]
[-hardMacro {true | false}]
[-areaIo {true | false}]
[-ioNetWeight netWtValue]
[-blockNetWeight netWtValue]
[-contour {true | false}]
[-ignoreScan {true | false}]
[-orientTop orientation]
[-orientBottom orientation]
[-orientLeft orientation]
[-orientRight orientation]
```

Places JTAG cells. Use this command for JTAG and other cells where placement is required to be close to the perimeter I/Os.

Note: The command does not honor MSMV design.

Parameters

`-areaIo {true | false}`	Considers the area around I/O cells as a legal placement location. When specifying this parameter, the `-ioNetWeight` parameter is applied to the nets that are connected to the Area I/O cells. Default: `false`
`-blockNetWeight netWtValue`	Specifies the weight for nets connecting to blocks. This allows `placeJtag` to place more critical block nets in a smaller area. Default: `20` Maximum value*:* `512`
`-contour {true | false}`	Creates an outline along the boundary of the chip, with its width based on the number of standard cell rows, as specified by the `-nrRow` parameter(s). You can specify different values for `-nrRowTop`, `-nrRowBottom`, `-nrRowLeft`, and `-nrRowRight`. Default: `false`
`-help`	Outputs a brief description that includes type and default information for each `placeJtag` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man placeJtag`.
`-hardMacro {true | false}`	Includes the boundaries of the hard macros in the JTAG placement. Default: `false`

`-ignoreScan {true | false}`	Ignores all scan-in pins, scan enable pins, clock pins, and asynchronous control pins. Default: `false` ⚠ `placeJtag` relies on the timing library to provide information, such as what pins are scan-in, scan enable, clk, and async control. If the timing library does not have the scan-in and scan enable information, `placeJtag` is not able to ignore them. In this case, before you run `placeJtag`, you must specify those terms using the `specifyScanCell` command.
`-ioNetWeight` *`netWtValue`*	Specifies the weight for nets connecting to I/Os. This allows `placeJtag` to place more critical I/O nets in a smaller area. Default: `100` Maximum: `512` `-ioNetWeight` applies to the nets that are connected to any I/O cell, whether it is a standard peripheral I/O cell or an Area I/O cell. This behavior is different from `-blockNetWeight`, which specifies the weight of the nets connected to blocks separately from the I/O nets.
`-nrRow nrRow`	Specifies the number of standard cell rows to place the JTAG instances.
`-nrRowBottom` *`nrRowBottom`*	Specifies the number of standard cell rows at the bottom of the core area to place JTAG logic.
`-nrRowLeft` *`nrRowLeft`*	Specifies the number of standard cell row heights at the left of the core area to place JTAG logic.
`-nrRowRight` *`nrRowRight`*	Specifies the number of standard cell row heights at the right of the core area to place JTAG logic.
`-nrRowTop` *`nrRowTop`*	Specifies the number of standard cell rows at the top of the core area to place JTAG logic.
`-orientBottom` *`orientation`*	Considers the specified orientation at each side first and then looks for other legal orientations. Specify one of the following values: `R0 R90 R180 R270 MX MX90 MY MY90`.
`-orientLeft` *`orientation`*	Considers the specified orientation at each side first and then looks for other legal orientations. Specify one of the following values: `R0 R90 R180 R270 MX MX90 MY MY90`.
`-orientRight` *`orientation`*	Considers the specified orientation at each side first and then looks for other legal orientations. Specify one of the following values: `R0 R90 R180 R270 MX MX90 MY MY90`.
`-orientTop` *`orientation`*	Considers the specified orientation at each side first and then looks for other legal orientations. Specify one of the following values: `R0 R90 R180 R270 MX MX90 MY MY90`.

Examples

The following command places the JTAG instances within four standard cell rows at the top and bottom of the chip and within four times the standard cell row height at the sides of the chip:

```
placeJtag -nrRow 4
```

The following command places the JTAG instances within ten standard cell rows at the top and bottom of the chip and within ten times the standard cell row height at the sides of the chip. It increases the I/O net weight to `256`.

```
placeJtag -nrRow 10 -ioNetWeight 256
```

placePad

```
placePad
[-help]
pad_name
[orientation]
location
```

Places an I/O pad instance. This command can be used before the `place_design` command.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `placePad` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man placePad`.
location	Coordinates of new origin. The option is a point and a must.
orientation	Specifies the orientation of the pad cell. Specify one of the following values: `R0`, `R90`, `R180`, `R270`, `MX`, `MX90`, `MY`, and `MY90`. *Default:* `R0`
pad_name	Specifies the pad instance name.

Example

The following command places the I/O pad instance with mirrored axis orientation, rotated 90 degrees counterclockwise:

```
placePad SH14/I412 498.3 5000.8 MX90
```

Related Information

- `place_design`

placePipeline

```
placePipeline
[-netGroup {netGroupName}]
[-region {true | false }]
[-status {fixed | placed}
[-timingBased]
[-utilization utilization_value]
```

Places the registers of the specified pipeline flip-flops (PFF) net group(s) so that the distances between the stages of each group are roughly equal. This command can be used if the pipeline net groups are specified in the design.

Parameters

`-netGroup {netGroupName}`	Specifies the PFF net group, or a list of net groups, to place. By default, all PFF net groups in design are considered.
`-region {true | false}`	Creates region constraints for flops in each stage of pipeline, to allow adjustments at a later stage. *Default:* `false`
`-status {fixed | placed}`	Places the PFFs with fixed placement status, or placed status. *Default:* `placed`
`-timingBased`	Automatically finds reserve lengths. The option is of type boolean and is optional.
`-utilization utilization_value`	Specifies the expected utilization of regions for flops. *Minimum:* `0` *Maximum:* `1` **Note**: The `-region` option is required with the `-utilization`.

Example

- The following command places the registers of all pipeline flip-flops (PFF) net groups at equal distance:
  ```
  placePipeline
  ```
- The following command places the registers of pipeline flip-flops (PFF) net group named `netGroup1` at equal distance and marked the registers status `FIXED`:
  ```
  placePipeline -netGroup netGroup1 -status fixed
  ```

Related Information

- `createPipelineNetGroup`
- `deletePipelineNetGroup`
- `modifyPipelineNetGroup`

placeSpareModule

```
placeSpareModule
-moduleName moduleName
{-numModules integer | -stepx stepDistance -stepy stepDistance}
[-area llx lly urx ury]
[-channel
    {-maxWidth maxWidth}
    {-minWidth minWidth}
    {-minLen minLength}]
[-offsetx offsetDistance]
[-offsety offsetDistance]
[-powerDomain powerDomainName]
[-prefix prefix]
[-util utilizationFactor]
```

Instantiates a created spare module, and places spare modules across the design. You can run this command before or after placement. However, if you run the command before placement it will only add the cells and mark all the added spare cells as unplaced. If you run it after placement, it calls `ecoPlace`.

Parameters

`-area llx lly urx ury`	Specifies box coordinates (*`llx, lly, urx, ury`*) in micron.
`-channel`	Places spare modules in thin channels between placement blockages.
`-maxWidth maxWidth`	Specifies the maximum channel width, in microns. The *`maxWidth`* determines whether the placeable area between two macro blocks is considered a channel.
`-minLen minLength`	Specifies the minimum channel length, in microns. The *`minLength`* must be greater than the specified *`maxWidth`*.
`-minWidth minWidth`	Specifies the minimum channel width, in microns. The *`minWidth`* should be greater than the width of the largest-space cell provided.
`-moduleName moduleName`	Specifies the name of the spare module. This module must have been created using the `createSpareModule` command.
`-numModules integer`	Specifies the total number of spare modules to add. The software calculates how far apart to place the modules.
`-offsetx offsetDistance`	Specifies the offset along the x axis, in microns, from the left core boundary.
`-offsety offsetDistance`	Specifies the offset along the y axis, in microns, from the bottom core boundary.
`-powerDomain powerDomainName`	Specifies the power domain in which to place the spare modules.
`-prefix prefix`	Specifies a prefix to add to the automatically generated prefix for spare modules. The software already uses the prefix spr_*n* for spare modules. If you specify `-prefix spareMod`, the instances of this module are named `spareMod_spr_1, spareMod_spr_2, spareMod_spr_3`, and so on.
`-stepx stepDistance`	Specifies the distance, in microns, between the instantiated spare modules along the x axis. The *`stepDistance`* must be greater than the spare module bounding box.
`-stepy stepDistance`	Specifies the distance, in microns, between the instantiated spare modules along the y axis. The *`stepDistance`* must be greater than the spare module bounding box.
`-util utilizationFactor`	Specifies the utilization factor of the spare modules. *Value Range:* Greater than 0.0; less than 1.0. If the value of util is low, the placeable region will be larger. There would be more space for placing the spare cells and they may not be tightly bound. Similarly, if the util value is high, the placeable region will be small and spares will be tightly bound. **Note**: If you specify a high util value, the placeable region will be small and as a result the tool might not be able to accommodate all spare modules in the small region. In such cases, the tool will give the following message: `*INFO: Some spare modules might not contain all the provided spare cells.`

Note: The `placeSpareModule` command does not honor `-util` when `-numModules` switch is used.

Command Order

Run this command after running `createSpareModule`.

Examples

The following command instantiates module `mod1` and places the instantiations at intervals of 50 microns along the x and y axis. It places the instantiations at an offset of 5 microns from the left core boundary and the bottom core boundary:

```
placeSpareModule -moduleName mod1 -stepx 50 -stepy 50 -offsetx 5 -offsety 5
```

The following commands create spare module SPGM with cells DFFNSRX2, INVX4, and NOR2X2 using clock net sysclk; then instantiates module SPGMand places the instantiations between channels that are between 4.7 um and 10.0 um wide and at least 11.0 um long. The step size is 10 um in the x direction and 10 um in the y direction and the maximum utilization rate is 60 percent:

```
createSpareModule -moduleName SPGM -cell {DFFNSRX2 INVX4 \
  NOR2X2} -clock sysclk
placeSpareModule -moduleName SPGM -channel -minWidth 4.7 -maxWidth 10 \
  -minLength 11 -stepx 10 -stepy 10 -util 0.6
```

power_integrity_place

```
power_integrity_place
[-help]
```

Calls Voltus to run irdrop analysis including power analysis, rail analysis, and debug IRdrop. The aggressors come from the Voltus feedback. Tool adds padding on the aggressors to push cell away to fix IRdrop. On the basis of the effort level set through this option, tool selects the IRdrop fixing strength flow.

The flow involves incremental placement and refine placement.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `power_integrity_place` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man power_integrity_place`.

queryDensityInBox

```
queryDensityInBox
query_box
```

Outputs placement density for a specific area in the design. Considers placement blockages and honors the metal layers specified by the `setPlaceMode -place_detail_preroute_as_obs`. The argument type is box in units of microns. This command is optimized for small area interactive queries.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `queryDensityInBox` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man queryDensityInBox`
query_box	Specifies box coordinates (*x1, y1, x2, y2*) in micron. • *x1: Specifies the area's lower left point on the x axis.* • *y1: Specifies the area's lower left point on the y axis.* • *x2: Specifies the area's upper right point on the x axis.* • *y2: Specifies the area's upper right point on the y axis.*

Example

The following command reports the placement density for the specific area 2835.342 3381.807 4807.673 4530.904:

```
queryDensityInBox 2835.342 3381.807 4807.673 4530.904
```

The output of this command is:

```
StdInstArea/freeSpace = 27.0%(197105.76/728824.32)
macroInstArea/totArea = 67.7%(1539687.84/2272665.60)
powerMetalArea/totArea = 0.0%(0.00/2272665.60)
PlacementObsArea/totArea = 0.0%(0.00/2272665.60)
Utilization in area (2835342 3381807) (4807673 4530904) = 27.04%
```

Related Information

- `setPlaceMode`

queryPinDensity

```
queryPinDensity
[-help]
[-area <x1 y1 x2 y2>]
```

Outputs pin density for the design. The argument type is box in units of microns.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `queryPinDensity` parameter. For a detailed description of the command and all of its parameters, use the man command: `man queryPinDensity`
`-area`	Species the box coordinates in microns. • *x1*: Specifies the area's lower left point on the x axis. • *y1*: Specifies the area's lower left point on the y axis. • *x2*: Specifies the area's upper right point on the x axis. • *y2*: Specifies the area's upper right point on the y axis.

Examples

The following command reports the pin density for the specific area 43.24 23.505 139.626 113.411:

```
queryPinDensity -area 43.24 23.505 139.626 113.411
```

```
calculate placement pin density in box (43.20, 16.00, 140.00, 120.00) Pin Density = 0.3223.
= total # of pins 507 / total area 1573.
```

refinePlace

```
refinePlace
[-help]
[-area {lx ly ux uy}]
[-eco {true|false}]
[-inst list_of_instances]
[-wire_length_reclaim {true|false}]
```

Corrects flawed cell locations and reports corrections or instance overlap problems. You do not need a fully placed design to run `refinePlace`. The `refinePlace` command only makes changes if the placement is not legal, such as for instance overlap, incorrect orientation, constraint violations, and placement/routing blockage violations. You can use the `checkPlace` command to highlight placement violations in the design. The `refinePlace` command is called automatically at the end of each major super command such as `place_opt_design`, `optDesign`, and `ccopt_design` to ensure that the final placement is violation-free. If any instances are moved manually, `refinePlace` can be run to legalize any cell placements that may have resulted in violations due to this manual movement.

To place unplaced instances, use the `ecoPlace` command.

`refinePlace` only operates on the cells which have the 'placed' placement status.

Note: You can also use `setPlaceMode` to specify parameters for this command. If you use `setPlaceMode`, the parameters apply every time you run `refinePlace` in the current session, unless they are overwritten by the `refinePlace` settings.

Note: `refinePlace` and other commands using `refinePlace` API honor instance padding constraint as a hard rule if `setPlaceMode -place_detail_honor_inst_pad` is set to `true`.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `refinePlace` parameter. For a detailed description of the command and all of its parameters, use the man command: `man refinePlace`
`-area {llx lly urx ury}`	Specifies `refinePlace` area. • *`llx`*: Specifies the area's lower left x coordinate. • *`lly`*: Specifies the area's lower left y coordinate. • *`urx`*: Specifies the area's upper right x coordinate. • *`ury`*: Specifies the area's upper right y coordinate. **Note**: The coordinates for the `-area` option should be provided in brackets, else the tool will report an error.
`-eco {true|false}`	Activates ECO mode for the post-route design. *Default*: `false` **Note**: This option is controlled by `setPlaceMode -place_detail_eco_max_distance`.
`-inst list_of_instances`	Legalizes the list of instances provided by the user. All other instances are treated as fixed. **Note**: This option is controlled by `setPlaceMode -place_detail_eco_max_distance`.
`-wire_length_reclaim {true|false}`	Activates the wire length reclaim mode.

Command Order

Use this command after finding an error with the `checkPlace` command.

Example

- The following command refines the placement in the specified area:

```
refinePlace -area {7.925 29.762 11.702 27.531}
*** Starting refinePlace (0:04:48 mem=991.9M) ***
Move report: Detail placement moves 0 insts, mean move: 0.00 um, max move: 0.00 um
        Runtime: CPU: 0:00:00.0 REAL: 0:00:00.0 MEM: 991.9MB
Summary Report:
Instances move: 0 (out of 6 movable)
Mean displacement: 0.00 um
Max displacement: 0.00 um
Runtime: CPU: 0:00:00.0 REAL: 0:00:00.0 MEM: 991.9MB
*** Finished refinePlace (0:04:48 mem=991.9M) ***
```

- ecoPlace
- setPlaceMode

report_cell_edge_spacing

```
report_cell_edge_spacing
[-help]
[-file fileName]
```

Reports all the cell edge spacing rules in both terminal and log file.

Parameters

`-file fileName`	Specifies the file name to dump cell edge spacing rules.
`-help`	Outputs a brief description that includes the type and default information for each `report_cell_edge_spacing` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_cell_edge_spacing`

Related Information

- `specifyCellEdgeSpacing`
- `deleteCellEdgeSpacing`

report_cell_edge_type

```
report_cell_edge_type
[-help]
[-cell cellName]
[-file fileName]
```

Reports the edge type of the specified cell.

Parameters

`-cell` *cellName*	Specifies the cell name for which edge type is to be reported. If the cell name is not specified, all the cell edge types are reported in the edge_type.rpt file report file.
`-file` *fileName*	Specifies the report file name. If no file name is specified, the edge_type.rpt file is used to generate the report.
`-help`	Outputs a brief description that includes type and default information for each `report_cell_edge_type` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man report_cell_edge_type`.

Related Information

- `specifyCellEdgeType`
- `deleteCellEdgeType`

report_cell_stack_area

```
report_cell_stack_area
[-help]
[-cell cell_name]
[-file file_name]
[-group group_name]
```

Reports the cell stack area definition for cells.

Parameters

`-cell cell_name`	Specifies the cell(s) for which the cell stack area definition needs to be reported.
`-file file_name`	Specifies the file name in which the reported information is saved. By default, all cell stack groups are reported to the `cell_stack_area.rpt` file.
`-group group_name`	Specifies the group(s) for which the cell stack area definition needs to be reported.
`-help`	Outputs a brief description that includes type and default information for each `report_cell_stack_area` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_cell_stack_area`

Related Information

- `specify_cell_stack_area`
- `delete_cell_stack_area`

report_cell_stack_group

```
report_cell_stack_group
[-help]
[-file <string>]
[-name <string>]
```

Reports the cell stack group definition.

Parameters

`-file` *`file_name`*	Specifies the file name in which the reported information is saved. By default, all cell stack groups are reported to the `cell_stack_group.rpt` file.
`-help`	Outputs a brief description that includes type and default information for each `report_cell_stack_group` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_cell_stack_group`
`-name` *`group_name`*	Specifies the group(s) that needs to be reported.

Related Information

- `specify_cell_stack_group`
- `delete_cell_stack_group`

report_cell_virtual_align

```
report_cell_virtual_align
[-help]
[-cell cells]
```

Reports the cells that need to be virtually aligned.

Parameters

`-cell cells`	Specifies the lib cells that require virtual alignment.
-help	Outputs a brief description that includes type and default information for each `report_cell_virtual_align` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_cell_virtual_align`

Related Information

- `specify_cell_virtual_align`
- `delete_cell_virtual_align`

report_inst_space_group

```
report_inst_space_group
[-help]
[-file fileName]
[-group groupName]
```

Reports all instance space groups into the inst_space_group report file by default.

Parameters

`-file fileName`	Specifies the file name to dump space group
`-group groupName`	Specifies the name of the group to be reported.
`-help`	Outputs a brief description that includes type and default information for each `report_inst_space_group` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_inst_space_group`.

report_pg_keepout

```
report_pg_keepout
[-help]
[-file file_name]
{-cell lib_cell_name | -inst instance_name}
```

Reports all PG keepout boxes in the design if no option is specified.

Parameters

-cell lib_cell_name	Reports PG keepout boxes applied to the specified lib cell only.
`-file file_name`	Specifies the file name where all the details are dumped.
-help	Outputs a brief description that includes type and default information for each `report_pg_keepout` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_pg_keepout`
-inst instance_name	Reports PG keepout boxes applied to the specified instance only.

Related Information

- `specify_pg_keepout`
- `delete_pg_keepout`

report_scan_chain

```
report_scan_chain
[-help]
[-chain chainName]
[-out_file fileName]
[-verbose {true|false}]
```

Prints the scan chain information.

Parameters

`-chain` *chainName*	Specifies the scan chain name.
`-help`	Outputs a brief description that includes type and default information for each `report_scan_chain` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man report_scan_chain`.
`-out_file` *fileName*	Specifies the output file name of scan chain.
`-verbose {true|false}`	Prints out more message

Related Information

- `specifyScanChain`
- `deleteScanChain`

reportCellPad

```
reportCellPad
[-help]
[-cell cellName]
[-file fileName]
```

Prints the number of cells, which contain user-specified padding, to the log file. Optionally, you can obtain a complete list of cells with their padding information in a file using the `-file` parameter. The format of this file is same as used in the `specifyCellPad` command, that is,

cellName padding (in grid units)

Parameters

`-cell cellName`	Specifies the cell name to report padding.
`-file fileName`	Specifies the generated file name to dump cell padding.
`-help`	Outputs a brief description that includes type and default information for each `reportCellPad` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man reportCellPad`.

Examples

The following steps show the usage of `reportCellPad` command:

1. Specify the following padding using the `specifyCellPad` command:

   ```
   specifyCellPad FF_SCAN 2
   specifyCellPad DFFSHQX1 5
   specifyCellPad DFFSRX4 4
   ```

2. Run the `reportCellPad` command. After running this command, you get the value `3` and the following message is printed to the log file:

   ```
   3 cells have padding.
   ```

3. To print the above-mentioned list of cells in the file `myfile`, specify the following command:

   ```
   reportCellPad -file myfile
   ```

4. After running this command, the following contents of `myfile` are displayed:

   ```
   FF_SCAN 2
   DFFSHQX1 5
   DFFSRX4 4
   # 3 cells have padding.
   ```

Related Information

- specifyCellPad
- deleteCellPad

reportCongestion

```
reportCongestion
[-help]
[-3d]
[-hotSpot]
[-includeBlockage]
[-num_hotspot number]
[-overflow]
```

Reports the average congestion and the local hotspot score. Route needs be called before using this command.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `reportCongestion` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man reportCongestion`.
`-3d`	Honors 3d congestion map. When specified, it enables the layer-based congestion reporting.
`-hotSpot`	Reports the local hotspot score. It reports the maximum and total hotspot area. Hotspot score refers to the contiguous area of gcells (there is some normalization done internally) which have routing overflow. Typically, a max hotspot score < 100 indicates that the design is routable. • Max hotspot – It is the largest contiguous area of gcells with overflow • Total hotspot – It is the total of all hotspots Greater the number of adjacent gcells with overflow, bigger will be the hotspot. **Note:** You can use this parameter to view the congestion hotspot regions seen by the router after global route.
`-includeBlockage`	Includes blockage area in the hotspot report.
`-num_hotspot number`	Specifies the number of hotspots to be reported.
`-overflow`	Reports horizontal and vertical overflow.

Examples

- The following command reports the congestion:

  ```
  reportCongestion -overflow
  ```

  Output:

  ```
  Usage: (10.0%H 8.1%V) = (2.425e+05um 3.107e+05um) = (72854 61452)
  Overflow: 210 = 7 (0.01% H) + 202 (0.33% V)

  Congestion distribution:

  Remain cntH cntV
  ------------------------------------
  -5: 0 0.00% 1 0.00%
  -4: 0 0.00% 7 0.01%
  -3: 0 0.00% 18 0.03%
  ```

```
-2: 1 0.00% 41 0.07%
-1: 6 0.01% 97 0.16%
--------------------------------------
0: 125 0.21% 256 0.42%

4: 7457 12.41% 917 1.51%
5: 50749 84.47% 44681 73.44%
```

- The following command reports the local hotspot score:

  ```
  reportCongestion -hotSpot
  ```

  Output:

  ```
  [hotspot] +-----+---------------------------------------+---------------+
  [hotspot] | Top |            hotspot bbox               | hotspot score |
  [hotspot] +-----+---------------------------------------+---------------+

```

reportDensityMap

```
reportDensityMap
[-help]
[-gridInMicron microns] [-gridInRow numberRows]
[-ignoreBlock {true|false}]
[-ignoreFiller {true|false}]
[-threshold density]
```

Generates a map that uses colors to represent placement density and generates a placement density report. If you run this command without parameters, it generates a map with a threshold of 0.75 and measures the grid in row height.

Note: You can also use `setDensityMapMode` to set the threshold, and specify whether the map displays bins in microns or rows.

Use this command any time after placement.

Use the Display Density Map form to select colors and step-size for the density levels in the map.

Parameters

`-gridInMicron` *microns*	Specifies the horizontal or vertical dimension of a bin in the map, measured in microns. *Default:* `50` *Upper limit:* `1000`
`-gridInRow` *numberRows*	Specifies the horizontal or vertical dimension of a grid in the map, measured in row height. If you specify a value less than 1, the software uses 1. *Default:* `10` *Upper limit:* `100`
`-help`	Outputs a brief description that includes type and default information for each `reportDensityMap` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man reportDensityMap`.
`-ignoreBlock {true|false}`	Skips block cells instances from both supply and demand calculation. *Default*: `false`
`-ignoreFiller {true|false}`	Ignores the density of fillers in the post-filler density heat map to show the density of standard cells . *Default*: `false`
`-threshold` *density*	Specifies a threshold density value for the grid. Any grid under the threshold value is not reported. The value must be positive. *Default:* `0.75` Upper limit: `2.0`

Example

The following are output from command `reportDensityMap`. It generates a map with default threshold of 0.75 and measured in row height:

```
powerDomain TOP: bins with density > 0.75 = 0.519 % ( 6 / 1156 )
bin size: 59 sites by 10 row(s). total 1156 bins ( 34 by 34 )
density range #bins %
0.75 - 0.8 5 0.4325
0.8 - 0.85 1 0.08651
total 6 0.519
```

Related Information

- Place Menu chapter of the *Innovus Menu Reference*
    - Display Density Map

reportInstPad

```
reportInstPad {instName | -all}
```

Reports the padding for a specific instance, or all instance padding in the design. This command can be used if there is instance padding specified.

Parameters

`-all`	Reports all instance padding in the design.
instName	Reports the padding for the specified instance.

Example

The following command reports the padding for a specified instance named U19567:

```
reportInstPad U19567
```

It outputs following:

```
Padding for Instant [U19567] is 2.
```

Related Information

- `deleteInstPad`
- `specifyInstPad`
- Placing the Design chapter in the *Innovus User Guide*
  - Adding Padding

reportJtagInst

```
reportJtagInst
[-outfile]
```

Displays JTAG information specified by the `specifyJtag` command or creates an output file that contains the information.

Parameters

`-outfile`	Specifies the name of the file. If you do not specify this parameter, the command prints the information to the screen without saving it in a file.

Related Information

- `specifyJtag`
- Placing the Design chapter in the *Innovus User Guide*
  - Specifying and Placing JTAG and Other Cells Close to the I/Os

reportPinDensityMap

```
reportPinDensityMap
[-help]
[-displayStep step_value]
[-gridInMicron micron]
[-gridInRow numberRow]
[-threshold density]
```

Generates a map that uses colors to represent pin density and generates a pin density report. Use this command any time after placement.

You can also use `setPinDensityMapMode` to set the threshold, and specify whether the map displays bins in microns or rows.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `reportPinDensityMap` parameter. For a detailed description of the command and all of its parameters, use the man command: `man reportPinDensityMap`
`-displayStep step_value`	Specifies the range step for displaying the pin density map. *Default*: `0.05`
`-gridInMicron micron`	Specifies the horizontal or vertical dimension of a bin in the map in microns. *Default:* `50` *Minimum*: `0.000000` *Maximum:* `1000.000000`
`-gridInRow numberRow`	Specifies the value (in row-height) of side of square grid for pin density calculations. *Default:* `10` *Minimum:* `1` *Maximum:* `100`
`-threshold density`	Specifies a threshold density value over which the densities must be reported. Any grid under the threshold value is not reported. The value must be positive. *Default*: `0.5` *Minimum*: `0.000000` *Maximum*: `2.000000`

Examples

The following command reports the pin density map:

```
reportPinDensityMap
*** Starting report pin density ***
default core: bins with pin density > 0.5 = 0 % (0 / 1)
bin size: 90 sites by 10 row(s). total 1 bins ( 1 by 1 )
pin density range   #bins     %
total                 0       0
```

Related Information

- setPinDensityMapMode

reportPipeline

```
reportPipeline
[-help]
[-netGroup netGroupNames]
[{-spacing value  | -timingBased  | -psPMBased } -file fileName]
```

The command can be used for analysis before the flops exist in the netlist; or it can be used post flop insertion to either report expected average wire-length between stages of a pipeline net group, or to report the achieved average distance between the placed stages of the pipeline. When used for analysis, the command reports expected number of PFF stages for each net group based on the user-specified value. Optionally the command generates bus-guides for reported route-path.

Parameters

`-file fileName`	Specified the output for additional information from the command. The output includes expected placement location of PFF at each stage in analysis flow.
`-netGroup netGroupNames`	Restricts the report to the net group name specified. If no net group name is specified, all pipeline net groups are reported.
`-spacing value | -timingBased | -psPMBased`	Given the target approximate wire-length spacing between stages, `-spacing` suggests the number of flop stages to insert. `-timingBased` is used to automatically estimate the number of pipeline FFs needed, based on timing delay on routing layers and the clock cycle requirement. It is mutually exclusive to option `-spacing` because the spacing can be decided automatically. `-psPMBased` is used to automatically find maximum spacing using pspm model.

Example

- The following command reports expected number of PFF stages for net group "netGroup1" if the distance between each stage is around 300 microns:
  ```
  reportPipeline -netGroup netGroup1 -spacing 300
  ```
- The following command reports the expected number of PFF stages for net group `netGroup1` if the distance between each stage is around 300 microns. Additional information of expected placement location of each stage are written in the file `PFF.rpt`:
  ```
  reportPipeline -netGroup netGroup1 -spacing 300 -file PFF.rpt
  ```

Related Information

- createPipelineNetGroup
- deletePipelineNetGroup

reportScanCell

`reportScanCell`

Displays a list of the scan cells that are read from the timing library or by the `specifyScanCell` command. This command can be called in any stage of flow after importing design if there are scan cell specifications in library; or else it can be used after the `specifyScanCell` command.

Parameters

None

Example

Following is an example of the output from `reportScanCell`:

```
ScanFF SEDFFXL
  FT SI is test_scan_in
  FT SE is Scan Enable Clock
  FT QN is test_scan_out_inverted
  FT Q is test_scan_out
ScanFF SEDFFX4
  FT SI is test_scan_in
  FT SE is Scan Enable Clock
  FT QN is test_scan_out_inverted
  FT Q is test_scan_out
...
```

Related Information

- `deleteAllScanCells`
- `specifyScanCell`
- Placing the Design chapter in the *Innovus User Guide*
  - Optimizing and Reordering Scan Chains

reportScanChainPartition

```
reportScanChainPartition
[-help]
```

Generates a report that lists compatible scan chains in scan chain partitions.

Specify scan chain partitions with the following command: `specifyScanChainPartition`.

Parameters

None

Example

To see a list of the compatible scan chain groups in a design with one partition, `clk1Domain`, that has two compatible scan chains, type the following command:

```
reportScanChainPartition
```

The command outputs the following messages:

```
Info: Scan Chain Partition Group set to:

      Partition group: clk1Domain

                chain: chain1

                chain: chain2
```

Related Information

- `deleteScanChainPartition`
- `specifyScanChainPartition`
- Placing the Design chapter in the *Innovus User Guide*
    - Optimizing and Reordering Scan Chains

reset_spare_insts

```
reset_spare_insts
[-help]
{-cell cellName | -inst instName | -hinst hinstName}
```

Asserts the specified instance is not a spare gate. This command can be used after `specifySpareGate`.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `reset_spare_insts` parameter. For a detailed description of the command and all of its parameters, use the man command: `man reset_spare_insts`.
`-cell cellName`	Specifies the name of the spare cell to be reset. Wildcards are supported.
`-hinst hinstName`	Specifies the name of the spare hierarchical instance to be reset. Wildcards are supported.
`-inst instName`	Specifies the name of the spare instance to be reset. Wildcards are supported.

Example

- In the following example, “AND2X1” cell is defined as a spare cell in the design. The example shows the query result of the spare cell of AND2X1:

```
innovus 36> dbGet [dbGet [dbGet top.insts.cell.name AND2X1 -p2 ].isSpareGate 1 -p ].name
spr_51/spr_gate0 spr_48/spr_gate0 spr_47/spr_gate0 spr_46/spr_gate0 spr_45/spr_gate0 spr_44/spr_gate0
spr_43/spr_gate0 spr_42/spr_gate0 spr_41/spr_gate0 spr_40/spr_gate0 spr_39/spr_gate0
```

- The following example resets the spare cell instance, `spr_39`, with the `-inst` option. As a result, the spare cell is removed from spare module list and is not a spare gate any more:

```
innovus 32> dbGet [dbGetInstByName spr_39/spr_gate0].isSpareGate
1
innovus 33> reset_spare_insts -inst spr_39/spr_gate0
Resetting spare instance [spr_39/spr_gate0].
Reset 1 spare instances.
innovus 34> dbGet [dbGetInstByName spr_39/spr_gate0].isSpareGate
0
```

- The following commands reset the spare cell hierarchical instance, `spr_40`, with the `-hinst` option, removes it from the spare module list, and it is not a spare gate any more.

```
innovus 29> dbGet [dbGetInstByName spr_40/spr_gate0].isSpareGate
1
innovus 30> reset_spare_insts -hinst spr_40
Resetting spare mode HInst [spr_40].
innovus 31> dbGet [dbGetInstByName spr_40/spr_gate0].isSpareGate
0
```

- The following commands reset the spare cell type, `AND2X1`, using the `-cell` option. All the instances of the `AND2X1` cell type are removed from spare module list and it is not a spare gate any more.

```
innovus 37> reset_spare_insts -cell AND2X1
Resetting all spare instances of cell [AND2X1].
innovus 38> dbGet [dbGet [dbGet top.insts.cell.name AND2X1 -p2 ].isSpareGate 1 -p ].name
0x0
```

Related Information

- addSpareInstance
- specifySpareGate

scanReorder

```
scanReorder
[-help]
[-addScanPortPrefix prefix]
[-clkAware {true|false}]
[-preferH {true|false}]
[-preferV {true|false}]
[-keepPDPorts {true|false} ]
[-scanEffort {low|medium|high|auto} ]
[-skipMode {skipNone|skipBuffer}]
```

Reorders the scan cells after running placement. Controls the skipping and removal of buffers and inverters in the scan chain.

Set global parameters for this command with the `setScanReorderMode` command.

This command automatically detects multiple power domains and minimizes the number of scan chains that pass through them. It respects rectilinear and rectangular power domain boundaries. If a scan chain crosses power domains that operate at the same voltage, the software does not insert level shifters. If the scan chain crosses power domains operating at different voltages, the software inserts the appropriate level shifters.

If scan reorder fails, use the `scanTrace -verbose` command to see where the scan chain stops.

Note: Parameters set by this command override the settings of the `setScanReorderMode` command.

Note: This command supports multithreading.

Parameters

`-addScanPortPrefix` *prefix*	Specifies the prefix to be added to scan hports. *Default:* `""`
`-clkAware {true | false}`	Specifies whether scan reordering is clock tree aware. • When `true`, scan reordering is clock tree aware, and is clock tree driven. • When `false`, scan reordering is not clock tree aware, and is wirelength driven. *Default:* `false` (The software is not clock tree aware) This parameter can also have the value `0, 1` or any floating point number between `0` and `1`. If this parameter is not specified, or if `0` is specified for this parameter, this indicates: Do not consider clock tree at all. If the value is close to `1`, this indicates: Give greater consideration to clock tree.
`-keepPDPorts {true | false}`	Maintains or corrects the hierarchical ports without deleting or inserting shifters, and reorders the remaining scan chain. To turn this option off, use `scanReorder -keepPDports false` or `setScanReorderMode -keepPDPorts false`. *Default:* `true` **Note:** This parameter works in the MSV flow only.

`-preferH {true | false}`	Specifies that the preferred direction for scan reordering connections is horizontal. Reorders the scan chain to snake a sideways "S" configuration if the block is short and wide or the design has vertical routing congestion. *Default:* `false` **Note:** If both `-preferV` and `-preferH` are set to `true`, the software does not honor the setting and treats them both as if they were `false`.
`-preferV {true | false}`	Specifies that the preferred direction for scan reordering connections is vertical. Reorders the scan chain to snake a vertical "S" configuration if the block is long and narrow or the design has horizontal routing congestion. *Default:* `false` **Note:** If both `-preferV` and `-preferH` are set to `true`, the software does not honor the setting and treats them both as if they were `false`.
`-scanEffort {low|medium|high|auto}`	Specifies the effort level for reordering scan chains. *Default:* `-medium` Specify one of the following values: • `auto`: Runs internal reorder effort, and it may tune at different stages. • `high`: Runs more iterations of scan reorder to achieve better net length. Using this parameter increases the run time. • `low`: Runs fewer iterations of scan reorder to minimize net length quickly. • `medium`: Runs a normal number of iterations.
`-skipMode {skipNone | skipBuffer}`	Specifies how scan reordering handles buffers and inverters in the scan chain. *Default:* `skipNone` Specify one of the following: • `skipNone`: Specifies that buffers and inverters remain after the scan chain reorder. • `skipBuffer`: Ignores buffers in the scan chain. If a buffer is not connected elsewhere in the design, `scanReorder` removes the buffer.

Command Order

Use this command after running placement with the ignore scan connection parameter (`setPlaceMode -place_global_ignore_scan true`), and after specifying the scan chain or loading scan chain information in the DEF or TDF files.

Example

The following command reconnects the scan chain so that buffers are skipped:

```
scanReorder -skipMode skipBuffer
```

Related Information

- `scanTrace`
- `setScanReorderMode`
- Placing the Design chapter in the *Innovus User Guide*
    - Optimizing and Reordering Scan Chains

scanTrace

```
scanTrace
[-help]
[-compLogic | -noCompLogic]
[-lockup | -noLockup]
[-verbose]
```

Records the total number of elements in the scan chain in the log file, and records the starting and ending scan points if the `-verbose` option is used. The `scanReorder` command automatically calls `scanTrace` internally if you have not previously run `scanTrace`.

Note: If scan chains are specified by reading in a DEF file, the software does a native scan trace. The scan DEF file is stored in the database and, when the `scanReorder` command runs, the software matches the scans and honors the ordered sections.

Parameters

`-compLogic`	Traces through multiple input gate on the scan path.
`-noCompLogic`	Does not trace through multiple input gate on the scan path.
`-lockup`	Specifies that the tracing detects lockup latches automatically. **Note:** If the lockup elements are flops (non scan flip-flops), the lockup elements must be identified using the `specifyLockupElement` command prior to running `scanTrace` in its default mode.
`-noLockup`	Specifies that the tracing will not detect lockup elements. This is the default.
`-verbose`	Prints the information stored in the logv file, i.e starting and ending scan points, and the cell instance names that `scanTrace` determines are part of the scan chain. If scan chain tracing fails, use this parameter to see where the scan chain tracing stops.

Command Order

Use this command after specifying scan chains using the `specifyScanChain` command.

Examples

The following set of commands traces all scan chains defined by `specifyScanChian` command:

```
specifyScanChain chain0 -start BG_scan_in_1 -stop BG_scan_out_1
specifyScanChain chain1 -start BG_scan_in_2 -stop BG_scan_out_2
specifyScanChain chain2 -start BG_scan_in_3 -stop BG_scan_out_3
scanTrace
```

Controls the behavior of `addWellTap` command. The mode setting is persistent and saved along with the database by the `saveDesign` command. Use `get_well_tap_mode` to return the current settings for `set_well_tap_mode` command.

Note: Parameters specified by the `addWellTap` command supersede those specified by the `set_well_tap_mode` command.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `set_well_tap_mode` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_well_tap_mode`.
`-avoid_vertical_well_abutment {none|ntap|ptap|all_tap}`	Specifies which type of well-tap cells to be forbidden from the vertical abutment. *Default*: `none`
`-avoidAbutment {true|false}`	Specifies whether the inserted taps should avoid horizontal and vertical abutment. *Default*: `false`
`-block_boundary_only {true|false}`	Specifies whether to insert termination tap cells only for well tap columns on the block boundary. Default is false, termination cells are inserted on both core boundary row and block boundary row. **Note**: This parameter works only when inserting termination cells.
`-bottom_tap_cell cellName`	Specifies well taps inserted into bottom rows during enclosed end cap insertion. **Note**: This parameter must be specified when '`setEndCapMode -boundary_tap true`'.

`-bottom_termination_cell` *cellList*	Specifies the list of bottom termination cells to be used. *Default*: `""`
`-cell`	Specifies the name of the cell in the technology library to use as a well-tap. The cell should be of class type CORE. *Default*: `""`
`-channel_offset` *offset_value*	Specifies the offset value between taps and blockage in channel. *Default*: `0` *Minimum*: `0` *Maximum*: `1.79769313486232e+308`
`-check_channel {true|false}`	Specifies whether the blockage channel will be checked.
`-column_cell` *cellist*	Specifies the list of well tap columns that need to be terminated. This parameter must be specified for termination tap cell insertion.
`-create_rows {true|false}`	Creates rows for welltap cell techSites which do not have rows in the floorplan. *Default*: `false`
`-disable_check_zone_at_boundary {none|vdd|vss|both}`	Disables the check zone at boundary. *Default*: `none`
`-inRowOffset` *offset_value*	Specifies the distance between the first welltap in a row and the start of the row. *Default*: 0 (first cell in beginning of row is the starting point) *Minimum*: `0` *Maximum*: `1.79769313486232e+308`
`-reset`	Resets all or specified options to the default value. Any values that do not already match the default value and are reset will be reported.

`-insert_cells` *`cellName rule dense_layer dense__rule boundary_layer boundary_rule`*	Inserts well-taps based on cell, layer, and interval. • *`cellName`*: Specifies the cell name. • *`rule`*: Cell with this rule would be added as a general tap cell for all placeable area. The center to center spacing of tap cells would be `≤ (2*$rule)` without `-checkerBoard` and `≤ (4*$rule)` with -`checkerBoard`. **Note**: Center of the tap cell is used to check the spacing. • *`dense_layername`*: Specifies the dense layer name. • *`dense_rule`*: Cell with dense layer would be added to the given layer regions only. Cell with dense layer must follow the dense rule. The center to center spacing of dense tap cells would be `≤ (2*$dense_rule)` without `-checkerBoard` and `≤ (4 *$dense_rule)` with `-checkerBoard`. • *`boundary_layername`*: Specifies the boundary layer name. • *`boundary_rule`*: A cell would be added for boundaries inside the given layer regions. The cell must follow the boundary rule. The spacing between the boundary to the center of boundary tap cells would be ≤ $ boundary rule. Boundary layer regions which cover partial sites should be extended. Boundary taps can be located in or out of boundary layer regions. Note: • You can define multiple cells for -insert_cells by separating each cell by { }. • There should be at lest one rule, dense layer or boundary layer, defined for each cell. • The order of tap cell insertion is: a. Dense tap b. Boundary tap c. General tap • If the area is covered by both dense layer region and boundary layer region, both layer rules must be satisfied. • If `-insert_cells` is defined multiple times, the last setting is accepted by the tool. • If `-insert_cells` is defined, you do not need define `-rule` while using the `verifyWellTap` command.
`-rule`	Specifies the rule to be honored when adding well taps.
`-siteOffset` *`number_of_sites`*	Specifies an offset value, in number of sites, so that the vertical taps are aware of.

`-tap_function_cells` *cell_list*	Defines the endcap cells which have tap functions. Use of tap function cells reduces the number of tap cells to be inserted. The defined endcap cells are treated as tap function cells during the tap cell insertion. The tool will consider the tap distance between welltap cell and the defined endcap cell with tap function. To insert tap cells considering the tap function not only on the checkboard but also on the termination tap cell insertion flow, `addWellTap` treats the endcap cell as a tap function cell when `set_well_tap_mode -tap_function_cells` is set. The `verifyWellTap` command honors the `set_well_tap_mode -tap_function_cells` settings to check the tap distance. *Default*: `""`
`-tap_termination_alignment {true|false}`	Specifies whether to align well-taps and termination cells. *Default*: false
`-termination_align {left|right|center}`	Specifies the termination cell alignment. *Default*: `left`
`-termination_cell` *cellList*	Specifies the list of cells that can be used as termination taps. The command `addWellTap` selects the best fit termination cells from this list and inserts them at the top and bottom of well tap column segment. The existing non-termination well taps are deleted as needed. If the well tap columns have already been terminated with a valid termination cell, the existing termination cell are kept in the incremental run and no changes are made. **Note:** It is recommended that well tap columns are added before termination cell insertion. **Note:** This parameter must be specified for termination tap cell insertion.
`-top_tap_cell` *cellName*	Specifies well taps inserted into top rows during enclosed end cap insertion. Note: This parameter must be specified when `setEndCapMode -boundary_tap` is set to `true`.
`-top_termination_cell` *cellList*	Specifies the list of top termination cells to be used. *Default*: `""`
`-vertical_boundary_spacing` *spacing_with_well_tap*	Specifies the spacing between center of tap cell and vertical boundary *Default*: `-1` *Minimum*: `-1` *Maximum*: `1.79769313486232e+308`
`-well_cut_cell` *cellist*	Specifies the list of cells with the well cuts. `addWellTap` considers the specified cells cutting the row.

- `verifyWellTap`

setDensityMapMode

```
setDensityMapMode
[-help]
[-reset]
[-gridInMicron microns] [-gridInRow numberRows]
[-ignoreBlock {true|false}]
[-ignoreFiller {true|false}]
[-threshold density]
```

Sets global parameters for the `reportDensityMap` command. Parameters that you specify with `setDensityMapMode` are then used when you run `reportDensityMap`.

Note: Parameters specified by the `reportDensityMap` command supersede those specified by the `setDensityMapMode` command.

See `getDensityMapMode` to return the current settings for `setDensityMapMode`.

Parameters

`-gridInMicron` *microns*	Specifies the horizontal or vertical dimension of a grid in the map, measured in microns. *Default:* `50`
`-gridInRow` *numberRows*	Specifies the horizontal or vertical dimension of a grid in the map, measured in number of rows. If you specify a value less than `1`, the software uses 1. *Default:* `10`
`-help`	Outputs a brief description that includes type and default information for each `setDensityMapMode` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setDensityMapMode`.
`-ignoreBlock {true|false}`	Skips block cells instances from both supply and demand calculation. *Default*: `false`
`-ignoreFiller {true|false}`	Ignores the density of fillers in the post-filler density heat map to show the density of standard cells . *Default*: `false`
`-reset`	Resets parameters to their default values. The `-reset` parameter *must* be the first parameter specified. If you specify `-reset` by itself, the software resets all `setDensityMapMode` parameters to their default values. If you specify parameters after `-reset`, the software resets only those parameters to their default values. Any values that do not already match the default value and are reset will be reported.
`-threshold` *density*	Specifies a threshold density value for the grid. Any grid under the threshold value is not reported. The value must be positive. Cadence recommends an upper limit of `1.20`. *Default:* `0.75`

Examples

- The following command resets the `-gridInRow` parameter to its default value:
  ```
  setDensityMapMode -reset -gridInRow
  ```
- The following command resets all `setDensityMapMode` parameters to their default values:

```
setDensityMapMode -reset
```

- The following command sets density threshold to 0.25 for `reportDensityMap`:

```
setDensityMapMode -threshold 0.25
```

```

Controls the behavior of `addEndCap` command. Specifies a list of cells that `addEndCap` command uses for end-cap or triple-well cap insertion.

Note: The options with *EVEN/*ODD are only for 10nm designs that need to fit even and odd sites. These options should not be used with the options that do not have *EVEN/*ODD.
For example, the `-rightEdge` option should not be used with the`-rightEdgeEven` or `-rightEdgeOdd` option.

Example for 10nm design if there is EVEN/ODD sites requirement:

```
setEndCapMode \
-rightEdgeOdd cellName \
-rightEdgeEven cellName \
-rightBottomCornerEven cellName \
-rightBottomCornerOdd cellName \
-rightTopCornerEven cellName \
-rightTopCornerOdd cellName \
-rightBottomEdgeEven cellName \
-rightBottomEdgeOdd cellName \
-rightTopEdgeEven cellName \
-rightTopEdgeOdd cellName \
-topEdge {ListOfCellNames} \
-bottomEdge {ListOfCellNames}
```

Parameters

`-help`	Outputs a brief description that includes type and default information for each `setEndCapMode` parameter. For a detailed description of the command and all of its parameters, use the man command: man `setEndCapMode`.
`-avoidTwoSitesCellAbut {true|false}`	Avoids two sites boundary cell abut to incorner cell in N10. *Default*: `false`
`-bottomEdge ListOfCellNames`	Specifies the list of cells that have n-well cap on their bottom-edge when in R0 orientation. Thus, these cells are used to cap a top-core row, or row at the bottom of a hard macro.

`-boundary_tap`	Specifies the boundary tap and is applicable to `getEndCapMode`. The type is boolean. *Default*: `false`
`-boundary_tap_swap_flow {true|false}`	Specifies the boundary tap swap flow. *Default*: `True`
`-cells ListOfCellNames`	Specifies end cap cell candidates for N10 that are defined in LEF.
`-create_rows {true|false}`	Creates rows for endtap cell techSites which do not have rows in the floorplan. *Default*: `false`
`-DoubleHeightIncornerProtrusion {true|false}`	Allows the double height in-corner cell to protrude into core area. *Default*: `false`
`-flipY {true|false}`	Flips the orientation of the end cap instances in Y direction if the site symmetry allows it. *Default*: `false`
`-incrementalLeftEdge` *`ListOfCellNames`*	Specifies the list of additional cells which should be treated as end cap by `verifyEndCap` when checking the right edge of the core rows or rows ending at left edge of a hard macro. *Default*=""
`-incrementalRightEdge` *`ListOfCellNames`*	Specifies the list of additional cells which should be treated as end cap by `verifyEndCap` when checking the left edge of the core rows or rows starting at right edge of a hard macro. *Default*=""
`-leftBottomCorner` *`ListOfCellNames`*	Specifies a list of cells that have n-well cap on its left-bottom corner when in R0 orientation. These cells are added on inner corners of core, or concave corner of a rectilinear hard macro.
`-leftBottomCornerEven cellName`	Specifies end cap with n-well at the left-bottom corner, even sites. *Default*: `""`
`-leftBottomCornerNeighbor` *`cellName`*	Specifies the cell to be abutted with the left side of leftBottomCorner in R0 orientation. *Default*: `""`
`-leftBottomCornerOdd cellName`	Specifies end cap with n-well at the left-bottom corner, odd sites. *Default*: `" "`
`-leftBottomEdge` *`cellName`*	Specifies the one cell that has n-well cap on its left-bottom edge when in R0 orientation. Thus, this cell, in R0 orientation, can be used to cap a row ending at left-bottom convex corner of a hard macro, or rectilinear core; and if allowed to flip in Y, it can be used on MY rows that end in left-top convex corner. With both X and Y symmetry, it can cap all convex corners, though only R0 rows at bottom, and MY rows for top corners.

`-leftBottomEdgeEven` *cellName*	Specifies end cap with n-well at the left-bottom edge, even sites. *Default*: " "
`-leftBottomEdgeNeighbor` *site1_cell site2_cell...*	Specifies the list of cells to be abutted with the right edge of leftBottomEdge in R0 orientation. *Default*: " "
`-leftBottomEdgeOdd` *cellName*	Specifies end cap with n-well at the left-bottom edge, odd sites. *Default*: " "
`-leftCornerBottomBorder` *ListOfCellNames*	Specifies the inner left corner bottom border cell. *Default*: " "
`-leftCornerTopBorder` *ListOfCellNames*	Specifies the inner left corner top border cell. *Default*: " "
`-leftEdge` *cellName*	Specifies the one cell that has n-well cap on its left edge when in R0 orientation. Thus, this cell is used to cap right edge of the core rows, or rows ending at left edge of a hard macro. This would be same as a post-cap, in a two well process.
`-leftEdgeBottomBorder` *cellName*	Specifies end cap with n-well at the left edge, poly at the bottom boundary. *Default*: " "
`-leftEdgeEven` *cellName*	Specifies end cap with n-well at the left edge, even sites. *Default*: " "
`-leftEdgeOdd cellName`	Specifies end cap with n-well at the left edge, odd sites. *Default*: " "
`-leftEdgeTopBorder` *cellName*	Specifies end cap with n-well at the left edge, poly at the top boundary. *Default*: " "
`-leftTopCorner` *ListOfCellNames*	Specifies a list of cells that have n-well cap on its left top corner when in R0 orientation. Thus, this cell is added on inner corners of core, or concave corner of a rectilinear hard macro.
`-leftTopCornerEven` *cellName*	Specifies end cap with n-well at the left-top corner, even sites. *Default*: " "
`-leftTopCornerNeighbor cellName`	Specifies the cell to be abutted with the left side of leftTopCorner in R0 orientation. *Default*: " "
`-leftTopCornerOdd` *cellName*	Specifies end cap with n-well at the left-top corner, odd sites. *Default*: " "
`-leftTopEdge` *cellName*	Specifies the cell that has n-well cap on its top-left edge when in R0 orientation. Thus, in R0 orient, it is the flipped-in-Y version of left-bottom edge cell.
`-leftTopEdgeEven` *cellName*	Specifies end cap with n-well at the left-top edge, even sites. *Default*: " "

`-leftTopEdgeNeighbor` *site1_cell site2_cell...*	Specifies the list of cells to be abutted with the right edge of leftTopEdge in R0 orientation. *Default*: `" "`
`-leftTopEdgeOdd` *cellName*	Specifies end cap with n-well at the left-top edge, odd sites. *Default*: `" "`
`-min_horizontal_channel_width` *channelWidth*	If horizontal channel width is smaller than specified value, addEndCap will cover this channel with hard blockage.
`-min_jog_height` *jogHeight*	If jog height is smaller than specified value, addEndCap will cover this jog with hard blockage.
`-min_jog_width` *jogWidth*	If jog width is smaller than specified value, addEndCap will cover this jog with hard blockage.
`-min_vertical_channel_width` *channelWidth*	If vertical channel width is smaller than specified value, addEndCap will cover this channel with hard blockage.
`-prefix` *endcap_prefix*	Adds prefix of EndCap cells.
`-reset`	Resets all or specified options to the default value. Any values that do not already match the default value and are reset will be reported.
`-rightBottomCorner` *ListOfCellNames*	Specifies a list of cells that have n-well cap on its right bottom corner when in R0 orientation. Thus, this cell is added on inner corners of core, or concave corner of a rectilinear hard macro.
`-rightBottomCornerEven` *cellName*	Specifies end cap with n-well at the right-bottom corner, even sites. *Default*: `" "`
`-rightBottomCornerNeighbor cellName`	The cell to be abutted with the right side of rightBottomCorner in R0 orientation. *Default*: `" "`
`-rightBottomCornerOdd` *cellName*	Specifies end cap with n-well at the right-bottom corner, odd sites. *Default*: `" "`
`-rightBottomEdge` *cellName*	Specifies the cell that has n-well cap on its right bottom edge when in R0 orientation. Thus, these cells are the flipped-in-X version of leftBottomEdge cell. Usuallym one of these 2 is sufficient for a library.
`-rightBottomEdgeEven` *cellName*	Specifies end cap with n-well at the right-bottom edge, even sites. *Default*: `" "`
`-rightBottomEdgeNeighbor` *site1_cell site2_cell...*	Specifies the list of cells to be abutted with the left edge of rightBottomEdge in R0 orientation. *Default*: `" "`
`-rightBottomEdgeOdd` *cellName*	Specifies end cap with n-well at the right-bottom edge, odd sites. *Default*: `" "`

`-rightCornerBottomBorder` *ListOfCellNames*	Specifies the inner right corner bottom border cell. *Default*: " "
`-rightCornerTopBorder` *ListOfCellNames*	Specifies the inner right corner bottom border cell. *Default*: " "
`-rightEdge` *cellName*	Specifies the cell that has n-well cap on its right edge when in R0 orientation. Thus, these cells are used to cap the left edge of the core-rows in R0. In 2 well process, this would be the pre-cap cell.
`-rightEdgeBottomBorder` *cellName*	Specifies end cap with n-well at the right edge, poly at the bottom boundary. *Default*: " "
`-rightEdgeEven` *cellName*	Specifies end cap with n-well at the right edge, even sites. *Default*: " "
`-rightEdgeOdd` *cellName*	Specifies end cap with n-well at the right edge, odd sites. *Default*: " "
`-rightEdgeTopBorder` *cellName*	Specifies end cap with n-well at the right edge, poly at the top boundary. *Default*: " "
`-rightTopCorner` *ListOfCellNames*	Specifies a list of cells that have n-well cap on their right top corner when in R0 orientation. Thus, this cell, in R0, is added on right corner of core, or concave corner of a rectilinear hard macro.
`-rightTopCornerEven` *cellName*	Specifies end cap with n-well at the right-top corner, even sites. *Default*: " "
`-rightTopCornerNeighbor` *cellName*	Specifies the cell to be abutted with the right side of rightTopCorner in R0 orientation. *Default*: " "
`-rightTopCornerOdd` *cellName*	Specifies end cap with n-well at the right-top corner, odd sites. *Default*: " "
`-rightTopEdge` *cellName*	Specifies the cell that has n-well cap on its right top edge when in R0 orientation. Thus, this cell is the R180 version of leftBottomEdge.
`-rightTopEdgeEven` *cellName*	Specifies end cap with n-well at the right-top edge, even sites. *Default*: " "
`-rightTopEdgeNeighbor` *site1_cell site2_cell...*	Specifies the list of cells to be abutted with the left edge of rightTopEdge in R0 orientation. *Default*: " "
`-rightTopEdgeOdd` *cellName*	Specifies end cap with n-well at the right-top edge, odd sites. *Default*: " "

`-topBottomEdge` *`ListOfCellNames`*	Specifies the cell that has an n-well cap on its top edge as well as bottom edge when in R0 orientation.
`-topEdge` *`ListOfCellNames`*	Specifies the list of cells that have n-well cap on their top edge when in R0 orientation. Thus, these cells are used to cap the bottom-core row, or row at top of a hard macro.
`-useEvenOddSite {none|even|odd}`	Specifies to use even or odd poly sites. • `none`: EVEN/ODD cells are not considered even if they are specified • `even`: Need to specify EVEN boundary cell, suc as `-leftEdgeEven` • `odd`: Need to specify ODD boundary cell, such as -l`eftEdgeOdd` *Default*: `none`
`-wall_keepout_from_vertical_boundary` *`macro`*	Specifies the wall keep-out spacing from left/right boundary cell. *Default*: 0 *Minimum*: 0 *Maximum*: 2147483647
`-wall_offset` *`macro`*	Specifies the x coordinate of the first wall column. *Default*: 0 *Minimum*: 0 *Maximum*: 2147483647
`-wall_pitch` *`macro`*	Specifies the wall pitch. *Default*: 0 *Minimum*: 0 *Maximum*: 2147483647
`-wall_to_convex_corner_spacing` *`macro`*	Constraints the spacing between wall and convex corner. *Default*: 0 *Minimum*: 0 *Maximum*: 2147483647

Example

- The following command controls that the cell ABC being placed at the end of each row and cell XYZ being placed at beginning of each row by `addEndCap` command:

  ```
  setEndCapMode -leftEdge ABC -rightEdge XYZ
  ```

- An example of a library with 4 types of cells, `RightEdge RE`, `TopEdge TE`, `LeftTopEdge LTE`, and `LeftTopCorner LTC`, would have the following placement of end caps:
  - Pre-caps for start of rows would be `cap_RE` in `R0 (N)` and `MX (FS)` orient.
  - Post-caps for end of rows would be `cap_RE` in `MY (FN)` and `R180 (S)` orient.
  - Caps for bottom of core, and in core-row on top of macro blocks would be `cap_TE` in `R0 (N)` orient (i.e. core has to start from `R0` row; else the bottom `FS` row would be wasted).
  - Caps for top of core, and at bottom of macro blocks would be `cap_TE` in `MX (FS)` orient (that is, if block gets placed on a `FS` row, and row below it is `N` row, then the `N` row has to be blocked so caps can be placed below it on `FS` orient row).

- A `cap_LTE` cell can be used at 4 corners in `R0` (left-bottom), `MY` (right-bottom), `R180` (right-top), and `MX` (left-top) orient.
- Similarly, a `cap_LTC` cell is used for inner edges of a rectilinear block macro in its 4 orients, just as the corner cell.

All the cells need to have `SYMMETRY X Y` defined in LEF.

[-y_flip_type { integer : { first | last } ... }]
```

Controls certain aspects of how the software adds filler cells. The mode setting is persistent and saved along with the database by the `saveDesign` command.

Use `getFillerMode` to return the current settings for the `setFillerMode` command.

The `setFillerMode` parameters affect the behavior of the following commands:

- `addFiller`
- `deleteFiller`

  Note: Parameters specified by the `addFiller` or `deleteFiller` command supersede those specified by the `setFillerMode` command.

Parameters

`-add_fillers_with_drc {true|false}`	Calls the second addFiller without DRC checking. *Default:* `true` **Note**: When `-add_fillers_with_drc` is `true`, only DRC checking is switched off with routing in the second pass `addFiller` for the opt stage.
`-avoid_abutment_patterns { 1:1 1:2 ...}]`	Specifies illegal abutment patterns.

`-check_signal_drc {true | false}`	When `addFiller` is called after routing, instructs the software to run DRC checks of filler pins with signal net wires. To disable the DRC checks, set this parameter to `false`. *Default:* `true`
`-core {{list_of_cells1} {list_of_cells2} ...}`	Specifies the filler cells to add with `addFiller`. Enclose the filler cell names in quotation marks (") or curly braces ({ }). You can specify multiple cell lists at one time, using curly braces ({ }) to separate each one. *Default:* `""` (empty string)
`-corePrefix` *prefix*	Specifies the prefix for the added filler cells. *Default:* `""` (empty string)
`-createRows {true | false}`	Instructs `addFiller` to create rows in the floorplan. *Default:* `true`. If a cell's site does not have rows in the floorplan, `addFiller` creates the rows.
`-keepFixed {true | false}`	Keeps the `FIXED` filler cells. *Default:* `false`
`-diffCellViol {true|false}`	Checks violations between different cell types. Default: `false` **Note:** Using this feature will increase the runtime of `addFiller`.
`-distribute_implant_evenly {true|false}`	Distributes implant evenly for fillers. *Default*: `false`
`-ecoMode {true | false}`	Resolves overlaps of standard cells with fillers by removing the overlapping fillers and inserting new fillers in existing or newly created gaps due to partial overlaps. If you use this parameter after routing, the command also resolves DRC violations of filler geometries of all fillers with regular wires. *Default:* `false`
`-fitGap {true | false}`	Fills a gap between cells by adding a combination of cells, instead of by adding the single largest cell that fits, if doing so avoids leaving an unfilled single-width gap. *Default:* `true`
`-help`	Outputs a brief description that includes type and default information for each `setFillerMode` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setFillerMode`.

`-honorPrerouteAsObs {true | false}`	Instructs `addFiller` to honor the setting of `setPlaceMode -place_detail_preroute_as_obs`. By default, `addFiller` does not consider any preroutes to be obstructions. When this parameter is `true`, `addFiller` treats preroutes on metal layers where filler cells have geometries as obstructions, and ignores preroutes on other layers. In most cases, this means that `addFiller` treats preroutes on *metal1* as obstructions and ignores preroutes on other metal layers. For example, if `setPlaceMode -place_detail_preroute_as_obs` is set to *metal1* and *metal2*, and all the filler cell geometries are on *metal1*, `addFiller` treats *metal1* preroutes as obstructions but does not treat *metal2* preroutes as obstructions. *Default:* `false`. `addFiller` ignores `setPlaceMode -place_detail_preroute_as_obs` and inserts fillers in all legal sites.
`-horizontal_exception_cell {fillerCell ...}`	Specifies the list of exceptional cells for horizontal stack checking. *Default*: `""`
`-horizontal_max_length` *instance_length*	Specifies the instance max length (in micron) aligned in the horizontal direction. *Default*: `100` *Min*: `0` *Max*: `50000`
`-horizontal_repair_cell {fillCell ...}`	Specifies the list of filler cells to fix the horizontal max length violation. *Default*: `""`
`-preserveUserOrder {true | false}`	Specifies whether using the user defined filler cells order for filler insertion. Default: `false` Filler cells in each core list are sorted from largest to smallest. **Note**: The `-fitGap` and `-preserveUserOrder` options are mutually exclusive.
`-scheme {locationFirst | cellFirst}`	Specifies the filler insertion scheme. Default: `locationFirst` `locationFirst` fills each given location with the best filler before proceeding to next location. It always starts with the first empty site. `cellFirst` inserts filler cells based on the user-specified list. The tool tries to insert the first filler from the user list in all possible locations before moving to the second cell in the list.
`-swap_cell {{cell swap pair1} {cell swap pair2} ...}`	Swaps the specified cell pairs. *Default*: `""`
`-vertical_stack_exception_cell` *ListOfCellNames*	Specifies the list of exceptional cells for vertical stack checking. *Default*: `""`
`-vertical_stack_left_edge_exception_cell` *ListOfCellNames*	Specifies a list of cells in which only the left edge will not be checked for vertical stack violation. *Default*: `""`

`-vertical_stack_max_length` *instance_length*	Specifies the instance max length (in micron) aligned in the vertical direction. *Default*: `50` *Min*: `0` *Max*: `20000`
`-vertical_stack_repair_cell {fillerCell ...}`	Specifies the list of filler cells to fix the vertical max length violation. *Default*: `""`
`-vertical_stack_repair_edge {left|right}`	Specifies the edge to use the vertical repair cell. *Default*: `left`
`-vertical_stack_right_edge_exception_cell` *ListOfCellNames*	Specifies a list of cells in which only the right edge will not be checked for vertical stack violation. *Default*: `""`
`-reset`	Resets parameters to their default values. The `-reset` parameter *must* be the first parameter specified. If you specify `-reset` by itself, the software resets all `setFillerMode` parameters to their default values. If you specify parameters after `-reset`, the software resets only those parameters to their default values. Any values that do not already match the default value and are reset will be reported.
`-y_flip_type { integer : { first | last } ... }`	Defines the first or the last cell with certain cell size should be y-flipped. *Default*: `""`

Examples

- The following command assigns a prefix of `ABC` to filler instances of cells `FILL64` and `FILL8` when `addFiller` inserts the instances:
  ```
  setFillerMode -corePrefix ABC -core "FILL64 FILL8"
  ```
- The following command resets all `setFillerMode` parameters to their default values:
  ```
  setFillerMode -reset
  ```
- The following command make addFiller insert filler cells based on the user specified cell order `{FILLER8 FILLER16 FILLER4}`.
  ```
  setFillerMode -core {FILLER8 FILLER16 FILLER4} -preserveUserOrder true
  ```

setPinDensityMapMode

```
setPinDensityMapMode
[-help]
[-reset]
[-displayStep step_value]
[-gridInMicron micron]
[-gridInRow numberRow]
[-threshold density]
```

Sets global parameters for the `reportPinDensityMap` command. Parameters that you specify with `setPinDensityMapMode` are then used when you run `reportPinDensityMap`.

⚠ Parameters specified by the `reportPinDensityMap` command supersede the parameters specified by the `setPinDensityMapMode` command.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `setPinDensityMapMode` parameter. For a detailed description of the command and all of its parameters, use the man command: `man setPinDensityMapMode`
`-reset`	Resets all or specified options to default value. Any values that do not already match the default value and are reset will be reported.
`-displayStep step_value`	Specifies the range step for displaying the pin density map calculations. *Default:* `.05`
`-gridInMicron micron`	Specifies the value (in micron) of side of the square grid for pin density calculations. *Default:* `50` *Minimum:* `0.000000` *Maximum:* `1000.000000`
`-gridInRow numberRow`	Specifies the value (in row-height) of side of the square grid for pin density calculations. *Default:* `10` *Minimum:* `1` *Maximum:* `100`
`-threshold density`	Specifies the threshold value over which the densities must be reported. *Default*: `0.5`

Controls certain aspects of how the software places cells.

Use the `getPlaceMode` command to return the current settings for the `setPlaceMode` command.

The `setPlaceMode` parameters affect the behavior of the following commands:

- `place_design`
- `refinePlace`

  Note: Parameters specified by the `place_design` or `refinePlace` commands supersede those specified by the `setPlaceMode` command.

Parameters

`-place_design_floorplan_mode {true | false}`	Runs placement in floorplan mode. This mode is used for prototyping and runs quickly to gauge the feasibility of the netlist, but might not place design components in legal locations. **Note:** When `-place_design_floorplan_mode` is set to `true`, it disables congestion-driven placement. Option `-place_global_cong_effort` is set to `low`. *Default:* `false`
`-place_design_integrity_ir_fix_effort {low|medium|high}`	Sets the power integrity placement IR fixing effort. *Default:* `low`
`-place_design_refine_macro {true|false}`	Specifies whether to run `refine_macro_place` after `place_design -concurrent_macros`. When `place_design -concurrent_macros` is run, it sets the value of `setPlaceMode -place_opt_run_global_place` to `seed`. *Default:* `false`
`-place_design_refine_place {true | false}`	Specifies whether to run detailed placement (`refinePlace`) to legalize placed standard cells. If `setDesignMode -powerEffort` is set to `high`, `-place_design_refine_place` automatically set to `true`. *Default:* `true`

`-place_detail_activity_power_driven {true|false}`	When `true`, it turns on the activity-driven tweakage, and flow change depends on the effort. *Default:* `false`
`-place_detail_allow_border_pin_abut {true | false}`	Some libraries have cells with pin geometry that is not set back by half-routing pitch from the normal PR-boundary of that cell. In cases where the pin geometries touch the cell PR_boundary, placement of an instance of this cell can cause a DRC violation with a normal pin geometry of the other cells. To avoid these DRCs, placer will add one Site padding to the cell-side during pre-processing, thus satisfying the min-spacing rules. The `-place_detail_allow_border_pin_abut` option disables this pre-emptive DRC avoidance behavior, and no auto-padding is done when the option is set to true. *Default*: `false`
`-place_detail_allow_single_height_row_symmetry_x` *`siteName`*	Specifies a single height row tech-site, which allows symmetry X during detail place. *Default:* `""`
`-place_detail_check_cut_spacing {true | false}`	Enables the via-to-via spacing check during `refinePlace` and `checkPlace`. *Default*: `false` This option is turned on by default for 16nm and below process designs.
`-place_detail_check_inst_space_group {true|false}`	Specifies whether the distance between instances that belong to the same space group would be honored during placement. *Default:* `false`
`-place_detail_check_route {true | false}`	Considers pre-routed `FIXED` signal wires and avoids creating DRC violations between `FIXED` signal wires and instance pins. When this parameter is not specified, `refinePlace` ignores `FIXED` signal wires. *Default:* `false` **Note:** Using this parameter might result in longer run time. If you specify `refinePlace -place_detail_io_pin_blockage`, you do not need to specify `-place_detail_check_route` for signal pins because `refinePlace` will treat the signal pins similar to supply pins for blockages. However, signal wires still need this parameter.

`-place_detail_color_aware_legal {true | false}`	Enables placer to honor and fix double pattern constraint violations between adjacent cells. *Default*: `false` **Note**: This option does not affect cell to pre-route color DRC checks.
`-place_detail_context_aware_legal {none|all|optional|required|user|ignore_soft}`	Instructs placer to support cell edge to cell edge spacing constraints as defined in the LEF files. The `optional`, `required`, `user`, `ignore_soft` argument values can be used separately or together, but they are exclusive to `all` and `none`. *Default*: `all`
`-place_detail_eco_max_distance` *maxDistance*	Specifies max distance, in microns, in the horizontal or vertical direction for the refinePlace ECO mode. For example, if the original location of the instance is at (x0 y0) and the specified eco max distance is M, the search window will be (x0-M, yo-M) (x0+M y0+M). The maximum movement should be less than 2M. *Default:* `0` *Minimum*: 0.000000 *Maximum*: 9999.000000 If `-place_detail_eco_max_distance` is not defined by the user, and the user does `refinePlace -eco`, the value of `-place_detail_eco_max_distance` is internally set to 10 Standard Cell height units. **Note**: This option will impact both `refinePlace -eco` and `refinePlace -inst`.
`-place_detail_eco_priority_insts {placed|fixed|eco}`	Specifies the instance priority for `refinePlace` ECO mode. • `placed`: Treats current instances as placeable but with higher priority. • `fixed`: Treats placed instances as fixed. • `eco`: Treats ECO instances with higher priority. *Default:* `placed`
`-place_detail_fixed_shifter {true | false}`	Specifies whether to set the shifters to `FIXED` status after placing them. When set to `true`, the level shifters are `FIXED` after placement. However, the placement for some of the level shifters can be skipped due to the following reasons: • The shifter has no connections outside its power domains. • The shifter has no valid location. *Default:* `false`

`-place_detail_honor_inst_pad {true|false}`	Honors padding from `specifyInstPad` in detail placement. *Default:* `false` When this option is set to `true`, instance padding is also considered in `refinePlace` and `checkPlace`.
`-place_detail_io_pin_blockage {true|false}`	Treats ioPins from top-level as pre-routes during DRV checks in legalization. *Default:* `false`
`-place_detail_iraware_max_drive_strength` *maxDriveStrength*	Specifies the current density value for the IR critical instances above which the instances gets padded during `refinePlace`. This means that the IR critical instances with the current density value more than the specified value gets padded. **Note**: There may be larger cell movement with this option, which can degrade the timing. So, it is preferred to be used at the pre-CTS stage in the flow. The current density values for the IR-critical instances are dumped in the Voltus Reports. *Default*: `0` *Minimum*: `0` *Maximum*: `2147483647`
`-place_detail_irdrop_aware_effort {none|low|medium|high}`	Used to enable the IR-aware feature in refinePlace. You can use the following settings to specify IR-drop optimization effort level to be used during `refinePlace`. You can specify the following optimization effort levels: • `none`: Disables the feature, default value. • `low`: Moves the IR-violating instances to nearby rows (in the vertical direction). The aggressor has the same priority as the other instances during legalization. • `medium`: : Moves the IR violating instances in both horizontal and vertical directions. The aggressor has higher priority than the other instances during legalization. • `high`: Moves the aggressor instances to nearby rows. The aggressor has higher priority than the other instances during legalization and considers the IR-drop violation as a hard rule during legalization. This option is not recommended in this version. *Default*: `none`

`-place_detail_irdrop_aware_timing_effort {none|standard|high}`	Specifies the timing-effort level to be used during IR-aware `refinePlace`. You can specify the following timing effort levels: • `none`: Disables the feature, refineplace is not timing aware. Tool uses the default value. • `medium`: `refineplace` is timing aware and minimizes the movement of the timing sensitive instances during `refineplace`. • `high`: `refineplace` is timing aware and does not move the timing sensitive instances during `refineplace`. *Default*: `high`
`-place_detail_irdrop_region_number` *valueOfDebugIrdrop*	Specifies the total number of regions in which the tool identifies the IR-violating instances. The tool dumps the IR-violating instances inside these regions in the reports. *Default:* `100`
`-place_detail_legalization_inst_gap` *numberOfSites*	Specifies the minimum sites gap between instances. *Default:* `0`
`-place_detail_max_shifter_column_depth` *microns*	Specifies the maximum distance from a vertical side that a shifter can be placed. *Default:* `999` (no effect)
`-place_detail_max_shifter_depth` *microns*	Specifies the maximum distance from a horizontal or vertical side that a shifter can be placed. *Default:* `999` (no effect)
`-place_detail_max_shifter_row_depth` *microns*	Specifies the maximum distance from a horizontal side that a shifter can be placed. The distance is measured from the power domain boundary, not from the edge of the placeable areas and accounts for gaps. *Default:* `999` (no effect)
`-place_detail_no_filler_without_implant {true|false}`	Specifies that there is no cell without the implant obs. For designs in which all standard cells and fillers have implant obs, you can specify this option to preserve enough spacing during refinePlace for later filler insertion. *Default:* `false`
`-place_detail_pad_fixed_insts {true | false}`	Specifies whether the `refinePlace` command honors cell padding on `FIXED` instances. *Default:* `false`
`-place_detail_pad_physical_cells {true|false}`	Honors cell-padding for physical instances in `refinePlace` and `addFiller`. *Default:* `false`

`-place_detail_preroute_as_obs {`*`layerNum ...`*`}`	Specifies layers on which preroute are taken as OBS. You can change this behavior by using the following command before running placement: `setPlaceMode -place_detail_preroute_as_obs` *Default:* `""` **Note**: This option is not recommended for Advanced nodes of 20nm and below.
`-place_detail_preserve_routing {true | false}`	Preserves all routed wires. This option is applicable to all the calls in `refinePlace`, either stand-alone, or internal to place_opt_design. *Default:* `true`. `refinePlace` deletes all routed wires.
`-place_detail_remove_affected_routing {true | false}`	Specifies whether `refinePlace` removes wires connected to moved cells only or to all cells. *Default:* `false`. Removes all wires, whether connected cells were moved or not.
`-place_detail_swap_eeq_cells {true | false}`	Determines whether master cells can be replaced by EEQ cells during detailed placement to improve routability. After detailed placement, the software reports the number of replacements. EEQ cells are defined in the LEF file. *Default:* `false`
`-place_detail_use_check_drc {true|false}`	Enables the FGC engine inside placement for DRC checking. This DRC engine is the same as one used by NanoRoute and `verify_drc`. *Default*: `false`
`-place_detail_use_diffusion_transition_fill {true|false}`	Specifies that the design has fillers with jogged diffusion obs . For designs where fillers with jogged diffusion obs are to be inserted between cells with varying diffusion widths, please specify this option. *Default*: `false`
`-place_detail_use_GA_filler_groups {true|false}`	Specifies that filler cell insts will only be replaced by logic insts that belong to the same GA groups. *Default*: `false`
`-place_detail_use_no_diffusion_one_site_filler {true|false}`	Specifies that all one-site fillers do not have diffusion obs. For designs in which all one-site fillers without diffusion obs, you can use this option to preserve enough spacing during refinePlace for later filler insertion. This option can override the setting of `-place_detail_legalization_inst_gap` to `0`. *Default*: `false`

`-place_detail_wire_length_opt_effort {none|medium|high}`	Optimizes wire length by swapping cells. Optimization can reduce the total wire length up to two percent without degrading placement. In high-effort mode, it might add up to ten percent to the run time. *Default*: `medium`
`-place_global_activity_power_driven {false|true}`	Identifies and constrains power-critical nets to reduce switching power. *Default*: `false`
`-place_global_activity_power_driven_effort {none|standard|high}`	Specifies `place_global_activity_power_driven_effort` mode. *Default*: `standard`
`-place_global_align_macro {true|false}`	Enables mixed-placer to align nearby same-size macros during the global placement. *Default*: `true`
`-place_global_allow_3d_stack {true|false}`	Enables the 3D placement. *Default*: `false`
`-place_global_auto_blockage_in_channel {none | soft| partial}`	Creates placement blockages in narrow channels between macros before Global Placement • `soft`: Adds physical soft blockages by calling the `finishFloorplan` command. • `partial`: Creates a partial blockage whose density will be determined automatically. • `none`: Prevents the creation of blockage automatically by placer. *Default*: `none` **Note:** The "soft" option only prevents cells being placed inside the channels during global placement. refinePlace called by optimization can still place the cells inside the channels. **Note:** The threshold to activate the soft blockage insertion when the option is set to "soft" is when the channels between macros are less than 50 um in width.
`-place_global_clock_gate_aware {true | false}`	Specifies that placement is aware of clock gate cells in the design. *Default*: `true`. **Note:** `-place_global_clock_gate_aware` now finds better placement for clock gating elements towards the center of gravity for fanout.
`-place_global_clock_power_driven {true|false}`	Improves clock wirelength and subsequently clock power by adding more weight to clock nets between clock gates and their respective Flops. *Default*: `true`

`-place_global_clock_power_driven_effort {low|standard|high}`	Specifies the place_global_clock_power_driven_effort mode. *Default:* `low`
`-place_global_cong_effort {low | medium | high |auto}`	Specifies the effort level for relieving congestion. *Default:* `auto` Specify one of the following values: • `auto`: Automatically determines whether the design is congested and performs extra congestion driven effort for highly congested designs. • `high`: Runs more iterations of placement in an effort to achieve better congestion results. This parameter increases the run time. • `low`: Runs fewer iterations of placement to arrive quickly at a legal placement. This parameter might decrease placement quality. • `medium`: Runs placement on designs at a normal effort level.
`-place_global_cpg_effort {low|medium|high}`	Specifies the effort level of pushing instances to the guided locations during the CPG flow. With higher level, placement will increase the force to push instances to the guided locations, but might degrade wire length and timing QOR **Note**: This option need to be specified together with `-place_global_cpg_file`. *Default*: `low`
`-place_global_cpg_file` *cpgFileName*	Specifies the CPG guide file. When this option is specified, the CPG flow is turned ON automatically. *Default*: "" **Note**: To run the CPG flow, you must save a guide file from the old version DB and read it during the mixed placement flow on the new version netlist.
`-place_global_enable_advanced_pipeline {true|false}`	Enables advanced pipeline placement. *Default*: `false`
`-place_global_enable_distributed_place {true|false}`	Enables distributed placement platform. *Default*: `false` **Note**: This option is part of a limited-access feature in this release. It is enabled by a variable specified using the `setLimitedAccessFeature` command. To use this feature, contact your Cadence representative to explain your usage requirements, and make sure this feature meets your needs before deploying it widely.

`-place_global_ignore_scan{true|1|false|0|auto}`	Disregards scan connections while placing the instances that belong to scan chains. Before you place the design, you must already have specified the scan cells with the `specifyScanCell` command, or the scan cell information must be in the timing library. *Default*: `true` **Note:** Scan groups are sometimes called scan partitions.
`-place_global_ignore_spare {true | false}`	Disregards spare cell connections while placing spare cells. Before you place the design, you must already have specified the spare cells with the `specifySpareGate` command, or the spare cell information must be in the timing library. *Default*: `false`. `place_design` ignores spare cell connections. **Note:** The placer disconnects high-fanout (nets with more than 75 terminals) from spare cells, even when this parameter is set to `false`.
`-place_global_max_density` *value*	Controls the maximum density of local bins during global placement. Sets the maximum density of core area so that the placement engine satisfies the maximum density constraint while working on timing, wire length, and congestion. Use a value between 0 (zero percent) and 1 (100 percent). For example, a value of 0.5 indicates that the maximum density in the entire design will be 50 percent or less. *Default*: `-1.000` **Note**: It is recommended that the `place_global_max_density` value should be greater than standard cell utilization of design. **Note**: Using this option might degrade congestion and timing QOR of Global placement.
`-place_global_module_aware_spare {true | false}`	Places spare cells in the netlist within a hierarchical module, even if no region or fence constraints are specified. • When this parameter is `true`, spare cells in a logical hierarchy are placed within the bounds of the hierarchy. • When this parameter is `false`, spare cells are spread out within the placement area, and are not bound to a hierarchical module. *Default:* `false`

`-place_global_module_padding` *`module factor`*	Specifies a module in which to add padding (placement clearance) and a factor to use to calculate the padding dimension. Adding padding reduces placement density and localized congestion (hotspots) by spreading out cell instances in the specified modules. Module padding provides guidance for global placement only, and is ignored during placement legalization (`refinePlace`). *Default:* `""` (empty string) • `module`: Specifies a hierarchical instance to which the factor applies. You can use "prefix matching" when you specify the instance name. For example, you can use the following command to specify the module padding for all u_ram_block_{2,4,6} module. `setPlaceMode -place_global_module_padding {u_ram_block_ 2.0}` • `factor`: Specifies a factor to use to calculate the padding dimension. The placer multiplies the instance area of all cell instances under the specified module by the factor. For example, a factor of 2 means that the placer "sees" each cell as twice its actual size. In most cases, a factor of 1.2 (which increases the area by 20 percent) is good enough. The placer ignores factors that are less than 1.0. *Default*: `1`
`-place_global_place_io_pins {true | false}`	Moves placed and unplaced I/O pins, based on the placement of connected instances in an attempt to find a better I/O pin placement than the one specified in the I/O pin placement or floorplan file. At the end of global placement, the I/O pin location is legalized. When the value of this parameter is `false`, I/O pins are ignored during global placement and no legalization is done at the end. *Default:* `false` ⚠ If `place_design` does not place the standard cells, for example if all instances are fixed or if there is no placeable area, then `place_design` also skips I/O pin assignment.
`-place_global_reorder_scan {true | false}`	Performs scan chain reordering after placement. If you specify `false` for this parameter, the software does not perform scan chain reordering after placement. *Default*: `true`

`-place_global_soft_guide_strength {low | medium | high}`	Instructs placement engine to place those modules which have been specified as softguide in the floorplan file closer. The degree of closeness depends on the strength given. In case, there are fixed/preplaced instances, the module placed gets affected by those fixed instances and therefore placed close to them. *Default:* `low`
`-place_global_timing_effort {medium|high}`	Specifies the level of effort for timing driven global placer. **Note**: `setPlaceMode -place_global_timing_effort high` is not recommended for congested designs. *Default*: `medium` ⚠ This option is part of a limited-access feature in this release. It is enabled by a variable specified using the `setLimitedAccessFeature` command. To use this feature, contact your Cadence representative to explain your usage requirements, and make sure this feature meets your needs before deploying it widely.
`-place_global_uniform_density {true | false}`	Enable even cell distribution for designs with less than 70% utilization. *Default*: `false`
`-place_hard_fence {true|false}]`	Specifies whether `refinePlace` and `checkPlace` honor or ignore the fence and region placement constraints while legalizing placed instances. *Default:* `true` (`refinePlace` and `checkPlace` honor the constraints) **Note**: In optimization, the fence and region constraints are disabled by default in non-MSV designs for better timing enclosure, which is controlled by `setOptMode -opt_honor_fences` with the `false` default value. For the fence and region constraints to be honored by optimization commands, both `setOptMode -opt_honor_fences` and `setPlaceMode -place_hard_fence` must be set to `true`.
`-place_hierarchical_flow {true|false}`	Enables hierarchical pin assignment flow. *Default*: `false`
`-place_opt_post_place_tcl` *`tcl_file`*	Sources the tcl script after placement and before running optimization inside `place_opt_design`. *Default:* `""`

`-place_opt_run_global_place {none|seed|full}`	Changes the Global Placement behavior inside `place_opt_design`. • `none`: Skips place_design and runs only preCTS Optimization inside place_opt_design. • `seed`: Uses seed placement from Concurrent Macro Placement or other sources and runs incremental standard cell placement, then runs preCTS optimization. • `full`: Runs full global placement and preCTS optimization. *Default:* `full` When `place_design -concurrent_macros` is run, it sets the value of `setPlaceMode -place_opt_run_global_place` to `seed`.
`-place_spare_update_timing_graph {true|false}`	Updates the timing graph during `placeSpareModule`. *Default:* `true`
`-reset`	Resets parameters to their default values. The `-reset` parameter *must* be the first parameter specified. If you specify `-reset` by itself, the software resets all `setPlaceMode` parameters to their default values. If you specify parameters after `-reset`, the software resets only those parameters to their default values. Any values that do not already match the default value and are reset will be reported.

Examples

- The following commands add padding to the cells in module `ABC` so that the placer sees them as 1.5 times (50 percent larger) than their actual area:

```
setPlaceMode -place_global_module_padding ABC 1.5
place_design
```

- The following command resets all `setPlaceMode` parameters to their default values:

```
setPlaceMode -reset
```

- The following command will enable `place_design` to improve congestion:

```
setPlaceMode -place_global_cong_effort high -place_global_max_density .8
```

setScanReorderMode

```
setScanReorderMode
[-help]
[-reset]
[-addScanPortPrefix prefix]
[-clkAware {true | false}]
[-compLogic {true | false}]
[-enable_for_partition {true|false}]
[-keepPDPorts {true | false}]
[-keepPort fileName]
[-preferH {true | false}]
[-preferV {true | false}]
[-scanEffort {low | medium | high | auto}]
[-skipMode {skipNone | skipBuffer | skipFloatingBuffer}]
[-swapEffort {low|medium|high}]
```

Controls certain aspects of how the software reorders scan chains.

Use the `getScanReorderMode` command to return the current settings for the `setScanReorderMode` command.

Note: Parameters specified by the `scanReorder` command supersede those specified by the `setScanReorderMode` command.

Parameters

`-addScanPortPrefix` *prefix*	Specifies the prefix to be added to scan hports. *Default:* `""`
`-clkAware {true | false}`	Specifies whether scan reordering is clock tree aware. • When `true`, scan reordering is clock tree aware, and is clock tree driven. • When `false`, scan reordering is not clock tree aware, and is wirelength driven. *Default:* `false` (The software is not clock tree aware.)
`-compLogic {true | false}`	If set to `true`, enables `-scanTrace` trace through multiple input logic gates (whose input/output pin is not defined in the input scan DEF) in the scan path. *Default*: `false` **Note:** When `-compLogic` is set to true, there can be multiple valid scan paths. In that case, `scanTrace` will select one of the valid paths. However, it is recommended that you specify the relevant gate's input/output pin to avoid trace through alternative paths.
`-enable_for_partition {true|false}`	Enables `scanReorder` for a design with partition. This option works with the `-keepPort` option. *Default*: `false`
`-help`	Outputs a brief description that includes type and default information for each `setScanReorderMode` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setScanReorderMode`.

`-keepPDPorts {true | false}`	Maintains or corrects the hierarchical ports without deleting or inserting shifters, and reorders the remaining scan chain. *Default:* `true` **Note:** This parameter works in the MSV flow only.
`-keepPort` *fileName*	Specifies a file that lists the names of hierarchical instances whose ports cannot be changed, removed, duplicated, or reordered during scan reordering. *Default:* `""`
`-preferH {true | false}`	Specifies that the preferred direction for scan reordering connections is horizontal. Reorders the scan chain to snake a sideways "S" configuration if the block is short and wide or the design has vertical routing congestion. *Default:* `false` **Note:** If both `-preferV` and `-preferH` are set to `true`, the software does not honor the setting and treats them both as if they were `false`.
`-preferV {true | false}`	Specifies that the preferred direction for scan reordering connections is vertical. Reorders the scan chain to snake a vertical "S" configuration if the block is long and narrow or the design has horizontal routing congestion. *Default:* `false` **Note:** If both `-preferV` and `-preferH` are set to `true`, the software does not honor the setting and treats them both as if they were `false`.
`-reset`	Resets parameters to their default values. The `-reset` parameter *must* be the first parameter specified. If you specify `-reset` by itself, the software resets all `setScanReorderMode` parameters to their default values. If you specify parameters after `-reset`, the software resets only those parameters to their default values. Any values that do not already match the default value and are reset will be reported.
`-scanEffort {low | medium | high | auto}`	Specifies the effort level for reordering scan chains. *Default:* `auto` Specify one of the following values: • `auto`: Runs internal reorder effort, and it may tune at different stages. • `high`: Runs more iterations of scan reorder to achieve better net length. Using this parameter increases the run time. • `low`: Runs fewer iterations of scan reorder to minimize net length quickly. • `medium`: Runs a normal number of iterations.

`-skipMode {skipNone | skipBuffer | skipFloatingBuffer}`	Specifies how scan reordering handles buffers and inverters in the scan chain. *Default:* `skipNone` Specify one of the following: • `skipNone`: Specifies that buffers and inverters remain after the scan chain reorder. • `skipBuffer`: Ignores buffers in the scan chain. If a buffer is not connected elsewhere in the design, `scanReorder` removes the buffer. • `skipFloatingBuffer`: Skips only buffers in the floating section and keeps the buffers that belong to an ordered section. **Note**: During scan reordering, the order of scan elements in the ordered section must be kept as importing scan specification. However, the order of the floating elements can be changed.
`-swapEffort {low|medium|high}`	Specifies the effort level for scanReorder different chains swapping. *Default:* `high` Specify one of the following values: • `high` • `low` • `medium`

Examples

- The following command resets the `-keepPDPorts` parameter to its default value:
  ```
  setScanReorderMode -reset -keepPDPorts
  ```
- The following command resets all `setScanReorderMode` parameters to their default values:
  ```
  setScanReorderMode -reset
  ```

specify_cell_stack_area

```
specify_cell_stack_area
[-help]
-cell cell_name
-group group_name
-rect {x1 y1 x2 y2}
```

Defines the cell area that needs to be involved while calculating stack rule of the corresponding group.

Parameters

`-cell` *`cell_name`*	Specifies the cell name that has the stack constraint.
`-help`	Outputs a brief description that includes type and default information for each `specify_cell_stack_area` parameter. For a detailed description of the command and all of its parameters, use the man command: man `specify_cell_stack_area`
`-group` *`group_name`*	Specifies the cell group name with the stack constraint. **Note**: The group name must be pre-defined in the LEF file or by the `specify_cell_stack_group` command
`-rect {x1 y1 x2 y2}`	Specifies the constraint rectangular area with respect to the cell origin. If the whole cell is constrained, the rectangular coordinates match the cell boundary. If the rectilinear area in cell is constrained, divide the rectilinear area into multiple rectangular area then define each rectangular area in separate command lines.

Related Information

- `delete_cell_stack_area`
- `delete_cell_stack_group`

specify_cell_stack_group

```
specify_cell_stack_group
[-help]
-name group_name
{-max_horizontal_length max_continuous_length }
```

Defines the stack rule of a cell group.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `specify_cell_stack_group` parameter. For a detailed description of the command and all of its parameters, use the man command: `man specify_cell_stack_group`
`-max_horizontal_length` *`max_continuous_length`*	Specifies the maximum continuous length in horizontal direction.
`-name` *`group_name`*	Specifies the cell group name with the stack constraint.

Related Information

- `delete_cell_stack_area`
- `delete_cell_stack_group`
- `specify_cell_stack_area`
- `report_cell_stack_group`

specify_cell_virtual_align

```
specify_cell_virtual_align
[-help]
[-cell cells]
[-mask <id>]
[-pin_x_loc <microns>]
```

Aligns a filler cell that does not have any pin or obs geometries to align, but the cell still needs to be aligned. For example, a GA-Filler cell after the post-mask ECO becomes a logic cell and needs to be correctly aligned for the router to eco-route it.

The `specify_cell_virtual_align` command can be used to provide mask for the first track inside the cell, or 'offset' to the first track (or both). You need to specify `-mask` or `-pin_x_loc`.

The command auto-detects the layer for vertical alignment. If as per the placement initialization there is no need for vertical alignment (site-width and vertical-track-pitch are same, pin-mask are not fixed), the virtual alignment is turned off. this means that the `specify_cell_virtual_align` command will not help.

Parameters

`-cell` *`cells`*	Specifies the lib-cells with virtual alignment requirement.
-help	Outputs a brief description that includes type and default information for each `specify_cell_virtual_align` parameter. For a detailed description of the command and all of its parameters, use the man command: `man specify_cell_virtual_align`
`-mask` *`virtual_mask_value`*	Specifies the virtual mask value for the first track in the cell. If you specify `-mask` only, the offset of the first track in the core is used as the offset.
`-pin_x_loc` *`location_in_microns`*	Specifies the location of the virtual geometry from the cell boundary. If you specify offset only, the track can be of any mask-color, as long as offset matches. Default: *First track location*

Related Information

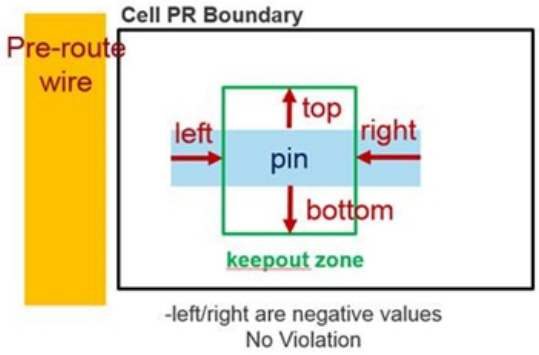
- `delete_cell_virtual_align`
- `report_cell_virtual_align`

specify_pg_keepout

specify_pg_keepout
```
[-help]
[-bottom value]
[-left value]
[-pin <string>]
[-right value]
[-top value]
{-cell lib_cell_name | -inst instance_name} {-layer layer_name | -layerId layer_id}
```

Defines the PG keepout box for a cell or a pin.

PG keepouts can be applied on the cell or cell pin. Keepout values can be positive or negative and are always from the edge for both pin and cell.



Parameters

`-bottom value`	Specifies the value to expand the keepout box on the bottom side.
`-cell lib_cell_name`	Specifies the lib cell that needs to be constrained by the PG keepout box.
`-help`	Outputs a brief description that includes type and default information for each specify_pg_keepout parameter. For a detailed description of the command and all of its parameters, use the man command: `man specify_pg_keepout`
`-inst instance_name`	Specifies the instance that needs to be constrained by the PG keepout box.
`-layer layer_name`	Specifies the layer on which the PG keepout box is applied. The layer is the LEF/OA name of routing layers.
`-layerId layer_id`	Specifies the layer Ids on which the PG keepout box is applied. The layer Id is the layer number of routing layers.
`-left value`	Specifies the value to expand the keepout box on the left side.
`-pin pin_name`	Specifies the pin that needs to be constrained by the PG keepout box.
`-right value`	Specifies the value to expand the keepout box on the right side.
`-top value`	Specifies the value to expand the keepout box at the top.

Example

The following command keeps `mycustomcell`/`the_m4_pin` away from M5 power stripes:

```
specify_pg_keepout -cell mycustomcell -pin the_m4_pin -layer M5
```

Related Information

- `delete_pg_keepout`
- `report_pg_keepout`

specifyCellEdgeSpacing

```
specifyCellEdgeSpacing
[-help]
{<edgeType1> <edgeType2> <spacing>
[-exceptAbutted | -forbiddenSpacing][-exceptNonFillerInBetween]} | [-reset]
```

Creates the cell edge spacing rule as in `CELLEDGESPACINGTABLE` in LEF.

⚠ The tool by default supports the latest Tcl settings. If a user tries to change the edge spacing, the tool will generate a warning message that resetting edge spacing would overwrite the old value.

Parameters

-exceptAbutted	Specifies that two abutted macros of the given edge types are also allowed.
edgeType1	Specifies edge `edgeType1` for edge spacing.
edgeType2	Specifies edge `edgeType2` for edge spacing.
`-exceptNonFillerInBetween`	Specifies that the edge spacing is only for adjacent instances. If two MACROs (cells) have a edge-spacing rule, say 0.8 micron, then normally the rule applies regardless of presence of another macro (cell) in the gap between. When the `-exceptNonFillerInBetween` option is used, the rule is exempted when a non-filler cell is present between the two constrained cell edges.
`-forbiddenSpacing`	Forbids *edgeType1* and *edgeType2* with the space.
`-help`	Outputs a brief description that includes type and default information for each `specifyCellEdgeSpacing` parameter. For a detailed description of the command and all of its parameters, use the man command: `man specifyCellEdgeSpacing`
`-reset`	Resets the cell edge spacing to LEF.
spacing	Specifies edge spacing between *edgeType1* and *edgeType2*. If there is no spacing defined between two edge types, it indicates that there is no spacing constraint (or 0.0 µm) between them.

Example

The following command creates `0.18 µm` spacing between `grp1` and `grp2`:

```
specifyCellEdgeSpacing grp1 grp2 0.18
```

Related Information

- deleteCellEdgeSpacing
- report_cell_edge_spacing
- specifyCellEdgeType

specifyCellEdgeType

```
specifyCellEdgeType
[-help]
{-left edgeType | -right edgeType | -top edgeType | -bottom edgeType | -reset }
[{-left edgeType | -right edgeType} [-cellRow rowNumber]]
[{-left edgeType | -right edgeType} [-half {top | bottom}]]
[{-top edgeType | -bottom edgeType} [-range {x y}]]
[{-cell cellName} [-reset]]
```

Specifies edge type for cell edges as `EDGETYPE` in macro LEF. It allows to specify one edge at a time for a particular cell.

To ensure the correct edge type specification, edge types asserted by `specifyCellEdgeType` command should be pre-defined by the `specifyCellEdgeSpacing` command.

For example:

```
specifyCellEdgeSpacing grp1 grp2 0.18
specifyCellEdgeType -cell BUF1X -left grp1
```

If the edge type is specified without corresponding spacing rule, tool gives a warning and ignores the edge type specification.

Parameters

`-bottom` *edgeType*	Specifies an edge type on the bottom side.
`-cell` *cellName*	Specifies cell to which to add edge constraint.

`-cellRow` *rowNumber*	Specifies the row number for horizontal edge type.
	You can define different edge types for each row of multiple height cells using `-cellRow`.
	For example, there is triple height cell CKBUF.
	 	The following commands define different edge types for different rows of the CKBUF cell.
	`specifyCellEdgeType -cell CKBUF -right grp1 -cellRow 1`
	`specifyCellEdgeType -cell CKBUF -right grp2 -cellRow 2`
	In the above example, grp1 is applied to the first row (bottom row) of the right edge, grp2 is applied to the second row of right edge, and no specific edge type is defined for the third row of right edge and is of DEFAULT type.
	The legal value of `-cellRow` is from 1 to n, where n is the number of cell height of the cell.

`-half {top bottom}`	Defines the edge types corresponding to the top or bottom half of the cell. The following example associates the edge type 'grp1' with the bottom row, top half of the multi-height cell SDFF8: `specifyCellEdgeType -cell SDFF8 -right grp1 -cellRow 1 -half top`

`-help`	Outputs a brief description that includes type and default information for each `specifyCellEdgeType` parameter. For a detailed description of the command and all of its parameters, use the man command: `man specifyCellEdgeType`
`-left` *edgeType*	Defines the edge types corresponding to the top or bottom half of the cell. The following example associates the edge type 'grp1' with the bottom row, top half of the multi-height cell SDFF8. `specifyCellEdgeType -cell SDFF8 -right grp1 -cellRow 1 -half top`

`-range {`*x y*`}`	Specifies the range for the vertical edge type.
	The range for the vertical edge type can also be negative.
	The following example defines a partial range of an edge that the type should be labeled.This could only be defined on TOP or BOTTOM edges.
	`specifyCellEdgeType -cell A -top GROUP1 -range 0 0.1`
	`specifyCellEdgeType -cell A -bottom GROUP1 -range 0 0.1`
	`specifyCellEdgeType -cell A -top GROUP2 -range 0.2 0.3`
	`specifyCellEdgeType -cell A -top GROUP3 -range 0.15 0.25`
	 	Blue line indicates GROUP1 edge
	Green line indicates GROUP2 edge
	Red line indicates GROUP3 edge
	Example of
	MACRO A
	…
	PROPERTY LEF58_EDGETYPE “
	EDGETYPE TOP GROUP1 RANGE 0 0.1 ;
	EDGETYPE BOTTOM GROUP1 RANGE 0 0.1 ;
	EDGETYPE TOP GROUP2 RANGE 0.2 0.3 ;
	EDGETYPE BOTTOM GROUP3 RANGE 0.15 0.25 ; “ ;
	…
	END A

`-reset`	Resets the specified cell constraint to the LEF status.
`-right` *edgeType*	Specifies an edge type on the right side.
`-top` *edgeType*	Specifies an edge type on the top side.

Example

The following commands specify one edge at a time for the `BUF1X` cell

- `specifyCellEdgeType -cell BUF1X -left grp1`
- `specifyCellEdgeType -cell BUF1X -right grp1 -cellRow 1`
- `specifyCellEdgeType -cell BUF1X -right grp1 -cellRow 2`

Related Information

- deleteCellEdgeSpacing
- `report_cell_edge_spacing`
- `specifyCellEdgeSpacing`

specifyCellPad

```
specifyCellPad
leaf_cellName
{padding | [[-right padding] [-left padding] [-top padding] [-bottom padding]]}
```

Specifies leaf cells to which padding (placement clearance) is to be added in the left, right, top, or bottom directions and a factor to use to calculate the padding dimension. The placer adds the padding on the sides of the specified cells during placement. The padding is retained during optimization and CTS.

If there are congestion problems, delete the padding by using the `deleteAllCellPad` command.

Parameters

`-bottom bottomPadding`	Specifies a factor to calculate the padding dimension on the bottom side. *Minimum*: `0` *Max*: `500`
leaf_cellName	Specifies the cell name(s) of a cell type to which the factor applies. You can use wildcards (`*`) with this parameter.
`-left leftPadding`	Specifies a factor to calculate the padding dimension on the left side.
padding	Specifies a factor to use to calculate the padding dimension. The placer multiplies the placement SITE by the factor. It reads the placement SITE value from the technology file. The factor should be integer number only. The unit of padding on left/right side is the number of sites. The unit of padding on top/bottom side is the number of rows
`-right rightPadding`	Specifies a factor to calculate the padding dimension on the right side.
`-top topPadding`	Specifies a factor to calculate the padding dimension on the top side. *Minimum*: `0` *Max*: `500`

Example

The following command adds padding that is twice the placement SITE to leaf cells named `FJK2`:

```
specifyCellPad FJK2 2
```

Related Information

- `deleteAllCellPad`
- Placing the Design chapter in the *Innovus User Guide*
  - Adding Padding

specifyInstPad

```
specifyInstPad
instName
{padding | [[-right padding] [-left padding] [-top padding] [-bottom padding]]}
```

Specifies a value (number of sites) for padding for an instance. Padding expands the area of an instance, so that the software leaves extra space around the instance during global placement (`place_design`), which helps reduce congestion in both the horizontal and vertical directions. In detail placement, user should specify `setPlaceMode -place_detail_honor_inst_pad` to `true` to honor left, right, top, and bottom instance padding.

Adding instance padding reduces horizontal and vertical congestion, but also decreases utilization.

Note: To remove instance padding, use the `deleteInstPad` command.

You can use the `reportInstPad` to report the padding for a specific instance, or all instance padding in the design.

Parameters

`-bottom` *padding*	Specifies the amount of padding at the bottom, in terms of number of rows.
instName	Specifies the instance to pad. You can use wildcards (`*`) when you specify the instance.
`-left` *padding*	Specifies the amount of padding on the left side, in terms of number of sites occupied by the instance.
padding	Specifies the amount of padding to add, in terms of number of sites occupied by the instance (sites are defined in the LEF file). For example, if an instance occupies eight sites, specifying 8 expands the area horizontally of the instance by 100 percent, and specifying 12 expands the area horizontally of the instance by 150 percent. The number you specify must be a whole number that is equal to or greater than zero.
`-right` *padding*	Specifies the amount of padding on the right side, in terms of number of sites occupied by the instance.
`-top` *padding*	Specifies the amount of padding at the top, in terms of number of rows.

Examples

- The following command adds padding of 2 sites around instance named U27316:

  ```
  specifyInstPad U27316 2
  ```

- The following command adds padding of 3 sites for all instances with prefix U2:

  ```
  specifyInstPad U2* 3
  ```

specifyJtag

```
specifyJtag
{-help}
{-cell leafCellName
    | -inst instName
    | -instGroup
    | -hinst hInstName
    | -group {hInstName | cellName}
    | -groupWArea {hInstName | cellName width height} }
```

Specifies instances to place with the `placeJtag` command. This command should be used before the `placeJtag` command.

Parameters

`-cell leafCellName`	Marks all instances of the specified cell type as JTAG instances.
`-group hInstName | cellName`	Marks all hierarchical instances or intermediate instances as JTAG instances.
`-groupWArea hInstName | cellName width height`	Marks all instances inside the hierarchical instance or intermediate cells as JTAG instances, and specifies a rectangular width and height where all instances or cells are placed within that rectangular region.
`-help`	Outputs a brief description that includes type and default information for each `specifyJtag` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man specifyJtag`.
`-hinst hInstName`	Marks a hierarchical instance as a JTAG instance.
`-inst instName`	Marks an instance as a JTAG instance. You can use a wildcard (`*`) character for this parameter.
`-instGroup`	Marks the instGroup name to be made JTAG instance

Command Order

Use this command before running the `placeJtag` command.

Example

- The following command specifies that the cell `jtag_FlipFlop` will be placed when using the `placeJtag` command:
  ```
  specifyJtag -cell jtag_FlipFlop
  ```
- The following command specifies that all instance names that begin with `instG` will be placed when using the `placeJtag` command:
  ```
  specifyJtag -inst instG*
  ```

Related Information

  - Specifying and Placing JTAG and Other Cells Close to the I/Os

specifyLockupElement

```
specifyLockupElement
{-cell leafCellName | -inst instName}
-in ftname
-out ftname
```

Specifies a cell or instance as a lockup element. Lockup elements are present in scan chains where the chain crosses between two different clock domains or clock phases. Use this command after running placement.

Parameters

`-cell leafCellName`	Specifies the cell to be a lockup element.
`-in ftname`	Specifies the name of the scan input.
`-inst instName`	Specifies the instance to be a lockup element.
`-out ftname`	Specifies the name of the scan output.

Example

The following command specifies that cell `TLATX1` is a lockup element with a scan input pin `D` and an output pin `Q`:

```
specifyLockupElement -cell TLATX1 -in D -out Q
```

Related Information

- Placing the Design chapter in the *Innovus User Guide*
  - Optimizing and Reordering Scan Chains

specifyScanCell

```
specifyScanCell
[-help]
[cellName]
[-in ftname]
[-out ftname]
[-scanClock ftname]
[-scanEnable ftname]
```

Specifies scan cells that are not listed in the timing library.

Parameters

cellName	Specifies name of the scan cell.
-in *ftname*	Specifies the name of the scan input.
-out *ftname*	Specifies the name of the scan output.
-scanClock *ftname*	Specifies the name of the scan clock.
-scanEnable *ftname*	Specifies name of the scan enable f-term or pin names.

Example

The following command specifies cell `SDFFQ` to be a scan cell:

```
specifyScanCell SDFFQ -in SI -out Q
```

Related Information

- `deleteAllScanCells`
- `deleteScanCell`
- `reportScanCell`

    - Optimizing and Reordering Scan Chains

specifyScanChain

```
specifyScanChain
[-help]
[scanChainName]
[-start {ftname | instPinName}]
[-stop {ftname | instPinName}]
```

Specifies a scan chain or group in a design. The actual tracing of the scan chain is performed by the `scanTrace` or `scanReorder` command. If scan chain specification fails, use the `scanTrace -verbose` command to see where the scan chain stops.

Note: Scan groups are sometimes called scan partitions.

> This command is not necessary for scan chains that are already specified in DEF or TDF files.

Parameters

scanChainName	Specifies a scan chain or scan group in a design.
`-start {`*ftname* `|` *instPinName*`}`	Specifies the starting scan pin name for the scan chain or scan group. Specifies the design input pin name. Specifies the instance output pin name.
`-stop {`*ftname* `|` *instPinName*`}`	Specifies the stopping scan pin name for the scan chain or scan group. Specifies the design output pin name. Specifies the instance input pin name.

Example

The following command sets scan chain `test_si` with a starting I/O pin name and a stopping pin name:

```
specifyScanChain test_si -start test23 -stop test_so
```

Related Information

- `deleteScanChain`
- `displayScanChain`

specifyScanChainPartition

```
specifyScanChainPartition
-partition partitionName
{-all | chainName1 chainName2 ...}
```

Defines a group (a partition) of compatible scan chains for the scan reordering flow. The software can swap elements in scan chains in the partition. Swapping elements helps reduce the total scan wire length in the partition and improves local congestion in the design.

To enable swapping, type the following command:

```
setScanReorderMode -allowSwapping true
```

Parameters

`-all`	All scan chains in the specified partition are compatible.
chainName1 chainName2 …	Only the specified scan chains in the specified partition are compatible.
`-partition` *partitionName*	Specifies a name for the partition and a list of the scan chains that belong to the partition. The scan flops in these chains are swappable.

Example

The following commands define two scan chains using `specifyScanChain` command, and define one partition using `specifyScanChainPartition`. The `setScanReorderMode -allowSwapping` parameter allows the software to swap elements between compatible chains.

```
specifyScanChain chain1 -start SI1 -stop SO1
specifyScanChain chain2 -start SI2 -stop SO2
specifyScanChainPartition -partition clk1Domain chain1 chain2
setScanReorderMode -allowSwapping true
scanReorder
```

specifySelectiveBlkgGate

```
specifySelectiveBlkgGate
[-help]
[-cell cellName]
[-inst instName]
```

Specifies cells and instances that are allowed to be placed inside the soft blockage during legalization.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `specifySelectiveBlkGate` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man specifySelectiveBlkGate`.
`-cell cellName`	Specifies the cell type name as legal for soft blockage. You can use wildcards (`*` or `?`) with this parameter.
`-inst instName`	Specifies the instance name as legal for soft blockage. You can use wildcards (`*` or `?`) with this parameter.

Examples

The following command specifies that cell `NR2RLX1` and all instance names that begin with `MEMCTLU` are allowed to be moved into soft blockage when legalization. `specifySelectiveBlkgGate -cell NR2RLX1 -inst MEMCTLU*`

Related Information

- `unspecifySelectiveBlkgGate`

specifySpareGate

```
specifySpareGate
{-help}
{-cell leafCellName
   |-inst instanceName
   | -hinst {hierarchicalInstanceName}}
```

Specifies spare gates to place. To localize spare gate placement, guide the module containing the spare gate during the floorplanning session. This command should be used before placing the design.

Parameters

`-cell leafCellName`	Specifies the cell type names of the spare gate cells. You can use this parameter to specify leaf cells (standard cells)--you cannot use it to specify spare modules. You can use wildcards with this parameter.
`-help`	Outputs a brief description that includes type and default information for each `specifySpareGate` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man specifySpareGate`.
`-hinst {hierarchicalInstanceName}`	Specifies a hierarchical instance that contains spare gate cells. A hierarchical instance acts as one unit (a submodule). The units are evenly spaced and are close together when they are distributed. You can use wildcards when specifying the hierarchical instance names.
`-inst instanceName`	Specifies the leaf instance names of the spare gates. You can use wildcards when specifying instance names.

Examples

- The following command specifies all cell types `YFD2S_SPG` to be spare gates:
  ```
  specifySpareGate -cell YFD2S_SPG
  ```
- The following command specifies instance `SH16/I1022` to be a spare gate:
  ```
  specifySpareGate -inst SH16/I1022
  ```
- The following command specifies that all instances in `SH16` to be spare gates:
  ```
  specifySpareGate -inst SH16/*
  ```
- The following command treats all instances with the cell type `NAND2X1` as spare cells. If the design uses some of these cells as spares and some as not spare, use the `-inst` parameter instead.
  ```
  specifySpareGate -cell NAND2X1
  ```
- The following example specifies multiple spare gates instances for the ECO placement:
  `specifySpareGate -inst spare_lv_more_* specifySpareGate -inst *SPAREcells_lv_*`
  Note: The `specifySpareGate` does not accept the "list" option for defining multiple spare gates.

swap_well_taps

```
swap_well_taps
[-help]
[-both_violation cellName]
-cells cellName
[-check_only]
[-default_cell defaultCellName]
-diffusion_forbidden_spacing float
[-left_violation cellName]
[-right_violation cellName]
[-skip_cells cellNameList]
[-swap_report reportName]
[-violation_report reportName]
```

Swaps to custom tap cell to avoid OD spacing rule.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `swap_well_taps` parameter. For a detailed description of the command and all of its parameters, use the man command: `man swap_well_taps`.
`-both_violation cellName`	Specifies well taps to swap if only violating rules on both sides.
`-cells cellNameList`	Specifies well taps to swap if there is violation of rules.
`-check_only`	Checks violations only without swapping tap cells.
`-default_cell defaultCellName`	Swaps to default well tap first. Default well tap must be one of *cells*.
`-diffusion_forbidden_spacing float`	Specifies forbidden spacing rule.
`-left_violation cellName`	Specifies well taps to swap if only violating rules on the left side.
`-right_violation cellName`	Specifies well taps to swap if only violating rules on the right side.
`-skip_cells cellNameList`	Specifies the cell that would skip the rule check.
`-swap_report reportName`	Reports the swapped instances.
`-violation_report reportName`	Reports the violated instances.

Related Information

- addWellTap
- set_well_tap_mode

traceJtag

```
traceJtag
-infile jtagPinFile
-outfile jtagInstanceFile
```

Traces JTAG logic between the I/O pins and the pins of given leaf instances. The input file contains a list of pins of instances that are the endpoints of JTAG logic. The command writes out a Tcl file that lists all the JTAG logic traced. You can then source the file to add this information to the Innovus database.

Parameters

`-infile jtagPinFile`	Specifies a file that lists the endpoints of JTAG logic. In the file, list each leaf instance or list the cell and its port.
	• To list the leaf instances, use the `instpin` statement, as follows:
	`instpin leafInstanceNamepinName`
	• If all instances of a cell are used only in JTAG logic, you can list that cell and its port by using the `cellport` statement, as follows:
	`cellport cellTypeNameportName`
	To avoid tracing non-JTAG cells, the cells you specify in a `cellport` statement must be JTAG-only cells. The cell type cannot be an intermediate cell. It must have at least one physical leaf instance.

`-outfile jtagInstanceFile`	Specifies the JTAG logic file in Tcl format.

The following commands trace the JTAG logic based on the input file `jtag.leaf`, write the output file `jtag.out`, and add the logic specified in the file to the Innovus database:Example

```
traceJtag -infile jtag.leaf -outfile jtag.out
source jtag.out
```

Following is an example of an output file:

```
specifyJtag -inst regA
specifyJtag -inst regB
specifyJtag -inst regC
specifyJtag -inst regD
specifyJtag -inst regE
specifyJtag -inst regF
specifyJtag -inst regG
specifyJtag -inst regH
```

- reportJtagInst
- unplaceJtag

- Placing the Design chapter in the *Innovus User Guide*
  - Specifying and Placing JTAG and Other Cells Close to the I/Os

unplaceJtag

`unplaceJtag`

Changes the placement status of JTAG inst from FIXED to PLACED. This command can be used after the `placeJtag` command.

Parameters

None

Examples

The following set of commands places all Jtag instances of cell INVX1 as FIXED, and then using `unplaceJtag` to change their status to PLACED:

```
specifyJtag -cell INVX1
placeJtag
unplaceJtag
```

Related Information

    - Specifying and Placing JTAG and Other Cells Close to the I/Os

unspecifyJtag

```
unspecifyJtag
{-cell leaf_cellName
 | -inst instanceName
 | -hinst hierarchicalInstanceName
 | -group hierarchicalInstanceName | cellName}
```

Unspecifies instances that were specified by the `specifyJtag` command. This command can be used if there is instance specified by the `specifyJtag` command.

Parameters

`-cell leaf_cellName`	Unmarks all instances of a specified cell type as JTAG instances.
`-group hierarchicalInstanceName | cellName`	Unmarks all hierarchical instances or intermediate instances as JTAG instances.
`-hinst hierarchicalInstanceName`	Unspecifies a hierarchical JTAG instance.
`-inst instanceName`	Unspecifies a JTAG instance. You can use wildcards (`*` or `?`) with this parameter.

Example

- The following command unspecifies cell `jtag_FlipFlop` that was specified by the `specifyJtag` command:
  ```
  unspecifyJtag -cell jtag_FlipFlop
  ```
- The following command unspecifies all instance names that begin with `instG` that were specified by the `specifyJtag` command:
  ```
  unspecifyJtag -inst instG*
  ```

Related Information

unspecifySelectiveBlkgGate

```
unspecifySelectiveBlkgGate
[-help]
[-cell cellName]
[-inst instName]
```

Specifies cells and instances that are forbidden to be placed inside the soft blockage during legalization.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `unspecifySelectiveBlkgGate` parameter. For a detailed description of the command and all of its parameters, use the man command: `man unspecifySelectiveBlkgGate`.
`-cell cellName`	Specifies the cell type name as illegal for soft blockage. You can use wildcards (`*` or `?`) with this parameter.
`-inst instName`	Specifies the instance name as illegal for soft blockage. You can use wildcards (`*` or `?`) with this parameter.

Examples

The following command specifies that cell `NR2RLX1` and all instance names that begin with `MEMCTLU` cannot be moved into soft blockage during legalization.

```
unspecifySelectiveBlkgGate -cell NR2RLX1 -inst MEMCTLU*
```

Related Information

- `specifySelectiveBlkgGate`

Placement Global Variables

- spgM3StripePushDown
- spgM3StripeShrink

spgM3StripePushDown

`spgM3StripePushDown`

Specifies the width threshold in site units for virtual push down of M3 stripe to M2 for M1 pin-access.

If the default value is set to `-1`, it indicates that no M3 stripe will be pushed down. If the default value is set to `0`, it indicates that all M3 stripes will be pushed down. If the default value is larger than `0`, then all m3 stripes having width greater than the specified value will be pushed down.

spgM3StripeShrink

`spgM3StripeShrink`

Specifies the shrink effort of the virtual M2 stripe by given total site units. This global should work with `spgM3StripePushDown`.

If the default value is set to `0`, it indicates that the entire pushed down M3 stripe is used to evaluate M1 pin access. If the default value is set to more than `0`, it indicates that M3 stripe will shrink by the specified value before it is pushed down to M2. The left side will shrink first. For example, if the specified value is set to `1`, the M3 stripe will shrink by 1 site on left, and if the specified value is set to `2`, 1 site on left will shrink, along with 1 site on right.

25

Power Analysis Commands

- getPGNetResis
- getSpecialNetResis

getPGNetResis

```
getPGNetResis
[-help]
[-net {netName +}]
[-outfile fileName]
[-temperature temperature]
[-view viewName]
[-worst | -p2p <x1 y1 layerName1 x2 y2 layerName2]
```

Computes the resistance of the power or ground net.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `getPGNetResis` parameter. For a detailed description of the command and all its parameters, use the man command: man `getPGNetResis`.
`-net {netName +}`	Specifies the name of the net for which resistance is to be computed. The command accepts multiple names. **Note:** The total resistance is the algebraic sum of the resistance of each individual wire and via, rather than the effective resistance of the entire resistor network.

`-outfile` *`fileName`*	Creates a report containing the nets' resistance values. The power analysis software adds the extension .res to the *fileName* you specify.
`-temperature` *`temperature`*	Specifies the temperature to be used during temperature-dependent resistance extraction. The temperature-dependent resistance coefficient is taken from the capacitance table.
`-view` *`viewName`*	Specifies the view to analyze.
`-worst`	For cases where a special net , that connects two or more instances by their non-PG pins, reports information on the worst (largest) effective resistance based on pair of pins, and the path that has the worst resistance.
`-p2p <x1 y1 layerName1 x2 y2 layerName2`	Computes the effective resistance between two instance pins. The point/layer specification is used to find the corresponding pin for calculation. • If you do not specify the option `-p2p`, the total resistance is the algebraic sum of the resistance of each individual wire and via. • If you specify the option `-p2p`, the total resistance is the effective resistance of the entire resistor network. Use the option `-p2p` with caution as it will take a while to get an effective R from large PG nets.

Example

- The following command displays a report within the Innovus console:
  ```
  pgNetResis vdd!
  ```
- The report is generated with the format shown in the following example:

```
Net Name: vdd!

total resistance: 5.843993e+01 Ohm

1 resistance: 3.530900e+01 Ohm

2 resistance: 0.000000e+00 Ohm

3 resistance: 0.000000e+00 Ohm

4 resistance: 0.000000e+00 Ohm

5 resistance: 2.459333e+00 Ohm

6 resistance: 2.324933e+00 Ohm

V12 resistance: 3.360000e+00 Ohm

V23 resistance: 3.360000e+00 Ohm

V34 resistance: 3.360000e+00 Ohm

V45 resistance: 5.600000e+00 Ohm

V56 resistance: 2.666667e+00 Ohm

resistance of selected wires/vias: 1.666667e-01 Ohm
```

getSpecialNetResis

```
getSpecialNetResis
[-help]
[-net {netName +}]
[-outfile fileName]
[-temperature temperature]
[-view viewName]
[-worst | -p2p <x1 y1 layerName1 x2 y2 layerName2]
```

Reports resistance values for specified nets. Use this command after power planning.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `getSpecialNetResis` parameter. For a detailed description of the command and all its parameters, use the man command: man `getSpecialNetResis`.
`-net {netName +}`	Specifies the names of regular or power/ground nets that appear in the `SPECIALNETS` section of the DEF file.
`-outfile` *`fileName`*	Creates a report containing the resistance values of nets. The power analysis software adds the extension `.res` to the *`fileName`* you specify.
`-temperature` *`temperature`*	Specifies the temperature to be used during temperature-dependent resistance extraction. The temperature-dependent resistance coefficient is taken from the capacitance table.
`-worst`	For cases where a special net , that connects two or more instances by their non-PG pins, reports information on the worst (largest) effective resistance based on pair of pins, and the path that has the worst resistance.
`-p2p <`*`x1 y1 layer1 x2 y2 layer2`*	Calculate resistance based on point-to-point coordinate and layer between two port layer shapes of instance pins. The pair of the pins are suggested both as PG pins or non-PG pins.

`-view` *viewName*	Specifies the view to analyze.

Examples

- The following command constructing power graph for P/G net `VDD_LOW`:

```
getSpecialNetResis -p2p 1095 2960 M5 3316 5705 M6 VDD_LOW

Inst1 is block0

Inst2 is WIR@IO@0154@0263

##### Start Calculating Resistance between each Dc Source and Current Sink #####

Width-based sheet resistance table (silicon width) is used ...

Resistance: 6.9025 Ohm : From block0/AVD (1094.94 2959.89 METAL5) To
WIR@IO@0154@0263/VDD (3298 5702 METAL6)

Resistance: 6.9014 Ohm : From WIR@IO@0154@0263/VDD (3316 5704.5 METAL6) To
block0/AVD (1082.44 2959.39 METAL5)

Effective resistance on net VDD_LOW between block0/AVD and WIR@IO@0154@0263/VDD =
6.9025 Ohms
```

- The following command to construct power graph for net `SPNS_RESDEL3V`:

```
getSpecialNetResis -worst SPNS_RESDEL3V

##### Start Calculating Resistance between each Dc Source and Current Sink #####

Resistance: 6.971 Ohm : From buff_RESETZ0/POCREL3V (506.12 -2755.78 METAL2) To
buff_RESETZ0/RESDEL3V (508.54 -2756.2 METAL2)

Resistance: 381.44 Ohm : From buff_RESETZ0/POCREL3V (506.12 -2755.78 METAL2) To
ctop0/vreg0/REGRES3V (-1094.98 -2191.92 METAL2)
```

```
Resistance: 29.175 Ohm : From buff_RESETZ0/POCREL3V (506.12 -2755.78 METAL2) To
ctop0/nf_RESETZ0/RESDEL3V (531.27 -2673.66 METAL2)

Resistance: 8.1427 Ohm : From buff_RESETZ0/POCREL3V (506.12 -2755.92 METAL3) To
buff_RESETZ0/RESDEL3V (508.54 -2756.2 METAL2)

Resistance: 382.62 Ohm : From buff_RESETZ0/POCREL3V (506.12 -2755.92 METAL3) To
ctop0/vreg0/REGRES3V (-1094.98 -2191.92 METAL2)

Resistance: 30.346 Ohm : From buff_RESETZ0/POCREL3V (506.12 -2755.92 METAL3) To
ctop0/nf_RESETZ0/RESDEL3V (531.27 -2673.66 METAL2)

…

…

Worst effective resistance on net SPNS_RESDEL3V between buff_RESETZ0/RESDEL3V and
ctop0/vreg0/REGRES3V = 388.32 Ohms
```

analyze_thermal

```
analyze_thermal
-help
```

Specifies to invoke Celsius Thermal Solver to run die-only thermal analysis. The command generates the die temperature map file that is used by Voltus to run temperature-aware power/IR/EM analysis. Before specifying this command, use the `set_thermal_analysis_mode` command to set the parameters for performing chip-centric thermal analysis.

Parameters

`-help`	Outputs the command usage and a brief description about the command parameters.

Examples

- The following command specifies to run die-only thermal analysis:
  ```
  analyze_thermal
  ```

Related Topics

- set_thermal_analysis_mode

create_thermal_model

```
create_thermal_model
[-help]
[-leakage_temperature_scale_table {$temp1 $scalefactor1 $temp2 $scalefactor2 $temp3 $scalefactor3 .....}]
[-leakage_temperature_scale_table_file filename]
[-metal_density_file filename]
[-power_db path_to_power_database]
[-vtm_SI_unit {true | false}]
[-vtm_conductivity_inputs filename]
[-vtm_densitytable_tile {Xint Yint}]
[-vtm_file filename]
[-vtm_format {simple | stack} ]
[-vtm_format_version {new | default} ]
[-vtm_header_include_file filename]
[-vtm_leakage_temp {temp1 temp2 temp3} ]
[-vtm_output_dir directory]
[-vtm_powertable_tile {Xint Yint} ]
[-vtm_tile {Xint Yint}]
[-vtm_tile_size {$X_um $Y_um}]
```

Sets the parameters for extracting the metal density information. This command must be specified before the `extract_metal_density` command.

Parameters

`-help`	Outputs the command usage and a brief description about the command parameters.
`-leakage_temperature_scale_table {$temp1 $scalefactor1 $temp2 $scalefactor2 $temp3 $scalefactor3 .....}`	
	Specifies the global scale factor for a temperature value to enable scaling of the leakage power values coming from the input dotlib file. This parameter allows you to scale the power values only at certain specific temperatures. This parameter allows you to generate a multi-temperature leakage power map table from a single input dotlib file in the power map generation flow. `-leakage_temperature_scale_table` and `-leakage_temperature_scale_table_file` are mutually exclusive.
`-leakage_temperature_scale_table_file filename`	

Specifies a file containing the user-defined temperature values and the corresponding scale factors for each library, cell, or instance. The format of the file is:

```
#Type Name temp1 temp2 temp3 temp4
Lib    library_name   scalefactor@temp1   scalefactor@temp2  scalefactor@temp3   scalefactor@temp4
Cell   cell_name      scalefactor@temp1   scalefactor@temp2  scalefactor@temp3   scalefactor@temp4
inst   instance_name  scalefactor@temp1   scalefactor@temp2  scalefactor@temp3   scalefactor@temp4
```

This parameter allows you to generate a multi-temperature leakage power map table from a single input dotlib file in the power map generation flow. `-leakage_temperature_scale_table` and `-leakage_temperature_scale_table_file` are mutually exclusive.

File Format Example for the Type Lib:

```
#Type Name         25 50 125 150
Lib   fast         1 2 10 100
Lib   bufao        1 2 10 100
Lib   header       1 2 10 100
Lib   pso_ring_wc  1 2 10 100
```

`-metal_density_file filename`

Specifies the VTM metal density file generated by the `extract_metal_density` command.

`-power_db path_to_power_database`

Specifies the path to the power database with cell boundary box, location, and rotation information. This is generated by specifying the `set_power_analysis_mode -save_bbx true` parameter.

`-vtm_SI_unit {true | false}`

Specifies the unit definition for power and length. The possible arguments are:

- `true`: unit will be in m and W.
- `false`: unit will be um and mW.

Default is `true` with unit m(meter) for length and W(Watt) for power.

`-vtm_conductivity_inputs filename`

This parameter is same as the `set_metal_density_options -thermal_conductivity_file` parameter. When you want to overwrite the thermal conductivity defined in the metal density file, you can provide a new thermal conductivity file using the `create_thermal_model -vtm_conductivity_inputs` command.

`-vtm_densitytable_tile {Xint Yint}`

Specifies the number of tiles in the X and Y directions for the metal density tables only.

`-vtm_file filename`

Specifies the name of the output Voltus thermal model file.

`-vtm_format {simple | stack}`

	Generates a tile-based power map file in the simple or stack format to perform accurate thermal analysis. The possible arguments are: • `simple`: generates only power tables without metal density tables. • `stack`: generates both power and metal density tables.
`-vtm_format_version {new | default}`	
	Determines whether to generate the default or the new power map file format. This parameter allows you to have different tile number between the power table and the metal density table. When set to `new`, the power map file format with non-uniform tile numbers for the power (`-vtm_powertable_tile`) and metal density tables (`-vtm_densitytable_tile`) can be generated.
`-vtm_header_include_file` *filename*	
	Allows you to define extra header information like file location.
`-vtm_leakage_temp {`*temp1 temp2 temp3*`}`	
	Specifies the leakage temperature values used for trilib (single voltage but different temperatures dot libs) in the power calculation flow to output user-defined temperature points' leakage power tables.
`-vtm_output_dir` *directory*	
	Specifies the directory path to the Voltus thermal model output folder.
`-vtm_powertable_tile {`*Xint Yint*`}`	
	Specifies the number of tiles in the X and Y directions for the power tables only.
`-vtm_tile {`*Xint Yint*`}`	
	Specifies the number of tiles in the X and Y directions for the generated Voltus thermal model file. The default is 10x10.
`-vtm_tile_size {`*$X_um $Y_um*`}`	
	Specifies the unit tile size in the X and Y directions for the generated thermal model file.

Examples

- The following command is an example of the trilib Tcl command, that is, uses the temperature in `vtm_leakage_temp` to calculate the leakage:

```
create_thermal_model \
-power_db powerdb \
-metal_density_file vtm_MD_db/my_chip.rpt \
-vtm_output_dir ./vtm_output \
-vtm_leakage_temp {20 50 80}
```

- The following command is an example of the mix-usage Tcl command, that is, some instances have trilib data while other instances only have a single library:

```
create_thermal_model \
-power_db powerdb \
-metal_density_file vtm_MD_db/my_chip.rpt \
-vtm_output_dir ./vtm_output \
-vtm_leakage_temp {20 50 80} \
-leakage_temperature_scale_table {0 1 20 2 50 3 100 10}
```

Related Topics

- `extract_metal_density`

dump_unannotated_nets

```
dump_unannotated_nets
[-help]
[-file filename]
-type annotationType
```

Shows the percentage of nets annotated by a specific type and also prints the names of all nets that are not annotated by that type.

Annotation information is stored on a per-file basis for activity, VCD, TCF, and user commands to provide detailed annotation reports when requested.

`dump_unannotated_nets` can be invoked multiple times with different report types (`-type`). You must specify this command before `report_power`.

Parameters

`-file filename`	Specifies the text file name that includes the annotation report information. If no file is specified, the report will be written to the default output file `annotation_type.log`, where `type` is taken from the `-type` argument specified.
`-help`	Outputs the command usage and a brief description about the command parameters.

`-type` *annotationType*	The type can be any of the following: • `all` Shows annotation reports for all types. • `activity` Shows annotation data for all types of activity specifications including TCF, VCD, SDC, TWF, and user commands that set activity. • `cap` Shows annotations from the SPEF files. • `fsdb` Shows annotations from the FSDB files. • `saif` Shows annotations from the SAIF files. • `tcf` Shows annotations from the TCF files. • `timing` Shows annotations from the TWF files. This type is applicable only to the dynamic power analysis flow. • `vcd` Shows annotation from the VCD files.

Example

- The following command dumps the nets in the netlist that are missing in the vcd file:
  ```
  dump_unannotated_nets -type vcd -file vcd.log
  ```
  The net names are written in the file `vcd`.log.
- The following command dumps the nets in the netlist which do not have an activity annotated from any source (VCD/TCF/SDC/TWF/user defined) and writes the net names in the file `unannotatednets.log`:
  ```
  dump_unannotated_nets -type all -file unannotatednets.log
  ```

Related Information

- `read_activity_file`
- "Dynamic Power and IRDrop Analysis" in the *Voltus IC Power Integrity Solution User Guide*

extract_metal_density

```
extract_metal_density
-help
```

Specifies to extract the metal density information. The command generates the Voltus Thermal Model (VTM) for Celsius only if you do not want to include power information. Before specifying this command, use the `set_metal_density_options` command to set the parameters for extracting the metal density information.

Parameters

`-help`	Outputs the command usage and a brief description about the command parameters.

Examples

- The following command specifies to run extract metal density:
  ```
  extract_metal_density
  ```

Related Topics

- `set_metal_density_options`

encrypt_thermal_file

```
encrypt_thermal_file
-input ASCII.txt
-output $encrypted_conductivity.txt
```

Specifies to encrypt the file containing the thermal conductivity value for layers, and to protect foundry's thermal conductivity parameters used for power map generation. This encrypted file is then specified with the `report_power -thermal_conductivity_inputs` parameter for generating a tile-based power map file.

Parameters

`-input ASCII.txt`	

	Specifies the name of the ASCII thermal file that needs to be encrypted. This file contains the thermal conductivity parameters used for power map generation.
	The `-input` parameter supports both layer type and layer name based thermal conductivity file.
	The following is a snippet of the input thermal conductivity file content (layer type based file):
	`Metal 430`
	`Silicon 250`
	`Dielectric 0.6`

`-output $encrypted_conductivity.txt`	

	Specifies the name of the encrypted output thermal file.
	The following is a snippet of the encrypted thermal conductivity file content:
	`Metal $encryption_value`
	`Silicon $encryption_value`
	`Dielectric $ecncryption_value`

Examples

- The following command encrypts the specified input file (`format_1.txt`) to generate the encrypted output file (`format_1_encr.txt`):

  ```
  encrypt_thermal_file -input encrypt/format_1.txt -output encrypt/format_1_encr.txt
  ```

  The encrypted file (`format_1_encr.txt`) is then specified for generating a tile-based power map file, as shown below:

  ```
  report_power \
      -outfile                    static.rpt \
      -thermal_power_map_tile     {5 5}\
      -thermal_power_map_format   stack \
      -thermal_power_map_file     powermap_format1_encr_in.txt \
      -thermal_conductivity_inputs ./encrypt/format_1_encr.txt
  ```

Related Information

- `report_power`
- "Static Power, IRdrop and EM Analysis" in the *Voltus IC Power Integrity Solution User Guide*

get_default_switching_activity

```
get_default_switching_activity
[-help]
[-clip_activity_to_domain_freq]
[-clock_gates_enable]
[-clock_gates_output]
[-clock_gates_output_ratio]
[-comb_clockgate_ratio]
[-duty]
[-global_activity]
[-icg_ratio]
[-input_activity]
[-macro_activity]
[-period]
[-seq_activity]
```

Displays the following information about a `set_default_switching_activity` parameter in the system log file and in the system console:

- Parameter name
- Current value

If you do not specify a parameter, the software displays information for all of the `set_default_switching_activity` parameters. The `get_default_switching_activity` command prints only the user-specified value for the parameters. If a parameter has not been set using the `set_default_switching_activity` command, the `get_default_switching_activity` command does not output any information in the console.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `get_default_switching_activity` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_default_switching_activity`.
`parameter_names`	Displays information for the specified parameters. You can specify one or more parameters. See `set_default_switching_activity` for description of the parameters you can specify.

Examples

The following command displays the current setting of the `-period` parameter:

```
get_default_switching_activity -period
```

The software displays the following information:

```
-period {20}
```

get_dynamic_power_simulation

```
get_dynamic_power_simulation
[-help]
[-activity_pattern]
[-period]
[-resolution]
```

Displays the following information about a `set_dynamic_power_simulation` parameter in the system log file and in the system console:

- Parameter name
- Current value

If you do not specify a parameter, the software displays information for all of the `set_dynamic_power_simulation` parameters. The `get_dynamic_power_simulation` command prints only the user-specified value for the parameters. If a parameter has not been set using the `set_dynamic_power_simulation` command, the `get_dynamic_power_simulation` command does not output any information in the console.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `get_dynamic_power_simulation` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_dynamic_power_simulation.`
`parameter_names`	Displays information for the specified parameters. You can specify one or more parameters. See `set_dynamic_power_simulation` for description of the parameters you can specify.

Examples

The following command displays the current setting of the `-period` parameter:

```
get_dynamic_power_simulation -period
```

The software displays the following information:

```
-period {20}
```

Related Information

- `set_power_analysis_mode`
- `set_dynamic_power_simulation`
- `set_default_switching_activity`
- "Dynamic Power and IRDrop Analysis" in the *Voltus IC Power Integrity Solution User Guide*

get_power_analysis_mode

```
get_power_analysis_mode
[-help]
[-quiet]
```

Use the `get_power_analysis_mode` command to display the current settings for the `set_power_analysis_mode` command.

If you do not specify a parameter, the software returns information for all of the `set_power_analysis_mode` parameters.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `get_power_analysis_mode` parameter. For a detailed description of the command and all of its parameters, use the man command `man get_power_analysis_mode`.
`-quiet`	Returns the current settings of all `set_power_analysis_mode` parameters in Tcl list format.

Example

- The following command returns the current settings for all `set_power_analysis_mode` parameters:

  ```
  get_power_analysis_mode \
  -honor_negative_energy true # bool, default=true \
  -ignore_control_signals true # bool, default=true \
  -leakage_scale_factor_for_temp 1 # float, default=1 \
  -off_pg_nets {} # string, default="" \
  -x_transition_factor 0.5 # float, default=0.5 \
  -z_transition_factor 0.25 # float, default=0.25
  ```

- The following command returns the current settings for all `set_power_analysis_mode` parameters in Tcl list format only:

  ```
  get_power_analysis_mode -quiet
  ```

  The software returns the following information:

  ```
  {honor_negative_energy true} {ignore_control_signals true} {leakage_scale_factor_for_temp 1}
  {off_pg_nets {}} {x_transition_factor 0.5} {z_transition_factor 0.25}
  ```

Related Information

map_activity_file

```
map_activity_file
[-help]
[-golden {rtl | gate}]
[-gate_block block_name]
[-reset]
-rtl2gate mapping_file
[-rtl_block block_name]
[-two_column_mapping_file mapping_file]
```

Specifies instance name mapping between RTL netlist and GATE level netlist. Power analysis uses this instance name mapping to annotate the output nets of this instance from the pin-based RTL VCD or TCF. The mapping file used for instance name mapping is generated by Conformal.

You must specify this command before `report_power`.

Parameters

`-gate_block` *`block_name`*	
	Specifies the GATE activity block name to map the block-level RTL mapping files to the top-level RTL activity files. The GATE block name is appended before the GATE level entries in the mapping file to match the entries in the top-level RTL activity file.
`-golden {rtl | gate}`	
	Specifies whether RTL or Gate is Golden. The one not specified as golden will be considered as Revised. Currently the Conformal MatchPoint file does not specify this. *Default*: `rtl`
`-help`	Outputs a brief description that includes the type and default information for each `map_activity_file` parameter. For a detailed description of the command and all of its parameters, use the man command `man map_activity_file`.

`-reset`	Specifies to reset and ignore all the previous mapping files specified using the `map_activity_file` command. *Default* : All the previous mapping files specified using the `map_activity_file` command are loaded and used.
`-rtl2gate` *`mapping_file`*	
	Specifies instance name mapping between RTL netlist and GATE level netlist. RTL level VCD or TCF are obtained from simulation on RTL Verilog netlist. Power analysis uses this instance name mapping to annotate the output nets of this instance from the pin based RTL VCD or TCF. The mapping file used for instance name mapping is generated by Conformal.
`-rtl_block` *`block_name`*	
	Specifies the RTL activity block name to map the block-level RTL mapping files to the top-level RTL activity files. The RTL block name is appended before the RTL level entries in the mapping file to match the entries in the top-level RTL activity file.
`-two_column_mapping_file` *`mapping_file`*	

	Specifies a file that contains the instance name mapping between the RTL netlist and GATE level netlist.
	This parameter can be used to specify a mapping file instead of the LEC generated mapping file (`-rtl2gate` *`mapping_file`*) to map points from RTL to Gate netlist. The format of the two column mapping file is:
	`#Gate name =>  # RTL name`
	`gate_inst_name1  => rtl_inst_name1`
	`...`
	Here, the first column corresponds to the gate name and the second column corresponds to the RTL name.

Example

- The following command specifies a mapping file rtl_map:
  ```
  map_activity_file -rtl2gate rtl_map
  ```

- The following command performs instance name mapping between RTL netlist and GATE level netlist, wherein the GATE level netlist is Golden and the RTL netlist is Revised; it specifies the mapping file MapFile.alt

```
map_activity_file -rtl2gate MapFile.alt -golden gate
```

- The following commands appends the RTL block name and GATE block name before the RTL and GATE level entries in the mapping file to match the entries in the top-level RTL activity file:

```
map_activity_file -rtl2gate LEC.top \
        -rtl_block  "core/block_top" \
        -gate_block "core/block_top"

map_activity_file -rtl2gate LEC.tile.top \
          -rtl_block  "core/tile_instance\[0\]/tile_inst" \
          -gate_block "core/tile_instance_0_tile_inst"
```

- The following commands specify to ignore the previous mapping file (`old.map`), and use the modified mapping file (`updated.map`):

```
map_activity_file -rtl2gate old.map
map_activity_file -reset
map_activity_file -rtl2gate updated.map
```

An example of the mapping file output from Conformal is described as follows:

```
Mapped points: SYSTEM class
1-th mapped points:
 (G) + 1 PI /x_ick
 (R) + 595 PI /x_ick
2-th mapped points:
 (G) + 2 PI /x_jreset_cp_p
 (R) + 594 PI /x_jreset_cp_p
3-th mapped points:
 (G) + 3 PI /x_mreset_cp_p
 (R) + 593 PI /x_mreset_cp_p
........
60-th mapped points:
 (G) + 4582 DFF /cpexec0/cpddecls0/gi_opls/q_reg_reg[35]
 (R) + 3856 DFF /cpexec0/cpddecls0/gi_opls/q_reg_reg_35_

61-th mapped points:
 (G) + 4583 DFF /cpexec0/cpddecls0/gi_opls/q_reg_reg[34]
 (R) + 3855 DFF /cpexec0/cpddecls0/gi_opls/q_reg_reg_34_

62-th mapped points:
 (G) + 4633 DFF /cpexec0/cpddecex0/gi_opex/q_reg_reg[21]
 (R) + 3805 DFF /cpexec0/cpddecex0/gi_opex/q_reg_reg_21_

63-th mapped points:
 (G) + 4634 DFF /cpexec0/cpddecex0/gi_opex/q_reg_reg[20]
 (R) + 3804 DFF /cpexec0/cpddecex0/gi_opex/q_reg_reg_20_

64-th mapped points:
 (G) + 4635 DFF /cpexec0/cpddecex0/gi_opex/q_reg_reg[19]
```

```
 (R) + 3803 DFF /cpexec0/cpddecex0/gi_opex/q_reg_reg_19_

65-th mapped points:
 (G) + 4636 DFF /cpexec0/cpddecex0/gi_opex/q_reg_reg[18]
 (R) + 3802 DFF /cpexec0/cpddecex0/gi_opex/q_reg_reg_18_
```

where, `G` refers to the Golden netlist name and `R` refers to the Revised netlist name.

By default, the tool assumes that the Golden netlist name refers to the RTL net name and Revised netlist refers to the GATE level net name.

Related Information

merge_vtm

```
merge_vtm
[-help]
-config filename
[-rundir directory]
[-merged_file filename]
[-format {simple | metal | stack}]
```

Specifies to import the top-level and other block-level Voltus thermal models (VTMs) having the specified design configuration to generate a merged uniform single VTM for Celsius usage.

Parameters

`-help`	Outputs the command usage and a brief description about the command parameters.
`-config filename`	

	Specifies the name of the design configuration file.
	The format of the file is:
	`$instance_name $Design_name $X(um),$Y(um) $Cell_orientation $VTM_file format`
	The file includes:
	• instance name
	• design name
	• X and Y locations of the instance
	• LEF/DEF style orientation for the instance
	• path to the thermal map file
	• format of the thermal map file
	Example:
	`octa octa 0,0 N vtm_output_top/top.vtm.txt both`
	`inst_8 super_filter 62.97,47.035 N vtm_output_block/block.vtm.txt both`
	`inst_1 super_filter 1157.09,765.605 FE vtm_output_block/block.vtm.txt both`
	`inst_2 super_filter 777.085,765.605 E vtm_output_block/block.vtm.txt both`
	`inst_3 super_filter 397.085,765.605 W vtm_output_block/block.vtm.txt both`
	`inst_4 super_filter 17.085,765.605 FW vtm_output_block/block.vtm.txt both`
	`inst_5 super_filter 1127.97,47.035 S vtm_output_block/block.vtm.txt both`
	`inst_6 super_filter 772.97,47.035 FS vtm_output_block/block.vtm.txt both`
	`inst_7 super_filter 417.97,47.035 FN vtm_output_block/block.vtm.txt both`

`-format {simple | metal | stack}`	

	Specifies the format of the thermal map file. The possible arguments are: • `simple`: contains only power tables. • `metal`: contains only metal density tables • `stack`: contains both power and metal density tables.
`-merged_file` *`filename`*	
	Specifies the name of the merged VTM.
`-rundir` *`directory`*	
	Specifies the output folder for the merged thermal model.

Examples

- The following command specifies to generate a merged VTM:
  ```
  merge_vtm -config /Run_Merge_VTM/design_both.cfg -rundir merged_vtm_out_both -merged_file
  merge_vtm.txt
  ```
- The following command specifies to generate a merged VTM containing only power tables:
  ```
  merge_vtm -config /Run_Merge_VTM/design_both.cfg -rundir merged_vtm_out_simple -merged_file
  merge_vtm.txt -format simple
  ```
- The following command specifies to generate a merged VTM containing only metal density tables:
  ```
  merge_vtm -config /Run_Merge_VTM/design_both.cfg -rundir merged_vtm_out_metal -merged_file
  merge_vtm.txt -format metal
  ```
- The following command specifies to generate a merged VTM containing both power and metal density tables:
  ```
  merge_vtm -config /Run_Merge_VTM/design_both.cfg -rundir merged_vtm_both_both -merged_file
  merge_vtm.txt -format stack
  ```

Related Topics

- `set_metal_density_options`

propagate_activity

```
propagate_activity

[-set_net_freq {true | false}]
```

Propagates the activity file in the database after it is read in using the `read_activity_file` command. This command propagates the activity for all primary inputs, nets, and other devices in the design whose activity has not been previously defined through user attributes.

`propagate_activity` can be used to propagate activities in the design and check for activity annotation before running power calculation. This is not a mandatory step as execution of `report_power` will also do the same and then do power calculation based on the propagated activities.

Parameters

`-set_net_freq {true | false}`	
	Specifies that activity from the generated TCF file needs to be used to capture net frequency for signal EM analysis. When this parameter is set, you do not have to read the TCF file to set net frequency.

Example

- The following commands read and propagate the activity file in the database:

  ```
  read_activity_file
  propagate_activity
  ```

Related Information

- `read_activity_file`
- "Dynamic Power and IRDrop Analysis" in the *Voltus IC Power Integrity Solution User Guide*

query_power_data

```
query_power_data
[-help]
[<in_file <file1[file2] ...>>]
[-average_current]
[-clock_average]
[-dump_pwl]
[-frame <string>]
[-instance_list <inst_list>]
[-instance_list_file filename]
[-list]
[-output <string>]
[-peak_current]
[-peak_time]
[-pin]
[-time_steps]
[-stdout]
[-total_current <input_current_file> ]
[-output_tap_name <tap_name>]
```

The `query_power_data` command allows you to query the binary current files (.ptiavg/.ptipeak) that Power Calculation/Rail Analysis creates. It reads the tap current data in the current files and reports various information for debugging.

Parameters

`-help`	Outputs the command usage and a brief description about the command parameters.
`<in_file <file1[file2] ...>>`	
	Specifies the names of the VDD and VSS instance voltage pti files.
`-average_current`	
	Specifies to write the average current of all instances.
`-clock_average`	
	Specifies to write the clock based current report.
`-dump_pwl`	
	Specifies to write the tap current in the PWL format. You can use this parameter to view the contents of the binary data file.
`-frame <string>`	

	Specifies intervals for the clock_average report.
`-instance_list <inst_list>`	
	Specify the list of instances to be dumped in the ASCII format, one instance per line. If not specified, it prints all instances. The `-instance_list` parameter is specified with the `-dump_pwl`, `-peak_current`, `-peak_time`, and`-average_current` parameters.
`-instance_list_file filename`	
	Specifies a file with the list of instances to be dumped in the ASCII format.
`-list`	
	Specifies to write the tap names from the input file.
`-output <string>`	
	Specifies the name of the output file.
`-output_tap_name <tap_name>`	
	Specifies the name of the output tap in the new current file, which is created using the `-total_current` parameter.
`-peak_current`	
	Specifies to write the peak current of all instances
`-peak_time`	
	Specifies to write the peak current time of all instances.
`-pin`	
	Specifies to print the pin names with the instance names. The `-pin` parameter is specified with the `-dump_pwl` and `-list` parameters.
`-stdout`	
	Specifies to print the report to standard output.
`-time_steps`	
	Specifies to summarize the minimum current, maximum current, average current, and total current for each interval in the data file. You can use this data to estimate which interval in a transient response might contain the worst-case data.
`-total_current <input_current_file> <output_total_current_file>`	

	Specifies to create a new current (.ptiavg) file containing the total current for all taps of a net. This parameter can be used if you have a very large current file generated by the Power Calculation engine and want to see only a total current waveform in the SimVision waveform viewer. *input_current_file* is the current file that will be read in (output from the Power Calculation engine). Use the following syntax to create a total current file: `query_power_data -total_current <input_current_file> -output <output_total_current_file>` `-output` is used to specify a user-defined output current filename, and is not a mandatory parameter. If not specified, the output file will be generated automatically with the name of the input file suffixed with `.ptiavg`.

Example

- The following command creates a total current waveform file `VDD` from the input file `dynamic_VDD.ptiavg`:
  ```
  query_power_data -output_tap_name vdd_tap -total_current dynamic_VDD.ptiavg -output VDD
  ```

Related Information

- `report_power`

- "Dynamic Power and IRDrop Analysis" in the *Voltus IC Power Integrity Solution User Guide*

read_activity_file

```
read_activity_file name
[-end { time1 time2 ...timen } ]
[-format { VCD | TCF | SAIF | FSDB | PHY | SHM}]
[-hier_separator separator ]
[-reset]
[-start { time1 time2 ...timen } ]
[-set_net_freq {true | false}]
[-block block_name ]
[-scope scope_name ]
[-scale_duration scalefactor ]
[-start_time_shift value ]
[-rtl {true|false}]
[-name_mapping_rule file]
[-weight value]
[-zero_delay {true|false}]
[-cell cell_name ]
```

Specifies the name and type of activity file to be used as input. This command must be used when specifying activity files for static or dynamic power calculation.

Parameters

`-block block_name`	
	Specifies the name of the FSDB/SAIF/TCF/VCD block to map a sub-block activity file with a top level Verilog file. Provides the ability to support multiple activity files based upon block instance names. The block argument is added to the FSDB/SAIF/TCF/VCD name before comparing it to the Verilog file.
`-cell cell_name`	

	Specifies the master cell name for the activity file. This parameter allows you to support master-cell-based activity specification. That is, you need to specify only the master cell name for the activity file, instead of specifying all the instances that were instantiated from a master cell.
	Example
	Let us consider a design that has a cell named "super_filer" with four block instances "super_filer1", "super_filer2", "super_filer3",and "super_filer1":
	Instance-Based Use Model:
	`read_activity_file -format VCD -block super_filer1`
	`read_activity_file -format VCD -block super_filer2`
	`read_activity_file -format VCD -block super_filer3`
	`read_activity_file -format VCD -block super_filer4`
	Master-Cell-Based Use Model:
	`read_activity_file -format VCD -cell super_filer`

`-end {`*`time1 time2 ...timen`*`}`	

	When you use the vector-driven method of performing dynamic instance-based power-consumption calculation, you can specify the part of the activity file from which you want power analysis to use for the power calculation. This option specifies the end time of this range and is used in conjunction with the `-start` option. Specifies the end time as time-value pairs to report the average power across non-overlapping multiple windows specified in the activity file for a block, level of hierarchy, or other part of the design that you want to analyze. Units are in seconds (`s`), milliseconds (`ms`), microseconds (`us`), nanoseconds (`ns`), or picoseconds (`ps`). *Default*: The time unit is defined in the first `.lib` file read during design import. You can specify the `$worst_power_window_end` variable with the `-end` parameter to take the worst case end time from the last vector profiler run. Not required for TCF and SAIF. **Note**: You can read multiple windows in a single VCD file by specifying multiple pairs of the start time and end time for the non-overlapping multiple windows specified in the activity file. The use model for reading multiple windows is: `read_activity_file -format VCD design.vcd -start {start1 start2 start3} -end {end1 end2 end3}` The *start1/2/3* and *end1/2/3* values should be in the ascending order. Multiple current waveforms representing multiple VCD windows are merged into a single continuous current waveform. To capture the waveform for signals at the edge of user windows, a buffer time is added between the windows being stitched using the `set_power_analysis_mode -settling_buffer` parameter. This buffer time ensures that the stitched waveform is contiguous. The generated waveform hence has the duration of user windows and the intervening settling buffers. The default settling buffer period is 400ps.
`-format {VCD | TCF | SAIF | FSDB | PHY | SHM}`	
	Specifies the net activity of the design using an activity file in the VCD, TCF, FSDB, SAIF, PHY, or SHM format. The arguments specified with the `-format` parameter are case-sensitive. • The VCD file format uses the toggle count information as the basis for the power consumption calculation. These files can be in compressed (zipped) format using the .gz extension. • The TCF file format contains data on the switching activity of the nets in the design. The switching activity includes the toggle count information and the probability of the net or pin being in the logic 1 state. These files can be in compressed (zipped) format using the .gz extension. Supports extended TCF which contains transition density for X and Z as shown in the following extended TCF example:

"out" :"0.0 0" "0.005000 2" "0.0 0"

The fields are defined as follows:

Field 1: net or pin name
Field 2: duty and transition density for transition of 0-1
Field 3: duty and transition density for transition of X(0-X-1)
Field 4: duty and transition density for transition of Z(0-Z-1)

- The SAIF file format contains aggregate switching activity information on the nets and/or ports in the design. It does not contain time-based information. This file format is used for quick average power analysis of the design.
- The FSDB file format specifies the net activity of the design using an activity file in FSDB format. Innovus supports the FSDB version up to 6.0.
  Use Model

  ```
  read_activity_file -format FSDB fsdbfile
  report_power
  ```

  (or)

  ```
  report_vector_profile
  ```

  Example

  ```
  read_activity_file -format FSDB test.fsdb -scope top
  ```

- The PHY (Palladium database format generated in the Palladium environment) format contains the simulation activity data generated during emulator-based simulation. The PHY format can be used in all vector-based power analysis flows (vector profiler, static power analysis and dynamic vector-based power analysis).
  Use Model

  ```
  read_activity_file-format PHY <path to PHY database directory>
  ```

  Example

  ```
  read_activity_file -format PHY ./phy2/trace.phy -scope test
  ```

  Notes:

  - The xeDebug software must be present in the `PATH` environment. Add xeDebug in the path using the following command:
    ```
    set path = (<install_dir>/bin $path)
    ```
    The xeDebug software version should be the same as the one using which the PHY database is generated.
  - The PHY database generated from the following UXE/VXE version is supported:

    ```
    UXE18.6.0 onwards
    VXE18.6.0 onwards
    ```

  - When reading a PHY format activity file, you require a DPA

(DPA_ToggleCountFormat) license.

- For information on error messages displayed while reading the PHY database, refer to the `xe.msg` file in the PHY database directory.
- Make sure that the PHY database is not locked before invoking the Voltus software.
- Make sure that the xeDebug software is not already running on the machine.
- Ensure that the following directories are present in the top-level PHY database directory: `*.phy`, `PDB`, `cellList`, `QTDB`, `dbFiles`, and `.design`.
- It is recommended that the write permission is assigned on the entire PHY database. In case the write permission cannot be granted, you must set the `SWFV_FREEZE_PHY` environment variable to `1`.
- If you want to run parallel Voltus executables on the same top-level PHY directory with multiple `*.phy` databases, it is suggested to create local copies of the multiple top-level directories, with links to the original PHY database. This will allow local copies of the PHY database to acquire separate locks.

- The Simulation History Manager (SHM) database format is a record of the data signal changes that occur during design simulation. The SHM database consists of a directory, typically with the "`.shm`" suffix. The directory contains two disk files, namely `*.trn` and `*.dsn`. For more information about the SHM format, refer to the *SimVision Analysis Environment* manual available on the Cadence Online Support (COS) website.
  Example
  ```
  read_activity_file -format SHM  /../shm/ADDER.trn -scope
  adder_e/u1 -start 0ns -end 60ns
  ```

`-hier_separator` *separator*

Specifies the separator character in the hierarchical net names, bus names, and pin names for the block or other part of the design that you want to analyze. It must be the same as the separator character in the design netlist.

Default: slash (/)

`-name_mapping_rule` *file*

	Specifies to enable rule-based mapping to map RTL vectors to gate-level netlist. This parameter helps in resolving name mismatch between RTL and gate level netlists.
	The name mapping rule file format is:
	`Name_Mapping_Rule_file`
	`# RTL  # Gate`
	`<rtlstring> <gatestring>`
	where, each line is a rule. The string in the first column(RTL) is what we want to replace with the string in the second column(Gate). The rules in every line are added onto the previous rules.
	For example, to replace all the square `[]` brackets with under score _ for RTL-to-Gate matching, the rule file will be:
	`#RTL  #GATE`
	`[  _`
	`]  _`
	Note: `-name_mapping_rule` is not supported when the `set_power_analysis_mode -comprehensive_automapping` parameter is set to `true`.

`-reset`	If `-reset` is specified, all previous activity files specified using the `read_activity_file` command will be reset and ignored. *Default*: All the previous activity files specified using the `read_activity_file` command are loaded and used (They are additive).
`-rtl {true|false}`	
	Specifies to process the vector as an RTL vector and perform state propagation. The propagation behavior is global and the full design is propagated. RTL vectors are zero-delay vectors so delay annotation is always done for signals from this vector file. *Default*: `false`
`-scale_duration` *scalefactor*	
	Scales the FSDB/SAIF/TCF/VCD duration value by the specified scale factor. For example, an FSDB scale of 2 will double the FSDB duration value. **Note:** The `-start` and `-end` parameters of the `read_activity_file` command are post scaled.
`-scope` *scope_name*	

Specifies the FSDB/SAIF/TCF/VCD scope, that is, the name of the module within the activity file associated with the block or other part of the design that you want to analyze.

The scope argument is removed from the FSDB/SAIF/TCF/VCD name before comparing it to the Verilog file.

⚠ If the scope value has backslash '\' or square brackets '[]', you must specify the scope within curly brackets {{…..}} to ensure that '\' or '[]' are correctly processed by the Tcl Interpreter. In the following example, the scope value is specified within curly brackets as it contains '\' and '[]':

```
read_activity_file -scope
{{reg_based_buffer.reg_inst\/sv_xpol_trans_q_reg[0][14][7]
[sv_re][4]}}
```

If '\' and '[]' are not there, curly brackets are not required.

Example

The following command specifies the u1 module within the VCD file as the module associated with the part of the design being analyzed, and specifies the `dut_5buf_full_chip` block instance as the block to map:

```
read_activity_file \
-format  VCD \
-scope  adder/u1 \
-start  {0ps 2000ps} \
-end    {1100ps 3100ps} \
-block  ../vcd/dut_5buf_full_chip
```

`-set_net_freq {true | false}`

This option should be set when an activity from a TCF or VCD file needs to be used to capture net frequency for signal EM analysis (`verifyACLimit`). In addition, you must use the `verifyACLimit -use_db_freq` option to read the toggle rates from the activity file.

Default: `false`

Example

The following example reads a TCF file which is used to capture net frequency for signal EM analysis:

```
read_activity_file -format TCF -set_net_freq true design.tcf
verifyACLimit -use_db_freq -report signal_em.rpt
```

`-start { time1 time2 ... timen }`

	When you use the vector-driven method of performing dynamic instance-based power-consumption calculation, you can specify the part of the activity file from which you want power analysis to use for the power calculation. This option specifies the start time of this range and is used in conjunction with the `-end` option. Specifies the start time as time-value pairs to report the average power across non-overlapping multiple windows specified in the VCD file for a block, level of hierarchy, or other part of the design that you want to analyze. Units are in seconds (`s`), milliseconds (`ms`), microseconds (`us`), nanoseconds (`ns`), or picoseconds (`ps`). *Default*: The time unit is defined in the first `.lib` file read during design import. You can specify the `$worst_power_window_start` variable with the `-start` parameter to take the worst case start time from the last vector profiler run. Not required for TCF and SAIF. **Note**: You can read multiple windows in a single VCD file by specifying multiple pairs of the start time and end time for the non-overlapping multiple windows specified in the activity file. The use model for reading multiple windows is: `read_activity_file -format VCD design.vcd -start {start1 start2 start3} -end {end1 end2 end3}` The *start1/2/3* and *end1/2/3* values should be in the ascending order. Multiple current waveforms representing multiple VCD windows are merged into a single continuous current waveform. To capture the waveform for signals at the edge of user windows, a buffer time is added between the windows being stitched using the `set_power_analysis_mode -settling_buffer` parameter. This buffer time ensures that the stitched waveform is contiguous. The generated waveform hence has the duration of user windows and the intervening settling buffers. The default settling buffer period is 400ps.
`-start_time_shift` *value*	
	Specifies to shift the start time of the specified activity files. When you specify the `-scale_duration` parameter with the `-start_time_shift` parameter, it scales the start time shift along with the start/end time.
name	The name of the activity file.
`-weight` *value*	

	Specifies the weight number of the TCF file. `1.0` is the default value. The value should be a floating number that is smaller than `1.0`. This parameter allows you to merge multiple TCF files at different function modes for static power estimation of a design.
	In the following example, TCF *file1*, *file2*, and *file3* has the weight numbers 0.3, 0.2, and 0.4, respectively.
	`read_activity_file -format TCF file1 -weight 0.3`
	`read_activity_file -format TCF file2 -weight 0.2`
	`read_activity_file -format TCF file3 -weight 0.4`
	Here, *file1*, *file2*, and *file3* will be merged together to represent the toggle and duty for the nets/pins in the design. The relative weight of 0.3/0.9, 0.2/0.9, and 0.4/0.9 would be used for static power calculation. In this example, 0.9 is the sum of weights.

`-zero_delay {true|false}`	
	Specifies to process the vector as a zero-delay vector and perform delay annotation. *Default* : `false`

Activity Precedence

The following commands can define activity:

```
read_activity_file file
     [-format { VCD | TCF | SAIF ]}
     [-hier_separator separator ]
     [-start time ]
     [-end time ]
     [-reset]
     [-scope scope_name ]
     [-block block_name ]

set_default_switching_activity
    [-input_activity factor ]
    [-seq_activity factor ]
    [-period value ]
    [-duty value ]
    [-global_activity factor ]
    [-hier hierarchy _name]
    [-clock_gates_output activity_factor ]

set_switching_activity
    [-reset]
    [-clock clock_name]
    [-period value ]
    [-unclocked]
```

```
[-activity factor | -density transition_density ]
[-net net_name | -port port_name | -pin pin_name ]
[-duty value ]
[-inst]
```

The precedence of activity is as follows:

1. User-Defined: Activities applied to specific nets/pins/ports
2. Activity File: Activity specification through a VCD/FSDB/SAIF/TCF format
3. Clock Gates Output Activity: Activity specification to the output of all clock gates
4. SDC/TWF constants: Set constants to a list of pins or ports for use by the timing engine (timing analysis)
5. Hierarchical Global Activity: Activity specification for a specific hierarchy
6. Global Activity: Activity specification for all instances that are part of the data network.
7. Sequential Element Activity: Activity specification applied to the output of all sequential elements.
8. Primary Input Activity: Activity specification for all primary inputs

If you specify multiple activity data for the same items, the power engine will use the one with the higher precedence.

Examples

- The following command reads the compressed ap_wait_test_pll1_mod.vcd.gz VCD file that contains the toggle count information for the power consumption calculations, specifies the crm_ap module within the VCD file as the module associated with the part of the design being analyzed, specifies the slash character (/) as the hierarchical separator for hierarchical net names, bus names, and pin names for the part of the design being analyzed, and specifies the start (180002ns) and end (189802ns) times from the VCD file for the part of the design being analyzed:

```
read_activity_file -format VCD \
-scope testbench/top/ap/mcu_platform/crm_ap \
-hier_separator \
-start 180002ns \
-end 189802ns \
ap_wait_test_pll1_mod.vcd.gz
```

- The following command reads the compressed A.vcd.gz VCD file that contains the toggle count information for the power consumption calculations, specifies A1 as the block to map a sub-block VCD file with a block instance at the top-level, and specifies the start (180002ns) and end (189802ns) times from the VCD file for the part of the design being analyzed:

```
read_activity_file -format VCD \
-block ap/A1 \
-start 180002ns \
-end 189802ns \
A.vcd.gz
```

- The next example specifies a VCD activity file called dmac_mac.vcd for the scope top/dma_dut.

```
read_activity_file -format VCD -start 10ns -end 20ns \
-scope top/dma_dut dmac_mac.vcd
```

- The following command specifies multiple pairs of the start time and end time for the multiple windows in the VCD file：

```
read_activity_file \
-format  VCD \
-scope  adder/u1 \
-start  {0ps 2000ps} \
-end    {1100ps 3100ps} \
-block  ../vcd/dut_5buf_full_chip.vcd
```

- The following command specifies to read the RTL-level VCD activity file:

```
read_activity_file -format VCD -scope scope_top -start 300ns -end 700ns /DesignData/VCD/rtl.vcd -block
inst_C1 -rtl true
set_power_analysis_mode -method vector_profile -vector_profile_mode transient -worst_window_type full
-power_grid_library /DesignData/PGV/library_pv.cl
```

report_instance_power

```
report_instance_power
[-help] instance [-file filename]
```

Generates a text based report for the specified instance. This command enables you to determine how the different components of static power are calculated. You can use the report to debug static power numbers after performing power analysis (`report_power`).

This command is available through both the static and dynamic power engines. This command is supported in the dynamic power engine by including this command in the power include file through the command `set_power_include_file`.

Note: For dynamic power engine, the `report_instance_power` command does not generate text reports incrementally. If the dynamic run has been performed and you need the debug information for a static power number, you should re-run power analysis.

Parameters

`-file` *filename*	Writes out the static power analysis report into the file that you specify.
`-help`	Outputs the command usage and a brief description about the command parameters.
instance	Specifies the instances to include in the instance power report.

Example

- The following command specifies an instance power report file `debug.rep` for the instance `top/i_1`:

  ```
  report_instance_power -file debug.rep top/i_1
  ```

```

Reports global power, specific instance power, clock network power, clock domain power, and net switching power. The command also reports the power for power domains and specific power nets. The power unit used throughout the reports is Milliwatt.

This command starts the execution of power analysis (both static and dynamic). The `report_power` command has a character limit of 1015.

> The parameters of the `report_power` command, except `-cap`, `-clock_gating_efficiency`, `-register_gating_efficiency`, and `-cluster_gating_efficiency`, are not supported in the dynamic-only mode (`set_power_analysis_mode -disable_static true`). These parameters are only supported in the static mode. However, the `-power_domain` parameter is not supported even if the static power mode is enabled.
> The `set_power_include_file` command can be used to pass the `report_power` command options in the dynamic analysis mode.

The `report_power` command allows generation of multiple power reports with a single `report_power` command. It can be used to generate all the static reports during dynamic analysis. `report_power` eliminates the need to run incremental `report_power` in static power analysis using a Verilog netlist. By default, a detailed power summary report, and a short summary will be printed at the beginning of all reports. To enable this flow, specify the following parameters:

- `-output/o`
- `-report_prefix`

The following `report_power` command parameters are supported by the multi-report flow, both in static and dynamic power analysis:

- `-cell`
- `-clock_gating_efficiency`
- `-register_gating_efficiency`

- `-cluster_gating_efficiency`
- `-net`
- `-instances`
- `-pg_net`
- `-clock_network`
- `-hierarchy`

The following parameters are not supported in the multi-report flow:

- `-cell_type`
- `-power_domain`
- `-clock_domain`
- `-clock_gating_efficiency` and `-clock_network` in the same run

⚠ In the static power analysis flow, you can run the `report_power` command after the `restore_power_database` command without loading the design. The following command is an example of the use model:

```
restore_power_database -file power.db
report_power -output same -report_prefix report -clock_network {all} -instances {*}
```

The following parameters of the `report_power` command are supported without design loading:

- `-cell`
- `-cell_type`
- `-instances`
- `-clock_network`
- `-clock_domain`
- `-pg_net`
- `-pg_net -format detailed`
- `-hierarchy`
- `-hierarchical_instances`

Parameters

`-cap`	Dumps out the list of net, pin, and total capacitances in three different columns.
`-cap_unit` *unit*	
	Sets the capacitance unit to be used for power report generation. The default unit is pF (picoFarads).
`-cell` **{***cell_list***}**	
	Specifies the cells to be included in the power report. Accepts wildcards (*)
`-cell_list_file` *filename*	
	Specifies a file containing a list of cells that are to be included in the power reports.
`-cell_type {all | {macro io combinational sequential clock_combinational clock_sequential}}`	
	Specifies the cell types to be included in the power report. *Default*: `all` When you specify the cell types, `-cell_type combinational` or `sequential`, the power report does not show the combinational clock or sequential clock cells.
`-clock_domain` ***{****clock_domain_list****}***	
	Generates detailed instance power reports for the specified clock domains. Wildcards are not accepted. **Usage** `report_power -clock_domain {clock_domain_list} -outfile filename`
`-clock_gating_efficiency`	

	Generates a report that includes the Clock Gating Efficiency (CGE) for all clock gating instances, as well as different hierarchies in the design. Average CGE for different hierarchies is also reported.
	Clock Gating Efficiency is calculated as:
	`CGE = (toggles at clock gate output / toggles at clock gate input)`
	`Average CGE = (avg of all CGEs above)`
	When a CGE report is generated using the command `report_power -clock_gating_efficiency -outfile cge.rpt`, the following information will be displayed:
	• **Clock-gating Efficiency Report** - for each clock domain, it includes the toggle rate, number of registers, number of clock gates, average clock toggle at registers, average toggle savings at registers, and average toggle savings histogram.
	• **Hierarchical View of Average Toggle Savings** - number of clock gates and average toggle savings for each hierarchical module in the design.

`-clock_network` {`all` | **{***clock_list***}**}	

	Reports the power consumption of the clock networks, including the power for the generated clocks. Use `clock_list` to report the power consumed by specific clocks. *Default*: `all`
`-cluster_gating_efficiency`	
	Generates a cluster efficiency report in the RGE report. This report shows the CGE/RGE metrics for the registers at the fan-out of each clock gate instance in the design.
`-comb_seq_power`	
	Generates a report that shows the ratio of combinational versus sequential power for all modules of a given hierarchy. This parameter must be specified with the `-instances` parameter.
`-compress` *`compression_ratio`*	
	Specifies to compress the power analysis report files in the GNU Zip format. The compressed files will have the suffix `.gz`. *`compression_ratio`* is from 0-9. `0` indicates that the report files are not to be compressed. The compression levels vary from `1` to `9`. `1` provides the fastest compression speed but at a lower ratio, so the file size will be larger. `9` provides the highest compression ratio but at a lower speed. *Default*: 0
`-count_seq_elements_in_clock_network`	
	Includes the leaf flip-flop power in the clock network power report. *Default*: The leaf flip-flop power will not be included in the clock network power report.
`-die_instance_name` *`dieinstname`*	
	Specifies the die instance name for multi-die analysis.
`-distribute`	Enables standalone distributed power analysis. This parameter is used for running dynamic power analysis in the multi-CPU mode without running rail analysis.
`-exclude_cells {`*`cell_list`*`}`	
	Specifies a list of cells that should be excluded from power analysis.
`-exclude_cells_file` *`filename`*	

Specifies a file containing a list of cells (one per line) which should be excluded from power analysis.
`-exclude_instances {`*`instance_list`*`}`
Specifies a list of instances that should be excluded from power analysis.
`-exclude_instances_file` *`filename`*
Specifies a file containing a list of instances (one per line) which should be excluded from power analysis.
`-float_precision` *`value`*
Sets the precision value to be used for power report generation. The default value is 4.
`-format { simple | detailed }`
Specifies the type of report summary required for static power reporting. The possible arguments of this parameter are: • `simple` - reports the amount of power consumed by all power nets in a condensed format, breaking down power based on the switching, internal, and leakage components. • `detailed` - reports the amount of power consumed by all power nets in a detailed format. The detailed format includes additional information, such as output pin capacitance (`Cpin Sum`), output net capacitance (`Cnet Sum`), Total Load Capacitance (`Cpin Sum` + `Cnet Sum = Total Load_Cap`), maximum frequency at the input and output pins (`Max_Clk_Freq`), maximum activity factor at the input and output pins (`Max_Activity`), cell name of the instance (`Cell Name`), clock or data cell (`C/D`), and library used in power analysis for the specific cell (`Lib`). The libraries are numbered in the header section. The name of the generated report file is `report.*.detailed.rpt`. Currently, the `-format detailed` parameter is only available when it is used with the `-pg_net` parameter.
`-hierarchical_instances {`*`hierarchy_inst_list`*`}`
Specifies to report all the power content for the specified hierarchical instances/ blocks. It reports the `Total Power` (a breakup of power components) and `Group` (a breakup of power by cell type) of the specified block at each hierarchy. To generate a complete hierarchical instance power report, it is recommended to specify `-hierarchical_instances` with `-report_prefix`. The report is written in the specified output directory. If you specify `-outfile` instead of `-report_prefix`, an instance file is output without hierarchy-level details. `-report_prefix` generates the following 3 reports: • `<`*`prefix`*`>.rpt` - reports power details for all instances in the design. • `<`*`prefix`*`>.hierpwr.rpt` - reports hierarchical power, that is, power summary, internal, switching, leakage, and total power for all hierarchical instances. • `<`*`prefix`*`>.hierinstpwr.rpt` - reports power details for the requested block instances. **Note**: `-hierarchical_instances` must be specified with `-hierarchy` to include hierarchy-level power report. When `-hierarchical_instances` is used without `-hierarchy`, only top-level summary of the power consumption is written.

`-hierarchy {all | hierarchy_level}`	
	Specifies the hierarchy level that is included in the power report. You can specify the *hierarchy_level* as a number that corresponds to a specific hierarchy level in the design. A *hierarchy_level* of 0 specifies the top level. *Default*: `all`
`-instances {instance_list}`	
	Specifies the instances to include in the power report. The power report provides the amount of power consumed by a specified list of hierarchical or leaf-level instances. *instance_list* accepts wildcards (*) for leaf-level instances only. An instance with 0 power will not be listed in the power report.
`-inst_list_file filename`	
	Specifies a file containing a list of instances that are to be included in the power reports.
`-leakage`	Reports leakage power of the design.
`-net`	Reports the net switching power, load capacitance, toggle rate, and switching values for each net in the design.
`-no_wrap`	Displays the `report_power -cell_type all` output on a single line in the output report file.
`-nworst number_of_nets`	
	Limits the reporting to the specified number of nets having the highest switching power. **Note:** The `-nworst` parameter must be specified with the `-net` parameter.
`-output/-o directory`	
	Specifies the name of the directory where the power analysis reports are saved. The default is the current working directory. This parameter eliminates the need to specify `set_power_output_dir`. However, if both `report_power -output` and `set_power_output_dir` are specified, `-output` has higher priority.

`-outfile filename`

Specifies the name of the report file to which the power consumption information is written. Hierarchical directory names can be included.

You can convert a power report file to the gzip file format by specifying `-outfile filename.gz`.

Note: If you do not specify this parameter, the software directs the power report to the command line, as well as the log file, and no power report is written to a separate file.

`-pg_net {all | pg_net_name_list}`

When set to `all`, the amount of power consumed by all power nets is reported. If a list of nets is specified, the power consumption of each instance that is connected to the specified power net is separately reported.

Note: When using this parameter, the static power calculation engine always performs propagation and power calculation.

Default: `all`

`-pg_pin`

Reports power consumed by all power pins in a design.

`-power_db_directory directory`

Specifies the location of the power database that the Power Calculation engine uses for generating standalone power reports.

`-power_domain {all | {power_domain_list}}`

When set to `all`, the power consumed by all power domains is reported. If a list of power domains is specified, the reporting will be limited to those power domains. A summary of power break-down for each domain, before listing power for each instance in the domain, is also generated.

`-power_density_tiles value`

Specifies the number of tiles used for power density calculation.

Default: `100`

`-power_density_tiles_row_col {value1 value2}`

Defines the number of tiles by rows * columns. *value1* is the number of tile rows and *value2* is the number of tile columns.

The following example specifies to perform power density aware vector profiling using 2 tile rows and 2 column rows:

```
set_power_analysis_mode -method vector_profile -vector_profile_mode power_density -
worst_step_size 10ns
report_power  -power_density_tiles_row_col  {2 2} -time_based_report -outfile tiling1.rpt
```

The following is the vector profile report for this command:

```
Tile 0_0_0 5.06 5.33 14.95 14.555
Tile 1_0_1 14.95 5.33 24.84 14.555
Tile 2_1_0 5.06 14.555 14.95 23.78
Tile 3_1_1 14.95 14.555 24.84 23.78
...
...
```

`-power_density_tiles_size {`*value1 value2*`}`

Defines the absolute tile size. *value1* is the horizontal width of a tile (in micron) and *value2* is the vertical height of a tile (in micron).

`-power_unit` *unit*

Sets the power unit to be used for power report generation. The default unit is mW (miliAmps).

`-print_memory_power`

Specifies to report power values for the memory and macro cells under separate groups (`Memory` and `Macro`).

The following is a snapshot of the power report showing separate groups for memory and macro cells:

Group	Internal Power	Switching Power	Leakage Power	Total Power	Percentage (%)
Sequential	0.4031	0.1283	0.006583	0.538	18.38
Memory	0.1624	0.004345	0.011	0.1778	6.074
IO	0	0	0	0	0
Physical-Only	0	0	2.91e-06	2.91e-06	9.945e-05
Combinational	0.8711	1.05	0.01579	1.937	66.2
Clock (Combinational)	0.002302	0.01018	7.654e-05	0.01255	0.429
Clock (Sequential)	0.01177	0.008387	0.000347	0.0205	0.7005
Macro (non-mem)	0.2317	0.007259	0.001234	0.2402	8.208
Total	1.682	1.209	0.03503	2.926	100

`-group_type` *user_defined_group_name*

Specifies to report power (internal/switching/leakage/total) for a user-defined collection of cells that are stated under a power group in the power summary report. The following Tempus commands can be used to create power groups:

- `define_property` - define a property.
- `set_property` - assign the defined property (group type) and its value (power group) to a list of cells.

The use model of the `-group_type` parameter is:

```
report_power -group_type user_defined_group_type
```

Here, *`user_defined_group_type`* is the user-defined power group type applied to a list of cells in a design. When the `-group_type` parameter is specified, the command reports power for the power groups associated with the specified group type in the power summary report.

Example:

The following command defines the `poly_bias` property (group type) on library cells:

```
define_property poly_bias -object_type lib_cell -type string
```

The following commands apply the property `poly_bias` with the group name `P0` and `P10` to the collection of cells:

```
set_property [get_lib_cells -of_objects [get_cells -hier * -filter {ref_name=~*PB0*}]] poly_bias
P0
set_property [get_lib_cells -of_objects [get_cells -hier * -filter {ref_name=~*PB10*}]]
poly_bias  P10
```

The following command reports power for the user-defined power groups that are associated with the property `poly_bias`:

```
report_power -outfile basic_group_type.rpt -group_type poly_bias
```

The following is a snippet of the power report that shows the user-defined power groups `P0` and `P10` that are associated with the property `poly_bias`, in addition to the existing groups (sequential, macro, IO, and so on):

```
User Group                          Internal   Switching     Leakage       Total  Percentage
                                    Power      Power         Power         Power  (%)
-------------------------------------------------------------------------------------------
P0                                   0.01498   0.0002017     0.01765     0.03283       15.63%
P10                                   0.1268     0.04026     0.01011      0.1772       84.37%
-------------------------------------------------------------------------------------------
Total                                 0.1418     0.04047     0.02776        0.21          100%
-------------------------------------------------------------------------------------------
```

```
Group                          Internal   Switching     Leakage       Total  Percentage
                               Power      Power         Power         Power  (%)
-------------------------------------------------------------------------------------
Sequential                      0.02958   0.0003768     0.01458     0.04453       16.62
Macro                                 0           0           0           0           0
IO                                    0           0           0           0           0
Combinational                0.008217     0.002633     0.01025      0.0211       7.877
Clock (Combinational)           0.1239      0.04421    0.007419      0.1755       65.51
Clock (Sequential)              0.01773    0.008783   0.0002459     0.02676       9.988
-------------------------------------------------------------------------------------
Total                            0.1794       0.056     0.03249      0.2679         100
-------------------------------------------------------------------------------------
```

`-register_gating_efficiency`

Generates a report that includes the Register Gating Efficiency (RGE) and Data Aware Gating Efficiency (DAGE) for all sequential cell instances, as well as different hierarchies in the design. Average RGE and DAGE for different hierarchies is reported. It also displays a section on ICG cluster information, that is, information about registers at the fan-out of each ICG instance along with their RGE metrics.

Register Gating Efficiency is calculated as:

```
RGE = 1 - (toggles at register clock pin/root clock toggles)
```

When an RGE report is generated using the `report_power -register_gating_efficiency -outfile rge.rpt` command, the following information will be included:

- **Register-gating Efficiency Report** - for each clock domain, it includes the toggle rate, number of registers, number of clock gates, average clock toggle at registers, average toggle savings at registers, and average toggle savings histogram.
- **Register Gating Opportunities Report** - this report is sorted based on the Q/CLK toggle ratio. When a register's Q/CLK ratio is greater than .25 (25%), Q toggles every other clock cycle. However, when it is less than 25%, there is a gating opportunity to reduce power.

Data Aware Gating Efficiency is calculated as:

```
DAGE = 1 - ((toggles at clock pin - 2*toggles at Q pin)/(root clock toggles))
```

`-report_prefix` *`prefix`*

Specifies a prefix for the report in which the top-level summary of the power consumption information is written. All reports will be named *`prefix`*`.*.rpt`. The detailed summary will be named `prefix.rpt`.

`-sort` {`internal | switching | leakage | total`}

Sorts the instance-based power consumption data by `internal`, `switching`, `leakage`, or `total` power.

Default: `total`

`-stat`

Reports a set of statistics on the net status after propagation, for example, duty, transition density, or activity. This parameter is useful in viewing and debugging user-defined activity factors after the power run is complete.

Example:

```
report_power -time_based_report -distribute -outfile power.rpt -stat
-------------------------------------------------------------------------------------------
-- Net status after propagation --
-------------------------------------------------------------------------------------------
Net          Transition Density        Duty           Activity        Ref. Freq
-------------------------------------------------------------------------------------------
VDDA1             0              1               0             1.25e+08
VSSA1             0              0               0             1.25e+08
...
```

`-thermal_conductivity_inputs` *`file_name`*

Specifies a file containing the thermal conductivity value for layers. You can use this parameter to include the thermal conductivity value of the following layers in the power map file:

- Silicon
- Metal
- Dielectric
- Micro Bump (optional for 3DIC design)
- Fill material in micro bump layer (optional for 3DIC design)

The thermal conductivity file format is:
Section 1 (layer type based thermal conductivity value)

```
#default
$layer_type1 $thermal_conductivity_parameter1
$layer_type2 $thermal_conductivity_parameter2
...
```

Section 2 (layer name based thermal conductivity value)

```
#perlayer
$layer1_name $thermal_conductivity_parameter1 $dielectric_thermal_conductivity_1
$layer2_name $thermal_conductivity_parameter2 $dielectric_thermal_conductivity_2
...
```

Here,

- You can either specify both Section 1 (layer type based) and Section 2 (layer name based), or specify one of the two sections. If both sections are specified, then layer name based section takes precedence over layer type based section.
- The layer name based section has thermal conductivity value and its dielectric layer's thermal conductivity value for each metal/via layer.
- If section 2 has no parameters defined, the software will use the default parameters defined in the section 1.

Example:
###default

```
Metal      430
Silicon    250
Dielectric 0.6
```

###Perlayer

```
Metal1    430    0.4
Via1      410    0.5
Metal2    390    0.5
Via2      410    0.5
```

...

For information on the thermal conductivity input file and power map file, refer to the "Static Power, IRdrop and EM Analysis" chapter in the *Voltus User Guide*.

`-thermal_leakage_temp {temp_list}`

Defines the temperature to calculate leakage for the power map file.

`-thermal_leakage_temperature_scale_table {$temp1 $scalefactor1 $temp2 $scalefactor2 $temp3 $scalefactor3 .....}`

Specifies the global scale factor for a temperature value to enable scaling of the leakage power values coming from the input dotlib file. This parameter allows you to scale the power values only at certain specific temperatures.

This parameter allows you to generate a multi-temperature leakage power map table from a single input dotlib file in the power map generation flow. `-thermal_leakage_temperature_scale_table` and `-thermal_leakage_temperature_scale_table_file` are mutually exclusive.

`-thermal_leakage_temperature_scale_table_file filename`

Specifies a file containing the user-defined temperature values and the corresponding scale factors for each library, cell, or instance. The format of the file is:

```
#Type Name temp1 temp2 temp3 temp4
Lib    library_name   scalefactor@temp1   scalefactor@temp2  scalefactor@temp3
scalefactor@temp4
Cell   cell_name      scalefactor@temp1   scalefactor@temp2  scalefactor@temp3
scalefactor@temp4
inst   instance_name  scalefactor@temp1   scalefactor@temp2  scalefactor@temp3
scalefactor@temp4
```

This parameter allows you to generate a multi-temperature leakage power map table from a single input dotlib file in the power map generation flow. `-thermal_leakage_temperature_scale_table` and `-thermal_leakage_temperature_scale_table_file` are mutually exclusive.

File Format Example for the Type Lib:

```
#Type Name         25 50 125 150
Lib   fast         1 2 10 100
Lib   bufao        1 2 10 100
Lib   header       1 2 10 100
Lib   pso_ring_wc  1 2 10 100
```

`-thermal_material_file filename`

Specifies the name of a file containing the user-specified substrate layer thickness. The layer thickness value for the power map generation flow can either be a user-specified value or derived from the technology file. If both the values are available, the user-specified value takes precedence.

`-thermal_power_map_bottom_layer layer_name`

Writes zero metal density tables for layers lower than the user-specified layer in the power map file. This parameter prevents duplication of metal density tables when merging the top and block thermal power map files.

`-thermal_power_map_densitytable_tile {Xint Yint}`

Specifies the number of tiles in the X and Y directions for the metal density table.

`-thermal_power_map_file file_name`

Generates the power map file with the specified name in the output directory.
`-thermal_power_map_format {simple | stack }`
Generates a tile-based power map file in the simple or stack format to perform accurate thermal analysis. The stack format must be used to support multiple dies in a package for thermal analysis.
`-thermal_power_map_format_version {new|default}`
Determines whether to generate the default or the new power map file format. When set to `new`, the power map file format with non-uniform tile numbers for the power (`-thermal_power_map_powertable_tile`) and metal density tables (`-thermal_power_map_densitytable_tile`) can be generated. The following are the features of the new report format: • version number added to the header "Version : 2020.0" • nx/ny under the "DIE_AREA" section has been removed • XCOR/YCOR for each layer has been removed • nx/ny has been added for the POWER and METAL_DENSITY sections
`-thermal_power_map_header_include_file` *`filename`*
Specifies a file that contains comments or additional information to be included in the header section of the power map file.
`-thermal_power_map_powertable_tile {`*`Xint Yint`*`}`
Specifies the number of tiles in the X and Y directions for the power table.
`-thermal_power_map_top_layer` *`layer_name`*
Writes zero metal density tables for layers higher than the user-specified layer in the power map file. This parameter prevents duplication of metal density tables when merging the top and block thermal power map files.
`-thermal_power_map_SI_unit {true | false}`
Specifies to change chip thermal power map units to SI in the thermal power map file. This parameter was introduced to support the thermal power map file format used by foundry. When this parameter is set to `true`, the values for all the power map parameters (length, power, and thermal conductivity) will be reported in the SI units. • **Length Unit:** default is `um` and SI is `m` • **Power Unit**: default is `mW` and SI is `W` • **Metal/Silicon Thermal Conductivity Unit**: default is `mW/(um * C)` and SI is `W/(m * C)` *Default* : `true`
`-thermal_power_map_tile {`*`Xint Yint`*`}`
Defines the tile number in the X and Y direction. By default 10*10 will be used.

`-threshold` *value*

Filters out the instances whose total power dissipation is more than the specified value. The power unit used is Milliwatt.

Default: `0`

`-threshold_voltage_group { all | group_name}`

Reports leakage by voltage threshold group in the power report. This parameter supports the argument `all` or any other string, such as hvt or lvt.

Default: `all`

`-time_based_report`

Writes out a detailed VCD profiling report into the file that you specify.

`-time_unit` *unit*

Sets the time unit to be used for power report generation. The default unit is ns (nanoseconds).

`-toggle_rate`

Specifies to print instance-based activity to the outfile. The toggle rate for each instance is calculated based on the clock domain to which it belongs. If multiple clocks are reaching the instance, then the fastest clock is used as a reference.

`-use_geometry_cell_size {true | false}`

Specifies whether to use the actual geometry or placement bounding box for macro PGV cell size during generation of tile-based power map file. This parameter is used when a macro's power is distributed across multiple tiles. When this parameter is set to `true`, the geometry-based bounding box will be used for power map generation and power will be distributed evenly across tiles.

Default : `false`

`-view` *view_name*

Specifies the active timing view that was created using the multi-mode multi-corner (MMMC) `set_analysis_view -setup|-hold` command. Power analysis is performed for the specified view. The command prints the `MMMC` view name in the output file even if you do not specify the `-view` parameter.

If `report_power -view` *view_name* is set, it will override the view set in the `set_power_analysis_mode -view` command. However, if you specify the `set_analysis_view -dynamic` and `-leakage` parameters, then the view set using these `set_analysis_view` command parameters has higher priority over the `report_power -view` command.

Default : Uses current view in Innovus.

Examples

- The following command reports the amount of power consumed by the clock nets clk and test_clk (including leaf flip-flop power) and writes the output information to a power report file named clk_pwr.rep:

```
report_power -clock_network{clk test_clk} \
-count_seq_elements_in_clock_network -outfile clk_pwr.rep
```

- The following command reports the amount of power consumed down to hierarchy level 3 from the top and writes the output information to a power report file named hier.rep:

```
report_power -hierarchy 3 -outfile hier.rep
```

- The following command reports the power consumption and writes the power report file pg_net.rep in the compressed gzip format:

```
report_power -outfile pg_net.rep.gz
```

- The following command reports the amount of power consumed by leaf-level instances that match ECO* and writes the output information to a power report file named inst.rep:

```
report_power -instances ECO* -outfile inst.rep
```

- The following command reports the amount of power consumed by all cells that match buf*6 and writes the output information to a power report file named cell.rep:

```
report_power -cell buf*6 -outfile cell.rep
```

- The following command reports the amount of power consumed by all I/O and sequential cells and writes the output information to a power report file named cell_type.rep:

```
report_power -cell_type {io sequential} -outfile cell_type.rep
```

- The following command sorts the instance-based power consumption data by leakage power and writes the output information to a power report file named sort.rep:

```
report_power -sort leakage -outfile sort.rep
```

- The following command reports the total power of all instances whose total power dissipation is less than 1 milliwatt and writes the output information to a power report file named threshold.rep:

```
report_power -threshold 1 -outfile threshold.rep
```

- The following command reports the net switching power, load capacitance, toggle rate, and switching values for each net in the design, reports the top 100 nets with the highest net switching power, and writes the output information to a power report file named net.rep:

```
report_power -net -nworst 100 -outfile net.rep
```

- The following command reports the amount of power consumed by each power domain and writes the output information to a power report file named pd_all.rep:

```
report_power -power_domain all -outfile pd_all.rep
```

- The following command reports the amount of power consumed by each power domain PD2 and writes the output information to a power report file named pd.rep:

```
report_power -power_domain PD2 -outfile pd.rep
```

- The following command reports the amount of power consumed by view view_max-hp-max-lp1 and writes the output information to a power report file named view.rep:

```
report_power -view view_max-hp-max-lp1 -outfile view.rep
```

- The following command reports the amount of power consumed by each instance connected to power nets vdd and vdd1 and writes the output information to a power report file named pg_net.rep:
  ```
  report_power -pg_net {vdd vddl} -outfile pg_net.rep
  ```
- The following command reports the leakage for the threshold voltage group HVT:
  ```
  report_power -leakage -threshold_voltage_group { HVT }
  ```
- The following command writes out a detailed vector profiling report for the combinational and macro cell types in the `vectorprofile.rpt` file:
  ```
  report_power -time_based_report -outfile vectorprofile.rpt -cell_type {combinational macro}
  ```
- The following command is an example of generating multiple reports at the same time:
  ```
  report_power -output static_power -report_prefix design -net {name1} -instance {inst_name}
  ```
  The following reports will be generated:
  ```
  static_power/design.rpt
  static_power/design.netpwr.rpt
  static_power/design.instpwr.rpt
  ```
- The following command specifies to report power for combinational cells on the clock network.
  ```
  report_power -cell_type clock_combinational -output static_power -report_prefix power_clk
  ```
- The following command generates a power map file in the simple format for the specified tile:
  ```
  report_power -outfile powermeter.txt -thermal_power_map_file powermap.txt -thermal_power_map_tile { 4 6 } -thermal_power_map_format simple
  ```
- The following command specifies to report the power content for the `inst1` hierarchical instance in the `report.hierinstpwr.rpt` report:
  ```
  report_power -output static -report_prefix report -clock_network {all} -instances * -no_wrap -hierarchy {all} -hierarchical_instances inst1 -cell_type {all}
  ```
- Example of the output of the power report.
  ```

reset_power_activity

```
reset_power_activity
```

Resets all activity in the database. You can specify this command to reset all activity and power information in a given session.

> You can reset activity from an activity file using `read_activity_file -reset`, reset activity for nets, pins, and ports using `set_switching_activity -reset`, and reset the default switching activities using `set_default_switching_activity -reset`.

Parameters

None

Related Information

- `read_activity_file`
- `set_default_switching_activity`
- `set_switching_activity`
- "Static Power, IRdrop and EM Analysis" in the *Voltus IC Power Integrity Solution User Guide*

restore_power_database

```
restore_power_database
[-help]
-file {file1 file2 file3 ...}
[-hierarchy {prefix1 prefix2 prefix3 ...}]
[-hierarchy_separator "/"]
```

Restores any `power.db` file in the Voltus/Innovus session. This command can be used after restoration of a design to view the static power results or incremental report generation without having to do power analysis again.

Note: You will be able to restore the power database that you created previously, only if you created the power database using the `set_power_analysis_mode -create_binary_db true` command. Also, the command loads power databases created in the 9.1 release only, and not in the older releases.

- The command can map a hierarchical instance to a flat netlist.
- It can restore multiple power dbs for blocks and top level, that are generated separately.
- When the information for a net or an instance is present in multiple power dbs, the last one will overwrite.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `restore_power_database` parameter. For a detailed description of the command and all of its parameters, use the man command `man restore_power_database`.
`-file {file1 file2 file3 ...}`	
	Specifies the name of the power database file.
`-hierarchy {prefix1 prefix2 prefix3 ...}`	
	Specifies to map each instance in the file with a prefixN/instance (for example, prefixA/inst) in the flat netlist, where '/' is the hierarchy separator. This is an optional parameter. *Default*: `all`
`-hierarchy_separator "/"`	

	Specifies the separator character in the hierarchical net names, bus names, and pin names for the block or other part of the design that you want to analyze. It must be the same as the separator character in the design netlist. This is an optional parameter. *Default*: slash (/)

Use Model

```
restoreDesign
restore_power_database -file power.db
report_power # for text based power reports
```

Example

For each instance in file 'file2' a prefix "A" is added to instance name such as instC, A/instC. No prefix is added to 'file1' since prefix1 is none for file1.

```
restore_power_database -file {file1 file2} -hierarchy {none A}
```

set_default_switching_activity

```
set_default_switching_activity
[-black_box_density value]
[-black_box_duty value]
[-duty value]
[-global_activity factor]
[-hier hierarchy_name]
[-input_activity factor]
[-period value]
[-seq_activity factor]
[-reset]
[-reset_type { global_activity | seq_activity ... }]
[-clock_gates_enable {activity_factor}]
[-icg_ratio num]
[-comb_clockgate_ratio num]
[-clock_gates_output {activity_factor}]
[-clock_gates_output_ratio num]
[-clip_activity_to_domain_freq {true | false}]
[-name activity_name]
[-macro_activity factor]
```

Specifies the switching activity for all primary inputs, nets, and other devices in the design whose activity has not been previously defined through user attributes, the toggle count format (TCF) file, the value change dump (VCD) file, or the tracing of the clock network.

You can use this command to specify user-defined activities at the design level.

Parameters

`-black_box_density value`	
	Specifies to set the default transition density on all the output pins of all blackboxes in the design. The `-black_box_density` and `-black_box_duty` parameters must be used together. If one or both of these parameters are not specified, then the software will use the average transition density from all the input pins of the blackboxes.
`-black_box_duty value`	

	Specifies to set the default duty on all the output pins of all blackboxes in the design. The `-black_box_density` and `-black_box_duty` parameters must be used together. If one or both of these parameters are not specified, then the software will use the average transition density from all the input pins of the blackboxes.
`-clip_activity_to_domain_freq {true | false}`	
	Specifies to perform domain-based activity clipping. This parameter clips data paths to 1x frequency whereas the clock networks are still at 2x frequency. This parameter allows you to have more control to determine the rate of clipping with respect to frequency.
`-clock_gates_enable {`*`activity_factor`*`}`	
	Specifies the activity at the enable pin(s) of the clock gating cells.
`-clock_gates_output {`*`activity_factor`*`}`	
	Specifies the activity at the output pin(s) of the clock gating cells. This works for both ICGs as well as combinational clock gating cells. **Example**: `set_default_switching_activity -global_activity 0.02 -clock_gates_output 2.0` (clock is transparent) transition_density of clock gate output is calculated by: `(1/clock_domain_frequency) * clockgateOutputsActivity = 1/(0.431*e-9) * activity_factor` In this case, transition_density = `clock_domain_frequency * clockgateOutputsActivity` = 1e9/0.431 * 2 = 4,640,371,200
`-clock_gates_output_ratio` *`num`*	

	Specifies to control transition density at the output pin(s) of the integrated and combinational clock gating cells. This parameter is equivalent to specifying the parameters `-icg_ratio` and `-comb_clockgate_ratio` together with the same value.
	
	For example, the `set_default_switching_activity -clock_gates_output_ratio 0.6` is equivalent to `set_default_switching_activity -icg_ratio 0.6 -comb_clockgate_ratio 0.6`.
	
	Note: This parameter has a cascading effect when there are multiple levels of ICG cells on the clock path. For example, when `-clock_gates_output_ratio` is set to `0.5`, the first level ICG cell will have 0.5 ratio of the root clock's toggle density, the second level ICG cell will have 0.5*0.5=`0.25` ratio of the root clock's toggle density, and the third level ICG cell will have 0.5*0.5*0.5=`0.125` ratio of the root clock's toggle density, and so on.
	
	Note: For dynamic power analysis, fastest clock on the path is used for calculating output toggle density. However, for static power analysis, weighted averaging of input toggle densities is used.
	
	Example for static power analysis:
	`set_default_switching_activity -global_activity 0.02 -clock_gates_output_ratio 1.0`
	
	Transition density for either a combinational or an integrated clock gating cell with 'N' inputs is calculated by:
	`output_pin_transition_density = (summation) weighted_input_transition_density = clock_gates_output_ratio * [(duty_input_pin1 * Td_input_pin1) + (duty_input_pin2 * Td_input_pin2) + ... + (duty_input_pinN * Td_input_pinN)]`
	
	Given a 2:1 clock Mux and assuming duty of 0.5 for all input pins:
	Td is the toggle density for each input pin of the instance `(Td_pinSe1 , Td_pinI0 , Td_pinI1).`
	
	`output_pin_transition_density = 1.0 * [0.5 * Td_pinSe1 + 0.5 * Td_pinI0 + 0.5 * Td_pinI1]`

`-comb_clockgate_ratio` *num*	

	Specifies to set the propagation ratio for combinational clock gate cell outputs. When specified, this parameter sets the output activity of any instance that is identified as a combinational clock gating cell to *num* times the fastest transition density arriving on the instance's clock inputs. This parameter cannot be specified with the `-hier` parameter. **Notes:** • This parameter does not apply to combinational clockgates with a constant data input, that is, a select pin tied low. • For dynamic power analysis, fastest clock on the path is used for calculating output toggle density. However, for static power analysis, weighted averaging of input toggle densities is used. For a detailed static power analysis example, refer to '`-clock_gates_output_ratio`', limiting calculations only to combinational clock gates.
`-duty` *value*	Specifies the duty cycle, which is the probability that the signal is a logical 1. **Note:** You must specify the `-period` parameter when assigning a duty. *Default*: `0.5` (equivalent to a 50 percent duty cycle)
`-global_activity` *factor*	
	Specifies the average number of times that all unset nodes switch in a clock cycle. If not specified the fastest domain frequency will be used unless one turns off clock domains. **Note**: Due to activity precedence, the `-global_activity` and `-seq_activity` parameters of the `set_default_switching_activity` command are mutually exclusive. If both the parameters are specified, `-global_activity` takes precedence.
`-hier` *hierarchy_name*	
	A hierarchical name that the global activity is being assigned to. If not provided, the whole design is assumed.
`-icg_ratio` *num*	
	Specifies to set the propagation ratio for integrated clock gate (ICG) cell outputs. When specified, this parameter sets the output pin of all identified ICG instances to *num* times the fastest transition density arriving on clock inputs of the instance. This parameter cannot be specified with the `-hier` parameter.
`-input_activity` *factor*	
	Specifies the average number of times that a primary input switches in a clock cycle. It can be any positive number. *Default*: `0.2` (Switches once every five clock cycles.)

`-macro_activity` *factor*	
	Specifies the activity factor for macros in a design. The allowed values for this parameter are between `0` to `1`. If you set the macro activity to `.30`, 30% of macros in the design would be selected for switching in a given cycle during dynamic simulation. When `-macro_activity` is specified for the static power analysis, all output pins of the macros are assigned the specified activity. *Default*: `0.2`
`-name` *activity_name*	

	Allows you to set the activity level for the specified jitter activity name. You can define a low/high activity level for jitter analysis.
	Examples:
	`set_default_switching_activity -name low -clock_gates_output 0 -global_activity 0.01`
	`set_default_switching_activity -name high -clock_gates_output 2 -global_activity 0.2`

`-period` *value*	Specifies the default operating period (1/frequency). It is the period that the activity is referenced to. If not specified, the software uses the *dominant* clock in the design. The specified period will only be applied to nets that do not have reference clock (ref_clock) associated with the net. If no clock is specified, the software generates an error and prompts you to enter one. Units in seconds (`s`), milliseconds (`ms`), microseconds (`us`), nanoseconds (`ns`), or picoseconds (`ps`). **Note:** If you enter the period as a negative number, the software reverts back to using the default frequency. *Default*: The time unit is defined in the first `.lib` file read during design import.
`-seq_activity` *factor*	
	Specifies the activity of outputs of the sequential logic. This value will be used at the output ports of flops for propagating activity. If the sequential activity is not specified, propagation will be done for the full design starting from the input ports.
`-reset`	Resets all specified options back to default values.
`-reset_type { global_activity | seq_activity ... }`	
	Specifies to selectively reset the global specifications. **Note:** You must use the `-reset_type` parameter in conjunction with the `-reset` parameter.

Activity Precedence

See "Activity Precedence" in `read_activity_file`.

Examples

- The following command specifies that the primary inputs in the design will switch once every ten clock cycles, with a clock period of 7520 ns and a duty cycle of 50 percent:
  ```
  set_default_switching_activity -input_activity 0.10 -period 7520ns -duty .5
  ```
- The following command specifies that all unswitched nodes in the design will switch once every ten clock cycles, with a clock period of 7520 ns and a duty cycle of 50 percent:
  ```
  set_default_switching_activity -global_activity 0.10 -period 7520ns -duty .5
  ```
- The next example defines the switching activity, sequential activity, and the period:
  ```
  set_default_switching_activity -input_activity 0.2 -period 10 \
      -seq_activity 0.1
  ```
- The next example sets the default global activity to 0.5 for the hierarchy dma_dut:
  ```
  set_default_switching_activity -global_activity 0.5 -hier dma_dut
  ```
- The following command resets the sequential and global activity specification:
  ```
  set_default_switching_activity -reset -reset_type
  {seq_activity,global_activity}
  ```

set_dynamic_power_simulation

```
set_dynamic_power_simulation
[-help]
[-period value]
[-resolution value]
[-reset]
[-activity_pattern {time1 activity_name1 time2 activity_name2 .... }]
```

Specifies the period and resolution for a dynamic power simulation. This command is used to specify the simulation period in the dynamic vectorbased/vectorless and power-up flows.

Generally, the number of simulation steps (simulation period divided by resolution) should be selected such that the number is around 1000. Around 20 clock cycles of the dominant clock specified as period and 20/50ps specified as resolution will capture all switching events in the design. This can be fine-tuned to balance the run time and accuracy. For example, if the dominant clock frequency is 1GHz, and the clock period is 1ns, the recommended simulation period is 20ns and resolution is 20ps, as shown in the following example:

```
set_dynamic_power_simulation -period 20ns -resolution 20ps
```

In this case, the number of simulation steps is 1000.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `set_dynamic_power_simulation` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man set_dynamic_power_simulation`.
`-activity_pattern {time1 activity_name1 time2 activity_name2 .... }`	

	Divides the total simulation time based on the windows given in the `activity_pattern` parameter. For a particular window, it uses the defined activity specified with the `set_default_switching_activity` command. When the user-defined low cycle and high cycle time is specified for the input/sequential activity, all the clocks will be in the low or high cycle until completely past the cycle transition time. Following is the use model of this parameter: • `set_default_switching_activity` **`-name low -input_activity 0.05 -seq_activity 0.1`** `-clock_gates_output 0.2` • `set_default_switching_activity` **`-name high -input_activity 0.1 -seq_activity 0.2`** `-clock_gates_output 2.0` • `set_dynamic_power_simulation -period 15ns -resolution 50ps` **`-activity_pattern {0 high 5ns low 10ns high}`** Here, high activity is used for 0ns to 5ns, low activity is used for 5ns to 10ns, and high activity is used for 10ns to 15ns.
`-period` *value*	Specifies the simulation period that dynamic power analysis will use. The supported time units are `s`, `ms`, `us`, `ns`, and `ps`. If no explicit time unit is specified, the default `ns` (nanosecond) will be applied.
`-reset`	Resets all specified options back to default values.
`-resolution` *value*	
	Specifies the transient time step size or resolution. The supported time units are `s`, `ms`, `us`, `ns`, and `ps`. If no explicit time unit is specified, the default `ps` (picosecond) will be applied.

Examples

- The following command sets up the period and resolution for a dynamic simulation:
  `set_dynamic_power_simulation -period 5ns -resolution 100ps`

set_inst_temperature_file

```
set_inst_temperature_file
file
[-reset]
```

Specifies the instance temperature file to support thermal-aware leakage. You can use this command to do thermal-aware power calculation. Based on the temperature specified in the file, the software will calculate temperature and leakage power.

In the presence of a trilib set, the internal and leakage power will be interpolated as the per the given temperature specification.

Parameters

file	Specifies the name of the instance temperature file..
-reset	Resets the temperature file.

set_metal_density_options

```
set_metal_density_options
[-metal_density_include_file filename]
-power_grid_library pgv_path
[-reuse_md_db_path MD_db_path]
-tech_file tech_file_path
-thermal_conductivity_file thermal_file
[-user_defined_metal_density_file user_defined_md_file}]
[-vtm_densitytable_tile {Xint Yint} ]
[-vtm_densitytable_tile_size {Xsize Ysize}]
[-vtm_header_include_file user_defined_header_content_file]
-vtm_path output_path
```

Sets the parameters for extracting the metal density information. This command must be specified before the `extract_metal_density` command.

Parameters

`-metal_density_include_file` *filename*
Specifies the file for listing the additional variables that can be included when extracting metal density information. For example, you can specify "`setvar report_with_lef_layer_names true`" to output the LEF layer names.
`-power_grid_library` *pgv_path*
Specifies the path to the power cell libraries (`.cl`).
`-reuse_md_db_path` *MD_db_path*
Specifies to reuse the generated metal density database for `extract_metal_density`. When specified, the PGV/tech file specified with `set_metal_density_options` will be ignored.
`-tech_file` *tech_file_path*
Specifies the path to the extraction technology file to be used for top-level power-grid extraction.
`-thermal_conductivity_file` *thermal_file*

Specifies a file containing the thermal conductivity value for layers. You can use this parameter to include the thermal conductivity value of the following layers in the power map file:

- Silicon
- Metal
- Dielectric
- Micro Bump (optional for 3DIC design)
- Fill material in micro bump layer (optional for 3DIC design)

The thermal conductivity file format is:
Section 1 (layer type based thermal conductivity value)

```
#default
$layer_type1 $thermal_conductivity_parameter1
$layer_type2 $thermal_conductivity_parameter2
...
```

Section 2 (layer name based thermal conductivity value)

```
#perlayer
$layer1_name $thermal_conductivity_parameter1 $dielectric_thermal_conductivity_1
$layer2_name $thermal_conductivity_parameter2 $dielectric_thermal_conductivity_2
...
```

Here,

- You can either specify both Section 1 (layer type based) and Section 2 (layer name based), or specify one of the two sections. If both sections are specified, then layer name based section takes precedence over layer type based section.
- The layer name based section has thermal conductivity value and its dielectric layer's thermal conductivity value for each metal/via layer.
- If section 2 has no parameters defined, the software will use the default parameters defined in the section 1.

Example:
###default

```
Metal      430
Silicon    250
Dielectric 0.6
```

###Perlayer

```
Metal1    430    0.4
Via1      410    0.5
Metal2    390    0.5
Via2      410    0.5
...
```

`-user_defined_metal_density_file` *user_defined_md_file*}

Allows you to define the metal density in the user-defined metal density flow.

The format of the user-defined metal density file is:

```
CELL <cell_name>
CELL_AREA [ xmin ymin xmax ymax | x1 y1 x2 y2 x3 y3 x4 y4 ... x1 y1]     # Must specify if cell PGV
is not imported
LAYER <layer_name(s)>                          # Layer to be defined metal density; multiple layers
are available (LEF layer name based)
ALL <metal_density_value>                      # To define metal density for whole cell area as
'ALL' only 'ALL' can be used now
END_LAYER
END_CELL
```

Example:

```
CELL Macro1
CELL_AREA 0 0 32 16
LAYER Metal1 Metal2 Metal3
ALL 0.2
END_LAYER
LAYER Via1 Via2
ALL 0.05
END_LAYER
END_CELL

CELL Macro2
CELL_AREA 0 0 32 16
LAYER Metal1 Metal2 Metal3
ALL 0.2
END_LAYER
LAYER Via1 Via2
ALL 0.05
END_LAYER
END_CELL
```

`-vtm_densitytable_tile {Xint Yint}`

Specifies the number of tiles in the X and Y directions for the metal density table.

`-vtm_densitytable_tile_size {Xint Yint}`

Specifies the size of tiles instead of tile number in the X and Y directions for the metal density table.

`-vtm_header_include_file user_defined_header_content_file`

Allows you to define extra header information like file location.

`-vtm_path output_path`

Specifies the directory path to the metal density file output folder.

Examples

- The following command specifies to set the metal density parameters:

```
set_metal_density_options \
-power_grid_library "$DesignDir/PGV/tech_pgv/techonly.cl" \
-tech_file $DesignDir/QRC/qrcTechFile \
-vtm_path ./vtm_MD_db \
-thermal_conductivity_file $DesignDir/MISC/thermal_conduct.txt \
-vtm_densitytable_tile {10 10} \
-vtm_header_include_file $DesignDir/MISC/user_header.txt
```

[-no_propagation]
[-static_mode { custom_label_name | mode_name }]
[-slew value]
[-signal_net netname]
[-default_dynamic_pgv_mode { mode_name }]
```

Specifies the amount of power for all or part of the design. This command is used to define user-specified power on cells and instances. You must specify this command before `report_power`.

The `set_power` command can accept a cell/instance list using the `get_cells`/`get_lib_cells` commands. You can use the `get*` commands to create a collection of cells/instances whose name matches the supplied pattern list. Therefore, providing you with the flexibility in providing lists through use of regular filter patterns. This feature is supported in both static and dynamic analysis engines.

Parameters

```
-ascii_power_file filename
```

	Specifies the name of an instance list file. This file contains the list of instances in the following format: *instance_name power_value <pin_name>* Here, • *instance_name* is the instance name to which power is to be distributed. • *power_value* is the power value for the instance in watts. • *pin_name* is an optional argument to specify the pin name. When specified, allows you to assign power to the specific pin of the instance. • The three fields should be in one line, and each instance should be in a new line.
`-cap` *value*	
	Specifies the capacitance value to all instances with nets more than or equal to the fanout limit (`-fanout_limit`).
`-cell` *cell_name value*	
	Specifies the cell name. If the cell or instance name is not specified, the power will be distributed to all rails. If you want to specify power for a group of cells/instances, use the `get_cells`/`get_lib_cells` commands. The `-cell` parameter can accept these commands to create a collection of cells/instances whose name matches the supplied pattern list. For example, `-cell[get_lib_cells NAND*] 2mw`
`-clock {all|`*clock_name*`}`	
	Specifies the power value for clock networks. You can specify the power value for a specific clock network or the clock network power value for the whole design. **Note:** This parameter cannot be used with the `-cell`, `-instance` and `-pg_net` parameters.
`-custom_macro_pwl` *filename*	
	Specifies to use a custom trigger file to apply instance or cell PWL waveforms. Given one master cell PWL waveform, the software can automatically generate scaled PWL waveforms of the other companion cells defined in the trigger file proportional to the cell internal power. **Note**: This parameter must be used with `set_power -dynamic_switch_pattern` in the vectorless flow. For more information on the trigger file format, see Trigger File Format.
`-default_dynamic_pgv_mode {` *mode_name* `}`	

	Specifies the current characterization mode to be used during dynamic power and jitter analyses. This parameter can be specified when using a PGV with multiple functional modes. When this parameter is specified, the Power Calculation engine uses this preferred mode in scheduling the switching events for the macro blocks, and saves these events in the trigger file. The use model of this parameter is: `set_power -cell {} | -instance {} -default_dynamic_pgv_mode { mode_name }` This parameter is mutually exclusive to the `-dynamic_switch_pattern` parameter. If a cell or instance has both the `-dynamic_switch_pattern` and `-default_dynamic_pgv_mode` parameters defined in the same Tcl script, `-dynamic_switch_pattern` takes higher priority.
`-dynamic_async_mode { mode_name }`	

	Specifies to trigger asynchronous macros based on the length of the PWL waveform to create a single continuous waveform. This parameter allows you to specify the asynchronous mode for an instance or a cell. The start and end of the PWL saved in the PGV must have similar current value in order to avoid sudden jump in the current.
	Use model:
	`set_power -dynamic_async_mode {mode} [-instance {name} | -cell {name}]`
	Example:
	`set_power -cell pll -dynamic_asynchronous_mode {READ_C}`
	Here, power analysis will trigger the `READ_C` mode and automatically splice the waveform based on its length.

`-dynamic_switch_event { switching_events }`	
	Specifies the switching events for cells, instances, and pins along with their rise and fall time. `switching_events` is a string of toggle time followed by “r” or “f”, where “r” is for rise toggle and “f” is for fall toggle. The `-dynamic_switch_event` parameter should not be specified with the `-repeat` parameter.
`-dynamic_switch_pattern pattern`	

	Specifies stimulus pattern on the pins of an instance and cell. Specify this parameter only in the dynamic mode for the type `instance` and `cell`.
	
	The *`pattern`* is applied to all pins (input and output) on the instance/cell. It is a string.
	
	`pattern` specifies the switching pattern. If there is more than one clock domain with timing windows on a pin, only the windows on the fastest clock will be used, and the pattern will be applied to that clock period. It is a string of `0`, `1`, `r`, and `f` values. `0` for cycles not to switch and `1` for cycles to switch. `r` is for rise only and `f` for fall only.
	
	The pattern string should include enough digits to cover all of the clock cycles in the simulation period. If there are not enough digits, the pattern will be padded with 0 values at the end. If there are too many, the pattern will be truncated to the number of applicable cycles. Transitions will be scheduled in the center of each applicable timing window.
	
	Notes
	• `0` and `1` is supported only in the probability-based vectorless flow. It is not supported in the state-propagation-based vectorless flow and the vector-based flow.
	• In case of macros, you can specify the mode names, that is, which mode switches in which clock cycle `-dynamic_switch_pattern { mode1 - mode2 - }`.
	
	You can specify "`-`" to indicate that instances will not switch in a particular clock cycle. If "`-`" is the first value in the string of values specified within `{}`, you must insert a space before "`-`", as shown below:
	• no switching: `-dynamic_switch_pattern { - - }`
	• no switching in the 1st clock period: `-dynamic_switch_pattern { - r }`
	
	Examples:
	
	In the following example, instance will not switch in the 4th clock cycle:
	`set_power -dynamic_switch_pattern { f r f - r }`
	
	In the following example, the mode `write` will switch in the 1st clock cycle, the mode `read` will switch in the 2nd and 4th clock cycle, and none of the modes will switch in the 3rd clock cycle:
	`set_power -dynamic_switch_pattern { write read - read }`
	
	Note: Wildcards are supported only for `-dynamic_switch_pattern` with `-pin`. When `-dynamic_switch_pattern` is applied for `-instance` or `-cell` without the `-pin` parameter, wildcards are not supported.

`-exclude_clock`	Excludes clock networks when specifying a scale factor or power specification for the whole design. This parameter cannot be used with the `-cell, -instance` and `-pg_net` parameters.
`-exclude_ddv_modes {`*`pattern_list`*`}`	

	Excludes the current characterization (or Dynamic Detailed View) modes that match with the specified patterns. This parameter allows you to control the modes to be switched, instead of switching all the current characterization modes defined in the power-grid view. **Use Model** `set_power -instance|-cell` *`name`* `-exclude_ddv_modes {`*`pattern_list`*`}` Here: • *`pattern_list`* is a list of mode names, separated by space or comma • the instance, cell, and pattern names can contain wildcard characters
`-fanout_limit` *`value`*	
	Specifies the fanout limit for nets. If an instance has nets more than or equal to the fanout limit, its switching/internal/leakage power is taken to be zero. When this parameter is specified, the user-defined power value is applied to all the driver instances that have nets more than or equal to the fanout limit.
`-force`	Specifies to apply the `set_power` command even if there are Verilog mismatches. For dynamic or DEF-based static analysis, this parameter allows you to apply `set_power` to the DEF instances that do not exist in Verilog.
`-help`	Outputs the command usage.
`-include_ddv_modes {`*`pattern_list`*`}`	
	Includes only the current characterization (or DDV) modes that match with the specified patterns. This parameter allows you to control the modes to be switched, instead of switching all the current characterization modes defined in the power-grid view. **Use Model** `set_power -instance|-cell` *`name`* `-include_ddv_modes {`*`pattern_list`*`}` Here: • *`pattern_list`* is a list of mode names, separated by space or comma • the instance, cell, and pattern names can contain wildcard characters
`-internal`	Specifies the target internal power of the design, cell, or instance. To specify internal power for cells and instances, you can use the `-internal` parameter in conjunction with the `-cell` or `-instance` parameter.
`-instance` *`inst_listvalue`*	
	Specifies the instance name. If the cell or instance name is not specified, the power will be distributed to all rails.

`-leakage`	Specifies the target leakage power of the design, cell, instance, or power net. To specify leakage power for cells and instances you can use `-leakage` option in conjunction with `-cell` or `-instance` option. To specify leakage power of a certain power net in the design you can use `-pg_net` option along with `-leakage` option.
`-no_propagation`	
	Specifies that the user-defined switch pattern is applied only after state-propagation is complete. The use model of the command parameter is: `set_power -dynamic_switch_pattern {pattern} -no_propagation` The `-no_propagation` parameter must be specified with the `-dynamic_switch_pattern` parameter. When the `-no_propagation` parameter is specified, the dynamic power engine performs state-propagation first, and then overrides the single instance switching event by the user-defined dynamic switch pattern without any further propagation.
`-pg_net railname`	
	Optional. The specified power or pwl for the cell, instance or design is applied to the specified rail. When not specified, the power or pwl is applied to all the rails associated with the instance. This option is generally used for MSMV cells. When this option is not specified the behavior is different for pwl and power options. When not specified and power option is used, the power is applied for the whole design, cell, or instance. When not specified and pwl option is used, the pwl is applied to every rail of the cell or instance.
`-pg_pin {pg_pin}`	
	Specifies the switch pattern for a specific PG pin of an instance. This parameter must be specified with the `-dynamic_switch_pattern` parameter.
`-pin pin_name pin_power`	

	Specifies pin-wise power numbers for a specific instance. This parameter allows you to control the power assigned to power ground pins of an instance. Following is the use model of this parameter:
	`set_power -instance <inst_name> -pin <VDDA> <pin_power>`
	`set_power -instance <inst_name> -pin <VDDB> <pin_power>`

`-pwl`	Specifies that power argument (`power | pwl`) is a waveform rather than a power number.
`-repeat`	Repeats dynamic switch pattern of all the clock cycles in the simulation period.
`-reset`	This parameter causes all previous `set_power` commands to be ignored. Note: You can selectively reset the instance/cell specifications. In addition, you can also selectively reset the cell and instance specifications of a list of objects through the `get_cells` and `get_lib_cells` commands.

`-scale_factor` *value*	

	Scales the power value by the specified scale factor. This parameter allows you to set a user-defined scale factor in the trigger file to scale the dynamic current of the PGV.
	To modify the scale factor, use the `-reset` parameter with the `-scale_factor` parameter.
	Example:
	`set_power -leakage -reset  -scale_factor 5 -instance A`
	You can use the following power scaling commands in the power-driven optimization flow when running Voltus within the Innovus platform:
	• `set_power -scale_factor <value> -leakage` => scale the leakage power value by the specified scale factor
	• `set_power -scale_factor <value> -internal` => scale the internal power value by the specified scale factor
	• `set_power -scale_factor <value> -switching` => scale the switching power value by the specified scale factor
	• `set_power -scale_factor <value>` => scale the leakage, internal, and switching power values by the specified scale factor
	When specifying these commands in the optimization flow, you must not specify any other parameter of the `set_power` command.
	Optimization Flow Example:
	`setOptMode -opt_power_effort high`
	`setOptMode -opt_leakage_to_dynamic_ratio 0.5`
	`set_power -scale_factor 15 -internal`
	`set_power -scale_factor 20 -switching`
	`report_power`

`-signal_net` *netname*	
	Specifies the signal net name for power assignment. When this parameter is specified, the driver instances connected to the signal net will be assigned the user-defined power value.
`-slew` *value*	
	Specifies the slew value to all instances with nets more than or equal to the fanout limit (`-fanout_limit`).
`-static_mode { custom_label_name | mode_name }`	

	Specifies the mode name or the custom label name associated with a cell or instance for computing instance current from PGV with static multi-voltage multi-frequency (MvMf) modes. This current is used to compute the instance's internal power, and its switching and leakage power components would be set to zero. The use model of this parameter is given below: `set_power -instance -static_mode READ` If you specify custom label of a static MvMf mode, currents would be taken from it directly. Alternatively, if only mode name is specified for a cell/instance, the software snaps to the nearest custom label defined within this mode, based on the instance's voltage and frequency to get the currents.
`-sticky`	Applies the simulation based PWL waveform as is, to the specified cell/instance for dynamic power analysis. Use this option only if you have specified `-pwl`.
`-switching` *value*	
	Specifies the target switching power of the design, cell, or instance. To specify switching power for cells and instances, you can use the `-switching` parameter in conjunction with the `-cell` or `-instance` parameter.
`-trigger_time_adjustment` *time*	
	Specifies to adjust the trigger time of the current waveforms for the various functional modes (read/write/idle) of the custom macros. This parameter allows you to start the waveform before the trigger time (negative time support), as shown below:  The specified time will be applied to the computed trigger time for each mode in the trigger files generated by power analysis. For example, if the trigger time (from timing window/vector) is computed as 1ns, 2ns, and 3ns, and if you specify `set_power -trigger_time_adjustment -100ps`, the software will adjust the trigger time to .9ns, 1.9ns, and 2.9ns.

value	Specifies power in milliwatts during static power calculation or piecewise linear (`-pwl`) current waveform, during dynamic power calculation for cell or instance. The command accepts a unit specification (e.g. 10w).
	The format of the PWL waveform is:
	`{time1 current1 time2 current2 ...time_n current_n}`
	Time is in ns and current in mA.
	Example:
	`set_power -pwl -pg_net {} -cell BUFX2MTL {0 0 10 0 10.1 5 10.5 0}`
	Here, at `0ns` its value is `0mA`, at `10ns` its value is `0mA`, at `10.1ns` its value is `5mA`, and so on.

Examples

- The following command sets power for vdd rail to 10 milliwatts:
  ```
  set_power -pg_net vdd 10mw
  ```
- The following command sets a power value of .005 milliwatts on power net vdd for instance clkin_neg_L14_I1:
  ```
  set_power -pg_net vdd -instance Top/A/clkin_neg_L14_I1 .005
  ```
- The following command sets a power value of .005 milliwatts for any cell named INVX2 in the design:
  ```
  set_power -cell INVX2 .005mw
  ```
- The following command defines a piecewise linear waveform of {0 0 10 0 10.1 5 10.5 0} for the cell of type BUFX2MTL for all power rails.
  ```
  set_power -pwl -pg_net {} -cell BUFX2MTL {0 0 10 0 10.1 5 10.5 0}
  ```
- The following command specifies the leakage power for the cell DFFRX1.
  ```
  set_power -leakage -cell DFFRX1 10mw
  ```
- The following commands specify the target leakage power for power nets VDD1 and VDD2.
  ```
  set_power -leakage -pg_net VDD1 100mw
  set_power -leakage -pg_net VDD2 200mw
  ```
- The following command specifies the PWL description of current for the instance SEHD130_1024X32X1CM8. The -sticky option tells the software to use the specified PWL simulation based waveforms as is.
  ```
  set_power -pwl -instance SEHD130_1024X32X1CM8 -sticky {0 0 1 1 2 2 7 0}
  ```
- The following command scales the total power of the instance i_1 by a scale factor of 2:
  ```
  set_power -scale_factor 2 -instance i_1
  ```
- The following command sets the total power of the design to 20mw while keeping the clock network power the same:
  ```
  set_power 20mw -exclude_clock {all}
  ```
- The following command assigns a switching power of 3mw to all instances of the cell AND1:
  ```
  set_power -cell AND1 -switching 3mw
  ```
- The following command assigns 2mw power to all cells that match the specified pattern:

```
set_power -cell[get_lib_cells NAND*] 2mw
```

- The following command specifies that mode1 switches in the first cycle, mode2 switches in the third cycle and no switching in others:
  ```
  set_power -dynamic_switch_pattern { mode1 0 mode2 0 }
  ```
- The following command resets power of all cells that match the specified pattern:
  ```
  set_power -reset -cell[get_cells A/*]
  ```
- The following command is an example of cell-based switching:
  ```
  set_power -cell HS65_LS_* -dynamic_switch_pattern {1101}
  ```
- The following command specifies that the switching pattern value `1010` will be applied to all the instance names starting with `m_inst`:
  ```
  set_power -instance m_inst* -dynamic_switch_pattern {1010}
  ```
- The following command does not schedule DDV mode `scan*`:
  ```
  set_power -cell { * } -exclude_ddv_modes { scan* }
  ```
- The following command does not schedule DDV mode `scan*` for instance "`A1`":
  ```
  set_power -instance { A1 } -exclude_ddv_modes { scan* }
  ```
- The following command only schedules DDV mode names with the `*read*` and `*write*` pattern:
  ```
  set_power -cell { * } -include_ddv_modes { *read*, *write* }
  ```
- The following commands specify the toggle time for the pin names Q7 and Q6:
  ```
  set_power -dynamic_switch_event { 1.1ns r 5.5ns f } -instance clk_b_i2 -pin Q7
  set_power -dynamic_switch_event { 2.2ns r 6.6ns f } -instance clk_b_i2 -pin Q6
  ```

Trigger File Format

For specifying a custom trigger file, you must use the `-custom_macro_pwl` parameter. The format of the trigger file is:

Trigger File Format	Description
#Cell names	
`MASTER CELL <cellname1>`	Name of the reference cell.
`COMPANION_CELLS <cellname1 cellname2 … >`	Name of the cells that will use scaled PWL from the master cell.
#Mode and conditional details for trigger	
`MODE_NAME <mode1>` `CONDITIONAL_INPUT <conditional input statement for cellname1>`	Mode name and conditional input statement for the cell. Conditional input of current for the given mode.
`CONDITIONAL_PIN <pin_name> (rise|fall|both)`	Conditional pin statement for the cell. Signal pin for which the tool should rise or fall.

CONDITIONAL_STIMULUS_FILE <usim1.txt>	Simulation vector detail in the given mode.
USER_PWL_FILE <pwl1.txt>	User-specified PWL file that contains information about the PWL waveforms (power/ground currents). For an example of a PWL file, see PWL Format Example.
END_MODE	End mode section
#End cell section	
END	End cell section

Example of a Custom Macro Power Trigger File

```
MASTER_CELL         SRAM_A1
COMPANION_CELLS     { SRAM_A2, SRAM_A3, SRAM_A4, SRAM_A5 }
      MODE_NAME WRITE
               CONDITIONAL_INPUT = ( !SD & !SLP & !CEB & !WEB )
               CONDITIONAL_PIN = CLK { RISE }
               USER_PWL_FILE write_rise.txt
       END_MODE
      MODE_NAME READ
               CONDITIONAL_INPUT = ( !SD & !SLP & !CEB & WEB )
               CONDITIONAL_PIN = CLK { RISE }
               USER_PWL_FILE read_rise.txt
       END_MODE
      ...
END
```

Example of “USER_PWL_FILE” (Multiple regions)

```
UNIT CURRENT mA
UNIT TIME ns
       NET VSS
               REGION { 0 0 0.1 -1 0.2 -2 0.3 -3 0.4 -10 0.5 -50 0.6 -40 0.7 -30 0.8 -20 1 0 2 0 3 0 3.9 0
4 -0.1 4.5 -0.2 5 -4 5.5 -3 6 -2 7 0 }
       NET VDD
               REGION { 0 0 0.1 1 0.2 2 0.3 3 0.4 10 0.5 50 0.6 40 0.7 30 0.8 20 1 0 2 0 3 0 3.9 0 4 0.1

```

Sets the parameters for doing the power analysis.

Parameters

```
-add_simulation {true | false}
```

	Default: `false` Specifies to add simulation if there are no simulation vectors or if all primary sources are not annotated by vectors. This parameter can be used to ensure complete design coverage. Event simulation is done for primary sources like primary input, flops, and macros. **Usage Guidelines**: This parameter is only applicable to the event-based power analysis flow (`set_power_analysis_mode -method event_based`).
`-adjust_input_activity_in_iterations {true | false}`	
	Default: `true` Specifies whether to keep the input activity fixed or automatically adjust the activity value for each iteration of state propagation. **Usage Guidelines**: This parameter is only applicable to the power target flow (`set_power_analysis_mode -enable_power_target_flow true`).
`-adjust_macro_activity_in_iterations {true | false}`	
	Default: `true` Specifies whether to keep the macro activity fixed or automatically adjust the activity value for each iteration of state propagation. **Usage Guidelines**: This parameter is only applicable to the power target flow (`set_power_analysis_mode -enable_power_target_flow true`).
`-annotation_detail_report {true | false}`	
	Specifies to generate a detailed annotation report per instance in the Vector Profiling flow (`set_power_analysis_mode -method vector_profile`). When specified, it creates the `AnnotationDetail.rpt` file in the user-specified output directory. *Default* : `false`
`-auto_twf_delay_annotation {true | false}`	
	Default: `false` Specifies to automatically detect the zero-delay vectors and perform delay annotation. As a result, you do not need to specify additional parameters (`set_power_analysis_mode -use_zero_delay_vector_file` and `read_activity_file -zero_delay`) to indicate the vectors that have delay annotation. **Usage Guidelines**: This parameter is only applicable to the event-based power analysis flow (`set_power_analysis_mode -method` **`event_based`**).

`-average_rise_fall_cap {true | false}`

Default: `false`

When set to `true`, the software uses the average of rise and fall capacitance from the liberty file. This parameter can be specified for all library formats.

Usage Guidelines:

This parameter is not applicable to the `-static_netlist def` flow.

`-binary_db_name` *`filename`*

Default: The default file name is `power.db`

Specifies the name of the binary power database file (`filename.db`) used for analyzing power plots. This database contains instances, locations, and power. The generated power database allows you to perform GUI interactive debugging using the *Power & Rail Plots* and *Power Debug* forms.

You can specify this parameter in scenarios where more than one database is generated and you need to track which one was generated in which mode when restoring the database, or if your design has several blocks and analysis is done on one block all the time and all the databases are named `power.db`.

Usage Guidelines:

You must specify this parameter with the `-create_binary_db true` parameter. This parameter is applicable to both the static and dynamic power calculation flows.

`-block_independent_peakpower {true | false}`

Default: `false`

Specifies to identify the worst power interval of each block, and run power analysis of the full design using the worst interval of each block. This parameter allows you to perform power and current analysis for design blocks that have independent peak power intervals.

When set to `false`, power analysis is performed using the common worst interval found using simulation of all vectors together.

`-boundary_gate_leakage_file` *`filenname`*

Specifies a list of Liberty side files required for boundary gate leakage (context-aware leakage) calculation. This file defines the boundary current for different threshold voltage (Vt) layers at different operating conditions. The file includes:

- multiple leakage tables corresponding to different operating conditions.
- leakage probability factor for different abutments (when abutting instances are on the same Vt layer or when they are on different Vt layers).

When `-boundary_gate_leakage_file` is specified, the `power.boundarygateleakage.rpt` file is dumped by default. This file contains the design-level summary for the three combinations of Vt select fail ratio (0, 1 and the one specified with HighVT_select_fail_ratio).

`-boundary_gate_leakage_report {true | false}`

	Default: `false` Generates a verbose report for every abutted instance-edge for boundary leakage calculation. This detailed report is useful in debugging and understanding the leakage power calculation for an instance. The generated report name is `boundarygateleakage.detailed.rpt`.
`-boundary_leakage_cell_property_file` *filenname*	
	Specifies the list of edge information files containing cell properties.
`-boundary_leakage_edge_annotation_file` *filenname*	
	Specifies the edge annotation file with updated Vt layers at a given edge location to be used during boundary leakage calculation. This parameter is used to provide custom Vt layers for an abutted edge at a given location to be used during power computation. **Note**: When running the edge annotation feature, the user-defined VT will have precedence over the one from the cell properties file.
`-boundary_leakage_multi_pgpin_support {true | false}`	
	Default: `false` Enables support for cells with multiple power/ground pins.
`-boundary_leakage_pessimism_removal {true | false}`	
	Default: `true` Enables pessimism removal for the Source to FCs to Source abutment type. This abutment type normally has 0 CNOD leakage. Therefore, the non-zero leakage computed at the starting S-FC and terminating FC-S boundaries needs to be removed for accurate estimation. This parameter is specified to remove the non-zero leakage or pessimism. Revised CNOD leakage = CNOD Leakage – Leakage (S-FC-S). `-boundary_leakage_pxe_support {true | false}`	

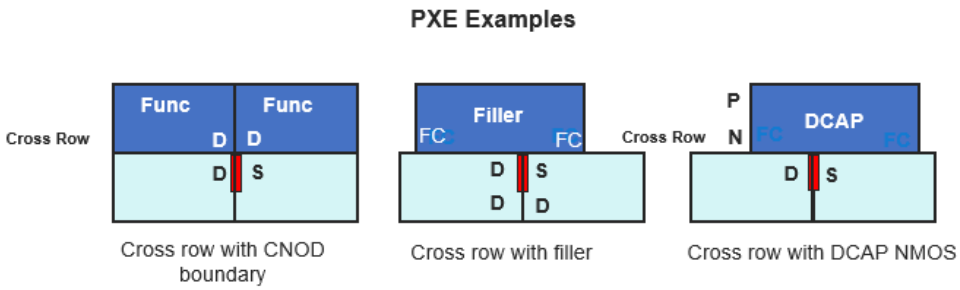
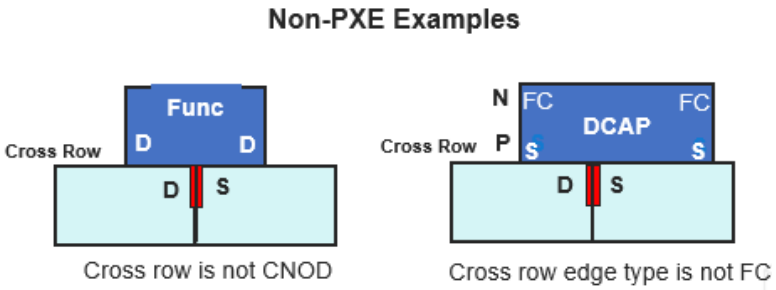
Default: `false`

Enables the PXE feature. PXE is used for calculation of CNOD leakage by cross row environment. The T structure or inverted T structure with both edges of the type FC is PXE.

The following diagram illustrates examples of PXE:



Every scenario other than the ones mentioned in PXE examples is non-PXE. The following diagram illustrates examples of non-PXE:



- If this parameter is set to `false`, Voltus does not consider the relationship by cross row environment.
- If this parameter is set to `true`, Voltus will find out the PXE or non-PXE structure and look up different leakage tables for obtaining the leakage value.

`-bulk_pins {`*`bulk_pin_list`*`}`

	Default: None Defines power and ground bulk LEF pins for the design. Use this parameter when library cells have bulk pins defined in LEF but the liberty file does not contain power associated with these pins. If a liberty file does not have body bias definition, power analysis does not distribute power to the body bias domain. **Usage Guidelines**: This parameter is only applicable to the static power calculation flow. It does not support the `-static_netlist def` and dynamic power calculation flows.
`-capacity {low|medium|high}`	
	Enables segmented power processing. When this parameter is specified, the software performs concurrent processing of vector simulation annotation, power calculation, and report construction. This parameter enables performance optimization with some trade-off on memory consumption and runtime. The arguments of the `-capacity` parameter are: • `low` - reduces memory for a flat run. • `medium` - further reduces memory with moderate increase in runtime (1.2X). • `high` - maximum memory reduction at about 2X runtime. The `-capacity` parameter is used for reducing memory when processing long simulation vectors. In case of the FSDB and SHM format activity file, the runtime can increase up to 2X.
`-case_insensitive_mapping {true | false}`	
	Default: `false` Specifies whether instance name mapping between the RTL netlist and GATE level netlist in the mapping file is case-sensitive or case-insensitive. When set to `true`, name mappings are case-insensitive.
`-clock_source_as_clock {true | false}`	
	Default: `false` Specifies to use the correct clock frequency for activity calculation. If you stop the arrival of the clock signal by setting `set_case_analysis` to 0, the transition density at the output net of the flop is calculated using the topological source clock frequency instead of the default frequency. When this option is set to `false`, then the Verilog flow will stop clock propagation for any disable clock path that is set with `set_case_analysis`. **Usage Guidelines**: This parameter is not applicable to the `-static_netlist def` flow.
`-comprehensive_automapping {true | false}`	

	Default: `false` Specifies to perform all-inclusive instance name mapping between the RTL netlist and GATE level netlist. When set to `true`, the software honors all possible naming rules (includes handling of characters like '[' , ']', '.', '/', '\\', '_', ':' and handling of strings like "MBFF", "_reg", "_MB_" etc.) for better annotation coverage. This feature is applicable to both file-based mapping (`map_activity_file -rtl2gate | -two_column_mapping_file`) and automatic mapping (`set_power_analysis_mode -enable_auto_mapping`). When `-comprehensive_automapping` is specified with either `-rtl2gate` or `-two_column_mapping_file`, the RTL mapping entries are given priority over the automatic rule-based mapping entries and are used to annotate the design objects.
`-constant_override {true | false}`	
	Default: `false` Specifies to give higher precedence to propagated constants defined using the `set_case_analysis` command. It allows propagated constants to override global activity.
`-corner {min|max}`	
	Default: `max` Defines the library corner for the non-MMMC setup (`read_lib -min | -max | -typ`). • `min` corner means the power calculator will use min timing libraries for power calculation. • `max` corner means the power calculator will use max timing libraries for power calculation. **Usage Guidelines**: This parameter is applicable to both the static and dynamic power calculation flows.
`-create_binary_db {true | false}`	
	Default: `false` A value of `true` creates a binary database of power results. This database contains instances, locations, and power. The generated power database allows you to perform GUI interactive debugging using the *Power & Rail Plots* and *Power Debug* forms. **Usage Guidelines**: This parameter is applicable to both the static and dynamic power calculation flows.
`-create_driver_db {true | false}`	

	Default: `false` Specifies to generate all the flop-based drivers/receivers list. This parameter is required to run the noise margin calculation flow, and differential voltage calculation in the rush-current analysis flow. The driver/receiver pairs are generated only for the state-elements (flops) as noise margins will be calculated only for the driver-receiver pairs where flop is a receiver. Noise margins are calculated with worst voltages seen on the driver-receiver pins. The driver/receiver list is saved in the `power2rail_config.json` file located in the power output directory. **Usage Guidelines**: This parameter is applicable only to the dynamic power calculation flow.
`-create_gui_db {true | false}`	
	Default: `false` Specifies to create a binary database of power results in the XP mode. When set to `true`, the tool creates sliced power database file for each rail partition and saves it to the `gui.db` sub-directory under the power output directory (example: `power_dir/part_*/gui.db/rail_part_*/power.x.db` (x = 1, 2, ..., 14). The generated power database allows you to perform GUI interactive debugging using the *Power & Rail Plots* and *Power Debug* forms. **Usage Guidelines**: This parameter is applicable to both the static and dynamic power calculation flows.
`-current_generation_method { avg | peak }`	

	Default: `avg` Specifies the method of instance current discretization (or continuous current waveform generation) based on the user-specified time step size (`set_dynamic_power_simulation -resolution <value in ps>`). The current waveform generated for an instance depends on the time step size/resolution for dynamic power simulation. The recommended value for `-resolution` is 20ps. The two possible arguments of this parameter are: • `peak` - Specifies to use the peak current value of each time step. The output current filename is *filename*`.ptipeak`. It is recommended to use the `peak` method when using the Composite Current Source Power (CCSP) Liberty files. This is because the CCSP library provides real current waveforms from simulation that is used directly by the software. • `avg` - Specifies to use the average current value of each time step. The output current filename is *filename*`.ptiavg`. It is recommended to use the `avg` method when using the non-CCSP (NLPM) library. In this case, the Voltus power engine heuristically constructs a triangular waveform from the look-up table. **Usage Guidelines**: • This parameter is applicable only to the dynamic power calculation flow. • It is used only for instance current waveform generation, and does not apply to total current waveform generation. When generating total current (composite) waveform, the peak current values of all instances are summed up for each step. • For very small step size, the average and peak methods will converge.
`-default_frequency` *value*	
	Default: `100MHz` Specifies to set the default frequency in the MHz unit for net not annotated by TWF. You can specify a numerical value without unit.
`-default_slew` *value*	
	Default: For static analysis CTE flow, the default slew = 0. For TWF flow, the default slew = 0.1 * default frequency in MHz. Specifies to set the default slew in the ns unit for net not annotated by TWF. You can specify a numerical value without unit. **Usage Guidelines**: This option depends on `-default_frequency` for the TWF flow. If -default_frequency is not specified, then it will take frequency of the shortest clock period.
`-default_supply_voltage` *value*	
	Default: `1.0` Specifies to set a default voltage for power nets in a scenario where the power engine cannot determine the voltage of these nets.

`-detailed_view_current_only {true | false}`

Default: `true`

Controls instance power reporting for cells that have power information available in PGV. When set to `true`, specifies to skip writing of the switching and leakage current and use only the internal current from DDV PGV. When set to `false`, specifies to report the switching and leakage current values in addition to the internal current from DDV PGV. If a cell is defined in both PGV and dotlib, leakage is computed from dotlib. It is recommended to set this parameter to `true` because that would prevent over-estimation of the instance current.

`-disable_clock_gate_clipping {true | false}`

Default: `true`

Specifies to enable clock gate output clipping so that the output transition density of an ICG cell does not exceed the input clock pin transition density.

`-disable_leakage_scaling {true | false}`

Default: `false`

Specifies to exclude leakage power during scaling factor computation when target power is specified using the `set_power` command. When `set_power_analysis_mode -disable_leakage_scaling` is set to `true`, the leakage power does not get scaled, and only the internal and switching components are scaled to meet the user-specified total power.

This parameter is relevant only for the `set_power` commands for which total power is specified, and has no effect for the `set_power` command specified with the `-internal`, `-switching`, or `-leakage` parameters.

`-disable_static {true | false}`

Default: `false`

When set to true in the dynamic vector-based or dynamic vectorless flows, the command performs only dynamic analysis and turns-off static power calculation.

Note: When you perform static power calculation in the dynamic power analysis flow, you can use either the `-disable_static` or `-write_static_currents` parameter to enable static power calculation and write static current file. If only `-disable_static` is set to `false` and `-write_static_currents` is not set, the tool automatically sets `-write_static_currents` to `true`. Similarly, if `-write_static_currents` is set to `true`, and `-disable_static` is not set, the tool automatically sets `-disable_static` to `false`.

`-distribute_switching_power {true | false}`

Default: `false`

Specifies to equally distribute the switching power among all drivers if a net has more than one driver. When set to `false`, stores all switching power on one of the net drivers.

`-distributed_combine_report_format {none | detailed | reduced}`

	Specifies to generate consolidated XP power reports. This parameter allows you to combine power reports that are stored across multiple partition directories to give a single unified view of power data. The possible arguments of this parameter are:
	• `none` - generates distributed reports.
	• `reduced` - generates consolidated reports for the following:
	  ◦ power.missingdata.* (static and dynamic flows)
	  ◦ power.stateprop.* (dynamic flow)
	  ◦ power.stats.setpower (dynamic flow)
	• `detailed` - generates consolidated reports for the following:
	  ◦ power.rpt (static and dynamic flows)
	  ◦ power.instpwr.rpt (static flow)
	  ◦ power.lib.rpt (static flow)
	  ◦ power.pgpinpwr.rpt (static flow)
	  ◦ power.pgnet.detailed.rpt
	  ◦ power.missingdata.* (static and dynamic flows)
	  ◦ power.pgnet.detailed.rpt (static and dynamic flows)
	  ◦ power.stateprop.* (dynamic flow)
	  ◦ power.stats.setpower (dynamic flow)
	  ◦ pg_trigger.txt (dynamic flow)
	  ◦ trigger.txt (dynamic flow)
	  ◦ *.totalcurrent (dynamic flow)
	  ◦ voltus_power.cellstat (static and dynamic flows)
	  ◦ voltus_power.ptifiles (static and dynamic flows)

`-distributed_setup` *file*	

	Default: `""` Specifies a file containing the customized setup details for running power analysis in the distributed mode. The specified file has 4 columns: `INST/CELL <name> block <power.inc>` where, • `INST/CELL`: Keyword indicating cell or instance to be run in the distributed mode. Cell can be useful for repeated DEF blocks. • *`name`*: Name of the hierarchical block or instance. • `block`: Keyword `block` implies that only the lower level DEF will be included • *`power.inc`*: name of the power include file. This column is optional. The unspecified instance/cell will be run with the top level as a single group. Each distributed block/instance should have corresponding TWF and SPEF to improve runtime. **Note**: Each block will be run independently from other blocks, thus the external load or cell seen at the pin of the block can be different from flat analysis. If the partition boundary analysis is important, distributed processing is not recommended. **Usage Guidelines**: • This parameter is not applicable to the `-static_netlist verilog` flow.
`-decap_cell_list` *`cell_list`*	
	Default: `""` Specifies the physical only cells, such as decap cells, to include in the power report. **Usage Guidelines**: • This parameter is applicable only to the static power calculation flow. • This parameter is not applicable to the `-static_netlist def` flow.
`-domain_based_clipping {true | false}`	
	Determines the frequency to be used to clip propagated activity that is too high. When set to `false`, the frequency of the fastest clock in the design is used. If you set this parameter to `true`, the fastest clock domain on the net is used to clip propagated activity. *Default*: `false`
`-dynamic_glitch_filter` *`value`*	

	Sets the absolute threshold time (in ns) for filtering glitches in net toggles. When you specify a time value for this parameter, glitches in net toggles that are equal to or smaller in width than the specified time value are removed. *Default*: -1 **Usage Guidelines**: • This parameter is applicable only to the state-propagation-based vectorless flow (`set_power_analysis_mode -method dynamic_vectorless -enable_state_propagation true`).
`-dynamic_scale_clock_by_frequency { freq_A factor_A freq_B factor_B freq_C factor_C ... }`	
	Specifies the scale factors for the clock frequency values. This parameter allows you to perform frequency scaling for clocks running at relatively low frequencies, thereby ensuring higher toggle coverage for limited simulation period. The parameter is applicable only to the dynamic vectorless flow. The following units are supported for frequency: Hz, KHz, MHz, and GHz.
`-dynamic_scale_clock_by_name { clk_A factor_A clk_B factor_B clk_C factor_C ... }`	
	Specifies the scale factors for the low frequency clocks. This parameter allows you to perform frequency scaling for clocks running at relatively low frequencies, thereby ensuring higher toggle coverage for limited simulation period. The parameter is applicable only to the dynamic vectorless flow. The following units are supported for frequency: Hz, KHz, MHz, and GHz.
`-dynamic_vectorless_ranking_methods {load | clock | vector_activity}`	
	Default: "" Specifies to change the ranking method from the default to the following: • `load` - Prioritizes scheduling cells with higher fanout • `clock` – Prioritizes scheduling cells associated with faster clocks • `vector_activity` - Prioritizes scheduling cells with higher activity **Usage Guidelines**: • This parameter is applicable only to the state-propagation-based vectorless flow (`set_power_analysis_mode -method dynamic_vectorless -enable_state_propagation true`). • This parameter is not applicable to the `-static_netlist verilog` flow.
`-enable_auto_queue {true | false}`	
	Default: `false` Specifies to automatically determine the queue for power jobs. This parameter is used in the Voltus-XP distributed power flow with hierarchical DEFs. In the XP flow, partitions are divided into multiple queues depending on the number of CPUs (For example, Default queue: 1 CPU, Small Queue: 2 CPUs, Medium; 4 CPUs, Large : 8 CPUs, and so on.). By default, all power partitions run on the same queue. When the parameter is set to `true`, the blocks can run on different queues depending on the size (number of instances) of the blocks. The `-enable_auto_queue` parameter will be beneficial when there are uneven power block partitions. For example, if there are some blocks with 20-30M instances and there are some with 3-5M instances. Using this parameter, bigger blocks will be automatically assigned to a bigger queue, resulting in better runtime.

`-enable_auto_mapping {true | false}`	
	Default: `false` Specifies to automatically perform instance name mapping between the RTL netlist and GATE level netlist. This parameter allows you to map the RTL vector to the Gate level netlist without a mapping file. You can use this parameter with the `read_activity_file -name_mapping_rule <filename>` command parameter to specify a file containing customized or design-specific rules. **Usage Guidelines**: This parameter is applicable only to the vector-based static/dynamic power calculation flow (`set_power_analysis_mode -method static | dynamic_vectorbased | dynamic_mixed_mode`).
`-enable_disk_mapping {true | false}`	
	Default: `false` Specifies to enable disk caching of the toggles. Therefore, the toggles are stored in the disk instead of keeping them in memory. This has made large vectors or long simulation duration runs possible even with lesser available memory. **Usage Guidelines**: This parameter is only applicable to the event-based power analysis flow (`set_power_analysis_mode -method event_based`) in the XP mode.
`-enable_duty_prop_with_global {true | false}`	
	Default: `false` Specifies to propagate duty cycle with the global switching activity setting for all data nets in the dynamic vectorless analysis flow. **Usage Guidelines**: This parameter is applicable to the static power calculation and probability-based dynamic vectorless flows. It is not supported in the state-propagation-based vectorless flow (`set_power_analysis_mode -enable_state_propagation true`).
`-enable_dynamic_current_slew_load_interpolation {true | false}`	
	Default: `false` Specifies to use the charge-based slew load interpolation. When this parameter is set to `true`, Power Analysis takes dynamic currents from the 4 nearest slew/load values and performs either a 4-way (lower slew, lower load, upper slew, upper load) or a 2-way (lower slew, upper slew OR lower load, upper load) interpolation to calculate the dynamic current waveform. The parameter allows you to derive a more realistic dynamic current waveform based on the exact slew load values from the .lib dynamic current table.
`-enable_dynamic_scaling {true | false}`	

	Default: `false` Enables `set_power` scaling for dynamic power analysis. The power and scaling specifications are used to scale dynamic current on both the power and ground currents of the specified instance/cell. This parameter honors the user-defined average (static) power for leaf-level instances and hierarchies (instances/cells/modules) along with power net specification in the dynamic current scaling flows such that the average of the dynamic current is equal to the assigned average power. When you specify this parameter, the average of the dynamic current of these leaf-level instances will match the scaled static power numbers. **Usage Guidelines**: • This parameter is applicable to the probability-based vectorless flow. It is not supported in the state-propagation-based vectorless flow (`set_power_analysis_mode -enable_state_propagation true`). • This parameter is not applicable to the `-static_netlist verilog` flow.
`-enable_flop_state_propagation {true | false}`	
	Default: `false` Enables accurate clock state propagation for sequential cells. When this parameter is set to `true`, flops propagate in a manner that toggles on the output pins are in sync with the clock. This parameter helps to align the output pins' toggles with the clock toggles.
`-enable_generated_clock {true | false}`	
	Default: `true` Specifies to get generated clock frequency during activity propagation for static power analysis. **Usage Guidelines**: • This parameter is applicable only to the static power calculation flow. • This parameter is not applicable to the `-static_netlist def` flow.
`-enable_input_net_power {true | false}`	
	Default: `false` Specifies to calculate the switching power of input nets. **Usage Guidelines**: This parameter is applicable only to the static power calculation flow.
`-enable_interactive_reports {true | false}`	

	Default: `false` Specifies to generate multiple dynamic reports based on the power analysis run done for a netlist. When this parameter is set to `true`, you can generate various types of power reports interactively using the `report_power` command without the need to perform power calculation on the same netlist again. The `-enable_interactive_reports` parameter is useful when you need to generate reports for the unaltered netlist within the same power analysis session. **Usage Guidelines**: This parameter is applicable only to the event-based power analysis flow with area-based partitioning (`-use_physical_partition`) in the XP mode.
`-enable_mt_in_vectorbasedflow {true | false}`	
	Default: `false` Specifies to enable multi-threading for the VCD/FSDB based dynamic vector-based flows. To enable multi-threading in the vector-based flows, set this parameter to `true`. **Usage Guidelines**: • This parameter is applicable only to the dynamic vector-based flow. • This parameter is not applicable to the `-static_netlist verilog` flow.
`-enable_mt_reports {true | false}`	
	Default: `false` Specifies to enable multi-threading for generation of power calculation reports. When set to `true`, it improves the memory and runtime for power reporting in large designs with more than 100 million instances.
`-enable_mt_state_propagation {true | false}`	
	Default: `true` Specifies to enable multi-threading in state propagation to help improve the runtime for large simulations. For example, when the parameter was specified for a design with 300 million instances and simulation duration of 120 microseconds, the runtime has improved from 21 hours to 1.5 hours. **Usage Guidelines**: This parameter is only applicable to the event-based power analysis flow (`set_power_analysis_mode -method event_based`).
`-enable_pba_for_tempus_pi {true | false}`	

	Default: `false` Specifies to enable the Path-Based Analysis (PBA) for slack calculation in the Tempus PI flow. By default, the Graph-Based Analysis (GBA) is used. **Usage Guidelines**: This parameter is only applicable to the state-propagation-based vectorless flow (`set_power_analysis_mode -method dynamic_vectorless -enable_state_propagation true`).
`-enable_power_target_flow {true | false}`	
	Default: `false` Specifies to enable the power target flow. When set to `true`, the tool allows you to specify power targets for full-chip power analysis. You can use the `set_power` command to specify the power targets for full-chip, physical block, logical block, and power/ground net. When these targets are specified, Voltus will automatically scale the toggle rates of clock gate ratio, input, macro, and sequential activities to meet the specified power targets. **Usage Guidelines**: This parameter is only applicable to the state-propagation-based vectorless flow (`set_power_analysis_mode -method dynamic_vectorless -enable_state_propagation true`) in the XP mode.
`-enable_rtl_vectorbased_dynamic_analysis {true | false}`	
	Specifies to take an RTL or partial VCD/FSDB file as input and use that for dynamic vector-based flow. This parameter allows you to estimate current even for instances which are missing from the activity file. You must use this parameter in conjunction with the `-method dynamic_vectorbased` parameter. Default is `false`.
`-enable_scan_report {true | false}`	
	Default: `false` Specifies to generate all the scan mode analysis reports. The following reports will be generated: • `voltus_power.scanff.duplicated.rpt` - flip-flops that are specified in multiple chains • `voltus_power.scanff.missing.rpt` - flip-flops that are missing in the scan control file but exist in the design • `voltus_power.scanff.nonassigned.rpt` - flip-flops that do not exist in the design and are dropped from the scan control file • `voltus_power.scanff.nonscan`.rpt - assigned flip-flops that have no scan-out pin • `voltus_power.scanff.nonswitched.rpt` - non-switching flip-flops in the scan control file • `voltus_power.scanff.rpt` - detailed scan chain report containing global statistics for all scan chains and statistics for each scan chain in the design • `voltus_power.scanff.stateconflict.rpt` - flip-flops that have conflicting state assignment

`-enable_single_cycle_scheduling {true | false}`	
	Default: `false` Schedules macro instances in every dominant clock cycle in the dynamic vectorless flow. This parameter can be used achieve faster toggle coverage. After the scheduling of every instance and attaining the maximum toggle coverage, the scheduler cycles back to the same switch source element and then schedules it again with the opposite polarity. This parameter helps in achieving the same toggle coverage within half the simulation period compared to dual cycle scheduling. When the parameter is set to `false`, the macros are scheduled every two cycles wherein the adjacent cycle is used for reversing the transition polarity.
`-enable_slew_based_ccs_pin_cap {true | false}`	
	Default: `false` Specifies to use the Composite Current Source (CCS) capacitance value based on the slew given in the input pin section of the library cell in the Liberty file. If it is set to `true`, the tool honors the CCS pin capacitance; if it is set to `false`, it takes `max_capacitance` from .lib. This parameter can be used when timing windows and/or a Tempus timing session is not available.
`-enable_state_propagation {true | false}`	
	Specifies to enable the vectorless state-propagation-based dynamic analysis flow. Default is `false`. For more information, refer to the **State-Propagation-Based Vectorless Methodology** section in the "*Dynamic Power and IRDrop Analysis*" chapter of the *Voltus User Guide*.
`-enable_tempus_pi {true | false}`	
	Default: `false` Specifies to enable the Tempus Power Integrity (Tempus PI) analysis flow. When this parameter is set to `true`, data path scheduling is timing-aware, that is, scheduling is based on timing slacks. For more information, refer to the *Tempus Power Integrity Analysis* chapter in *Voltus User Guide*. **Usage Guidelines**: This parameter is only applicable to the state-propagation-based vectorless flow (`set_power_analysis_mode -method dynamic_vectorless -enable_state_propagation true`).
`-enable_xp {true | false}`	
	Default: `false` Specifies to run standalone report generation in the XP mode.
`-enhanced_blackbox_avg {true | false}`	
	Specifies to use the average toggle rate of related inputs for enhanced blackbox propagation. *Default* : `false`
`-enhanced_blackbox_max {true | false}`	

	Specifies to use the maximum toggle rate of related inputs for enhanced blackbox propagation. *Default* : `false`
`-equivalent_annotation {true | false}`	
	Default: `false` Specifies to enable equivalent annotation for Q or Qbar pins when only one of them is annotated.
`-event_based_leakage_power {true | false}`	
	Default: `false` Specifies to calculate state-dependent leakage power. When this parameter is set to `true`, it calculates leakage power and current based on the state of an instance at each time point. For example, at time 0ns, instance instA is in state !I ZN (0 on input, 1 on output), and at time 71ns, the instance is in state I !ZN (1 on input, 0 on output). The leakage power is calculated based on the different states of instA at different time points.
`-external_load_config_file` *`filename`*	

	Specifies to honor the user-specified load capacitance values for power calculation. This parameter allows you to specify an external load capacitance file when you have a timing window file without the `EXTERNAL_LOAD` constructs.
	File Format:
	The format of the user-specified input file is:
	`INST|CELL` *`blockName external_load_flle`*
	Here, the format of *`external_load_flle`* is:
	`NET|PORT` *`name load_value`*
	Examples:
	Configuration file:
	`INST TOP top_wcard.load`
	External load file (`top_wcard.load`):
	`UNIT pF`
	`NET result 0.02`
	`NET overflow 0.02`

`-extraction_tech_file` *`filename`*	
	Specifies the extraction technology file to be used for top-level power-grid extraction.
`-extractor_include` *`filename`*	
	Specifies the extractor (ZX) commands and variables in the form of an include file. This parameter is applicable only for the standalone report generation flow in the XP mode (`set_power_analysis_mode -enable_xp true`).
`-fanout_limit` *`value`*	

	Specifies the fanout limit for nets. If an instance has nets more than or equal to the fanout limit, its switching/internal/leakage power is taken to be zero.
`-flatten_xpgv_block_instances` *filename*	

	Specifies a file that includes a list of block instances that use DEF instead of xPGV for power analysis, that is, specify the instances that are not to be used as xPGV. This parameter allows you to specify a few instances of the same block that will use DEF, and the others that will use xPGV at the top-level. If you do not specify this parameter, and if both DEF and xPGV are given for a block, xPGV takes precedence over DEF.
	File Format:
	<*block_name*> <*block_instance_name*|All|None>
	In this file, you can specify if a block is using a DEF by specifying the block instance name, or with the `All` or `None` keywords. `All` indicates that all instances are using DEF, and `None` indicates that none of the instances are using DEF.
	Example:
	For a design with three blocks, if you want to use the DEF and xPGV as following:
	`Block_1 - > A1 (xPGV) & A2 (DEF)`
	`Block_2 - > B1 & B2 (xPGV for both instances)`
	`Block_3 - > C1 & C2 (DEF for both instances)`
	The specified file will contain the following information:
	`Block_1 A2`
	`Block_2 None`
	`Block_3 All`

`-force_library_merging {true | false}`	
	Specifies to force merge PGVs even if there are some minor conflicts in the merging libraries. The default value of this parameter is `false`. This parameter is applicable only for the standalone report generation flow in the XP mode (`set_power_analysis_mode -enable_xp true`). *Default* : `false`
`-from_x_transition_factor` *value*	
	Specifies how transitions from X to 0/1 are counted. The default value is `0.5`.
`-from_z_transition_factor` *value*	
	Specifies how transitions from Z to 0/1 are counted. The default value is `0.25`.
`-generate_activity_mapping_report {true | false}`	

	Default: `false` Specifies to generate the `activity_mapping.rpt` report in the vector-based dynamic power flow. This report gives the list of signal name mappings between the Golden (RTL netlist - input name in the vector file) and Revised (Gate netlist - annotated design object name) netlists that were used in the flow. The report displays the list of annotated and unannotated objects and helps to debug the mapping file for unannotated design objects. `activity_mapping.rpt` supports activity mapping done through the following methods: • User-specified mapping file (`map_activity_file -two_column_mapping_file`) • Conformal-generated RTL mapping file (`map_activity_file -rtl2gate`) • Voltus auto-generated mapping file (`set_power_analysis_mode -enable_auto_mapping`). **Usage Guidelines**: This parameter is only applicable to the vector-based dynamic flow (`set_power_analysis_mode -method dynamic_vectorbased`).
`-generate_current_for_rail` *railnames*	
	Generates current files for the specified rail. By default, the command generates current files for all power rails.
`-generate_flop_ranking_data` *directoryname*	
	Specifies the name of the directory where the flop ranking data is saved. Using this parameter, you can save the flop ranking data that can be reused across different versions of the design database for the same block or transferred from the top-level to the block-level run. This parameter is used with the `-reuse_flop_ranking_data` parameter.
`-generate_leakage_power_map_based_on_calculated_leakage {true | false}`	
	Default: `false` Specifies to scale the instance leakage power by directly multiplying the user-specified scaling factor with the final calculated leakage power value, instead of scaling the leakage power value from the input dotlib. If this parameter is not specified, the user-specified scaling factor will be applied on the leakage power values from the input dotlib.
`-generate_static_report_from_state_propagation {true | false}`	

	Default: `false` Specifies to directly generate the static power analysis result based on the RTL-VCD input and state-propagation. When this parameter is specified, the RTL vector power analysis flow does not require the generation of a TCF/FSDB file. **Usage Guidelines**: • This parameter is applicable only to the dynamic propagation-based flow (vector-based/vectorless/RTL/Mixed-mode). • This parameter is not applicable to the `-static_netlist verilog` flow.
`-handle_glitch {true | false}`	
	Default: `false` A transition is defined as a glitch when the time difference between two sequential toggles are less than half of the rise transition time + fall transition time in the vector-based static power calculation. Both static and dynamic current are derated for glitch transitions. The same derate factor is used for both power and current. If set to `true`, glitch power will be identified and calculated according to this definition and it will be reported in a separate column. Switching or internal power calculation does not include power due to glitches. If set to `false`, glitch power will not be identified, and the respective power will be calculated as normal signal switches. Hence, the total power will be a little higher.
`-handle_transport_glitch {true | false}`	
	Default: `false` Transport glitch is referred to as functional toggles for a net in a single clock period before it reaches a stable value. You can use this parameter to report the internal and switching power values for transport glitch. The transport glitch power is reported in the following reports: • Average Power Summary Report (`power.rpt.avgpwr`) - reported in the Total, Group, Clock, and Rail power sections. • Instance Power Report (`power.rpt.instpwr`) - reported for all instances. • Hierarchy Power Report (`power.rpt.hierpwr`) - reported for all hierarchies. This parameter is automatically set to `true` with `-handle_glitch true`. That is, reports both inertial and transport glitch power. When set to `false`, only the inertial glitch power is reported.
`-handle_tri_state {false|true}`	
	When set to `true`, all tristate device enable pin values will be taken into account when determining the propagation of the activity through tristate gates. *Default* : `false`
`-hier_delimiter` *character*	

	Specifies the hierarchical delimiter in the DEF file. The default hierarchical delimiter is a forward slash (/) but can be changed by setting the `-hier_delimiter` parameter. You can use this parameter to override the existing hierarchical delimiter.
`-honor_combinational_logic_on_clock_net {true | false}`	
	Specifies the behavior of combination logic on clock net. • `true` (default) - specifies to honor activity propagation through combinational logic. • `false` - specifies that the combination logic will be treated like a combinational clockgate.
`-honor_negative_energy {true | false}`	
	A value of `true` specifies that Voltus will keep negative internal energy numbers from the `.lib` internal power table. When set to false, negative power is treated as 0. *Default* : `true`
`-honor_net_activity {true | false}`	
	Specifies to use activity from the `Net` section of the Switching Activity Interchange Format (SAIF) file for power calculation and optimization, and to ignore the pin-based state-dependent path delay (SDPD) activity. The default value of this parameter is `true`. When this parameter is set to `false`, the power calculation engine can use both the net-based and pin-based activity. In this case, precedence will be given to activity from net or pin that appears later in the SAIF file.
`-honor_non_mission_leakage {true | false}`	

	Supports modeling of well-to sub-leakage information when the circuit power supply is off for the level shifter cells. This is referred to as the non-mission mode leakage power calculation. The leakage power for a level shifter cell depends on the state of each PG pin. The Liberty file contains sections for PG pin conditions of each mode/state and non-mission mode leakage power for each PG pin of that mode.
	When this parameter is set to `true`, Voltus identifies the pg_pin mode and assigns non-mission mode leakage power associated with the mode.
	The use model of the non-mission mode leakage power calculation feature is:
	`set_power_analysis_mode -honor_non_mission_leakage true`
	`set_power_analysis_mode -off_pg_nets {VDD VDDO}`
	Example:
	Let us consider a level shifter cell with the PG mode "`retained_VDDO_off`" and the following `pg_pin_condition`:
	`pg_setting_value (retained_VDDO_off) {`
	`pg_pin_condition : "!VBB*VDD*VDDI ";`
	`pg_pin_active_state (VBB, V1);`
	`pg_pin_active_state (VDD, V2);`
	`pg_pin_active_state (VDDI, V2);`
	When you specify a list of PG nets to be turned off along with the `-honor_non_mission_leakage` parameter, all cells/instances that have the PG state "`retained_VDDO_off`" associated with the specified PG pin condition, will use the corresponding non-mission leakage power.

`-hybrid_analysis {true | false}`	
	Default: `false` Specifies to perform both vector-based and vectorless power analysis in a single session.
`-ignore_control_signals {true | false}`	
	Specifies that control signals will be ignored when propagating activity. It is recommended to set this parameter to `true`. When set to `true`, the control pins (reset, preset) will not impact the sequential instance's output pin activity during activity propagation. *Default* : `true`
`-ignore_data_phase_for_clk {true | false}`	
	Default: `false` Specifies to ignore data frequency in the clock path for the clock instances in the design. When this parameter is set to `true`, the software propagates only the fastest clock pin frequency instead of the data pin frequency for activity propagation through clock network. In the default mode `(false)`, the software picks the fastest frequency between the data phase and clock phase on that pin.
`-ignore_glitches_at_same_time_stamp {true | false}`	
	Specifies to ignore glitches at the same transient time in the vector-based static and dynamic power analysis flow. When `-ignore_glitch_at_same_time_stamp` is set to `true`, only the last signal value change is honored, and all the preceding value changes at the same time stamp are ignored. The last signal value will overwrite the previous value for the same signal at the same time stamp, so the last value will represent the state of the signal at that time stamp. *Default* : `true`
`-ignore_inout_pin_cap {true | false}`	
	Default: `false` When set to `true`, ignores the bidirectional pin capacitances (`direction : inout`) defined for I/O cells in the .lib file, when calculating switching power and internal power; this also includes the default capacitance value for `inout` pins.
`-ignore_macro_leakage_scale_for_temp {true | false}`	
	Default: `false` The `-leakage_scale_factor_for_temp` parameter is used to perform linear scaling of the leakage power for temperature in both the standard cell and macro libraries. The `-ignore_macro_leakage_scale_for_temp` parameter allows you to selectively apply the scale factor only for standard cells, and not use the scale factor for macro cells.
`-ignore_end_toggles_in_profile {true | false}`	

	By default, the software profiles the toggles in the user-selected vector time window by steps including the toggles at the start/end boundary of the window. In each step, the toggles on the start boundary edge of the step is counted in the current step; the toggles on the end boundary edge is counted in the next step. When this parameter is set to `false`, the toggles on the end boundary edge is also counted in the last step, as there is no next step to it. This may lead to double count of the power profile for the last step, especially for zero-delay vector profiling. The default of this parameter is `false`. When this parameter is set to `true`, the software ignores the toggle on the end boundary of the last step.
`-include_seq_clockpin_power {true | false}`	
	Reports the clock pin power of flip-flops as part of the clock network power. *Default* : `false`
`-include_timing_in_current_file {true | false}`	
	Default: `false` Specifies to write timing bits for non-switching instances in the current files during the state-propagation-based flow. When specified, rail analysis will report effective instance voltage (EIV) for both switching and non-switching instances. If the parameter is set to `false`, rail analysis will report EIV for the switching instances only. **Usage Guidelines**: This parameter is only applicable to the state-propagation-based vectorless flow (`set_power_analysis_mode -method dynamic_vectorless -enable_state_propagation true`).
`-ir_derated_timing_view` *view_name*	
	Specifies the name of the timing view used to calculate timing slack and to rank the flops in the Tempus PI flow. This parameter must be specified if there are multiple views. The `-ir_derated_timing_view` parameter defines the timing view used to detect the IR-sensitive paths using a lower voltage than the actual analysis. This lower voltage simulates the IR-drop for each instance in the design. The software uses this view to prioritize the end-points that need to be prioritized for switching.
`-keep_clock_gate_ratio_in_iterations {true | false}`	
	Default: `false` Specifies whether to keep the clock gate output (CGO) fixed or automatically adjust the value for each iteration of state propagation. **Usage Guidelines**: This parameter is only applicable to the power target flow (`set_power_analysis_mode -enable_power_target_flow true`).
`-leakage_scale_factor_for_temp` *scale*	

	Performs a linear scaling of the leakage power for temperature in all libraries. This replaces the k-factor for temperature in the .lib file. For process and voltage, the scaling will continue to be based on the corresponding k-factors in the .lib file. A value of 0.8 scales the leakage power in the library to 80 percent. A value of 1.2 scales the leakage power in the library to 120 percent. *Default* : `1`
`-library_preference {voltage | ecsm_ccsp}`	
	Instances of the same cell can be attached to different power domains in a design. If you have specified different PVT libraries, then the software will by default bind each instance to the closest library definition. You can use this parameter to select either the closest Effective Current Source Model (ECSM)/Composite Current Source-power (CCSP), or the closest voltage library for the instance: • `voltage`: when specified, enables library binding to the closest voltage library. • `ecsm_ccsp`: when specified, enables library binding to the closest ECSM/CCSP library. The default is `voltage`.
`-macro_pgv_leakage {true | false}`	
	Default: `true` Controls leakage power reporting for cells that have power information available in both dotlib and PGV. When the parameter is set to `false`, the leakage current from Liberty is used and when the parameter is set to `true`, the leakage current from PGV is used.
`-macro_toggle_pin_percentage` *percentage*	
	Default: `50%` Specifies the percentage of output data pins (ignoring the control pins) to be scheduled for a macro cell. This parameter is applicable to the state-propagation based vectorless flow. The default macro pin toggle percentage is 50%.
`-mbff_toggle_behavior { simultaneous | independent | sbff }`	
	Specifies the toggle behavior of multi-bit flip-flops (MBFF). The possible arguments are: • `simultaneous`: The multiple bits of the MBFF will toggle or not toggle at the same time. The MBFF will be considered as one flip-flop. • `independent`: The multiple bits of the MBFF will toggle independently. The MBFF will be considered as one flip-flop. • `sbff`: The MBFF will be considered as multiple Single-Bit Flip-Flops (SBFFs). Each bit will be considered as one flip-flop, and will toggle independently. The default value is `independent`.
`-mbff_toggle_pin_percentage` *percentage*	

	Specifies the percentage of Multi Bit Flip Flop (MBFF) pins to be scheduled. This parameter is applicable to the state-propagation based vectorless flow. This parameter will only work when `-mbff_toggle_behavior` is set to `independent`.
`-memory_current_scaling_method {1 | 2 | 3}`	
	Specifies to enable scaling of the NLPM-based currents by a user-specified scale factor for macro cells that are switching. The applicable arguments are `1`, `2`, and `3`, which means enable a scaling factor of `0.5`, `0.25`, and `0.1` respectively.
`-merge_switched_net_currents { true | false}`	
	Specifies to merge switched net currents into always-on currents. For designs with a large number of switched nets, this parameter helps improve performance by merging switched net instance currents with always-on instance currents. However, when this parameter is set to `true`, you will not be able to use the generated current files to run power-up analysis. *Default* : `false`
`-method { static | dynamic_vectorless | dynamic_vectorbased | dynamic_mixed_mode | event_based | vector_profile}`	

	Specifies the type of analysis to be performed. You can perform two types of power analysis, namely static and dynamic.
	• `static` - specifies to perform static power analysis to calculate average power.
	Dynamic power analysis can be a vector-based or vectorless approach.
	• `dynamic_vectorbased` - uses the full VCD output of a logic simulator to identify the instances that are switching and when they switch.
	• `dynamic_vectorless` - uses the timing arrival window information from a static timing analysis tool to determine when instances switch. A timing arrival window describes when a signal can change within a clock cycle. An additional algorithm then determines the instances that switch.
	• `dynamic_mixed_mode` - specifies to combine the vector-based and vectorless (mixed) dynamic analysis. This flow can be used in the following cases:
	◦ **case 1**: vectors are not available for every block of a full-chip design.
	In this case, the software uses the vectorless methodology for blocks with incomplete vectors
	◦ **case 2**: blocks with vectors having unannotated combinational/ sequential logic.
	In this case, the software performs state propagation for the missing combinational/ sequential logic. It uses the vectorless methodology for a logic cone that does not have the primary inputs or flops annotated from the vector, and then performs state propagation
	To enable the dynamic mixed mode analysis flow, you must specify the following commands:
	`set_default_switching_activity -clock_gates_output 2.0 -global_activity <activity>`
	`set_power_analysis_mode -method dynamic_mixed_mode`
	`read_activity_file -scope <> -block <>` -> (for available blocks)
	• `event_based -` specifies to enable event-based power analysis. This method supports multiple power analysis flows simultaneously. When specified, the tool performs accurate state-based power estimation for all events of a scenario in a design. Event-Based Power Analysis is applicable to all

event-based vectors, such as VCD, FSDB, SHM, and PHY.
You can specify this method to generate and analyze multiple types of power analysis flow reports in a single run. The following table shows the additional options required for the different flows:

Power Analysis Flows	Additional Options for `-method event_based`
Static	`no additional option required`
Average Power & Current	`-write_static_currents`
Dynamic Vectorbased	`-write_dynamic_currents`
Mixed Mode	`-add_simulation`
Dynamic Vectorless	
Profiling	`-worst_step_size`

- `vector_profile` - specifies to enable vector profiling. This is used to identify windows with maximum activity and power which can then be used to drive dynamic vector-based power analysis.

Default : `static`

`-min_leaf_count` *value*

Specifies the minimum number of leaf instances required for writing the hierarchy data in the profiling database. It allows you to restrict the number of hierarchies for which waveforms are reported in the profiling database when using both the `-write_profiling_db` and `report_power -hierarchy` parameters.

The default value of this parameter is `0`. Any hierarchy whose leaf instance count in its complete sub-tree is less than the `-min_leaf_count` value will be skipped from getting reported in the profiling database. This parameter can be used to skip very small hierarchies and as a result save on the database writing time and disk space.

`-multi_scenario_simulation {true | false}`

	Specifies to create a long vector by combining multiple vectors and to identify the worst power intervals across the combined vector. The long vector includes all scenarios that are used sequentially and are non-overlapping.  This parameter allows you to perform power and current analysis using worst peak power interval across multiple simulation vectors. *Default* : `false`
`-off_pg_nets` *net_list*	
	The name of the power rails that will be turned off. The net name can contain instance hierarchy if appropriate. This data will be taken into account when figuring out the list of power gates which are switched off. **Note:** A net is turned off if all connected power gates are turned off by control signals. When a net is off, all instances connected to that net will contribute zero power.
`-output_current_data_prefix` *prefix*	
	Specifies a prefix to the static or dynamic current files generated by the software. When power analysis is done in the multi-CPU mode, the output current data directory name and the underlying current files will also use the same prefix by default.
`-partition_count` *value*	
	Default: `0` Specifies the number of physical partitions or jobs for a distributed run in the area-based partitioning flow. **Usage Guidelines**: • This parameter is only applicable to the event-based power analysis flow (`set_power_analysis_mode -method event_based`) in the XP mode. • This parameter must be specified with the `-use_physical_partition` parameter.
`-partition_twf {true | false}`	

	Specifies to read the input TWF data (flat or hierarchical TWF files), and generate block-level TWFs. The default is `false`. This parameter must be specified when the block/partition level TWF files are not available.
`-pin_based_twf {true | false}`	
	Specifies whether to generate pin-based TWF or net-based TWF. The default value is `false`. • When set to `false`, a net-based TWF file is generated. Net-based TWF file is smaller in size and therefore results in faster processing. • When set to `true`, a pin-based TWF file is generated. Pin-based TWF file is bigger in size and requires longer processing time, however, is more accurate because the slews numbers are pin-based. **Note:** This parameter must be used with the `read_sdc` command.
`-power_grid_library` **{** *`library_list`* **}**	
	Specifies the name of the Cadence power cell libraries (`.cl`). You can also specify a list of defined power-grid libraries having decap cells tagged in them. **Note**: When specifying a list of PGVs to power analysis using the `set_power_analysis_mode` command, you must specify the technology library as the first PGV library in the list, followed by the standard and macro PGV libraries. The selection between the standard and macro PGV library is order based. Therefore, if multiple power-grid libraries are specified for a cell, the power engine maps the cell with the first library after the technology library.
`-power_include_initial_x_transitions {true | false}`	
	Controls how the initial X state toggle should be counted. The initial X state means the state at time `0`. The default value is `true`. This means that the software counts the power caused by the `X->0` or `X->1` toggle. When set to `false`, the software does not count the power caused by the initial X state toggle.
`-power_match_state_for_logic_x` *`value`*	
	Controls how the logic X will be evaluated in the boolean function of the '`when`' state of a power table. The default value is `0`. The parameter uses the following arguments: • `0` - regards X as 0 • `1` - regards X as 1 • `x/X` - regards X as neither `0` nor `1`, that is, whenever there is any X logic in it, the boolean function will be evaluated false.
`-precision` *`value`*	
	Specifies precision of decimal range [1-8] to ensure consistent decimal places are displayed for each power component. The default value is `8`. This parameter is used for precision handling in `report_instance_power` and `report_power`.

`-pre_simulation_empty_period` *period*	
	Specifies to add an empty pre-simulation period before simulation during IR drop analysis. Power analysis is not done for the pre-simulation period and flat dynamic currents are created.
`-pre_simulation_period` *period*	
	Specifies to set a pre-simulation period for IR drop analysis. Pre-simulation is used for generating power analysis reports and dynamic currents.
`-pre_simulation_power_exclude_period` *period*	
	Specifies to exclude power analysis during the pre-simulation period used for IR drop analysis. Pre-simulation is used only to create dynamic currents and not used for power reports.
`-quit_on_activity_coverage_threshold` *threshold_value*	
	Specifies the activity (VCD/FSDB/TCF) coverage threshold value. This parameter allows you to control the acceptable activity coverage that you are expecting and enforce the software to quit when it does not meet the criteria. When you specify the threshold value, the software exits if the real activity coverage is below the threshold.
`-read_rcdb {true | false}`	
	Specifies to write a SPEF file containing only the total C for signal nets and pass it to the Dynamic Power engine. Dynamic power analysis requires only the total C for signal nets. Therefore, instead of writing a large SPEF file (with distributed RC) from the RCDB, this parameter specifies to create and pass a SPEF file with only total C for all the signal nets. This significantly reduces the parasitic annotation time in the Dynamic Power engine. *Default* : `false`
`-relax_arc_match {true | false}`	
	Specifies to relax arc match when the exact arc is not found in a .lib. When set to `true`, the internal energy is calculated as an average of multiple arcs with relaxed arc matching. If this parameter is set to `false`, relaxed arc search is not done and 0 internal energy is returned. *Default* : `true`
`-report_black_boxes {true | false}`	
	Specify this parameter to report cells that are used as black boxes. A black box is a cell which is either missing from the liberty file or has no functionality defined in the liberty file. *Default* : `false` This is an optional parameter.
`-report_clock_instance_switching_info {true | false}`	
	Specifies to generate a report for clock instances that switched during the state-propagation based vectorless flow. The generated report contains the toggle time, instance name, input pin event, and output pin event for each switching event of the clock instance.

`-report_idle_instances {true | false}`	

	Specifies to generate a report (`idleinstance.rpt`) that lists all the idle or non-switching instances.
	
	The default value is `false`.
	
	The following is a snippet of the `idleinstance.rpt` report:
	`DFF22/DFF F`
	`DFF42/DFF F`
	`...`
	
	Here, the first column is the instance name and the second column is the type of instance (`F` indicates flop and `C` indicates combinational).

`-report_instance_switching_info {all | output_logic | none}`	

	Specifies to generate a report for combinational instance switched during state-propagation. In the output file, it contains the toggle time, instance name, input pin event, and output pin event for each switching event of the combination gate. The possible arguments of this parameter are:
	• `all` - Specifies to report instance toggle information for both input and output pins. When this parameter is set to `all`, the switching of both the input and output pins of all the instances are reported in the `voltus_power.stateprop.switchinst` file and the switching of flops are reported in the `voltus_power.stateprop.switchsrc` file.
	• `output_logic` - Specifies to report instance toggle information for the output pins only. When this parameter is set to `output_logic`, the switching of the output pins of all the instances are reported in the `voltus_power.stateprop.switchinst` file and the switching of flops are reported in the `voltus_power.stateprop.switchsrc` file.
	• `none` - Disables generation of instance toggle report. This is the default option. When this parameter is set to `none`, only switching of flops are reported in the `voltus_power.stateprop.switchsrc` file. The file does not report switching of instances.
	The default value is `none`. This parameter is used for generating switching details of state-propagation and should be specified only for debugging purpose.
	The following is a snippet of the `voltus_power.stateprop.switchinst` report:
	`*-----------------------------------------------`
	`*Switch Time  Instance Name  Pin Name  Logic`
	`*-----------------------------------------------`
	`*`
	`  0.097  B11/BUFF  I  rise`
	`  0.097  DFF11/DFF  Q  rise`
	...
	Here,
	• `Switch Time`: switching time of instances that can be either combinational or sequential
	• `Instance Name`: instance name
	• `Pin Name`: input/output pin of the instance
	• `Logic`: present logic of the pin that can be either "rise" or "fall"

`-report_instance_switching_list` *filename*	

Specifies to generate a report (`voltus_power.stateprop.switchlist`) containing all the switching times for the specified instances when the `-enable_state_propagation` parameter is set to `true`.

The format of the specified file is:

```
instname1
instname2
...
```

The following is the format of the `voltus_power.stateprop.switchlist` report:

```
*-------------------------------------------------------------------------------------
*Instance Name   Pin Name   Pin Direction   Frequency   Switch Time
*-------------------------------------------------------------------------------------
*
```

Here,

- `Instance Name`: instance name that can be either combinational or sequential
- `Pin Name`: name of the input/output pin of the instance
- `Pin Direction`: indicates whether the pin is an INPUT (I) or OUTPUT (O) pin
- `Frequency`: clock frequency
- `Switch Time`: gives the switching pattern for the instance, that is, <*time1*> <*logic*> <*time2*> <*logic*>. The logic of the pin can be "`r`" or "`f`". `r` indicates rise and `f` indicates fall.

The following is a snippet of the `voltus_power.stateprop.switchlist` report:

```
*-------------------------------------------------------------------------------------
*Instance Name   Pin Name   Pin Direction   Frequency   Switch Time
*-------------------------------------------------------------------------------------
*
   DFF11/DFF        QN        O              100       0.106 f 10.107 r
   DFF11/DFF        Q         O              100       0.097 r 10.099 f
   DFF11/DFF        CP        I              100       0.059 r 5.056 f 10.059 r 15.056 ...
...
```

`-report_library_usage {true | false}`

Default: `false`

Specifies to report library usage statistics in a text report. The report contains information such as, cell name, library format used (CCSP/ECSM/NLPM) for each cell, library name, and so on. This parameter allows you to perform library integrity checking for debugging purpose.

The following is the use model of the `-report_library_usage` parameter:

```
set_power_analysis_mode -method static | dynamic_vectorless | dynamic_vectorbased \
                        ...
                        -report_library_usage true
report_power -output <power_dir> -report_prefix <prefix>
```

The report is saved at `<power_dir>/<prefix>.lib.rpt`.

File Format:

```
Instance Cell  Net      Pin    Operational  Library   Library     Missing       Library
Name     Name  Name     Name    Voltage     Voltage   Format      Tables          Name
```

Examples:

```
Instance Cell  Net      Pin    Operational  Library   Library     Missing       Library
Name     Name  Name     Name    Voltage     Voltage   Format      Tables          Name
INV_178  INV   VDD,VDDA VDDG,VDD  0.9        1.0       NLDM      leakage,timing    A
INV_179  INV   VDDC     VDDG      0.75       0.75      CCSP,NLDM   leakage         B
```

Usage Guidelines:
This parameter must be specified with the `report_power -report_prefix` parameter.

`-report_missing_bulk_connectivity {true | false}`

Specifies to report missing bulk pins in the missing input report (`-report_missing_input`).

`-report_missing_input {true | false}`

Specifies to report missing netlist information in input files, such as library, LEF/DEF, PGV, SPEF, TWF, and missing logical connectivity for cell instance (PGNET).

The name of the report file is: `<prefix>_missingdata.<spef|lefdef|lib|pgv|twf|pgnet>`

Following is the use model:

```
set_power_analysis_mode -report_missing_input true
report_power -output <dirname> -report_prefix <prefix>
```

`-report_missing_nets { true|false }`

Controls reporting of missing nets in both static and dynamic power analysis.

This parameter controls reporting for TWF and activity files in static analysis, and controls reporting for TWF/SDC/SPEF and activity files in dynamic analysis.

Default : `false`

`-report_scan_chain_stats {true | false}`

Specifies to generate a report file called `voltus_power.scanchain.stat` during scan mode analysis that contains scan chain statistics.

The default value is `false`.

The report has 2 parts:

- **Global Statistics**: this section has the cumulative statistics of all scan chains in the design
- **Chain Statistics**: this section has the statistics for each scan chain in the design

The Global and Chain Statistics sections have the following information:

- `Total`: total instances specified in the control file or in a scan chain
- `AssignedFF`: flip-flops defined in the scan control file which exist in the design
- `SwitchedFF`: flip-flops that have switching event at the output
- `Non-ScanFF`: flip-flops that have no scan-out pin
- `DuplicatedFF`: flip-flops that are specified in multiple chains
- `StateConflictFF`: flip-flops that have conflicting state assignment

`-report_stat {true | false}`

Reports a set of statistics on the instance power, instance power density, clock power, or transition density. This parameter is useful in viewing and debugging user defined activity factors.

Default : `false`

`-report_time_display_fraction_digits` *value*

Sets the number of fractional digits or decimal places displayed for the instance switching time values in the `voltus_power.stateprop.switchinst` file. This parameter displays fractional digits that show the exact time difference if there are two events (rise/fall) of an instance switching at the same time.

Default : `-1`

`-report_twf_attributes {detailed | summary}`

Controls the generation of the TWF attribute report based on the TWF attributes that are specified using the `set_twf_attribute` command.

The possible arguments are:

- `summary` - generates a summarized static timing analysis report "`voltus_power.twf_attribute.summary`" that displays the number of user-defined TWF attributes (delay, slew, and slack values for both the rise and fall transitions) and the number of annotated TWF attributes for dynamic power analysis. The following is a snippet of the report:

```
STATISTICS:
                    User Defined            Annotated               Annotated/Total(%)
shift_arrival_time   5                       4                       80
rise_slew            2                       2                       100
fall_slew            2                       2                       100
rise_delay           5                       4                       80
fall_delay           5                       4                       80
rise_slack           2                       2                       100
fall_slack           2                       2                       100
```

- `detailed` - generates a detailed static timing analysis report "`voltus_power.twf_attribute.detailed`" that includes the summary report, and a detailed report of the rise and fall transitions for the TWF attributes of each annotated instance/pin. It also includes the shift arrival time report.

  This argument also allows you to generate a report `voltus_power.twf.rpt` containing the TWF statistics to highlight clock-frequency and delay used for the static and dynamic power calculation.

  The TWF statistics report is generated only if:

  - the `read_twf` command is specified before `set_power_analysis_mode`
  - the `set_power_analysis_mode -method static -static_netlist def` or `set_power_analysis_mode -method dynamic_vectorless | dynamic_vectorbased` command is specified.

  The format of the `voltus_power.twf.rpt` report is:

```
# Voltus TWF Statistics
# Units: Freq (Hz), Delay (second), Slew (second)
# TWF File List:
#     TWF_file1
#     TWF_fileN

USER DEFINED TWF ATTRIBUTE STATISTICS
<Clock Freq> <Min Rise_Delay> <Rise Delay> <Max Rise Delay> <Min Fall Delay> <Fall
Delay> <Max Fall Delay> <Net>
```

  The `USER DEFINED TWF ATTRIBUTE STATISTICS` section is included in the report only if the TWF attributes are defined using the `set_twf_attribute` command.

Example:

#check all instances of inst_C1 get shifted by 3ns

```
set_twf_attribute -pin inst_C1 -shift_arrival_time 3
```

#check all instances of inst_D1 get shifted by 3ns

```
set_twf_attribute -net inst_D1 -shift_arrival_time 3

set_power_analysis_mode -method dynamic_vectorless -create_binary_db false -disable_static
false -enable_state_propagation true -current_generation_method peak -power_grid_library
/../library_pv.cl -report_twf_attributes summary
```

`-reset`	Resets all or specified parameters to their default values. When you specify only the `-reset` parameter, the software resets all parameters for the `set_power_analysis_mode` command. When resetting specific parameters, the `-reset` parameter must be the first followed by the specific parameter. For example, you can specify the following command to reset only the `-method` parameter while keeping all other parameters' values unchanged: `set_power_analysis_mode -reset -method` **Note:** When resetting a specific parameter, you must not specify any arguments for that parameter.
`-reuse_flop_ranking_data` *`directoryname`*	
	Specifies the name of the directory where the flop ranking data to be reused is placed.
`-reuse_flop_ranking_data_hier` *`blockname`*	
	Allows you to choose the block/hierarchy whose ranking data is to be used for the block-level analysis. This parameter is used when the flop ranking data is transferred from a top-level analysis where blocks are flattened to another block-level analysis. The `-reuse_flop_ranking_data_hier` parameter enables you to specify the required block if the top-level contains multiple instantiations of the same DEF block.
`-save_bbox {true | false}`	
	Default: `false` Specifies to save the boundary box of each instance, its placement, and rotation at the top level. When set to `true`, generates the power database with each instance boundary box, placement, and rotation information at the top level. **Usage Guidelines**: This parameter must be specified when generating the Voltus thermal model.
`-scale_to_sdc_clock_frequency {true | false}`	

	Specifies to enable the VCD clock frequency to be scaled up to the SDC clock frequency. This allows you to match the VCD clock to the SDC clock to run analysis. By default, the clock frequency is scaled based on the activity file (Default: `false`). When you set the `-scale_to_sdc_clock_frequency` parameter to `true`, the power report and current waveforms apply the after-scaled clock frequency. The default behavior for clock frequency scaling in the RTL and Gate level VCD flows is different, as described below: • **RTL VCD** - By default, the clock frequency is scaled to the SDC clock frequency (`-scale_to_sdc_clock_frequency true`) when the RTL VCD flow is enabled (`set_power_analysis_mode -enable_rtl_vectorbased_dynamic_analysis true`). You can disable clock frequency scaling by setting the `set_power_analysis_mode -scale_to_sdc_clock_frequency` parameter to `false`. • **Gate VCD** - By default, scaling of the clock frequency is disabled (`-scale_to_sdc_clock_frequency false`) . You can enable the VCD clock frequency to be scaled up to the SDC clock frequency by setting the `set_power_analysis_mode -scale_to_sdc_clock_frequency` parameter to `true`. This works only when `set_power_analysis_mode -use_zero_delay_vector_file` is set to `true`, which means that the gate VCD is a zero-delay gate VCD.
`-scan_chain_activity {design_name chain_name activity_number} | {vectorless activity_number}`	

	Specifies to either provide vectorless activity for all scan chains or provide a specific activity for a specific chain. This parameter allows you to specify vectorless or user-defined activity to scan chains.
	The following are the two use models:
	• Generate the scan control file for a specific chain:
	`set_power_analysis_mode -scan_chain_activity {design_name chain_name activity_number}`
	• Generate the scan control file for all scan chains:
	`set_power_analysis_mode -scan_chain_activity {vectorless activity_number}`
	The `-scan_chain_activity` parameter is supported only in the XP mode.

`-scan_chain_name {`*`design_name chain_name pattern`*`}`	
	Specifies to automatically generate a scan-chain control file from a scan-chain based DEF file for the shift mode scan-chain analysis. This parameter allows you to create a control file for a large-sized DEF containing long chains or for multiple-DEF files. The generated scan-chain control file is saved in the power output directory. The use model of the parameter is: • `-scan_chain_name {all pattern}` - generate scan control file for all scan chains. **Example**: `-scan_chain_name {all 11010}` • `-scan_chain_name {design_name chain_name pattern}` - generate scan control file for a specific chain. **Example**: `-scan_chain_name {counter AutoChain_1_seg1_clk_rising 10010}` Using this parameter, you can generate the control file for both flat and hierarchical DEFs.

`-scan_control_file` *filename*	
	Specifies the scan control file name required to run the Scan Mode Analysis flow. The scan control file contains details about the scan analysis mode used for testing. For more information, refer to Scan Control File Format.
`-scan_mbff_chain_type` *type*	
	Specifies the type of multi-bit scan flip-flop. • `liberty` - specifies to use the syntax in Liberty to decide the multi-bit flip-flop type. • `serial` - specifies to pick the first flop as the starting flop, and treat the scan chain as serial, regardless of .lib. • `parallel` - specifies to treat the scan chain as parallel, regardless of .lib.
`-set_power_event_based {true | false}`	

	Default: `false`
	Specifies the instance-based power constraints that are to be taken into consideration for the power analysis flow. The parameter controls whether the power constraints are applied to the dynamic or static flow. The power constraints are specified using the `set_power` command.
	The default value of `false` specifies to apply the power constraints in the static flow. When set to `true`, the constraints are applied to the dynamic flow.
	Example:
	The following command specifies to honor the instance-based power constraints in the dynamic power analysis flow:
	`set_power_analysis_mode -method event_based -set_power_event_based true`
	`set_power -ascii_power_file instPower.txt`
	`report_power -outfile power.rpt`

`-settling_buffer` *value*	

Specifies the settling buffer time (in ps unit) between multiple windows of a VCD file. This parameter is used when you specify multiple pairs of the start time and end time for the non-overlapping multiple windows specified in an activity file (using the `read_activity_file` command).

Multiple current waveforms representing multiple VCD windows are merged into a single continuous current waveform. To capture the waveform for signals at the edge of user windows, a buffer time is added between the windows being stitched. This buffer time ensures that the stitched waveform is contiguous. The generated waveform hence has the duration of user windows and the intervening settling buffers. The default settling buffer period is 400ps.

You must specify the buffer value without unit.

The following is an example of this feature:

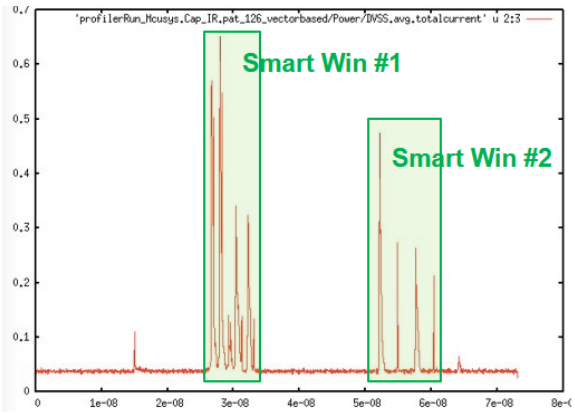
```
set_power_analysis_mode -verbosity true \
    -settling_buffer 200 -report_missing_nets true

read_activity_file \
    -format  VCD -scope  adder/u1 \
    -start  {0ps 2000ps} -end    {1100ps 3100ps} \
    -block  ../vcd/dut_5buf_full_chip.vcd
```

`-smart_window {true | false}`

Default: `false`

Specifies to enable the smart window feature to extract peak power scenarios from a vector-based activity file. A smart window is a variable size window to capture maximum regions of high power dissipation. An activity file can have multiple variable-sized regions that are ranked in the descending order of power metric.



The use model of the parameter is:

```
set_power_analysis_mode -smart_window true
set_power_analysis_mode -worst_step_size value
set_power_analysis_mode -worst_window_type [ power | activity
| delta_power | delta_activity | ir | critical_inst_power ]
```

`-split_bus_power {true | false}`

A value of `false` applies the internal power number to each individual bit.

A value of `true` divides the internal power number by bus width, before applying it to the bus bit.

Default : `false`

`-state_dependent_leakage {true | false}`

When set to `false`, power analysis performs state independent leakage power calculation.

Default : `true`

`-stateprop_ignore_unannot_pins {true | false}`

Default: `false`

Specifies to ignore unannotated pins in the functional logic of output pins for the RTL propagation flow. This parameter is set to `true` if there are unannotated input pins for instances and such pins are used in the functional logic of output pins that are propagated. For example output pin Q is propagated with functional logic A & B where A is unannotated and might cause wrong propagation for the Q pin.

`-static_multi_mode_scenario_file` *filename*

Specifies a file with information on instance scaling scenario for the static multi-mode IR analysis flow. When this parameter is specified, Power Analysis creates the multi-mode static current file that is used during rail analysis. The format of the input file is:

```
INST_NAME       PIN_NAME        SCALE_FACTOR_1       …..   SCALE_FACTOR_N
```

Here, the first column indicates the macro instance name, the second column indicates the pin name, followed by multiple current scaling factors. Each column of the scaling factor is referred to as a scenario. You must specify positive values only for scale factors.

The following is a snippet from the specified input file:

```
top/macroA     VDD     1     0.5     0.5     1
top/macroA     VDDM    0.5   0.5     0.5     1
top/macroB     VDD     0.5   1       0.5     0.5
```

If scale factors are not specified for certain scenarios, the tool will automatically use the instance's last stored scale factor value to complete current file generation.

In the following example, scale factor value `0.45` will be used in the 3rd and 4th scenario for instanceC, and scale factor value `0.35` will be used in the 4th scenario for instanceD:

```
instanceA VDD 0.45 0.55 0.65 0.31
instanceB VDD 0.31 0.5 0.67 0.21
instanceC VDD 0.25 0.45
instanceD VDD 0.31 0.25 0.35
```

`-static_netlist {verilog | def}`

	Specifies to perform static power analysis using a Verilog or DEF only neltist. By default, the static power analysis is performed using the Verilog netlist as the primary netlist. Using this parameter, you can specify DEF when a DEF netlist with logical connectivity is available, and use it as primary and not consider the Verilog netlist. This parameter is also enabled when `set_rail_analysis_mode -report_power_in_parallel` is `true` for static power computation. *Default* : `verilog`
`-start_time_alignment {true |false}`	
	Specifies to align all the signals of the activity file at time zero. When set to `true`, the simulation period is `max(endtime - starttime)`. When it is `false`, the simulation period is `max(endtime)- min(startime)`. *Default* : `true` **Note:** This parameter is not supported in the vector profiling flow. In the vector profiling flow, the start time will always be the `min(starttime)` and the end time will always be `max(endtime)`.
`-switching_power_on_rise_only {true | false}`	
	Default: `false` Specifies to perform switching power analysis only for rise toggles.
`-thermal_input_file` *file*	

Specifies to read a power map file to perform thermal analysis. Thermal input file contains die area divided into tiles, and temperature value for each tile. This temperature of each tile is used to calculate power of all the instances that fall in that tile's bounding box.

The format of the thermal input file is:

```
DIE_TEMPERATURE_MAP
DIE_AREA   xmin(um) ymin(um) xmax(um) ymax(um) nx(int) ny(int)

NUMBER_OF_LAYERS    nLayers(int)
LAYER    layer_name(string)
TEMPERATURE
XCOOR    x0(0)    x0(1)    x0(2)... ...x0(nx-1)
YCOOR    y0(0)    y0(1)    y0(2)... ...y0(ny-1)

T0(0,0)    T0(1,0)    ...    T0(nx-1,0)
T0(0,1)    T0(1,1)    ...    T0(nx-1,1)

:
T0(0,ny-1)    T0(1,ny-1)         T0(nx-1,ny-1)
END_TEMPERATURE
END_LAYER
END_DIE_TEMPERATURE_MAP
```

where,

- `DIE_AREA` specifies the coordinates of the four points of die outline as well as the tile number in X and Y direction.
- `NUMBER_OF_LAYERS` is the number of layers in each die instance
- `LAYER` specifies the LEF layer name
- XCOOR and YCOOR are the coordinates of each tile
- `T0(0,0)` …. is the temperature value assigned to a tile at a specific coordinate

`-thermal_leakage_temperature_scale_table_file` *filename*

Specifies a file containing the user-defined temperature values and temperature scale factors for each instance. This parameter allows you to use the current file (.ptiavg) with re-adjusted leakage power values to perform thermal-aware IR drop analysis.

When this parameter is specified, the generated power will include the scaled leakage power values. The `-thermal_leakage_temperature_scale_table_file` parameter must be specified with the `-thermal_input_file` parameter to import the temperature map file generated by Celsius.

The following is the format of the temperature-aware leakage scaling table:

```
#Type    Instance_Name        temp1             temp2             temp3             temp4
(Type: Lib/Cell/inst)

inst    inst_name1    scalefactor@temp1   scalefactor@temp2  scalefactor@temp3
scalefactor@temp4
inst    inst_name2    scalefactor@temp1   scalefactor@temp2  scalefactor@temp3
scalefactor@temp4
```

File Format Example:

```
#Type     Name        25    50    125    150

inst    ring/b213    1     2     5      10
inst    ring/b212    1     2     5      10
inst    ring/b211    1     2     5      10
inst    ring/b210    1     2     5      10
```

`-to_x_transition_factor` *value*

Specifies how 0/1 to X transitions are counted. The default value is `0.5`.

`-to_z_transition_factor` *value*

Specifies how 0/1 to Z transitions are counted. The default value is `0.25`.

`-transition_factor_based_duty {true | false}`

Default : `false`

Specifies that duty for X and Z toggles is calculated using the X and Z transition factor of toggle specified using the following parameters:

- `-from_x_transition_factor`
- `-from_z_transition_factor`
- `-to_x_transition_factor`
- `-to_z_transition_factor`

The default value of `false` specifies to use the duty value given with the `set_default_switching_activity`/`set_switching_activity` `-duty` parameter.

`-transition_time_method {min | avg | max}`

	Default: The default value is: • `min` for static power analysis using the Verilog netlist (`-static_netlist verilog`). • `avg` for static power analysis using the DEF netlist (`-static_netlist def`) and dynamic power analysis. Specifies the minimum, maximum, or average transition time method that will be used with the integrated timer or the external TWF.
`-twf_delay_annotation {min | avg | max}`	
	Allows you to choose between min, max, or avg arrival times from the timing window file (TWF). The arrival time is annotated to the vectors processed from the RTL VCD/FSDB Zero-Delay flows. The default value is `avg`.
`-twf_load_cap {min | avg | max}`	
	Allows you to select minimum, maximum, or average value of TWF external load or capacitance for power calculation. *Default* : `max`
`-unified_power_switch_flow {true | false}`	
	Default: `false` Specifies to enable the unified analysis of the always-on and switch nets. When set to `true`, the power-up and always-on analyses are performed in a single flow, wherein the switch nets and always-on nets are simulated together resulting in improved performance and accuracy.
`-use_cell_leakage_power_density {true | false}`	
	Specifies to use library leakage density times area (`default_leakage_power_density`), if defined, instead of the library's default cell leakage power (`default_cell_leakage_power`). This is used when leakage power for cells are missing or not defined. The default value of this parameter is `true`.
`-use_fastest_clock_for_dynamic_scheduling {true | false}`	
	Specifies to use only the respective fastest clock associated with each net or pin to schedule events for a given simulation period. The default value of this parameter is `false`.
`-use_lef_for_missing_cells {true | false}`	
	Allows a combination of LEF and PGV in the dynamic analysis flow. The default value of this parameter is `false`. If there are cells that are common to LEF and PGV, the PGV cell will get the precedence.
`-use_only_ddv_current {true | false}`	

	Default: `true` Controls the use of static current of a detailed dynamic power-grid view (DDV PGV) cell for static power calculation. The parameter is set to `true` by default, that is, the DDV PGV static current is not used in the static power calculation flow. If you want to use the DDV PGV static current for static power calculation, set this parameter to `false`.
`-use_physical_partition {true | false}`	
	Default: `false` Enables tile or area-based partitioning of a design for distributed processing. When this parameter is specified, the top-level design is divided into physical tiles, which are then grouped to ensure that each group or partition has the same instance count. Each partition is considered and processed as a separate job. **Usage Guidelines**: • This parameter is only applicable to the event-based power analysis flow (`set_power_analysis_mode -method event_based`) in the XP mode. • This parameter must be specified with the `-partition_count` parameter.
`-use_zero_delay_vector_file {true | false}`	
	Enables zero delay mode in vector-based dynamic analysis to avoid pessimism in current estimation. When set to `true`, the software reads the cycle accurate (zero delay) VCD/FSDB file and adds the timing/delay information from the Timing Analyzer or external TWF file to the VCD/FSDB file. Default: `false`
`-vector_profile_mode {activity | event_based | power_density | transient}`	

	Default: `event_based` Specifies the method used to perform vector profiling. The possible arguments are: • `activity` - performs activity profiling. This parameter generates only the worst activity report, and does not generate the average power report. The name of the file is as specified using the `report_power -outfile` parameter. • `event_based` - generates the average power report. This is the average power of all events in the user-specified window. This report includes a summary based on the power components, cell type, power rail, and clock network. The worst window report is captured in a file specified with the `report_power -outfile` parameter, and the report is suffixed by '`.avgpower`'. When `-outfile` is not specified, the `vectorprofile.report.avgpower` report file is created. • `power_density` - performs area or power density profiling. For this method, power is reported for each tile of the design, where design can be considered to be physically divided into equal area tiles. By default, a design is divided in 10x10 tiles. • `transient` - generates the event-based average power report and current files for the worst power window. **Usage Guidelines**: This parameter must be specified with the `-method vector_profile` parameter.
`-worst_case_vector_activity {true | false}`	
	Default: `false` Specifies to use the worst activity value when multiple vectors are specified in the static power calculation flow.
`-worst_step_size` *value*	
	Default: Total simulation duration/100 Specifies the step size or resolution for vector profiling. Activity/ Power profiling is carried out for every step size that you specify. When this parameter is used with `-worst_window_size`, the specified step size is the resolution at which window sliding is performed. The supported time units are s, ms, us, ns, and ps. If no explicit time unit is specified, the default ns will be applied.
`-worst_window_count` *value*	
	Default: 1 (implements single worst window) Specifies the number of worst windows from the last vector profile run to be used for dynamic power analysis. It provides n top windows with maximum activity/power/IR. This parameter is used when you need to combine dynamic power analysis and vector profiling for multiple worst-case windows in a single run.
`-worst_window_coverage { top | tile }`	

Default: `top`

Specifies how the worst window type is applied for multi-window analysis in the vector profiling flow. The following are the possible options of this parameter:

- `top`: worst window selection for the full design
- `tile`: interval selection as per the worst tile power

Use Model:

```
set_power_analysis_mode -method event_based -worst_window_coverage tile
report_power -outfile power.rpt -power_density_tiles 100
```

This flow should be run with `-method event_based`.

When the `-worst_window_coverage tile` parameter is specified, you should include any one of the following parameters to specify the total number of tiles:

- `report_power -power_density_tile_size " 15 15 "`
- `report_power -power_density_tiles_row_col " 2 2 "`
- `report_power -power_density_tiles 100`

The software generates the `power.rpt.density` report that has the power density tiles profile report with an additional section "Intervals covering unique tiles having worst power density".

`-worst_window_reports {full | worst | both}`

Specifies to generate static power analysis reports for the specified worst window type. The possible arguments are:

- `full`: creates the static power report for the full simulation window specified with the `-start`/`-end` parameters of the `read_activity_file` command.
- `worst`: creates the static power report for the worst window only.
- `both`: creates the static power report for both the full simulation and worst windows.

The default value is `full`.

The worst window report is created with '**.1**' added in the file name, as shown below:

- Static reports for full simulation: `power.rpt.avgpwr`, `power.rpt.instpwr`
- Static reports for worst window: `power.rpt.1.avgpwr`, `power.rpt.1.instpwr`

`-worst_window_size` *value*

Default: None

Specifies the duration of dynamic analysis. This parameter is used for sliding window vector profiling that involves sliding the profiling windows by using a very small resolution value to get the window with the worst current profile. `-worst_window_size` must be specified with `-worst_step_size`.

The supported time units are s, ms, us, ns, and ps. If no explicit time unit is specified, the default ns will be applied.

`-worst_window_type { power | activity | delta_power | delta_activity | ir | critical_inst_power }`

	Default: `power` Specifies the window type to be used for multi-window analysis. The possible arguments are: • `power` - worst instance power • `activity` - worst instance activity • `delta_power` - worst dp/dt (rate of change of power) • `delta_activity` - worst da/dt (rate of change of activity) • `ir` - worst IR • `critical_inst_power` - worst power for critical/IR-sensitive instance (worst timing and IR)
`-write_boundary_leakage_edge_annotation {true | false}`	
	Default: `false` Writes an edge annotation summary file for boundary leakage calculation. This parameter is used to report location-based Vt layer information on all the abutted edges in the design. The generated report name is `boundarygateleakage.edgeannotation.rpt`.
`-write_default_uti {true | false}`	
	Default: `true` For instances that are not hooked to any power/ground rail, the current for these instances are reflected in the default static current files: • `static_default_ground_rail.ptiavg` • `static_default_power_rail.ptiavg`
`-write_dynamic_currents {true | false}`	

	Default: `false`
	Specifies to create dynamic current files either for full simulation duration or for user-specified duration.
	Usage Guidelines:
	This parameter is only applicable to the event-based power analysis flow (`set_power_analysis_mode -method event_based`).
	Example:
	`set_power_analysis_mode -method event_based -write_dynamic_currents true -enable_state_propagation true`
	`read_activity_file sim.vcd -format VCD`
	`report_power -outfile power.rpt`

`-write_profiling_db {true | false}`	

	Default: `false` Writes out profiling databases which can later be viewed as histograms using the SimVision interface. You can specify this parameter during both the activity and power vector profiling. The profiling databases support instance level and power/ground net histograms. It creates an output file name with the `*.trn` extension.
`-write_simulation_db {true | false}`	
	Default: `false` Specifies to save functional waveforms for each instance when parsing a vector-based activity file. When set to `true`, creates SimVision waveform database (SHM database) for toggle simulation used during power analysis, which can later be viewed as histograms using the SimVision interface. The simulation database (shmdb.trn) is generated in the power analysis output directory.
`-write_static_currents {true | false}`	
	Default: `false` A value of `true` tells Voltus to generate the current data files per net. **Note:** When you perform static power calculation in the dynamic power analysis flow, you can use either the `-disable_static` or `-write_static_currents` parameter to enable static power calculation and write static current file. If only `-disable_static` is set to `false` and `-write_static_currents` is not set, the tool automatically sets `-write_static_currents` to `true`. Similarly, if `-write_static_currents` is set to `true`, and `-disable_static` is not set, the tool automatically sets `-disable_static` to `false`.
`-x_count_transition_using_3_states {true | false}`	
	Default: `false` Specifies to calculate the toggle rate using 3 states, pre-previous, previous and current states.
`-x_transition_factor` *value*	
	When using VCD/FSDB, one can specify how transitions to and from X are counted. These transitions are defined as shown in Table 5-1. Transitions to and from the X state will be treated as full transitions multiplied by the specified factor. **Note:** 0 -> X -> 1 or 1 -> X -> 0 count as full transitions and they are not controlled by the parameter. *Default* : `0.5`
`-z_transition_factor` *value*	
	When using VCD/FSDB, one can specify how transitions to and from Z are counted. These transitions are defined as shown in Table 5-1. Transitions to and from the Z state will be treated as full transitions multiplied by the specified factor. **Note:** 0 -> XZ-> 1 or 1 -> Z-> 0 count as full transitions and they are not controlled by the `parameter`. *Default* : `0.25`
`-zero_delay_vector_toggle_shift` *value*	

	Specifies to shift the current waveform in the zero-delay VCD flow. This parameter is useful in removing the idle period for the current waveform result with a long idle period (small flat current) before the first high current peak because of delay annotation. The parameter allows to offset the idle period from the delay values. The use model is given below: `set_power_analysis_mode -zero_delay_vector_toggle_shift -3.0ns` The default value is 0ns. The supported time units are s, ms, us, ns, and ps. The default unit is ns. You can specify a negative or a positive value. A positive value means right shift in the timeline or add more delay to the original arrival time, and a negative value means left shift in the timeline or trim the unwanted idle period. The `-zero_delay_vector_toggle_shift` parameter enables you to make a more realistic current waveform that can be easily aligned with the other current waveforms. **Note**: This parameter is similar to the `set_twf_attribute -shift_arrival_time` parameter, with the only difference that `-zero_delay_vector_toggle_shift` supports both positive and negative values while `-shift_arrival_time` supports only a positive value.

Table 5-1 **Transitions from/to X and Z values and**

Transition	Definition	Default
`to/from X`	`[ 0 or 1 or Z] <-> X`	`0.5`
`to/from Z`	`[ 0 or 1 ] <-> Z`	`0.25`

Scan Control File Format

The use model for the Scan Mode Analysis flow is:

`set_power_analysis_mode -method dynamic_vectorbased -scan_control_file` *`filename`*

The format of the scan control file is:

```
MODE = [ SHIFT | VECTORLESS]
VECTORLESS_GLOBAL_ACTIVITY = <factor> [Between 0 - 1]
<chain_name> <flop_inst> <initial_state> <master_cell_name> <scale> <mode> <scan_in_pin> <scan_out_pin>
<scan_en_pin>
```

Note that <`chain_name`> is optional, <`initial_state`> is optional in vector-less mode, and <`master_cell_name`>, <`scale`>, <`mode`>, <`scan_in_pin`>, <`scan_out_pin`>, <`scan_en_pin`> are optional and only needed for the first internal scan flop inside one macro.

Where,

- `Mode` specifies the mode used for scan design analysis. The two modes are: `SHIFT` and `VECTORLESS`.
- `VECTORLESS_GLOBAL_ACTIVITY` specifies the activity specification used in the `VECTORLESS` mode.
- `chain_name` is the name of the scan chain.
- `initial_state` is the initial state of all scan flops.
- `master_cell_name` is the name of the macro.
- `scale` is the scaling factor applied to the current.
- `mode` is mode name of the scan mode in the PGV view.
- `scan_in_pin` is the macro's scan_in pin name.
- `scan_out_pin` is the macro's scan_out pin name.
- `scan_en_pin` is the macro's scan_enable pin name.

Examples

- The following command uses the negative internal power from the .lib files during analysis, specifies that the transitions that are to and from the Z state will be multiplied by.2, and specifies that the transitions that are to and from the X state will be multiplied by .45:

```
set_power_analysis_mode -honor_negative_energy true \
-z_transition_factor .2 \
-x_transition_factor .45
```

- The following command resets the -honor_negative_energy parameter to its default value:

```
set_power_analysis_mode -reset -honor_negative_energy
```

- The following command resets all set_power_analysis_mode parameters to their default values:

```
set_power_analysis_mode -reset
```

- The following command ignores leakage power, and scales only the switching and internal power by the specified scale factor:

```
set_power -instance top.block2 2mW
set_power_analysis_mode -disable_leakage_scaling true
```

- The following command sets up dynamic power analysis.

```
set_power_analysis_mode \
    -method dynamic_vectorless \
    -corner max \
    -create_binary_db true \
    -write_static_currents true \
    -honor_negative_energy true \
    -ignore_control_signals false \
    -power_grid_library { fast_allcells.cl }
```

- The following command adds a prefix SM_ to the current data directory and the underlying current files:

```
set_power_analysis_mode -ouput_current_data_prefix SM_
```

The following current files are generated:

```
SM_dynamic_VDD.ptiavg
./SM_PTIData/SM_dynamic_1_VDD.ptiavg
./SM_PTIData/SM_dynamic_2_VDD.ptiavg
```

- The following command is another example of dynamic power analysis.

```
set_power_analysis_mode \
    -method dynamic_vectorless \
    -off_pg_nets VDDlu \
    -create_binary_db true \
    -write_static_currents true \
    -honor_negative_energy true \
    -ignore_control_signals false \
    -power_grid_library {accurate_stdcells.cl TSDN65LPA1024X32M8F.cl
```

- The following command is an example of the state-propagation-based dynamic vectorless flow, and also specifies to generate a report (`voltus_power.stateprop.switchlist`) containing all the switching times for the instances specified in the `inst_list` file:

```
set_power_analysis_mode -method dynamic_vectorless -enable_state_propagation true -
report_instance_switching_list inst_list
```

- The following is an example of running power analysis in the distributed mode:

```
set_distribute_host -rsh -add "m1 m2"

##The following blue-highlighted parameters specify the number of remote hosts and number of CPUs per
remote host
set_multi_cpu_usage -remoteHost 8 -cpuPerRemoteHost 2 -localCpu 16

##The following blue-highlighted parameter specifies that all the blocks included in the dp_setup.txt file will
be run in parallel
set_power_analysis_mode -method dynamic_vectorless -distributed_setup dp_setup.txt
```

The following is the content of the `dp_setup.txt` file:

```
INST top.block1 block
INST top.block4 block
CELL block2 block
```

In the above example, 4 power distributed jobs are created for: top.block1, top.block4, hierarchical cell block2, and any other hierarchical instances not specified in `dp_setup.txt` that are run with the top-level.

- The following is an example of performing standalone power report generation in the XP mode:

```
set_power_analysis_mode -method dynamic_vectorless \
-enable_state_propagation true \
-power_grid_library {  /pgv_dir/tech_pgv/techonly.cl  /pgv_dir/stdcell_pgv/stdcells.cl
/pgv_dir/macro_pgv/macros_pll.cl }\ -extraction_tech_file /qrcTechFile -enable_xp true
...
```

```
report_power
```

- The following command specifies to enable area-based partitioning, and distribute the event-based analysis into four jobs:
  ```
  set_power_analysis_mode -method event_based -enable_xp true -use_physical_partition true -
  partition_count 4
  ```
- The following command specifies to enable interactive generation of power reports:
  ```
  set_power_analysis_mode -method event_based -use_physical_partition true -partition_count 2 -
  enable_interactive_reports true -enable_xp true
  ```
- The following command specifies to enable disk caching of toggles:
  ```
  set_power_analysis_mode -method event_based -enable_disk_mapping true -enable_xp true
  ```

set_power_calc_temperature

```
set_power_calc_temperature
temperature
```

Sets the temperature for static power calculation.

In the presence of a trilib set, the internal and leakage power will be interpolated as the per the given temperature specification.

Parameters

temperature	Specifies the temperature for static power calculation. **Note:** The static power calculation software gets the temperature value of each instance from the following sources (in order of precedence): • Instance temperature file • `set_power_calc_temperature` command • The current operating condition temperature

Related Information

- `set_power_analysis_mode`
- "Static Power, IRdrop and EM Analysis" in the *Voltus IC Power Integrity Solution User Guide*

set_power_include_file

```
set_power_include_file
file
[-reset]
```

Specifies a PowerMeter include file. You can use the `set_power_include_file` command to specify certain commands of the dynamic engine which do not have an Voltus equivalent. For more information on the PowerMeter commands, refer to the "Advanced PowerMeter Options" chapter of the *Voltus Text Command Reference*.

Note: The `set_power_include_file` command is used to pass PowerMeter and `report_power` command options only in the dynamic mode (vectorbased and vectorless). If `set_power_analysis_mode` is set to `static`, the `set_power_include_file` command is ignored.

Parameters

file	Name of the include file. This is used when translating PowerMeter commands to Voltus IC Power Integrity Solution commands. This file will include all PowerMeter commands that can not be translated to Voltus commands. In addition, you can also include the `report_power` command options to generate different power reports.
`-reset`	Resets all options back to default values.

Examples

- The following command specifies a power include file of power.inc:
  ```
  set_power_include_file power.inc
  ```
- The following example shows the contents of the power.inc file.
  # power.inc file must use the pre-defined design and power objects as "design" # and "ChipPwr" respectively. The power output object is not supported.
  ```
  design calCellsToIgnore BUFX1
  ChipPwr calRailVoltage VDD 1.2

  report_power -net -outfile Net.rep
  report_power -cell {INV*} -outfile Invpower.rep
  ```

Related Information

- `set_power_analysis_mode`
- "Dynamic Power and IRDrop Analysis" in the *Voltus IC Power Integrity Solution User Guide*

set_power_output_dir

```
set_power_output_dir dir
[-reset]
```

Specifies the name of the directory that power information will be output to.

Parameters

dir	Specifies the name of the directory in which power analysis output information is written.
-reset	Resets all options back to default values.

Examples

- The following command specifies the output directory called `static_power_AvallOn` in which the power information is written.
  ```
  set_power_output_dir static_power_AVallOn
  ```

Related Information

- `set_power_analysis_mode`
- "Static Power, IRdrop and EM Analysis" in the *Voltus IC Power Integrity Solution User Guide*

set_switching_activity

```
set_switching_activity
[-reset]
[-activity factor | -density transition_density ]
[-clock clock_name]
[-duty value]
[-inst instance_name]
[-net net_name | -port port_name | -pin pin_name | -input_port port_name |-output_port port_name | -
bidir_port port_name]
[-period value]
[-unclocked]
[-icg_ratio num]
[-comb_clockgate_ratio num]
[-hier hierarchy_name]
[-scale_factor value]
[-cell cell_name]
[-force]
[-quiet]
```

Specifies activity for nets, pins, and ports. This command is used to specify user-defined activities at specific pins/nets/ports. You must specify this command before `report_power`.

The `set_switching_activity` command can accept a net/pin/port list using the `get_pins`/`get_ports`/`get_nets` commands. You can use the `get*` commands to create a collection of nets/pins/ports whose name matches the supplied pattern list. Therefore, providing you with the flexibility in providing lists through use of regular filter patterns. This feature is supported in both static and dynamic analysis engines.

Parameters

`-activity` *factor*	
	Specifies the activity for a net, pin, or top-level port. The *activity_factor* specifies the number of times the net, pin, or port switches in a clock cycle. Enter any positive number. If if the activity is set to 0.5, the activity happens once for every two clock cycles. If the activity is set to 2.0, the activity happens two times per clock cycle. There is no default value.
`-bidir_port` *port_name*	
	Specifies the name of the bidirectional port. The port names are in the following format: bidirectional*-port*. This parameter supports wildcards (*)

`-cell` *`cell_name`*	
	Specifies the activity on all output pins for all instances of the specified cell.
`-clock` *`clock_name`*	
	Assigns global activity factor to all nets in domain of *`clock_name`* if and only if *`clock_name`* is the fastest clock in the domain set. To use this option, `-clock` and `-activity` must be used without any other options.
`-comb_clockgate_ratio` *`num`*	
	Specifies to set the propagation ratio for combinational clock gate cell outputs. When specified, this parameter sets the output activity of any instance that is identified as a combinational clock gating cell to *`num`* times the fastest transition density arriving on the instance's clock inputs. You can specify this ratio for a net, pin, port, or clock. This parameter cannot be specified with the `-hier` parameter.
`-density` *`transition_density`*	
	Specifies the transition density for a specific net, pin, or top-level port. Transition density specifies the number of transitions per second. it can be any positive number. There is no default value. **Note:** If you specify the `-density` parameter in conjunction with the `-period` parameter, the software issues a warning and the `-period` parameter is ignored.
`-duty` *`value`*	
	Specifies the duty cycle, which is the probability that the signal is a logical 1. The `-period` parameter must be specified to add a duty. If not specified, the `set_switcing_activity` command picks this value from the external TWF or SDC through the Common Timing Engine (CTE). *Default*: Uses the duty specified by the `set_default_switching_activity` command if the `-duty` parameter is not specified.

`-force`	
	Specifies to apply user-defined activities for specific nets, pins, and ports, without having to load a verilog netlist using the `set_top_module` command. When the `set_top_module` command is not specified, the `set_switching_activity` command does not support the `-cell` parameter, and the net/pin/port list using the `get_pins/get_ports/get_nets` commands.
`-hier` *`hierarchy_name`*	
	A hierarchical name that an activity is being assigned to.
`-icg_ratio` *`num`*	
	Specifies to set the propagation ratio for integrated clock gate (ICG) cell outputs. When specified, this parameter sets the output pin of all identified ICG instances to *`num`* times the fastest transition density arriving on clock inputs of the instance. You can specify this ratio for a net, pin, port, or clock. This parameter cannot be specified with the `-hier` parameter.
`-input_port` *`port_name`*	
	Specifies the name of the input port. The port names are in the following format: *`input-port`*. This parameter supports wildcards (`*`)
`-inst` *`instance_name`*	
	Specifies the activity on a specific instance.
`-net` *`net_name`*	
	Specifies the name of the net. This parameter supports wildcards (`*`).
`-output_port` *`port_name`*	
	Specifies the name of the output port. The port names are in the following format: *`output-port`*. This parameter supports wildcards (`*`)
`-period` *`value`*	

	Specifies the period that the activity is referenced to. If not specified, a default frequency is used. If a negative number is specified, the static power calculation engine reverts back to the default frequency. Units in seconds (`s`), milliseconds (`ms`), microseconds (`us`), nanoseconds (`ns`), or picoseconds (`ps`). **Note:** If you specify the `-period` parameter in conjunction with the `-density` parameter, the software issues a warning and the `-period` parameter is ignored. *Default*: The time unit is defined in the first `.lib` file read during design import. If the time unit is not defined, the period specified in the `set_default_switching_activity` command is used.
`-pin` *pin_name*	
	Specifies the name of a pin. The pin names are in the following format: *instance-name + default-hierarchy-separator + pin*. This parameter supports wildcards (`*`)
`-port` *port_name*	
	Specifies the name of a top-level port. The port names are in the following format: *top-level-port*. This parameter supports wildcards (`*`)
`-quiet`	Suppresses all error and warning messages generated when the `set_switching_activity` command is run.
`-reset`	Resets all specified options back to default values. The reset option should be the first option specified, otherwise all options set prior to this will be reset. **Note:** You can selectively reset the pin/port/net specifications. In addition, you can also selectively reset the pin/port/net specifications of a list of objects through the `get_pins`/`get_ports`/`get_nets` commands.
`-scale_factor` *value*	

	Specifies to scale frequencies of the specified clock domains. This parameter allows you to scale transition densities of all instances associated with the clock domain by the specified scale factor to compute internal and switching power. This parameter must be specified with the `-clock` parameter. The `-scale_factor` parameter is only applicable to static power and dynamic vectorless power analysis.
`-unclocked`	Applies *`activity`* (with reference *`period`*) to all nets that have no clock domain (`-unclocked`). To use this option, `-unclocked` must be used with `-activity` and `-period` with no other options.

Activity Precedence

See "Activity Precedence".

Examples

- The following command specifies that net `n189` will switch once every ten clock cycles, with a clock period of `7520ns` and a duty cycle of 50 percent:
  ```
  set_switching_activity -net n189 -activity 0.10 -period 7520ns -duty .5
  ```
- The following command sets the transition density of port `out_cpu_top` to `20000` transitions per second:
  ```
  set_switching_activity -port out_cpu_top -density 20000
  ```
- The following command applies a transition density of `1e+06` to all input ports that match the specified pattern:
  ```
  set_switching_activity -port[get_ports "mode*" -filter {port_direction==in}] -density 1e+06
  ```
- The following command resets the previously defined activity on all nets that match the specified pattern:
  ```
  set_switching_activity -reset -net[get_nets n23*]
  ```
- The following command specifies the clock gate ratio for the clock domain `sys_clk`:
  ```
  set_switching_activity -clock sys_clk -icg_ratio 0.8 -comb_clockgate_ratio 0.5
  ```
- The following command specifies to set the default switching activity for all other clock domains of the design:
  ```
  set_default_switching_activity -icg_ratio 1.0 -comb_clockgate_ratio 1.0
  ```

set_thermal_analysis_mode

```
set_thermal_analysis_mode
[-help]
[-boundary_condition_file filename]
[-power_map_file filename]
[-temperature_map_file filename]
[-tool_path path]
```

Sets the parameters for performing chip-centric thermal analysis after generation of the Voltus thermal model (VTM). This command must be specified before the `analyze_thermal` command.

Parameters

`-help`	Outputs the command usage and a brief description about the command parameters.
`-boundary_condition_file filename`	

	Specifies the name of the boundary condition file. The format of the boundary condition file is:
	`#Length Unit : um`
	`#Temperature Unit: C`
	`die_thickness=100`
	`front Tfix=25`
	`back Tfix=25`
	`top Tfix=50`
	`bottom Tfix=50`
	`left Tfix=25`
	`right Tfix=25`

`-power_map_file filename`	
	Specifies the name of the generated power map file.
`-temperature_map_file filename`	
	Specifies the name of the output temperature map file. Each analysis run would create a directory named “ThermalDir_<number>” automatically. Soft links to the power mapping file and boundary condition file would be created inside the directory. The analysis’s final result is a temperature map named as “`<DieName>_TemperatureMap.dat`”, and is saved in this directory.
`-tool_path path`	
	Specifies the full path to the bin folder of the thermal analysis tool (Celsius).

Examples

- The following command specifies to set thermal analysis parameters:

```
set_thermal_analysis_mode -tool_path $CELSIUSTOOL \
-boundary_condition_file $bcDir/bc_100.txt \
-temperature_map_file temperatureMap_100 \
-power_map_file vtm_output/top.vtm.txt
```

- analyze_thermal

set_twf_attribute

```
set_twf_attribute
[-help]
[-clock clock_name]
[-clock_edge {rise | fall}]
[-clock_freq value]
[-fall_delay {min:max or single_value}]
[-fall_slack {min:max or single_value}]
[-fall_slew {min:max or single_value}]
[-net net_name]
[-pin pin_name]
[-reset]
[-rise_delay {min:max or single_value}]
[-rise_slack {min:max or single_value}]
[-rise_slew {min:max or single_value}]
[-type {data | clock}]
[-shift_arrival_time   time]
[-clear_twf_attr]
```

Specifies static timing analysis information. The command allows you to override timing parameters, such as slew and clock, on desired pins/nets from an existing timing windows file (TWF).

Parameters

`-clear_twf_attr`	
	Specifies to reset the TWF file values for a specific pin or net. The use model of this parameter is: `set_twf_attribute -clear_twf_attr -pin/-net <name>`
`-clock clock_name`	
	Specifies the clock name. This indicates that the nets and pins that are timing constrained have arrival times (timing windows) caused by this clock.
`-clock_edge {rise | fall}`	
	Specifies the capturing clock edge direction: rise or fall.
`-clock_freq value`	
	Specifies the clock frequency. You must specify the `-clock` parameter along with the `-clock_freq` parameter to assign the clock for which the frequency needs to be updated.
`-fall_delay {min:max` or `single_value}`	

	Specifies the fall delay for the pin. This parameter is not supported in the static power analysis flow.
`-fall_slack` *{min:max* or *single_value}*	
	Specifies the fall slack for the pin.
`-fall_slew` *{min:max* or *single_value}*	
	Specifies the fall slew for the pin.
`-net` *net_name*	
	Specifies the net name. The `-net` and `-pin` parameters are mutually exclusive.
-pin pin_name	
	Specifies the pin name. The `-net` and `-pin` parameters are mutually exclusive.
`-reset`	Resets all specified options back to default values.
`-rise_delay` *{min:max* or *single_value}*	
	Specifies the rise delay for the pin. This parameter is not supported in the static power analysis flow.
`-rise_slack` *{min:max* or *single_value}*	
	Specifies the rise slack for the pin.
`-rise_slew` *{min:max* or *single_value}*	
	Specifies the rise slew for the pin.
`-shift_arrival_time` *time*	

	Specifies to filter the idle period of the current waveform in the dynamic power analysis flow. This parameter is useful in removing the idle period of the current waveform result with long idle period (small current) before the 1st high current peak because of TWF delay annotation. The parameter allows to offset idle period from the TWF delay values.
	The use model is given below:
	`set_twf_attribute -shift_arrival_time 3.0ns`
	The default value is 0ns. The supported time units are s, ms, us, ns, and ps. The default unit is ns. You must specify a positive value only. A positive value means shift right in the time line or add more delay to the original arrival time.
	You can specify the `-clock` parameter to limit the changes to a clock domain. In addition, you can further add the `-pin/-net` parameter to limit the changes to a block. The following are examples of shifting different delays to different clock domains because different clocks may have different clock insertion delays at the top level:
	`set_twf_attribute -shift_arrival_time 1.2ns -clock clk_a`
	`set_twf_attribute -shift_arrival_time 2.3ns -clock clk_b`
	If a clock domain is not specified, the delay will be applied to all the specified nets/pins.
	Note: The final rise/fall delays for the annotated nets/pins after the shift has been applied are reported under the "Shift Arrival Time Report" section of the detailed TWF Attributes report. This report is generated using the `set_power_analysis_mode -report_twf_attributes detailed` parameter.
	The following example illustrates a sample command and report snippet:
	Command:
	`set_twf_attribute -shift_arrival_time 3.0ns`
	`set_power_analysis_mode -method dynamic_vectorless ... -report_twf_attributes detailed`
	Report:
	`Clock domain annotated`
	`- CK1_1`
	`- CK1_2`
	`- CK2_1`
	`- CK2_2`
	`Rise Delay Fall Delay Net Name`
	`1e-09 1e-09 CK1_1`
	`1e-09 1e-09 CK1_2`
	`1e-09 1e-09 CK2_1`
	`...`

`-type {data | clock}`	
	Specifies whether the net or pin is part of the clock or data network.

Examples

- The following command specifies to use the following TWF attributes for the net `netB1`:

  ```
  set_twf_attribute -net netB1 -rise_delay 2.1978:2.1978 -rise_slew 0.05:0.05 -rise_slack 0.2741:3.6961
  -fall_delay 2.1819:2.1819 -fall_slew 0.05:0.05 -fall_slack 0.237:3.6948 -clock CK1_1 -clock_freq 100 -
  type data
  ```

- The following commands reset the TWF values for the "`DFF11/DFF/Q`" pin to default, and then sets the rise/fall delay:

  ```
  set_twf_attribute -clear_twf_attr -pin "DFF11/DFF/Q"
  set_twf_attribute -pin "DFF11/DFF/Q" -rise_delay 0.35 -fall_delay 0.45 -clock CLK1
  ```

set_virtual_clock_network_parameters

```
set_virtual_clock_network_parameters
[-help]
[-cell cell_name]
[-clock list_of_clocks]
[-library library_name]
[-max_fanout value]
[-wire_load_model wireload_model]
[-reset]
```

Specifies to estimate power for a virtual clock tree. When the command is specified, the software reports the power of the clock network based on the buffers inserted in the clock tree. It also reports the number of buffers used for implementing the clock tree and the depth of the clock tree.

You can use this command for fast power estimation of clock network power of a pre-CTS netlist.

This command should be invoked before running the `report_power` command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `set_virtual_clock_network_parameters` parameter. For a detailed description of the command and all of its parameters, use the man command `man set_virtual_clock_network_parameters`.
`-cell cell_name`	
	Specifies the name of the buffer or inverter cell that has to be used to build the clock tree.
`-clock list_of_clocks`	
	Specifies the list of clocks for which the clock tree needs to be implemented. The default is for all the clocks.
`-library library_name`	
	Specifies the name of the library which contains the cell.
`-max_fanout value`	
	Specifies the maximum fanout that the buffer cell can drive.

`-wire_load_model` *wireload_model*	
	Specifies the wire load model used to compute the wire load model for the nets in the clock network.
`-reset`	Resets all specified parameters back to default values.

Example

The following command specifies to use the cell `BUFX12`, with a maximum fanout value of `2`, to build a virtual clock tree:

```
set_virtual_clock_network_parameters -cell { BUFX12 } -library typical -max_fanout 2 -wire_load_model B0X0
```

write_power_constraints

```
write_power_constraints
[-help]
[-outfile filename]
```

Writes out all the power constraints such as the power analysis mode, activity file specifications, simulation period specifications, and so on, into a file. You can use this command at any time during the session to dump out the power commands/ options specified till that point.

You can source this file into other Voltus/Tempus/Innovus sessions in order to use the same settings.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `write_power_constraints` parameter. For a detailed description of the command and all of its parameters, use the man command `man write_power_constraints`.
`-outfile` *`filename`*	Specifies the output file into which the power constraints are to be written.

Example

```
write_power_constraints -outfile test1.tcl
```

Related Information

- `set_power_analysis_mode`
- `report_power`

write_tcf

```
write_tcf file
[-block block_name]
[-exclude_hier_insts list_of_instances]
[-primary_input]
[-seq_output]
[-pin]
[-macro_output]
```

Writes out the propagated switching activity information to a toggle count format (TCF) file. The TCF file contains switching activity information, toggle count information, and the probability of the net or pin being in the logic1 state.

Parameters

`-block block_name`	
	Specifies to generate the block-level TCF from the top-level design. When specified, it writes out the block-level duty and activity in the generated TCF file. The use model of this parameter is: `write_tcf -pin -block blockname TCF_filename`
`-exclude_hier_insts list_of_instances`	
	Excludes the specified hierarchical modules or instances when writing out a pin-based TCF. This parameter allows you to ignore the activity generated for the excluded instances. The use model of this parameter is: `write_tcf -pin -exclude_hier_insts {list_of_instances}`
`-macro_output`	Specifies to generate a TCF file that includes all the activities for the macro outputs in the design.
`-pin`	Specifies to write out pin-based TCF.
`-primary_input`	Generates a TCF file that includes only the primary inputs in the design.
`-seq_output`	Generates a TCF file that includes all the activities for the sequential outputs in the design.
file	Specifies the name of the output TCF file.

Example

- The following command writes the propagated switching activity information to TCF file mmm.tcf:
  ```
  write_tcf mmm.tcf
  ```
- The following command writes a pin-based TCF for the whole design:
  ```
  write_tcf -pin pin_design.tcf
  ```
- The following command writes out a TCF which only includes activity information for the primary inputs and sequential outputs in the design:
  ```
  write_tcf -primary_input -seq_output Power.tcf
  ```
- The following command writes out a pin-based TCF that excludes the specified hierarchical instances:
  ```
  write_tcf -pin -exclude_hier_insts {DTMF_INST/CORE_INST DTMF_INST/RAM_128x16 DTMF_INST/RESULTS_INST }
  ```

check_pg_library

```
check_pg_library
[-help]
power_library_paths
[-cell_list_file file]
[-check_compatibility {PGV1 PGV2 ...} | -lef_consistency]
[-check_parameters]
[-integrity_check]
[-output file]
[-list]
[-report]
[-rule_file file]
[-skip_signal_net_check {true | false}]
[-skip_layer_list_file filename]
[-summary]
[-tech_layers]
[-total_currents]
[-report_detail_multiple_voltage_cap]
[-command_dump]
[-metal_density_map]
```

Specifies to perform a comprehensive check of power-grid views (PGV) to be used in rail analysis. These checks include:

- Verify that all the PGV views exist: Early/IR/EM
- Report the dynamic PWL and static current
- Perform a compatibility check on version, layermap and resistivity parameters
- Check any missing information, such as temperature, qrcTechFile location, and so on.

Parameters

`-help`	Outputs the command usage.
power_library_path	

	Default: None **(Mandatory)** Specifies the absolute path to the power library (`.cl`) file. You can run multiple power library files (.cl) at the same time.
`-cell_list_file` *file*	

	Default: None
	Specifies a file containing the list of cells for which the LEF consistency checks will be done. This parameter allows you to perform the consistency checks only for the user-defined cells.
	The format of the input file is:
	`CELL1`
	`CELL2`
	`CELL3`

`-check_compatibility {`*PGV1 PGV2 ...*`}`	
	Default: None Checks for compatibility between the specified cell libraries. It checks whether the following parameters are the same for the libraries that are to be merged: • Time Units • Capacitance Units • Layout Scale Factor • Manufacturing Grid If one or more of these parameters are not the same, a warning message appears stating that the libraries are not compatible and cannot be merged. It also specifies the parameters that are different. Based on the above electrical/physical parameter check, a compatibility report (compatibility.report) with pass/fail is generated. Fail implies that the library is not compatible and cannot be used in Voltus rail analysis.
`-check_parameters`	
	Default: None Checks for the following electrical parameters of the specified cell libraries: • `CINT_MIN and CINT_MAX:` Intrinsic device capacitance • `CG_MIN and CG_MAX:` Grid capacitance • `RON_MIN and RON_MAX:` On-resistance for powergates • `IDSAT_MIN and IDSAT_MAX:` Saturation current for powergates • `ILEAK_MIN and ILEAK_MAX:` Leakage current for powergates • `IAVG_MIN and IAVG_MAX:` Static current • `IPEAK_MIN and IPEAK_MAX:` Dynamic peak current • `ESR_MIN and ESR_MAX`: Equivalent series resistance For powergates, `-check_parameters` will check the Vds-Ids table for the correct trend. It checks whether: • for a given `Vgs`, `Ids` increases with `Vds` • for a given `Vds`, `Ids` increases with `Vgs` where; `Vgs` is voltage across gate and source `Vds` is voltage across drain and source `Ids` is current from drain to source (of a transistor)
`-command_dump`	

	Default: None Specifies to print the settings used during PGV characterization to a text file called `command_list.txt`. This parameter allows you to determine the user-specified or default settings used during PGV generation for the specified power library (.cl).
`-integrity_check`	
	Specifies to load all the views from a power-grid library to ensure that the library contains the required data. This parameter checks if there are any missing files or views, and that the PGV is usable in rail analysis.
`-lef_consistency`	
	Default: None Checks for LEF consistency of the cells in the specified cell libraries. It reads the LEF and PGV files, and compares the given LEF file with the LEF file used in PGV generation.

`-list`	**Default**: None
	Specifies to list the PGVs and the cells in each PGV. The parameter allows you to determine the name of the PGV library that contains a specific cell and determine whether a cell is there in multiple libraries.
	The format of the output file is:
	`PGV Library: <Number of PGV libraries>`
	`<Lib_1> <TOOL VERSION> <PGV VERSION> <GENERATE_DATE> <Path>`
	`<Lib_2> <TOOL VERSION> <PGV VERSION> <GENERATE_DATE> <Path>`
	`...`
	`Duplicated Cells: <Number of cells in multiple libraries>`
	`<CELLNAME> <Lib_1 Lib_2 Lib_3>`
	`Cell List: <Number of cells in a library>`
	`<CELLNAME> <LIB#>`

`-metal_density_map`	
	Default: None Generates the metal density map report file (`<pgvname>.metal_density`) in the PGV output directory. This file contains information about the macro size, number of tiles in the x and y direction, metal layer ID, layer name, and metal density values for each tile. **Usage Guidelines**: This parameter is used with the `-calculate_metal_layer_density` parameter of the `set_pg_library_mode` command.
`-output` *dir_name*	
	Default: The default is the current working directory. Specifies the name of the output directory in which the power-grid library report is created.
`-report`	**Default**: None Specifies to generate the power-grid library report. The report name is `<pgvname>.report`.
`-report_detail_multiple_voltage_cap`	
	Default: None Specifies to generate a voltage-dependent capacitance table that contains the detailed capacitance values of the given power-grid library. The capacitance table file is called `<pgvname>.cap_table`. **Usage Guidelines**: This parameter is used with the `-enable_multi_voltage_cap_generation` parameter of the `set_pg_library_mode` command.
`-rule_file` *file*	

	Default: None
	Specifies the rule file name used for parameter checking. This file contains the list of electrical parameters to be checked.
	File Format:
	`CINT_MIN <min cap value>`
	`CINT_MAX <max cap value>`
	`RON_MIN <value>`
	`RON_MAX <value>`
	`IDSAT_MIN <value>`
	`IDSAT_MAX <value>`
	`ILEAK_MIN <value>`
	`ILEAK_MAX <value>`
	`IPEAK_MIN <value>`
	`IPEAK_MAX <value>`
	`IAVG_MIN <value>`
	`IAVG_MAX <value>`
	`ESR_MIN <value>`
	`ESR_MAX <value>`
	Usage Guidelines:
	This parameter must be specified with the `-check_parameters` parameter.

`-skip_layer_list_file filename`	
	Default: None Specifies the name of a file containing a list of layers to ignore while checking PGV and LEF compatibility. Its format is one layer per line. **Usage Guidelines**: This parameter must be specified with the `-check_compatibility` parameter.
`-skip_signal_net_check {true | false}`	
	Default: `false` Specifies to skip LEF consistency checks for signal nets. This forces skipping of the signal pin checks when performing a comprehensive check of power-grid views to be used in rail analysis. The `-skip_signal_net_check` parameter can be used if you want to check LEF consistency of only the power and ground pins.
`-summary`	
	Default: None Specifies to generate a detailed report of the library contents for the specified cells that can be used for debugging purpose.
`-tech_layers`	
	Default: None Specifies to report technology layer information and layer mapping.
`-total_currents`	
	Default: None Specifies to report the static current for each power/ground net, and dynamic PWL for each mode. For each mode, it reports the peak and average current, and the number of points for power supply nets. When specified, the total current is reported in `<lib_name>.total_current` for each library.

Examples

- The following command creates a report for the library std_cells.cl:
  ```
  check_pg_library std_cells_fast/std_cells_fast.cl -report
  ```
- The following command checks for LEF consistency:
  ```
  read_lib -lef ddk.0.lef
  read_lib -lef ddk.1.lef
  check_pg_library -lef_consistency \
  ```

```
"/../library1.cl\
/../library2.cl"
```

- The following command displays the list of layers (defined in the technology file) on stdout:
  ```
  check_pg_library -tech_layers ./check_param/powergate/stdcells.cl
  ```
- The following command checks for compatibility between the specified cell libraries and generates a compatibility report (compatibility.report) in the output directory:
  ```
  check_pg_library -output out -check_compatibility  {/../lib1.cl /../lib2.cl}
  ```
- The following command specifies to list the cells corresponding to the specified libraries, `pgv1.cl` and `pgv2.cl`:
  ```
  check_pg_library -list {/../pgv1.cl  /../pgv2.cl}
  ```
- The following command checks for electrical parameters of the stdcells.cl library:
  ```
  check_pg_library -output OUT -check_parameters ./stdcells.cl
  ```
  The following is a sample output of this command:

```
           PARAM        VALUE            RANGE         PASS/FAIL

Cell: Cell1
   Net VDDG
        Device Cap    4.50e-14    (1.00e-18,1.00e-11)    PASS

   Net VSS
        Device Cap    2.61e-14    (1.00e-18,1.00e-11)    PASS

   Net VDD
        Device Cap    2.13e-14    (1.00e-18,1.00e-11)    PASS

   Power Gate SLEEP
             Ron      1.84e+01    (2.00e+01,1.00e+03)    FAIL
             Ileak    7.01e-08    (1.00e-15,1.00e-06)    PASS
             Idsat    3.36e-02    (1.00e-09,1.00e-02)    FAIL

   Trend Checks:
       Ron Trend   : PASS
       Idsat Trend  : PASS
       Ileak Trend : PASS
```

- The following command reports the static current for each power/ground net:
  ```
  check_pg_library -total_currents /../pg.cl
  ```
  The following is a sample output of this command:

```
Net VSS
Static current = -0.00021181

Net VDD
Static current = 0.000211809

MODE1
Trigger Condition: ( !CEN & !WEN )
Net VDD
    Peak = 0.0138308
    Avg = 0.000276053
    Number of points 190

Net VSS
    Peak = -0.0166879
    Avg = -0.000300184
    Number of points 190

MODE2
...
```

- The following command generates a capacitance table (`powergate_stdcells.cap_table`) that contains the detailed capacitance values of the powergate_stdcells.cl library:
  ```
  check_pg_library -report_detail_multiple_voltage_cap ../powergate_stdcells.cl
  ```
  The following is a snippet of the capacitance table file (`powergate_stdcells.cap_table`):

```
========================================================================
CellName    NetName      Voltage       Capacitance
------------------------------------------------------------------------
```

```
powercell    vccm        0.1000        4.586e-14
powercell    vccm        0.2825        4.102e-14
...
```

- The following command specifies to output the settings used during generation of `macros_pll.cl` to a text file called `command_list.txt`:
  ```
  check_pg_library -command_dump macro_pgv/macros_pll.cl
  ```

  The following is a sample snippet of the `command_list.txt` file:
  ```
  temperature 25
  spice_subckts /../spice.sp
  spice_models /../spectre_load.sp
  extraction_tech_file /../tech.tch
  gds_files /../file1.gds
  stop@via VIA_1
  spice_subckts_xyscaling 1000
  use_powergate_data_from_lib 0
  default_frequency 2e+08
  decap_frequency 1e+08
  ```
- The following command generates the power-grid library report:
  ```
  check_pg_library -output report -report /../pg.cl
  ```

  The following is a sample output of this command:
  ```

generate_pg_library

```
generate_pg_library
[-help]
[-output dir_name]
[-library_prefix prefix]
```

Generates the output for power-grid library generation.

Parameters

`-help`
Outputs the command usage.
`-library_prefix prefix`
Specifies a prefix for the power-grid library. When this parameter is specified, the default PGV for each cell type is as follows: • techonly - `prefix_techonly.cl (default: techonly.cl)` • stdcells - `prefix_stdcells.cl (default: stdcells.cl)` • macros - `prefix_cellname.cl (default: macros_cellname.cl)` You can generate macro PGVs without the "`macro_`" string in the name and without any prefix by specifying an empty string for `-library_prefix`, as shown below: `generate_pg_library -output output_folder -library_prefix ""`
`-output dir_name`
Specifies the name of the output directory in which power-grid libraries are created. The default is the current working directory. **Note**: If you specify both `-output output_dir` and `-library_prefix prefix` parameters, the command generates the PGV in the *output_dir* directory with PGV name `prefix_<name>.cl`.

Examples

- The following command generates a power-grid library in the *temp* folder:
  ```
  generate_pg_library -output temp/
  ```
- The following command specifies to generate a technology library with the default PGV name `techonly` and prefix `ab`:
  ```
  set_pg_library_mode -celltype techonly ...
  generate_pg_library -output ./ -library_prefix ab
  ```
  The generated library name will be `ab_techonly.cl`
- The following command specifies to generate a macro library with the default PGV name `<cell_name>` and prefix `ab`:
  ```
  set_pg_library_mode -celltype macros ...
  generate_pg_library -output ./ -library_prefix ab
  ```
  The generated library name will be `ab_<cell_name>.cl`

generate_tech_pg_lib

```
generate_tech_pg_lib
[-help]
[-decap_cells cell_list]
[-default_power_voltage value]
[-esd_cells cell_list]
[-filler_cells cell_list]
[-keep {true | false}]
[-lef_layermap filename]
[-output_dir dir_name]
[-power_gate_file filename]
```

-tech_file *filename*
[-tech_only {true | false}]

Generates the technology power-grid library on the fly. The generated tech-PGV will be deleted after the session is over. If this command is specified, the Power Analysis and Rail Analysis engines will automatically use the on the fly generated tech-PGV. The purpose of generating the tech-only PGV on the fly is that you do not need to keep a track of the tech-only PGVs. Thus, it ensures that the tech-only PGV is generated from the correct Quantus technology file.

The tech-only PGV library will be generated under the working directory and will be called by Power/Rail Analysis on the fly, as shown in the following log file snippet:

```
Begin Loading PGV Libraries for Power Calculation
.//pgv/techonly.cl
Ended Loading PGV Libraries for Power Calculation: (cpu:0:00:00,real=0:00:00,mem(process/total/peak)=275.25MB/2585.14MB/1194.52MB)

Begin Processing Cell Libraries for Rail Analysis

Merging libraries:
.//pgv/techonly.cl
../../LIBS/voltus_pgv/macro_pgv/macros_sram.cl
../../LIBS/voltus_pgv/stdcells_pgv/stdcells.cl

Output library: ./work/lib_merged.cl
```

Parameters

`-help`
Outputs the command usage.
`-decap_cells cell_list`
Specifies the names of cells that have explicit decoupling capacitance for use in decap optimization. These cells are nearly equivalent to feedthrough cells, except that there is typically an active device between the power and ground nets to provide extra decoupling capacitance. Power-grid view library generation uses this list of cells to ensure that a capacitance value is associated with each cell. If no capacitance is associated with a cell, a warning message will be issued.
`-default_power_voltage value`
Specifies voltage for the power pins which are present in LEF. The default value is 1.2.
`-esd_cells cell_list`
Specifies a list of Electrostatic Discharge (ESD) cells. You can use this parameter to characterize ESD cells.
`-filler_cells cell_list`
List the names of the filler or feedthrough cells that have no GDS data. These cells can be swapped out for decaps during decap optimization.
`-keep {true | false}`
Specifies that the generated library should be retained after the session completes. The default value is `false`.
`-lef_layermap filename`

Specifies a file that provides the mapping of layers between the LEF and technology file. This parameter is optional. Library Generation automatically generates the layermap file using the technology LEF (containing all layer and via definitions) and Quantus Tech (extraction library) files, therefore, a LEF layermap file is not a mandatory input. The automatically generated layermap file is located in the PGV temp directory.

The following is the format and sample content of the auto-generated file (`lefdefLayerMap_AutoGenerated.txt`):

```
Layer Type   tech layername   lefdef    lefdef layername
via              VIA_9        lefdef      VIA9
metal            METAL_1      lefdef      METAL1
```

You can specify this parameter if you want to provide your own layermap file.

`-output_dir` *`dir_name`*

Specifies the name of the output directory in which tech-only power-grid library is created. The default is the current working directory.

`-power_gate_file` *`filename`*

Specifies a file with the information that technology library generation needs to characterize a powergate cell. Specifies the cell name, unswitched power pin, switched power pin, on resistance in ohms, saturation current in milliamps, and leakage current in milliamps. The format of the file is:

`cell supply switched Ron Idsat Ileak`

The following is an example of multiple footer powergate:

```
FOOTBUFVHSV16 VSSG VSS 63 3.167 0.000128252
FOOTBUFVHSV32 VSSG VSS 63 3.167 0.000128252
FOOTBUFVHSV64 VSSG VSS 63 3.167 0.000128252
FOOTBUFVHSV8 VSSG VSS 63 3.167 0.000128252
```

`-tech_file` *`filename`*

Mandatory parameter. Specifies the name of the technology file that will be used for extraction.

`-tech_only {true | false}`

Specifies to generate the technology PGV without any cells. The default value is `false`.

Examples

- The following command generates a tech-only power-grid library:

```
generate_tech_pg_lib -tech_file $tech_path/qrcTechFile -filler_cells *FILL* -decap_cells *DCAP* -default_power_voltage 0.9
```

Related Information

- `set_pg_library_mode`
- `set_advanced_pg_library_mode`
- `generate_pg_library`
- "Power-Grid Library Generation" in the *Voltus IC Power Integrity Solution User Guide*

generate_xpgv

```
generate_xpgv
-cell cell_name
[-inst_list inst1 inst2 .. instn ]
[-libgen_include file_name]
[-output_dir directory_name]
[-rail_include file_name]
[-reuse_block_state_directory directory_name]
-state_directory directory_name
[-mvmf_config config_file]
```

Creates power-grid view (xPGV) models for large digital blocks.The block xPGV can be generated either after the signoff dynamic IR drop analysis or after the dynamic Early Rail Analysis (ERA) of the block. In both cases, the xPGV is generated using the R-C grid of the block and currents captured at the via layer during the analysis. These block-level xPGVs can then be instantiated during the next level of the design or the top-level full-chip analysis. The next level rail analysis will run faster with the block-level xPGVs because these runs use the power-grid that is modeled inside the xPGV.

Parameters

`-help`	Outputs the command usage.
`-cell` *`cell_name`*	
	Specifies the block name for which xPGV model is generated.
`-inst_list` *`inst1`* `inst2 ..` *`instn`*	
	Specifies the block instances for which xPGV model is generated.
`-libgen_include` *`file_name`*	
	Specifies a file that includes additional library generation options that will be run for xPGV model generation.
`-mvmf_config` *`config_file`*	
	Specifies to generate a single xPGV model with different functional modes. Using this parameter, you can specify a file that includes the different modes and the mapping state directory for each mode. When `-mvmf_config` is specified, the block-level currents are saved for multiple voltages and frequency (MvMf) per each functional mode in a single PGV. During xPGV instantiation, the different modes are automatically selected based on the power domain to which each mode is connected. The format of the *`config_file`* file is: *<modeName1> <stateDir_1>* *<modeName2> <stateDir_2>* … *<modeNameN> <stateDir_N>* Before generating MvMf-xPGV, you need to perform multiple rail analysis runs for different corners to generate different state directories (stateDir_*) to be included in the configuration file.
`-output_dir` *`directory_name`*	
	Specifies the name of the output directory in which the power-grid library report is created. The default is the current working directory.
`-rail_include` *`file_name`*	
	Specifies a file that includes additional rail analysis options that will be run for xPGV model generation.
`-reuse_block_state_directory` *`directory_name`*	

	Specifies an existing rail analysis state directory to skip block extraction. The software assumes that the design data (DEFs and GDS) and power-grid libraries are not changed, and will generate xPGV using the extraction data inside the specified state directory. If the state directory does not contain the necessary design and power-grid database files, it will issue an error message and provide information on the missing files. The `-reuse_block_state_directory` parameter is used if the entire design that is analyzed in the rail run should be used to create the xPGV. However, this parameter must not be used in case you require to generate xPGVs for each instance (sub-blocks) of a block. That is, for generating xPGVs for the sub-blocks B and C of the block A (rail analysis was performed on block A), you need to re-extract the block-level grids of B and C as part of xPGV generation for accurate current calculation. In this case, `-reuse_block_state_directory` must not be specified. For net based analysis, you should specify net-based state directory, as shown below: • `generate_xpgv -reuse_block_state_directory VDD_25C_avg_1` For domain based analysis, you should specify the domain's state directory, as shown below: • `generate_xpgv -reuse_block_state_directory domain_25C_dynamic_1` A new state directory will be generated for the new analysis with soft links to the old state directory files that were reused.
`-state_directory directory_name`	
	Specifies the path to the rail analysis state directory.

Examples

- The following command creates an xPGV library `hier_block.cl`:
  ```
  generate_xpgv -state_directory dynamic_rail/core_125C_dynamic_1/ -cell hier_block -output_dir ../xpgv/
  ```
- The following command creates an xPGV library `super_filter_A` with multiple functional modes specified in the `mode.config` file:
  ```
  generate_xpgv -cell super_filter_A -mvmf_config mode.config -output_dir ./mode_mvmf -rail_include rail.inc
  ```
  The following is a snippet from the mode.config file:
  ```
  label1 dynamic_rail/core_25C_dynamic_1
  lable2 dynamic_rail/core_25C_dynamic_1
  ```

merge_pg_library

```
merge_pg_library
[-help ]
[-force {true | false}]
-library_list_file file_name
[-library_prefix prefix]
[-merge_single_voltage_pgvs {true |false}]
[-output directory_name]
[-remove_tech {true | false}]
[-validate_rail_merge {true | false}]
```

Specifies to merge power-grid libraries. Using this command, you can merge multiple same-type power-grid libraries into one consolidated power-grid library.

Parameters

`-help`	Outputs the command usage.
`-force {true | false}`	
	Specifies to force merge PGVs with different resistivity and layers. It uses the technology information of the first library. If multiple tech-only PGVs a the first tech-only PGV definition and the first cell definition. If you are merging a tech-only PGV with other PGVs, it will keep the tech-only technol cell definition. The default value of the parameter is `false`.
`-library_list_file file_name`	
	Specifies the file containing the list of libraries.
`-library_prefix prefix`	
	Specifies a prefix for the generated power-grid library.
`-merge_single_voltage_pgvs {true |false}`	
	Specifies to merge all the single voltage PGVs into a multi-voltage PGV for better handling of the library characterization flow. This parameter is u you have generated multiple PGVs for different voltages, instead of generating a single multi-voltage PGV that has voltage-dependent capacitanc The default value of the parameter is `false`.
`-output directory_name`	
	Specifies the name of the output directory in which power-grid libraries are created. The default is the current working directory. **Note**: If you specify both `-output output_dir` and `-library_prefix prefix` parameters, the command generates the PGV in the *output_dir* directo `prefix.cl`.
`-remove_tech {true | false}`	
	Specifies to remove technology dependency from the specified or merged library. The newly created library will not contain the technology informa The default value of the parameter is `false`.
`-validate_rail_merge {true | false}`	
	Specifies to validate the merged PGV in the same way as done when merging PGV during rail analysis. When this parameter is specified, the log and info messages if the tool finds any issues during PGV merging. The parameter allows you to check the PGV merging issues as reported durin having to run the full design. `-validate_rail_merge` is used only for validation purpose, and the merged PGV is not to be used for analysis.

Examples

- The following command merges the power-grid libraries specified in the `merge_lib.list` file into one consolidated power-grid library:
  ```
  merge_pg_library -library_list_file "merge_lib.list" -output ./ -library_prefix "new_merged"
  ```
  The content of `merge_lib.list` file is:
  library1.cl
  library2.cl
  library3.cl

rename_pg_library

```
rename_pg_library
[-help]
[-cell_list_map_file filename]
[-merge_library_list_file filename]
[-output directory_name]
[-output_library new_library_name]
```

Specifies to copy and rename the specified power-grid view library. The command also allows you to rename the cells of the specified input library.

Parameters

`-help`	Outputs the command usage.
`-cell_list_map_file filename`	
	Specifies a file containing the list of cells to be renamed. The format of the specified file is: *<old cell name1> <new cell name1>* *<old cell name2> <new cell name2>* ...
`-merge_library_list_file filename`	
	Specifies a file containing the input library to be renamed. The format of the specified file is: *<path to the input library>*
`-output directory_name`	
	Specifies the name of the output directory in which the new power-grid library is created. The default is the current working directory.
`-output_library new_library_name`	
	Specifies the new name of the specified input library.

Examples

- The following command specifies to rename the input library to `new_lib`:

  ```
  rename_pg_library -merge_library_list_file new.list -cell_list_map_file cell.list -output_library new_lib -output .
  ```

```

Specifies the advanced power-grid library generation features. If the `set_advanced_pg_library_mode` command is specified twice, the last specified command takes precedence.

Parameters

`-abort_on_extraction_errors {true | false}`	
	Specifies whether the software should exit with an error message or continue when it encounters extraction errors. *Default*: `true`
`-add_port_labels file_name`	
	Specifies the name of a file containing details about the label of a switched rail. Using this parameter, you can add a label for the switched rail manually in the specified port file, if the switched rail is not labeled. The format of the port file is given below: MACRO *macro_name* PIN *pin_name*
`-assume_foreigns {true | false}`	
	Enables the Library Characterization engine to process LEF files in which FOREIGN statements are not defined as part of the macro definition. When generating detailed power-grid views, the engine assumes that FOREIGN statements are defined as part of the macro definition in the LEF file. When this option is set to `true`, the engine processes the LEF file by using the name defined by the MACRO statement rather than requiring a FOREIGN statement. The `-assume_foreigns` parameter ensures that the FOREIGN statement is placed at 0,0. Therefore, if the MACRO statement has an offset, you must provide a FOREIGN statement that contains an offset. This option works for offsets that are 0,0 or the inverse of the origin. *Default*: false
`-assume_foreigns_mode {1 | 0}`	
	Determines how the Library Characterization engine processes cells for which FOREIGN statements are assumed. If set to 0, the engine assumes that the cell for which FOREIGN statements are assumed is placed at (0,0). When you set it to 1, the engine assumes that the FOREIGN cell is placed at the inverse of the macro origin. *Default*: 1
`-cell_accura_data_file file`	
	Specifies the name of a file containing data about the electrical characteristics of cells. Voltus library simulator requires this data to generate currents during power-grid view generation.
`-cell_per_distributed_host value`	
	Specifies the number of cells to be submitted per host for distributed PGV generation. *Default*: 50
`-cell_pinnet_map_file file`	
	Specifies the mapping between the cell LEF pin names and the internal names of the net to which those pins are attached. It is used when multiple pins are attached to a single net.

`-circuit_include_file simulator.inc`

Specifies the name of the input file for Voltus library simulator in the Library Characterization command file.

`-cluster_via_rule {{via_layer1 number_of_equidistant_vias}...}`

Controls the number of vias to cluster on a layer basis. The VIA clustering rule specified using this parameter will override the default clustering rule for PGV generation. You can use this parameter when you need clustering at VIA1, or different clustering for different layers. The default cluster size for PGV generation is `64` for all via layers except VIA1.

Example:

The following command will cluster 100 equidistant VIA1 cuts, 200 equidistant VIA2 cuts, and 300 equidistant VIA7 cuts:

```
set_advanced_pg_library_mode -cluster_via_rule {{VIA1 100} {VIA2 200} {VIA7 300}}
```

`-cluster_via_size value`

Specifies that power-grid extraction for library cell needs to perform 64 (8x8) via clustering inside PGV for all via layers above VIA1 between Metal1 and Metal2.

The following command specifies to perform 16 (4x4) via clustering:

```
set_advanced_pg_library_mode -cluster_via_size 16
```

Default: 64

`-common_supply_pins{net_name+}`

Identifies the generic supply net or nets which could act as either a power or ground supply net. No wildcards are allowed for the specification of net names.

Generic supply nets are used for pads or bump cells that could be connected to either a power or ground net. They will be connected to the correct power-grid based on the DEF or GDS file.

`-create_static_view_from_dynamic_view {true | false}`

Specifies to generate static power-grid view by averaging of dynamic currents in the multi-mode characterization flow. When this parameter is specified, the software performs averaging of the dynamic currents of all the modes and saves it as static current in the power-grid view.

Default: `false`

`-damping_decap_cell_list {cell_list}`

Specifies a list of damping decap cells.

`-damping_decap_frequency value`

Specifies the frequency of operation of the damping decap cells. The default value is 200MHz.

Default: `200MHz`

`-decap_frequency value`

Specifies the decoupling capacitance frequency used during PGV generation. Intrinsic capacitance of cells has a significant dependency on frequency used during PGV generation. PGVs characterized with higher frequency may lead to pessimism during dynamic analysis due to less impact of intrinsic capacitance of the cells characterized with higher frequency. Using this parameter, you can specify the dominant frequency to be used for PGV generation.

The default value for decoupling capacitance frequency is 1GHz.

`-default_frequency value`

Specifies the default frequency of signal nets in hertz (Hz); this is used to calculate the current and capacitance values during the creation of detailed power-grid views.

For example, the following command specifies that the default switching frequency is 100 MHz:

- `set_advanced_pg_library_mode -default_frequency 100e+06`

`-default_power_voltage value`

Specifies the default voltage for power nets. This parameter assigns a default value to power nets for which voltage has not been defined using the `-power_pins` parameter.

`-delete_ddv_fsdb_files {true | false}`

	Specifies to delete the intermediate FSDB files generated in the Spice deck (user-specified) method of current characterization. This parameter allows you to retain or delete the huge FSDB files.
`-disable_powergate_rampup_simulation {true | false}`	
	Specifies whether to run power gate ramp-up simulation during power-grid view generation. When this parameter is set to `true`, the Ids-Vds table will not be present in PGV, therefore, this PGV cannot be used for the power-up or rush current analysis flow. This parameter can be specified to reduce the run time when you require only the RON/Idsat/Ileak and Cap values in PGV. `disable_powergate_rampup_simulation` is used when power gate parameters are specified using the `set_pg_library_mode -powergate_parameters_file` parameter. This parameter can only be used for the standard cell PGV generation. *Default*: `false`
`-distribute_current_to_switch_net {true | false}`	
	Distributes the PWL waveform, which is specified to the always-on power net, to the taps of both the always-on power net and the related switched power nets in the fine-grain memory characterization flow. By default, the current waveform is distributed only to the taps of the always-on power net when you specify the PWL to the always-on power net.
`-enable_ac_simulation_for_IO_characterization {true | false}`	
	Specifies to perform an AC analysis based coupled capacitance calculation for IO cells. When set to `false`, the software performs DC analysis based coupled capacitance calculation for IO cells. The AC analysis based coupled capacitance calculation is slower than the DC analysis based coupled capacitance calculation. *Default*: `false`
`-enable_spectre_netlist_flow {true | false}`	
	Specifies to use the Spectre simulator to read the Spice/Spectre netlist for the standard cells characterization flow. This option should be used when the netlist is in Spectre format, or when the netlist is encrypted by Spectre. *Default*: `false`
`-enable_subconductor_layers {true | false}`	
	Allows to control the generation of the sub-conductor layers in the PGV. When this parameter is set to `false`, the sub-conductor layers are not generated in the PGV. *Default*: `true`
`-enable_via_based_current_distribution {true | false}`	
	Default: `false` Specifies to enable location-based via current modelling during GDS-based macro power-grid view generation. When set to `true`, defines the current values only on the user-defined via location. This parameter allows you to define average and peak current values for specific-location vias. The `-enable_via_based_current_distribution` parameter must be specified with the `-via_based_current_config_file` parameter. If the parameter is set to `false`, current is uniformly distributed across all vias in the macro PGV.
`-esd_cells {`*`cell_list`*`}`	
	Specifies a list of Electrostatic Discharge (ESD) cells. You can use this parameter to characterize ESD cells. When you specify this parameter, the list of ESD cells are later used in the `check_esd` command while loading the power-grid view library. As a result, you do not need to specify the ESD cell names with the `-esd_cell_list` parameter of the `check_esd` command.
`-esd_cells_list_file` *`filename`*	

Specifies a file containing a list of ESD cells that are later used in the ESD analysis flow while loading the power-grid view library.

The `-esd_cells_list_file` parameter is the same as the existing `-esd_cells` parameter of the `set_advanced_pg_library_mode` command, except that the `-esd_cells_list_file` parameter allows you to specify a list of ESD cells in a file while the `-esd_cells` parameter allows you to specify the ESD cells in the command line itself.

The following is an example of this parameter:

```
set_advanced_pg_library_mode -esd_cells_list_file {./Esd_Cell_list.txt}
```

The following is the ESD cell file format:

```
CELL_1
CELL_2
...
CELL_n
```

`-esd_device_list {`*device1 device2 .... deviceN*`}`

Specifies the list of ESD devices. The ESD device information is used for accurate ESD analysis as it takes into account the internal grid from the ports to the ESD devices. The followings inputs are required for ESD tagging during macro PGV generation:

- an xDSPF file
- ESD device list

`-esd_parameters_file` *filename*

Specifies resistance information for the following types of ESD cells during ESD cell characterization:

- Diodes
- RC Clamp

When this parameter is specified, the software uses these electrical parameters from the generated PGV for ESD analysis.

The format of the input file is:

```
Cell <cell name>  <Ron> <Roff> <power_pin> <ground_pin> <voltage>
Type <esd cell type> <Ron> <Roff> <power_pin> <ground_pin> <voltage>
```

Here,

- `Cell` and `Type` are keywords
- *<cell name>* specifies the ESD cell name
- *<esd cell type>* specifies the ESD cell type, such as DIODE and CLAMP
- `RON` is the resistance of the complete cell when it is switched on.
- `ROFF` is the resistance of the complete cell when it is switched off.
- *power_pin* is the name of the power pin connected to the power net
- *ground_pin* is the name of the ground pin connected to the ground net
- *voltage* is the threshold value between the power and ground pin.
- When you specify the cell name, the RON and ROFF would be applied only for that cell, and when you specify the cell type, the RON and ROFF would be applied for all the ESD cells of the particular type.

The following is a snippet of the input file:

```
Cell HEADER_SWITCH 10 5 pwr_pin gnd_pin 0.4
```

`-esd_pin_list {`*pin1 pin2 ....pinN*`}`

Specifies the list of ESD pins. This parameter tags the user-specified pin as the ESD pin before running the `analyze_esd_network` command, and ensures that the software traces only this ESD power pin to bump and extracts resistance. The ESD cell pins that are tagged using this parameter are listed in the `.report` file.

`-exclude_tap_region_file` *filename*

Specifies to exclude certain tap points during macro PGV generation. This parameter helps to avoid false IR-drop violations inside macros caused by inadvertently assigning evenly-distributed tap current to certain undesired tie high/low paths or shielding paths at certain via layers. The Spice netlist and models are not mandatory parameters for excluding the tap points in the macro PGV generation flow.

The format of the region file is:

```
REGION X1 Y1 X2 Y2
REGION X3 Y3 X4 Y4
```

where, `REGION` keyword specifies that the coordinates following it is a tap current region. The unit for coordinates is micron.

`-extraction_command_file` *file*

Specifies the file name of an extraction command file.

`-followpins_tap_layer {lowest_lef_pin_layer | highest_lef_pin_layer | all_lef_pin_layers}`

Specifies the LEF metal layer used to generate current taps. This parameter has two arguments:

- `lowest_lef_pin_layer`: The tool generates current taps only on the lowest LEF metal layer. For example, if both METAL1 and METAL2 metal layers exist for the power/ground pin in the cell LEF, the tool uses METAL1 layer as the tap layer.
- `highest_lef_pin_layer`: The tool generates current taps only on the highest LEF metal layer. For example, if both METAL1 and METAL2 metal layers exist for the power/ground pin in the cell LEF, the tool uses METAL2 layer as the tap layer.
- `all_lef_pin_layers`: The tool generates current taps on all LEF metal layers. For example, if both METAL1 and METAL2 metal layers exist for the power/ground pin in the cell LEF, the tool uses both METAL1 and METAL2 layers as the tap layer. This is the default value.

`-followpins_interface_node_layer {lowest_lef_pin_layer | highest_lef_pin_layer | all_lef_pin_layers}`

Specifies the LEF metal layer used to generate interface nodes. This parameter has three arguments:

- `lowest_lef_pin_layer`: The tool generates interface nodes only on the lowest LEF metal layer. For example, if both METAL1 and METAL2 metal layers exist for the power/ground pin in the cell LEF, the tool will only generate the interface nodes on the METAL1 layer.
- `highest_lef_pin_layer`: The tool generates interface nodes only on the highest LEF metal layer. For example, if both METAL1 and METAL2 metal layers exist for the power/ground pin in the cell LEF, the tool will only generate the interface nodes on the METAL2 layer.
- `all_lef_pin_layers`: The tool generates interface nodes on all LEF metal layers. For example, if both METAL1 and METAL2 metal layers exist for the power/ground pin in the cell LEF, the tool generates the interface nodes on both METAL1 and METAL2 layers. This is the default value.

`-generate_bulk_pin_cap_separately {true | false}`

Specifies to generate separate capacitance values for body bias pins in the library report. This parameter allows you to check the bulk pin capacitance based on the Spice simulation. When set to `false`, the software would sum up the capacitance values for the body bias pins and power/ground pins.

Default: `false`

The following is a snippet of the library report:

```
cell_A
            VPP(0.9350)     2.3e-16         EARLY(1 taps) EM(1 taps) IR(1 taps)
            VBB(0.0000)     2.3e-16         EARLY(1 taps) EM(1 taps) IR(1 taps)
            VDD(0.9350)     8.1e-15         EARLY(1 taps) EM(1 taps) IR(1 taps)
            VSS(0.0000)     8.1e-15         EARLY(1 taps) EM(1 taps) IR(1 taps)
Cell Type = STDCELL                    Cell_Status: PASS
```

Here, the blue-highlighted text shows the capacitance values for the `VPP` and `VBB` body bias pins.

`-generate_graybox_data {true | false}`

Controls the generation of gray box data and storage of this data in the cell library. It is recommended to set this parameter to `false` to reduce the size of the PGV significantly (from 10MB to 1MB) without loss of accuracy.

Default: `true`

`-generate_itfnode_x_direction {true | false}`

When the LEF port geometry is bigger than the tap node distance (`set_advanced_pg_library_mode -tap_node_distance`), multiple interface nodes are generated. You can specify this parameter to generate the interface nodes along the X direction.

When set to `false`, interface nodes are not generated along the specified direction.

Default: `true`

`-generate_itfnode_y_direction {true | false}`

When the LEF port geometry is bigger than the tap node distance (`set_advanced_pg_library_mode -tap_node_distance`), multiple interface nodes are generated. You can specify this parameter to generate the interface nodes along the Y direction.

When set to `false`, interface nodes are not generated along the specified direction.

Default: `true`

`-generate_itfnodes_at_via_layer {true | false}`

Specifies to generate interface nodes at via locations in scenarios where the tap current source is a VIA layer.

`-ignore_pg_nets {{cellname netname}+}`

Skips the specified power or ground nets in PGV generation.

`-import_xdspf_list_file filename`

Specifies the name of the xDSPF (third-party netlist) parasitic file that is imported by the Library Characterization engine to create PGDB. You must also specify the mapping file using the `-xdspf_layermap` parameter.

When you specify this parameter, the following parameters are not supported:

- `-xtc_command_file`
- `set_pg_library_mode -spice_subckts`
- `set_pg_library_mode -gds_files`
- `set_pg_library_mode -gds_layermap`
- `-techgen_dir`

`-input_port_value_list {pin1 value1 pin2 value2 ....pinN valueN}`

Specifies the voltage conditions of the signal inputs during power-grid library characterization. A typical usage model of this parameter include setting the SET or RESET signal port to be the same voltage as supply or ground (tie high/low) to obtain the correct model of operation.

The following example illustrates the use model:

```
set_advanced_pg_library_mode -input_port_value_list { RESETVDD 3.3 }
```

`-interface_node_location_file filename`

Specifies a file containing the location of interface nodes where tap currents are to be generated. The specified file includes the cell name, net name, layer name, and location of the nodes. This parameter allows to generate current taps at user-specified locations during PGV generation.

The format of the file is:

```
CELL <cell_name>
NET <net_name>
LAYER <layer_name> (x1,y1),(x2,y2)
```

Example:

```
CELL cellA
NET VDD
LAYER M0 (0,0.15),(0.585,0.177),(0.2,0.15),(0.3,0.177)

NET VSS
LAYER M0 (0.485,0.019)

CELL cellB
NET VDD
LAYER M0 (0.49,0.008),(0.24,0.008)
```

`-lef_pin_short {true | false}`

Enables shorting of the unconnected LEF pins and ports to establish electrical connectivity. When set to true, shorts the interface nodes for all the cells that are being processed.

Default: false

`-lef_layer_ignore_list {lef_layername+}`

Specifies the names of the LEF layers that power-grid library generation is to ignore when it creates the cell library.

`-lef_layer_ignore_list_file filename`

Specifies the name of a file containing a list of the LEF layers that power-grid library generation is to ignore when it creates the cell library. Each line in the file must consist of a single LEF layer name.

The format of the file is:

```
layer1
layer2
...
layern
```

`-lef_pin_short_cell_file filename`

Specifies the name of a file containing a list of cells and the net name, metal layer name, and resistance value for each layer. It is used to short the LEF pins and ports by the user-specified resistance value. When this parameter is specified, only the given list of nets are shorted with the user-defined resistance values. If a resistance value is not specified for a layer, the default resistance value of 0.001 is used.

The format of the file is:

```
CELL <cell_name>
<net_name> <layer_name> <resistance_value>
```

Example:

```
CELL bump_70N_M4
VDD Metal4 12
CELL bump_70N_M5
VDD Metal4 15
VDD Metal5 12
```

`-lef_pin_short_cell_list {cell1 cell2 ...}`

Specifies a list of cells for which the the LEF pins and ports are shorted by the default resistance value of 0.001ohm. When this parameter is specified, all the nets of the given cells are shorted using the resistance value of 0.001ohm.

`-libgen_command_file file`

Specifies the file name of a power-grid library generation command file.

`-macro_parasitic_file filename`

Specifies the name of the SPEF file that provides signal net parasitics while creating a detailed dynamic view in Library Characterization. The SPEF should be extracted in the decouple_rc mode.

Note: A SPEF file is required only when you specify your own netlist in the Netlist-based flow. The SPEF file is a requirement when the netlist does not have signal caps. You should not specify the signal parasitics using the -ultasim_include_file option.

`-marker_layermap filename`

Specifies the GDS layer mapping file containing the list of marker GDS layers that are used for layer operations during XTC processing. Marker layers are layers which do not have corresponding tech layers.

This parameter is used to support extraction of Metal-Insulator-Metal Capacitor (MIMCAP) geometries during power-grid library characterization. The following is the format of the mapping file:

Layer_Type	marker_layername	GDS_keyword	gds_layer_number
metal	CTM_O	gds	77 1
metal	CBM_O	gds	88 1

`-mcpu_rerun_count count`

Specifies to rerun the cells that failed due to machine issues during PGV library generation. This parameter allows you to specify the number of times the failed cells can be resubmitted in the distributed processing mode.

Default: 0

`-pgdb_list_file filename`

Specifies the name of the PGDB header file containing the list of cells for which Library Characterization should generate power-grid views. The syntax of the file is:

CELL *cell_name*

PGDB *pgdb_directory*

The PGDB directory contains the PGDB for all the power and ground nets of the cell. The PGDB directory has cellname_Netname.* files.

When you specify this parameter, the following parameters are not supported:

- `-xtc_command_file`
- `set_pg_library_mode -spice_subckts`
- `set_pg_library_mode -gds_files`
- `set_pg_library_mode -gds_layermap`
- `-techgen_dir`

`-pgdb_layermap` *`filename`*

Specifies the name of the file containing the mapping between the layer name used in the technology file and the layer name used in the PGDB.

`-powergate_characterization_voltages { val1 val2 val3 .... }`

Supports characterization of power gates at multiple voltages. You can specify multiple values of voltages so that the library characterization engine will characterize the power gates at each of the voltages. The software will then be able to get the characterized cell from the cell library for a particular voltage.

`-powergate_multi_enable_characterization_method {enable_all | enable_single}`

Specifies the Ron/Idsat characterization method for power gate cells with multi-enable pins. This parameter allows you to control the generation of RON and Id-Vd curve for each enable pin. The possible characterization methods are:

- `enable_all`: All the enable pins are switched ON for Ron/Idsat characterization. The generated PGV model will contain a single Ron resistor with the total equivalent resistance value. The cell library report displays the equivalent Ron value of all the enable pins. This is the default method.
- `enable_single`: Only one enable pin is switched ON at a time for Ron/Idsat characterization, and the other pins are switched OFF. The generated PGV model will contain total number of Ron resistors that is equal to the number of enable pins. The cell library report displays Ron values separately for each enable pin.

This parameter is supported only for standard cells when the power gate parameters are specified using the `-powergate_parameters_file` parameter. For multi-enable power gate cells, Ileak/Roff are always calculated by keeping all the enable pins OFF.

Default: `enable_all`

Example:

```
set_pg_library_mode ... -powergate_parameters_file ./pg1.txt
set_advanced_pg_library_mode -powergate_multi_enable_characterization_method enable_all
```

`-process_bulk_diffusion_ports {true | false}`

Specifies to create the `DIFF` layer ports of body bias pins in PGV.

By default, library generation ignores ports on the diffusion layer. In order to process body bias pin's ports on the diffusion layer for electrical analysis on body bias network, set this parameter to `true` during library generation.

`-remove_emview_dangling_resistor {true | false}`

Specifies to restore or remove dangling resistors from power-grid views. It is recommended to minimize dangling resistors for optimal analysis of IR drops and accurate Blech length calculation at the top level in EM analysis.

Default: `false`

`-retain_generated_pgv_on_error {true | false}`

Specifies to retain an incomplete cell library created during PGV generation even if the tool exits with a fatal error. When set to `false`, the tool deletes the incomplete cell library. This parameter is recommended for use during initial library creation and debugging.

The default value is `false`.

`-ron_measure_threshold` *`value`*

	Specifies the switched pin voltage during Ron simulation. The specified value will be multiplied by the VDD voltage (<value>*vdd_vol) and applied to the switched pin during Ron simulation. The default value is `0.99`. You can specify a value between 0 and 1.
`-schematic {true | false}`	
	Specifies whether the subcircuit netlist is a schematic netlist.
`-skip_switch_net_extraction {true | false}`	
	Specifies to skip extraction of switched nets inside the GDS file for a fine-grain memory cell. The software will add the capacitance from the switched net to the always-on net. The software will thus consider the cell as a regular memory without switched/power-gated nets. When this parameter is specified, you do not need to specify the port file (`set_advanced_pg_library_mode -add_port_labels`) as the switched nets are not traced. The final PGV will be created with the always-on and VSS nets. The power-gate library report file will contain information about the missing switched net, and the capacitance and current that was contributed by the switched net.
`-spectre_path` *value*	
	Specifies an external Spectre path for PGV generation. This parameter allows you to use a different Spectre version than the one embedded with the software.
`-source_location_file` *filename*	
	Specifies the name of the file containing the locations of the voltage sources to be connected to the pad cells. For more information on the source location file, see Source Location File Format.
`-stdcell_characterization_voltage_value {`*val1 val2 val3* `...}`	

	Specifies capacitance characterization voltages when generating standard cell PGVs containing voltage-dependent capacitance table for the specified cell. This parameter allows you to compute capacitance based on the user-defined voltage values. The `-stdcell_characterization_voltage_value` parameter must be specified with the `set_pg_library_mode -enable_multi_voltage_cap_generation true` parameter.
	If this parameter is not specified with `-enable_multi_voltage_cap_generation`, capacitance is calculated based on the software-derived voltage range.
	When the `-stdcell_characterization_voltage_value` parameter is specified, the library generation engine prints the capacitance values and corresponding voltages in the report file, and the rail analysis engine prints the capacitance used for each instance.
	The following example illustrates the use model of this parameter:
	`set_pg_library_mode -ground_pins VSS -power_pins {VDD 0.9 TVDD 0.9 } -celltype stdcells \`
	`...`
	`-enable_multi_voltage_cap_generation true`
	`set_advanced_pg_library_mode` **`-stdcell_characterization_voltage_value`** `{1.0 1.2 1.5 2.0 3.3}`

`-strict_input_check {true | false}`	
	Specifies that the software should not create any view for the cell if the EM view is not generated. When set to `true`, the software displays an error message if the Spice netlist or GDS is not specified, and gives details about the cell name and the reason for not generating the view. *Default*: false
`-tap_node_distance` *value*	
	Specifies to set the maximum distance between interface nodes when they get generated in power-grid library generation. The default is `50` microns. Library generation creates interface nodes on port geometries in LEF and Extraction, uses them for top level connectivity tracing and also to connect the cell/block onto top level routing. The interface node generation is purely based on port geometries (tap points are placed one per port). For ports greater than `-tap_node_distance`, they are placed at `-tap_node_distance` apart. If the port pin geometry in LEF is bigger than the setting of the `-tap_node_distance` parameter, at least two nodes will get generated per port geometry.
`-techgen_dir` *directory*	
	Specifies the techgen directory.
`-thunder_command_file` *file*	
	Specifies the file name of a thunder command file.
`-trim_metal_layer_map` *file*	

Specifies the name of the file containing the mapping between a metal layer and its corresponding trim layer. When this parameter is specified, the trim layer shapes are automatically removed from the routing layer shapes to correctly extract all the nets in the generated PGV.

File Format:

metal_layer_name trim_layer_name

```
M0 CM0
M1 CM1
M2 CM2
```

`-use_embedded_spectre {true | false}`

When set to `false`, allows you to specify a different Spectre version than the one embedded with the software. Library Generation will automatically pick Spectre from users' path.

Default : `true`

`-use_peak_current_distribution {true | false}`

Default: `false`

Specifies to use the maximum currents of devices in the Spice netlist for current distribution in macros. When set to `true`, enables peak current distribution for faster PGV generation. The default (`false`) behavior is to enable activity propagation based current distribution.

`-verbosity {true | false}`

Controls the amount of information displayed in the console and written to the log files during power-grid library generation.

Default: false

You can use this parameter for detailed troubleshooting and controlling the verbosity level in the log file.

`-via_based_current_config_file filename`

Specifies the name of the configuration file containing tap current details for location-based via current generation. If `-enable_via_based_current_distribution` is set to `true`, this parameter must be specified.

Configuration File Format:

```
#-----------------------------------------------------------------------
CURRENT_UNIT <default_value>
INPUT_SLEW <default_value>
OUTPUT_SLEW <default_value>
MAX_DISTANCE <Threshold distance for snapping via tap if the exact xy location is not found as specified>
DELAY <default_value>
PERIOD <default_value>
INTRINSIC_CAP { power_net cap ground_net cap}
#-----------------------------------------------------------------------
ID     PGPIN_NAME     X     Y     AVG_CURRENT     PEAK_CURRENT
#-----------------------------------------------------------------------
```

Configuration File Example

```
#-----------------------------------------------------------------------
CURRENT_UNIT mA
INPUT_SLEW 20ps
OUTPUT_SLEW 10ps
MAX_DISTANCE 2.5
DELAY 5ps
INTRINSIC_CAP { VDD 40nF VSS 5nF }
#-----------------------------------------------------------------------
ID      PGPIN_NAME     X          Y     AVG_CURRENT     PEAK_CURRENT
#-----------------------------------------------------------------------
PVDD_1   VDD       16.3090   7.6470     50.0373       100.037
PVDD_2   VDD       16.6900   7.6470     50.0373       100.037
PVDD_3   VDD       17.0700   7.6470     50.0373       100.037
...
```

When this feature is enabled, the tool by default generates a report "`dropped_via_location_taps.txt`" in the output directory to give a list of via IDs that were dropped because they were not within the snapping threshold limit. By default, the snapping threshold is zero. It is controlled by "`MAX DISTANCE`" in the configuration file.

`-well_cap_file filename`

	Specifies the name of a file containing a list of cells and the well capacitance value for each.
`-xdspf_layermap` *filename*	
	Specifies the name of the xDSPF mapping file containing layer type and layer stack information from bottom most layer to top most. You must define layers in the stack from top most layers at the top of the stack to bottom most layers at the bottom of the stack. With reference to this layermap stack, library generation will create the PGDB for the layers as defined in the xDSPF layermap file.
`-xtc_command_file` *filename*	
	Specifies the name of the XTC command file.
`-xtc_include_file_for_qdv` *filename*	
	Specifies the file name of an XTC include file used during characterization. For example, you can include XTC commands to ignore GDS cells, to blackbox lower-level hierarchy cells, or to perform some basic GDS layer operations.

Examples

- The following command creates a power-grid library:
  ```
  set_advanced_pg_library_mode \
  -libgen_command_file library_inc.cmd \
  -thunder_command_file simulator.cmd
  generate_pg_library -output output_dir
  ```
- In the following example, power-grid library generation ignores the LEF *metal1* and *metal3* layers when it creates the cell library:
  ```
  set_advanced_pg_library_mode -lef_layer_ignore_list {metal1 metal3}
  ```
- The following line indicates that a file named *nolef.txt* contains a list of the LEF layer names that power-grid library generation should ignore:
  ```
  set_advanced_pg_library_mode -lef_layer_ignore_list_file {nolef.txt}
  ```
- The following commands tags the `VDD` and `TVDD` pins as the ESD pins:
  ```
  set_advanced_pg_library_mode -esd_cells {IOESD} -esd_pin_list {VDD TVDD}
  ```
- The following command specifies the ESD device `dev1` and the xDSPF file `cell1.xdspf` to be used for ESD tagging:
  ```
  set_advanced_pg_library_mode -import_xdspf_list_file cell1.xdspf -esd_cells {IOESD} -esd_device_list {dev1}
  ```
- The following example specifies that FOREIGN statements are to be assumed for cells with no FOREIGN statements and that the FOREIGN cells should be placed at the inverse of the origin:
  ```
  -assume_foreigns true
  -assume_foreigns_mode 1
  ```
- The following example specifies that FOREIGN statements are to be assumed for cells with no FOREIGN statements, and the FOREIGN cells should be placed at (0,0):
  ```
  -assume_foreigns true
  -assume_foreigns_mode 0
  ```

Source Location File Format

The voltage source location file format is as follows:

```
<MIN_SPACING spacing_value>
<DENSITY density_value>
CELL cell_name
<[PORT|DETAILED] {>
NET net_name
<[PORT|DETAILED] {>
lef_layer_name <PORT|DETAILED> x y [x y]
lef_layer_name <PORT|DETAILED> x y [x y]
<}>
<}>
This source location file syntax includes the following parameters:
```

- NET net_name
  These specifications apply to the voltage source locations that follow until Library Generation encounters a new CELL or NET line. You can specify voltage sources as single points or as rectangles. If you specify them as rectangles, Library Generation generates a grid of voltage sources inside these rectangles.
- PORT | DETAILED
  The source location file can specify voltage sources to be used with port or detailed views.

lef_layer_name <PORT|DETAILED> x y [x y]
Lines beginning with a LEF layer name specify the actual location of the voltage sources.

You can specify this location as a single point by providing one set of values for x and y. These x and y coordinates are specified in microns and use the same coordinate system as that used for LEF ports in the LEF file.

Alternatively, you can specify the voltage source locations as a rectangle by giving two sets of x and y locations. In this case, Library Generation attempts to generate a 10-by-10 grid of voltage sources inside this area. From a rectangle specification, it does not create voltage sources closer than 1 micron apart, so if the rectangle is less than about 10 microns on a side, it generates fewer voltage sources.

In the source location file, the location of the voltage sources is specified by using a LEF layer name and location in LEF coordinate space. However, because of the way LibGen uses this data internally, no LEF geometries are actually required to exist at the location where the voltage sources are to be placed. Library Generation uses this data internally with the layout of the block (that is, the GDS data) during detailed power-grid view generation, so it only requires that there be layout (GDS) geometries at the location of the voltage sources. Similarly, the LEF layer name used in the source location file does not actually have to be included in any of the input LEF files; it must be defined only in the layer map used by Library Generation.

This is an example of the contents of the voltage source location file:

```
CELL BUMP
NET vcc
METAL1 11.0 16.0
METAL1 0.0 15.0 22.1 17.5
```

Here is an example file using MIN_SPACING and DENSITY to create a 10 x 10 grid of voltage sources on the VSS net in the detailed view of the NAND1 cell:

```
DENSITY 10
MIN_SPACING 1
CELL BUMP
DETAILED
NET VSS
```

```

Specifies what kind of power-grid library will be created. This command is used to define the type of input and configuration for generating power-grid libraries. You must specify this command before running the `generate_pg_library` command.

Parameters

`-help`	
	Outputs the command usage.

`-add_ploc_cells` *cell1 cell2 ...*

Specifies the name of the low-dropout (LDO) cell for which a voltage source is to be added. You can specify a list of cells. This parameter is applicable to the LDO cells only, and must be used when creating voltage sources for these cells. When this parameter is specified, all the output pins will be made voltage sources using the highest voltage value of the cell.

The `-add_ploc_cells` parameter is used with the `-cell_ploc_details` parameter.

`-bulk_ground_pins { ground_pin_list }`

Specifies the names of nets that connect transistor bulk terminals to the ground net. This information is used to prevent any current from being assigned to these nets. If a net is connected to any transistor terminals other than a bulk terminal, you must specify that net with the `-ground_pins` parameter.

`-bulk_power_pins { pin1 voltage1 ... pinN voltageN }`

Specifies the names of nets that connect transistor bulk terminals to the power net. This information is used to prevent any current from being assigned to these nets. If a net is connected to any transistor terminals other than a bulk terminal, you must specify that net with the `-power_pins` parameter.

`-calculate_metal_layer_density {true | false}`

Enables metal layer density calculation for macros. The default value is `false`.

When this parameter is set to `true`, Library Generation calculates and stores the area density information for each metal layer in macros for accurate thermal analysis. Metal density for macros is calculated by dividing the macro cell into tiles, and computing the area of polygons in each tile. The calculated metal density values are used in the Power Analysis flow to generate the metal power density map. This power map file is later used as input by Celsius Thermal Solver, the thermal analysis tool for packages and boards.

This parameter is applicable only for macro PGV generation (`-celltype macros`).

`-cell_decap_file` *filename*

Specifies the name of a file containing a list of cells and the decoupling capacitance value for each. You can also specify the series resistance value along with the decoupling capacitance value to accurately model the cell decoupling capacitance. The cell decap file format allows you to specify capacitance for multiple voltage values to support multi-voltage capacitance simulation for standard cell and macro PGV generation.

File Format:

```
UNIT <X>
CELL cell_name
PIN pin_name capacitance resistance

or
UNIT <X>
CELL cell_name
VOLTAGE value1
PIN pin_name capacitance resistance
...
....

VOLTAGE value2
PIN pin_name capacitance resistance
...
...
```

Unit is optional, default is `1e-15`. The *value* for each cell will be multiplied by the unit, except if engineering notation is provided.

Examples:

```
UNIT 1
CELL cell1

VOLTAGE 1.0
PIN VDD  1e-18
PIN VSS  1e-18

VOLTAGE 0.9
PIN VDD  1e-18
PIN VSS  1e-18
```

`-cell_list_file` *filename*

Specifies a file containing a list of cells that will be processed.

The `-cell_list_file` parameter is required when `set_pg_library_mode -celltype macros` is selected. The program spawns the library generation job in serial mode for each macro in the cell list file. A separate library for each macro is generated. This facilitates debugging when library generation of any macro fails. It also helps in improving the overall performance. The following is a sample cell list file:

```
CELL1
CELL2
CELL3
```

`-celltype {techonly | stdcells | macros}`

Specifies the type of library creation.

- `techonly`
  Creates a technology Library that contains the tech file, area capacitance specification, decap/filler/powergate cells, and Tech view for all the cells. A technology library is a requirement for running rail analysis.
- `stdcells`
  Generates a power-grid library for all the standard cells using the Spice netlist. The stdcells power-grid library does not contain the tech file. Power-grid is connected at the LEF pin, and all the capacitance are derived from simulation. The power-grid library contains three kind of power-grid views (PGVs), Early/IR/EM, and the views are selected based on the accuracy mode of rail analysis.
- `macros`
  Generates a power-grid library for memory, I/Os and macros using the Spice and GDS netlist. GDS is mandatory for the cell type macros. The `macros` power-grid library does not contain the tech file. Power-grid is connected down to contact/specified via, and all the capacitance are derived from simulation. The power-grid library contains three kind of PGVs, Early/IR/EM, and the views are selected based on the accuracy mode of rail analysis.

`-cell_ploc_details` *`filename`*

Specifies a file that contains all the information required to add a voltage source at the desired location for the power pad and LDO cells. This file includes the pad cell name, pin name, layer name, and domain name.

The format of the file is:

```
cell_name      pin_name    layer_name  domain_name
PADCELL           VDD       Metal3       VDD
```

- *`pin_name`* is the power/ground name for pad cells, and is the output pin name for LDO cells. The pin name could be represented by using the wildcard character "*" to indicate that voltage sources are to be added to all pins of a power pad/LDO cell.
- *`domain_name`* is the pin name for pad cells. For LDO cells, it is the power or ground name whose voltage needs to be used.

Example:

```
set_pg_library_mode \
    -ground_pins                {VSS 0 ExtVSS 0} \
    -power_pins                 {VDD 1.2 ExtVDD 1.2} \
    -celltype                   techonly \
    ...
    -add_ploc_cells             {CELL1 CELL2 CELL3} \
    -cell_ploc_details          /VoltageSource/config.txt \
```

The following is a snippet of the config.txt file:

```
CELL1 VDD Metal3 VDD
CELL1 VSS Metal2 VSS
CELL1 Z Metal2 VDD
CELL2 Z Metal3 VSS
CELL3 * VDD
```

`-current_distribution {propagation | dynamic_simulation` *`trigger_file`* `| current_region` *`region_file`*`}`

Specifies the method of current distribution inside the cell.

- **Propagation** uses Voltus library simulator to determine the propagation activity to distribute the current.
- **Dynamic simulation** uses a trigger file to run detailed analysis to determine current distribution.
- **Current region** specifies the amount of current to distribute within a cell region. For more information on the format, see Current Region File.

`-custom_label` *`label`*

Saves the specified label in the PGV for easy identification. This label can be used for revision control, label for Spice netlist/model, and internal keywords. It will be stored as “Custom Label” in VERSION.TXT in the .cl

`-decap_cells` *cell_name_list*

Specifies the names of cells that have explicit decoupling capacitance for use in decap optimization. These cells are nearly equivalent to feedthrough cells, except that there is typically an active device between the power and ground nets to provide extra decoupling capacitance. Power-grid view library generation uses this list of cells to ensure that a capacitance value is associated with each cell. If no capacitance is associated with a cell, a warning message will be issued.

This parameter supports wildcards (*).

`-default_area_cap` *value*

Specifies the default amount of area based decoupling capacitance in a cell. The default area-cap is 0.0 (unit is fF per micron-square). You must provide a value for area-based decoupling capacitance.

`-default_power_voltage` *value*

Specifies voltage for the power pins which are present in LEF but not specified using the `-power_pins` parameter. As a result, the `-power_pins` parameter of the command is optional. The default voltage value specified using `-default_power_voltage`is added to all power pins of the cell.

If both the parameters `-power_pins` and `-default_power_voltage` are not specified, the default voltage of 1.2 will be used.

`-design_qrc_layermap` *file*

Default: None

Specifies a file that provides the mapping of the layer names in the LEF design file to the layer names in the Quantus technology file.
File Format:

```
lefdef_layername    technology_layername
M1                   METAL_1
VIA1                 VIA_1

M2                   METAL_2
VIA2                 VIA_2
...
```

`-enable_device_size_current_distribution {true | false}`

Specifies to compute the tap current distribution for a macro based on device sizes (Width, Length), without performing any simulation. This parameter is used for macro PGV generation in a scenario when the Spice netlist is available but the Spice models are not available.

Default: `false`

`-enable_distributed_processing {true|false}`

Specifies to enable parallel processing for the Library Generation flow.

`-enable_multi_voltage_cap_generation {true | false}`

Specifies to compute capacitance values over a range of input voltages, including the nominal voltage. It generates 10 values from 0.1 to 1.3 times the vdd/vss voltage. The default value is `false`.

When set to `true`, it generates a PGV that contains the voltage-dependent capacitance table for the specified cell. This parameter allows you to use the accurate cell capacitance at different supply voltages in power-up analysis and in different voltage domains in dynamic analysis.

`-exclude_cell_list_file` *filename*

Specifies a file containing a list of cells (one per line) which should be excluded from power-grid library generation.

`-extraction_tech_file` *file*

Specifies the name of the technology file that will be used for extraction.

`-filler_cells` *cell_name_list*

List the names of the filler or feedthrough cells that have no GDS data. These cells can be swapped out for decaps during decap optimization.

This parameter supports wildcards (*).

`-fine_grain_memory_cell {true | false}`

Specifies to tag the cell as the fine-grain cell in the PGV library when characterizing the cell, and ensures that the software automatically uses this information to identify the fine-grain memory cells in the rail analysis flow. The default value is `false`.

This parameter is used with the `-internal_power_pins` and `-internal_ground_pins` parameters to specify the list of switch power/ground pins. It is recommended to use these parameters when characterizing fine-grain cells to avoid any potential cell type identification conflict in the rail analysis flow.

`-gds_files` *file_list*

Specifies the names of the GDSII files used during power-grid library generation.

`-gds_layermap` *file*

Specifies a file that provides the mapping of layers between the LEF and GDS files. The following is a sample GDS layermap file:

```
type    name    gds    #
via     VIA9    gds    59
```

`-generate_port_using_gds` *mbb_layer_name*

Identifies the layer name that library generation uses to compute the placement bounding box for GDSII cells that are placed by the DEF file.

`-ground_pins { ground_pin_list }`

Specifies the names of the nets considered ground nets for all cells for which the ground nets are not specified.

`-ignore_gds_cells {`*gds_cell_name_list*`}`

Specifies to ignore the specified cells during macro PGV generation. When this parameter is specified, the Library Generation engine does not extract data for these cells. This parameter supports wildcards.

Example:

The following command does not extract data for the `cell3` cell:

```
set_pg_library_mode -ignore_gds_cells {cell3}
```

`-internal_power_pins` *power_pin_list*

Specifies the list of switch power pins.

`-internal_ground_pins` *ground_pin_list*

Specifies the list of switch ground pins.

`-layer_tap_node_distance { {`*LayerName1 tap_node_distance*`} {`*LayerName2 tap_node_distance*`} ... }`

Default: None

Specifies tap node distances for certain layers. Using this parameter, you can customize the tap node distance for each layer during power-grid library generation.

The tap node distance is in micron. If the tap node distance is specified for a single layer, double brackets {{}} are still required.

`-layers_to_be_ignored_during_tap_creation {`*layername*`+}`

Specifies the names of the layers that library generation is to ignore when it creates the current taps. This parameter can be used to suppress the generation of any nodes or taps on layers that should not be extracted. Some technologies include layers that are only used to influence the extraction of other layers.

`-layers_to_have_ports_created {`*layername*`+}`

Specifies the names of the layers for which ports are to be created. This parameter can be used to create ports for the poly and diffusion layers in the technology file. By default ports are only created on metal layers.

`-lef_layermap` *file*

Specifies a file that provides the mapping of layers between the LEF and technology file. This parameter is optional. Library Generation automatically generates the layermap file using the technology LEF (containing all layer and via definitions) and Quantus Tech (extraction library) files, therefore, a LEF layermap file is not a mandatory input. The automatically generated layermap file is located in the PGV temp directory.

The following is the format and sample content of the auto-generated file (`lefdefLayerMap_AutoGenerated.txt`):

```
Layer Type   tech layername   lefdef    lefdef layername
via              VIA_9        lefdef      VIA9
metal            METAL_1      lefdef      METAL1
```

You can specify this parameter if you want to provide your own layermap file.

`-liberty_files` *file_list*

Specifies to directly read decoupling capacitance and resistance from the specified Liberty file for standard cell and macro PGV generation.

The following is an example of the Liberty construct required for capacitance/resistance:

```
intrinsic_parasitic () {
  when : "I";

  intrinsic_capacitance (VDD) {
    value : 0.000248992;
  }

  intrinsic_resistance (VSS) {
    related_output : ZN;
    value : 1.89195;
  }

  intrinsic_capacitance (VSS) {
    value : 0.000639008;
  }
}
```

If there are multiple `when` conditions, the average intrinsic resistance/capacitance value is taken.

`-macros_config_file` *filename*

Specifies to provide configuration details for each macro cell per Library Generation run. This is an additional input for `macros` cell type wherein you can provide macro specific Spice and GDS. The format of the file is:

```
CELL <cell1>
GDS_FILE <gds_file1>
SUBCKT_FILE <subckt_file1>
DECAP_FILE <decap_file1>
TRIGGER_FILE <trigger_file1>
POWER_GATE_PARAMS supply <supplyName> switched <switchedName>
CELL <cell2>
GDS_FILE <gds_file1>
SUBCKT_FILE <subckt_file1>
```

`CELL` is the keyword to specify a new cell that is to be characterized. This is a mandatory keyword. This keyword is followed by optional keywords, like `GDS_FILE` and `SUBCKT_FILE`, that are specific to the cell.

`-max_metal_density_tile_dimension {`*maxlength maxwidth*`}`

Specifies the tile dimensions, wherein *`maxlength`* denotes maximum length and *`maxwidth`* denotes maximum width in µm. The default value for length or width is 50µm. The number of tiles in the X and Y direction is determined using the length and width dimension.

This parameter should only be used when the `-calculate_metal_layer_density` parameter is set to `true`.

`-non_zero_ground_pins {`*pin1 voltage1 ...pinN voltageN*`}`

Default: None

Specifies the name and voltage of the nets considered ground nets for all cells for which the elevated ground nets need to be specified. This parameter allows you to provide a list of non-zero ground be it positive or negative for the ground nets. If the same name has been specified for both the parameters `-non_zero_ground_pins` and `-ground_pins`, then `-non_zero_ground_pins` will be given priority.

This parameter is applicable only for standard cell and macro PGV generation (`-celltype stdcells | macros`).

Example:

```
set_pg_library_mode -non_zero_ground_pins {VSS -1.05 VSSA 0.08 VSSA1 1.09}
```

`-pin_shape_current_distribution` *filename*

Default: None

Specifies a current distribution file that allows you to state how current should be distributed across multiple pin shapes of power and ground pins. Multiple pin shapes exist for VDD and VSS pins, and current drawn through each pin shape is non-uniform depending upon the output bit that is switching. This parameter allows you to define current distribution for multi-height multi-bit flip-flop (MBFF) characterization. The parameter allows you to accurately model the current through each pin shape.

File Format

```
CELL <cell name>
PGPIN VDD:(<LEF_layer_name>,<LEF_coordinates>):(<LEF_layer_name>,<LEF_coordinates>)
PGPIN VSS:(<LEF_layer_name>,<LEF_coordinates>):(<LEF_layer_name>,<LEF_coordinates>)
PIN <signal_pin_name> <current_ratio_for_VDD> <current_ratio_for_VSS>
```

Here,

- *<LEF_layer_name>,<LEF_coordinates>* specifies to assign the current ratio to the pin shape occupying the coordinates.
- *LEF_layer_name* the layer name to which the current taps are to be created

Example

```
CELL NAND3X8
PGPIN VDD:(Metal1,1,1):(Metal1,4,1)
PGPIN VSS:(Metal1,2,2):(Metal2,5,2):(Metal2,8,2)
PIN Q1 0.00:1.00 0.00:0.00:1.00
PIN Q2 0.90:0.10 0.95:0.05:0.00
```

`-spice_netlist_list_file` *filename*

Specifies a file containing all the spice netlists to be used for library generation, the format is one netlist per line. These spice netlist files must contain the subcircuit definitions for the cells being processed by power-grid library generation.

The following example specifies a file called *spice_netlist_list_file* that contains the list of spice netlist files:

```
set_pg_library_mode -spice_netlist_list_file spice_netlist_list_file
```

`-power_pins { pin1 voltage1 ... pinN voltageN }`

Specifies the name and voltage of the nets considered power nets for all cells for which the power nets are not specified. If both the parameters `-power_pins` and `-default_power_voltage` are not specified, the default voltage of 1.2 will be used.

`-powergate_finegrain_simulation [true|false}`

Specifies to enable finegrain powergate simulation.

`-powergate_parameters {{ cell supply switched Ron Idsat Ileak Control_Pin_Logic} + }`

Specifies the information that technology library generation needs to characterize a powergate cell. It includes the cell name, unswitched power pin, switched power pin, on resistance in ohms, saturation current in milliamps, leakage current in milliamps, and control pin logic.

If ron, idsat, or ileak values are specified, they will be used to override the data extracted by Voltus library simulator. `Control_Pin_Logic` can have the following values

- `enableHigh` - control pin(s) of the control logic will be connected to the power net to turn on the power gate instances.
- `enableLow` - control pin(s) of the control logic will be connected to the ground net to turn on the power gate instances.

The control pin logic allows you to specify whether the enable pin of the specified power gate is active high or active low, thus ensuring that the appropriate voltages are applied to the enable pins.

This parameter also allows you to specify multiple functional modes to enable different combinations of control pins in each mode. For multiple functional modes, the tool calculates RON for each mode separately and generates a single PGV for the specified modes.

Format for Multiple Functional Modes:

```
set_pg_library_mode -powergate_parameters { {cell_name mode_name1 {supply switch Ron Idsat Ileak Control_Pin_Logic} mode_name2
{supply switch Ron Idsat Ileak Control_Pin_Logic}... mode_nameN {supply switch Ron Idsat Ileak Control_Pin_Logic} }
```

Examples:

- For control pin logic:
  ```
  -powergate_parameters {  {HEADER_SWITCH TVDD VDD enableHigh} }
  ```
- For Single Powergate:
  ```
  -powergate_parameters {{HDRSID0 TVDD VDD}}
  ```
- For 2 Header Powergate:
  ```
  -powergate_parameters {{HEAD16_A12TH_C35 VDDG VDD} {HEAD8_A12TH_C35 VDDG VDD}}
  ```
- For Multiple Footer Powergate
  ```
  -powergate_parameters {{FOOTBUFVHSV16 VSSG VSS} {FOOTBUFVHSV32 VSSG VSS} {FOOTBUFVHSV64 VSSG VSS} {FOOTBUFVHSV8 VSSG VSS}}
  ```
- For Multiple Functional Modes:
  ```
  -powergate_parameters { {HEADER_SWITCH S1 {TVDD VDD 750 .5 4.0e-8V} S3 {TVDD1 VDD 350 .3 5.0e-8V} S2 {TVDD VDD 450 .5 4.0e-8V} }
  {RING_SWITCH TVDD VDD 750 .5 4.0e-8} }
  ```

`-powergate_parameters_file` *filename*

Specifies a file that contains details of power switches that have multiple control pins, input pins, and power nets. The control pins, input pins, and power nets can have either sweep voltages or user-defined voltages.

This parameter also allows you to specify multiple functional modes to enable different combinations of control pins in each mode. For multiple functional modes, the tool calculates RON for each mode separately and generates a single PGV for the specified modes.

File Format:

```
CELL <cell_name>
PGATE_PAIR  <AON_PIN> <SW_PIN> <CTRL_PIN> <Polarity|VoltageValues>
PGATE_PAIR  <AON_PIN> <SW_PIN> <CTRL_PIN> <Polarity|VoltageValues>
…
PWR_PIN <net_name> {voltage_values}
PWR_PIN <net_name> {voltage_values}
…
INPUT_PIN <pin_name> <Polarity|VoltageValues>
INPUT_PIN <pin_name> <Polarity|VoltageValues>
…

PGATE_OFF_PIN <CTRL_PIN> <Polarity|VoltageValues>
PGATE_OFF_PIN <CTRL_PIN> <Polarity|VoltageValues>
PGATE_OFF_PIN <CTRL_PIN> <Polarity|VoltageValues>
…

CHARACTERIZATION_VOLTAGES { val1 val2 val3 .... }
END
```

File Format for Multiple Functional Modes:

```
CELL <cell_name>
MODE_NAME mode_name1
PGATE_PAIR <AON_PIN> <SW_PIN> <CTRL_PIN> <Polarity|VoltageValues>
PWR_PIN <net_name> {voltage_values}
INPUT_PIN <pin_name> <Polarity|VoltageValues>
```

```
PGATE_OFF_PIN <CTRL_PIN> <Polarity|VoltageValues>
CHARACTERIZATION_VOLTAGES <VolageValues>
END_MODE

MODE_NAME mode_name2
PGATE_PAIR  <AON_PIN> <SW_PIN> <CTRL_PIN> <Polarity|VoltageValues>
PWR_PIN <net_name> {voltage_values}
INPUT_PIN <pin_name> <Polarity|VoltageValues>
PGATE_OFF_PIN <CTRL_PIN> <Polarity|VoltageValues>
CHARACTERIZATION_VOLTAGES <VolageValues>
END_MODE
...

END
```

- PGATE_PAIR and CHARACTERIZATION_VOLTAGES are mandatory keywords.
- PGATE_PAIR is the keyword to specify the always-on power pin, switched power pin, and control pin names, and the voltage values at which these pins are simulated. If you specify voltage values, then the software uses these user-defined values during power gate characterization. Alternatively, if you specify polarity (high/low), then the software uses the sweep voltage values (CHARACTERIZATION_VOLTAGES) during power gate characterization. If you do not specify both polarity or voltage values, then the software by default uses the sweep voltage values (CHARACTERIZATION_VOLTAGES) during power gate characterization.
- CHARACTERIZATION_VOLTAGES is the keyword to specify sweep voltage values. The number of voltage values specified with the PGATE_PAIR keyword must match with the number of voltage values specified with the CHARACTERIZATION_VOLTAGES keyword.
- PWR_PIN is the keyword to specify additional power pins of the cell other than the always-on and switched power pins.
- INPUT_PIN is the keyword to specify additional signal pins of the cell other than the control pins. If you specify voltage values, then the software uses these user-defined values during power gate characterization. Alternatively, if you specify polarity (high/low), then the software uses the sweep voltage values (CHARACTERIZATION_VOLTAGES) during power gate characterization. If you do not specify both polarity or voltage values, then the software by default uses the sweep voltage values (CHARACTERIZATION_VOLTAGES) during power gate characterization.
- PGATE_OFF_PIN is the keyword to specify the control pin names and the voltage values at which the off-resistance is computed. If you specify voltage values, then the software uses these user-defined values during power gate characterization. Alternatively, if you specify polarity (high/low), then the software uses the sweep voltage values (CHARACTERIZATION_VOLTAGES) during power gate characterization. If you do not specify both polarity or voltage values, then the software by default uses the sweep voltage values (CHARACTERIZATION_VOLTAGES) during power gate characterization.

Examples:

Example 1: User-specified voltage values for control pins, input pins, and power nets

```
CELL cellA
PGATE_PAIR AONVDD SWVDD SLEEPN {0.600 0.660 0.700 0.750 0.800 }
PWR_PIN VDD_PS {0.7 0.8 0.9 1.0 1.1 }
INPUT_PIN PS_DISABLE {0.600 0.660 0.700 0.750 0.800 }
CHARACTERIZATION_VOLTAGES {0.600 0.660 0.700 0.750 0.800 }
END
```

Example 2: User-specified polarity

```
CELL cellb
PGATE_PAIR TVDD VDD SLEEPN
PWR_PIN VDD_SIDE
INPUT_PIN S1 HIGH
CHARACTERIZATION_VOLTAGES {0.600 0.660 0.700 0.750 0.800 }
END
```

Example 3: powergate_param_file.txt

```
CELL HEADER_SWITCH
MODE_NAME S1
PGATE_PAIR TVDD VDD NSLEEPIN LOW
CHARACTERIZATION_VOLTAGES {0.9 1.0 1.1}
END_MODE

MODE_NAME S2
PGATE_PAIR TVDD VDD NSLEEPIN HIGH
CHARACTERIZATION_VOLTAGES {0.9}
END_MODE

MODE_NAME S3
PGATE_PAIR TVDD1 VDD NSLEEPIN LOW
```

```
CHARACTERIZATION_VOLTAGES {0.9 1.1}
END_MODE

END
```

`-spice_corners` *corner_list*

Specifies a list of SPICE corners. This is an optional parameter. If you specify SPICE corner(s), the number of corner items should be equal to the number of SPICE model files specified in `-spice_models` *file_list*. One Spice model can map to many Spice corners but not vice versa.

Examples:

- if there are three model files but only two corners, a blank corner definition is required to match the model-corner pair, as shown below:

  ```
  -spice_models { model1.scs model2.scs model3.scs}
  -spice_corners {{corner1} {} {corner2}}
  ```

- if a SPICE model1 has three corners and model2 has two corners, you should specify:

  ```
  -spice_models { spice_1.model spice_2.model }
  -spice_corners { {s11 s12 s13} {s21 s22} }
  ```

  Based on the above parameter description, the following information gets updated in the library generation file:

  ```
  spice_model_file spice_1.model {s11 s12 s13}
  spice_mode_file spice_2.model {s21 s22}
  ```

`-spice_models` *file_list*

Specifies the names of the SPICE model files used by the SPICE netlist file (`-spice_subckts`).

Some Spice process models use `wnom/Wn` and `lnom/Ln` instead of `w` and `l` (device model parameters names for length and width) for MOS models. Voltus recognizes and supports these alternate parameter names.

`-spice_subckts` *file_list*

Specifies the names of the SPICE netlist files containing the subcircuits corresponding to the cells being processed during power-grid library generation. These subcircuit netlists will be used to calculate pin capacitances using Voltus library simulator.

`-spice_subckts_xyscaling` *value*

Specifies the current region scale factor for the Netlist-based flow . The current region scale factor is the factor by which the netlist coordinates are scaled before finding the closest node to attach the tap currents.

The netlist-based flow fails when there is a mismatch in the units of the PGDB coordinates (in nm) and the coordinates in the SPICE netlist causing improper current tap creation. To match these coordinates, you need to specify the current region scale factor. The default scale factor is `1000` considering that the SPICE netlist coordinate unit is `um`.

`-stop@via` *layername*

Stops the extraction of the power-grid network inside a cell at the specified via layer.

`-tap_node_distance_file` *filename*

Specifies a file containing the distance between tap nodes for the given list of cells. The specified file includes the cell name and tap node distance in micron. The default unit for tap node distance is `micron`, and the default tap node distance is `50 microns`. This parameter is applicable for technology and standard cell PGV generation.

This parameter allows you to customize the tap node distance for each cell during power-grid library generation.

The format of the file is:
cell_name tap_node_distance

Example:

```
OA_cellA 1
OA_cellC 1
```

`-tech_gds_layermap` *filename*

Specifies a file that provides the mapping of the layer names in the Quantus technology file to the layer names in the GDS file.

File Format:

```
technology_layername   use      gds_number  data_type
METAL_1                text       131          0
VIA_1                   x          51          0

METAL_2                text       132          0
VIA_2                   x          52          0
...
```

If `-design_qrc_layermap` is specified along with `-tech_gds_layermap`, then the format of `-tech_gds_layermap` is treated as:

```
lefdef_layername   use      gds_number  data_type
      M1           text       131          0
```

`-temperature` *temp_value_in_degree_celcius*

Specifies the temperature in degree celcius used in library characterization for thermal aware EM/IR analysis.

Default: 25

`-use_lefonly_for_detailedview_generation {true | false}`

Specifies to generate a detailed PGV with the bump LEF without loading a GDS file. You can specify this parameter to perform the RC extraction of a hybrid bump or via cell while skipping the extraction of its top and bottom routing metal layers. When set to `true`, the top and bottom metal layers are preserved as geometries in the library and promoted to the top level, whereas the via layer shapes are dropped and their resistance is used directly from the PGV.

Default: `false`

`-use_powergate_data_from_lib {true|false}`

Specifies to read powergate parameters ron, saturation current, and leakage current from the Liberty files specified using the existing `-liberty_files` parameter. This parameter allows you to obtain the powergate parameters from a Liberty file when a Spice netlist is not available, or when the Liberty file contains the powergate parameters.

Examples

- The following command sets the power library mode:

```
set_pg_library_mode
-extraction_tech_file RCgen.tch
-lef_layermap lefdef.map
-celltype techonly
-power_pins { VDD 1.08 VDDO 1.08 VDDG 1.08 }
-ground_pins { VSS GND VSSG }
-cell_list_file built_cells_list
-temperature -40
-spice_models models/v1d1_usage.l
-spice_corners { ss_lib }
-spice_subckts { typical_max_m40.spice }
-powergate_parameters { { cell1 VDDG VDD } { cell2 VDDG VDD } }
-current_distribution propagation
```

- The following command generates a PGV that contains the voltage dependent capacitance table for the specified cells:

```
set_pg_library_mode -celltype stdcells -cell_list_file cellfile -extraction_tech_file ./../qrcTechFile -lef_layermap
./../lefdef.layermap -temperature 125 -power_pins { vcc 1.26 vccpg 1.26 vccr 1.26 } -ground_pins { vss } -powergate_parameters
{{powercell_pg1 vcc vccpg} {powercell_pg1 vcc vccr} {powercell_pg2 vcc vccpg} {powercell_pg2 vcc vccr}} -spice_corners { tt } -
spice_models spice_model/libspice -spice_subckts { powercell_pg.net powercell_pg2.net } -enable_multi_voltage_cap_generation true
```

The PGV report includes the following information:

```
INFO: PGV contains voltage dependent cap table for this cell
```

Current Region File Format

The following shows the current_region_file format:

```
 UNIT CURRENT default_unit_in_amps
UNIT CAPACITANCE default_unit_in_farads
CELL cell_name
<PROP [FLAT | HIER]>
NET net_name
LAYER layer_name
[ REGION x1 y1 x2 y2 current_value <cap_value> | REGION current_value <cap_value> ]
```

UNIT	Defines the default scale to be used with the current and capacitance values read from the current region file. These scales apply to any value that is not followed by an explicit unit specification. Valid current values are: A (Amps), mA (miliAmps), uA (microAmps), and nA (nanoAmps). Valid capacitance values are: F(Farads), mF (miliFarads), uF (microfarads), nF (nanofarads), pF (picoFarads), and fF (femtoFarads).
CELL *cell_name*	This command specifies the name of the cell. All the following NET, LAYER, and REGION commands will apply to this CELL until another CELL specification is encountered. Wildcards can be used in the cell_name.
<PROP [FLAT | HIER]>	If the keyword FLAT is applied, LibGen will not perform hierarchical tracing for the given net in this cell. If the keyword HIER is presented, LibGen will perform hierarchical tracing for the given net in this cell. This provides the ability for LibGen to automatically specify a current value to all instances of a cell in the design hierarchy. The assumption is that all of these instances of the cell will consume the same power. The default is HIER.
NET *net_name*	This command specifies that all the LAYER and REGION commands following it applies to the net_name. This stays in effect until another NET or CELL specification is encountered. Wildcards can be used in the net_name.
LAYER *layer_name*	This command specifies that all the REGION commands following it apply to the layer_name. This stays in effect until another LAYER, NET, or CELL command is encountered. The layer_name must be a library layer name. If the layer is not found, LibGen will issue an error message and exit. You must provide a valid layer name for LibGen to run. If you specified a valid layer, but LibGen does not find any via in the assigned current region, LibGen will issue a warning message, but the process will still continue and exit successfully. In this case, you may get a 0 current value for the specified cell.
REGION *x1 y1 x2 y2 current_value cap_value*	This command specifies that the current value and optionally the capacitance value to be associated with the rectangular region specified by the bounding box (*x1 y1 x2 y2*). Current taps will be created at the locations of the vias or contacts specified by the most recent LAYER command. These current taps will be attached to the layer that is below the specified via or contact layer. Coordinate values are assumed to be in GDSII coordinate units and will be interpreted according to the scale and precision settings contained in the GDSII file (or spice netlist with device XY location) that contains the cell. The value of the current drawn by each current tap will be 1/n of the value specified for the current region, where n is the number of taps within the current region. The second variation of the REGION command without the bounding box is valid only if there is only one current region. In this case LibGen can automatically uses the bounding box of the cell for the region.

Example of Current Region File

```
UNIT CURRENT uA
UNIT CAPACITANCE fF
CELL an4_80
NET vcc
LAYER CONT
REGION 0 14000 28900 17000 3.0 5.0
NET gnd
LAYER CONT
REGION 1.5e-2mA
```

trim_pg_library

```
trim_pg_library
[-help]
[-delete_cells cell1 cell2 ...]
[-delete_cells_file file_name]
-library_list_file file_name
[-output directory_name]
-output_library library_name
```

Specifies to remove a list of cells from the specified PGV. This command allows you to trim the size of a cell library by removing unwanted cells, which can reduce the overall time required for extraction.

Parameters

-help	Outputs the command usage.
-delete_cells *cell1 cell2 ...*	
	Default: None Specifies the name of a cell or a list of cells to be removed from the power-grid library.
-delete_cells_file *file_name*	
	Default: None Specifies the name of a file containing the list of cells (one per line) to be removed from the power-grid library. **File Format**: cell1 cell2 cell3
-library_list_file *file_name*	
	Default: None (**Mandatory**) Specifies the name of a file containing the library or libraries (one per line) that are to be trimmed. If multiple libraries are given, Library Generation merges the multiple same-type power-grid libraries into one consolidated power-grid library. **File Format**: PGV1 PGV2 PGV3
-output *directory_name*	
	Default: current working directory Specifies the name of the output directory in which the trimmed power-grid library will be created.
-output_library *library_name*	
	Default: None (**Mandatory**) Specifies the name of the trimmed power-grid library created after removing the specified cells.

Examples

- The following command removes the cell `AND2X2` from the power-grid libraries specified in the `library_list.txt` file and generates one consolidated power-grid library `trimlibrary`:

```
trim_pg_library -library_list_file library_list.txt -output_library trimlibrary -delete_cells AND2X2
```

validate_pg_library

```
validate_pg_library
[-help]
[-activity value]
-cell cell_name
[-clock {clk1 clk2 ...}]
[-disable_rail_analysis {true | false}]
[-dynamic_analysis_duration value]
[-enable_xp {true | false}]
-extraction_tech_file tech_file_path
[-frequency value]
[-input_pin_set_case_analysis_low {pin1 pin2 ...}]
[-input_pin_set_case_analysis_high {pin1 pin2 ...}]
[-liberty liberty_file ]
[-max_ir_drop value]
[-net_capacitance value]
[-output output_dir]
[-pin_capacitance value]
-power_grid_library_path pgv_path
[-power_grid_library_view view_name]
[-power_pad_size value]
[-rail_analysis_type {static | dynamic}]
[-sdc_file filename]
[-set_power_switching_pattern trigger_file]
[-set_total_power value]
[-step_size value]
[-supply_voltage value]
-tech_lef_file tech_lef_file_path
[-transition_time time]
[-power_include_file filename]
[-rail_include_file_begin filename]
[-rail_include_file_end filename]
[-rail_trigger_switching_pattern pattern]
[-temperature value]
[-twf_path twf_location]
[-user_defined_ploc_file filename]
[-pgv_mode_dynamic_switch_pattern pattern]
```

Specifies to validate a macro PGV. The command takes a macro PGV and Liberty file as input, and performs IR Drop based validation by running static and dynamic power and rail analysis. In this flow, Library Generation will read the input PGV and generate a dummy DEF file that has an instance of the macro (one-cell design). It will then run static/dynamic power and rail analysis on this design. You can analyze the power and rail results to check for hotspots, connectivity, and current distribution inside the PGV.

Parameters

`-help`	
	Outputs the command usage.
`-activity value`	
	Specifies the activity value for input pins. If not specified, a default activity of 0.2 is used. The activity specifies the number of times an input pin switches
`-cell cell_name`	
	Specifies the name of the cell to be validated.
`-clock {clk1 clk2 ...}`	
	Specifies the list of clock pins.
`-disable_rail_analysis {true | false}`	

Specifies to disable rail analysis during macro PGV validation. The following is the behavior of `-disable_rail_analysis true` with the `-enable_xp` para

- if `-enable_xp` is set to `true`, the tool will run only power analysis in the XP mode
- if `-enable_xp` is set to `false`, the tool will enable only power analysis in the non-XP or normal mode

Default: `false`

`-dynamic_analysis_duration value`

Specifies the simulation period that dynamic power analysis will use. It is the duration for which a window is selected for calculation of IR drop during pc default value is 10ns.

`-enable_xp {true | false}`

Specifies to validate the macro PGV in the extensively parallel (XP) mode.

Default: `false`

`-extraction_tech_file tech_file_path`

Specifies the path of the extraction technology file.

`-frequency value`

Specifies the clock frequency. The default value is 100Mhz.

`-input_pin_set_case_analysis_low {pin1 pin2 ...}`

Specifies the list of pins to be kept at a logical low. The `set_case_analysis` command in the SDC file will have the same effect as the set pin to constant described here.

`-input_pin_set_case_analysis_high {pin1 pin2 ...}`

Specifies the list of pins to be kept at a logical high. The `set_case_analysis` command in the SDC file will have the same effect as the set pin to constan described here.

`-liberty liberty_file`

Specifies the name of the Liberty file for power calculation.

This parameter is optional for the static power analysis flow, and is mandatory for the dynamic power analysis flow. In the static flow, you need to specify `set_total_power`. If both the parameters are specified, the `-set_total_power` parameter will be honored.

`-max_ir_drop value`

Specifies the maximum IR drop allowed. Default is 5 (in percentage).

`-net_capacitance value`

Specifies the value of the net capacitance. The default value is 1pF.

`-output output_dir`

Specifies the name of the output directory. This directory saves the power and rail reports, and the design output (such as .lef, .def, and so on).

`-pgv_mode_dynamic_switch_pattern pattern`

Specifies the switching patterns for the functional modes in the dynamic power calculation flow. The use model of this parameter is same as the `set_pov dynamic_switch_pattern` parameter.

In the following example, the mode `write` will switch in the 1st clock cycle, the mode `read` will switch in the 2nd and 4th clock cycles, and none of the mo 3rd clock cycle:

```
validate_pg_library -pgv_mode_dynamic_switch_pattern { write read - read }
```

`-pin_capacitance value`

Specifies the value of the pin capacitance. The default value is 1pF.

`-power_grid_library_path pgv_path`

Specifies the path of the power-grid library file.

`-power_grid_library_view` *view_name*

Specifies the power-grid view name.

`-power_include_file` *filename*

Specifies a power analysis include file. This file specifies certain commands of the dynamic engine that do not have a Voltus equivalent. This parameter the dynamic power analysis flow.

`-power_pad_size` *value*

Specifies the distance between two adjacent DEF voltage sources. The default value is `50` (in Micron).

`-rail_analysis_type {static | dynamic}`

Specifies whether static or dynamic analysis will be done. The default value is `static`.

`-rail_include_file_begin` *filename*

Provides a file that includes additional rail options that will be run prior to the `analyze` command. This can be used for those legacy rail analysis comma Voltus equivalent.

`-rail_include_file_end` *filename*

Provides a file that includes additional rail options that will be run after the `analyze` command. This can be used for those legacy rail analysis command Voltus equivalent.

`-rail_trigger_switching_pattern` *pattern*

Default: None

Specifies a dynamic trigger file. When a Macro EM view with current signature is used in a design, it needs to be determined when this block/cell is trigg trigger file is used to determine this. The use model of this parameter is same as the `set_rail_analysis_mode -dynamic_trigger_file` parameter.

`-sdc_file` *filename*

Specifies the name of the timing constraints file.

`-set_power_switching_pattern` *trigger_file*

Default: None

Specifies the stimulus pattern on the pins of an instance and cell. Specify this parameter only in the dynamic mode for the type instance and cell. The us parameter is same as the `set_power -dynamic_switch_pattern` parameter.

`-set_total_power` *value*

Specifies the total power for the design in Watts. This power is distributed based on cell area.

`-step_size` *value*

Specifies the simulation step size, in picoseconds. The default value is 20ps. This parameter is applicable only to the dynamic power analysis flow.

`-supply_voltage` *value*

Specifies the voltage of each power supply pin. The default value is 1V.

`-tech_lef_file` *tech_lef_file_path*

Specifies the path of the technology LEF file.

`-temperature` *value*

Sets the temperature for static power calculation. The default is 125 degrees.

`-transition_time` *time*

Specifies the transition time for specific pins or instances in the design. This parameter is applicable only to the dynamic power analysis flow.

`-twf_path` *twf_location*

Specifies the location of the Timing Window File (TWF) for noise and power calculation.

`-user_defined_ploc_file` *filename*

Specifies the name of a file containing net names and corresponding user-defined ploc or power pad files (.pploc). The .pploc file includes power pin or locations for power and ground nets. The parameter gives you the flexibility to include either user-specified or tool-generated voltage sources.

The following is a sample file with the list of nets and power pad files:

```
----ploc.list----
#<NET_NAME> <Pointer to ploc file>

VDD   input/ploc/VDD.pploc
VDDA  input/ploc/VDDA.pploc
VDDF  input/ploc/VDDF.pploc
VSS   input/ploc/VSS.pploc
```

When specified, the voltage source location files (.pploc) in the given *ploc.list* file will be used for library generation. If the pploc file is missing for a few file, then library generation will automatically generate `.pploc` for those nets.

Examples

- The following command specifies to validate the cell `cell1` by running static power and rail analysis:

```
validate_pg_library -cell cell1 -liberty 125c.lib -clock {CLKW CLKR} -power_grid_library_path macros_cell.cl -extraction_tech_file caps.tch -tech_lef_file tech.lef -output validate_pg_output_static -rail_analysis_type static
```

- The following command specifies to validate the cell `cell1` by running dynamic power and rail analysis

```
validate_pg_library -cell cell1 -liberty 125c.lib -clock {CLKW CLKR} -power_grid_library_path macros_cell.cl -temperature 122 -extraction_tech_file caps.tch -tech_lef_file tech.lef -output validate_pg_output_dynamic -rail_analysis_type dynamic
```

add_target_pg

```
   add_target_pg
[-help]
[-area {x1 y1 x2 y2}{x1 y1 x2 y2 x3 y3 x4 y4 ...}]
[-force]
[-instance {list_of_instances}]
-nets {list_of_nets}
-pin_layer layer
[-stack_layer_config {stack_layer_pattern}]
[-stack_layer_config_file filename]
-target_layer {layer1 layer2}
[-uda subclass_string]
```

Creates a PG path for a certain cell or instance. There are several cases where the IR drop hotspots occur only on certain cells, like high driving strength clock buffer cell, and there are some cells wherein secondary PG pins need to be connected with power mesh. So, instead of increasing the density of regular PG mesh, the `add_target_pg` command allocates a dedicated PG path from the top layer low resistance PG stripe to these cells and solves most of the IR-drop hotspot issues. As a result, more resources can be preserved for routing.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `add_target_pg` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man add_target_pg`
`-area {x1 y1 x2 y2}{x1 y1 x2 y2 x3 y3 x4 y4 ...}`	
	Signifies that an instance inside the specified area can be connected.
`-force`	Keeps the added PG even when the connection has a DRC, and adds a DRC marker. When this parameter is not set, the newly added PG will remain DRC clean. In such a case, if the PG pin cannot connect to the target layer with DRC clean, the added PG is deleted and leaves the pin open.
`-instance {list_of_instances}`	Specifies the instances to be connected. Note that only those instances are connected, which belong to the cell defined by the `set_add_target_pg_mode -pins` parameter.
`-nets {list_of_nets}`	Specifies the power/ground nets to be connected.
`-pin_layer layer`	Specifies the layer name of the cell pin to be connected.
`-stack_layer_config {stack_layer_pattern}`	
	Defines the pattern of the stripes on intermediate layers between the `pin` layer and target layer. The value of this parameter is in the `{layer1:n1:s1:w1:p1:g1 layer2:n2:s2:w2:p2;g2 …}` format. Here: • `layer1`, `layer2`, … specifies the layer names. • `n1`, `n2`, … specifies the stapling count in a set. • `w1`, `w2`, … specifies the stapling width. • `s1`, `s2`, … specifies the spacing inside a stapling set. • `p1`, `p2`, … specifies the pitch (set-to-set distance) between the stapling sets. • `g1`, `g2`, … specifies the grid or half grid. Following is an example of the `-stack_layer_config` parameter value: `-stack_layer_config {M3:2:0.12:0.04:0.36 M4:1:0.08:0.08:0.9}`

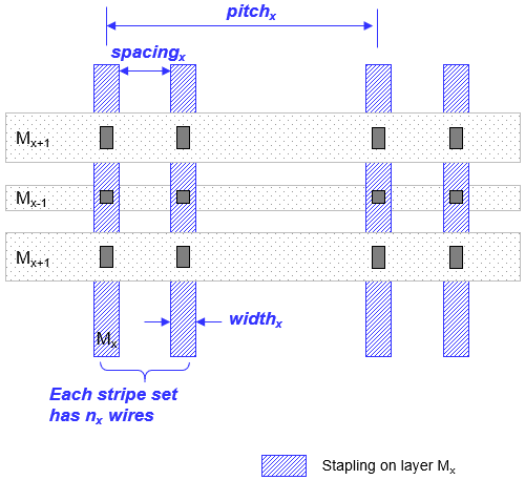
`-stack_layer_config_file filename`	Specifies the stack layer configuration file defining the pattern of the stripes on intermediate layer between the pin and target layers. Stack layer denotes the intermediate layer(s) between the cell pin and target stripe. Following is the syntax of the stack layer configuration file:
	`STACKLAYER COUNT SPACING WIDTH PITCH SNAP`
	`…`
	`<M_x> <n_x> <spacing_x> <width_x> <pitch_x> <Grid/Half_Grid/->`
	`…`
	`END STACKLAYER`
	Here:
	• `STACKLAYER`: Specifies the LEF name of the layer.
	• `COUNT`: Specifies the number of stripes on the layer. The default `COUNT` value is `1`.
	• `WIDTH`: Specifies the stripe width in microns. The default `WIDTH` value is the minimum width in LEF.
	• `SPACING`: Specifies the stripe spacing in microns. The default `SPACING` value is the minimum spacing in LEF.
	• `PITCH`: Specifies the set-to-set distance in a stripe. It indicates the range that one stripe set can cover. The default `PITCH` value is `MAX`, which means one set.
	• `SNAP`: Controls the wires' snap to grid or half grid. The default value of `SNAP` is `Grid`.
	`COUNT`, `WIDTH`, `SPACING`, or `SNAP` can be omitted in the configuration file by specifying a

hyphen (-). For example, `2` stripes on `M4` with minimum width and spacing can be described as:

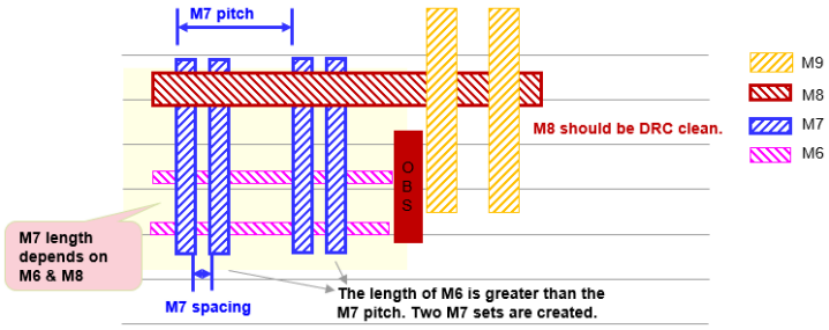
```
M4 2 - -
```

If the entire line of a layer is omitted, it means that the layer will have one stripe with minimum width and spacing.

Following is an example of a pattern defined in the stack layer configuration file:



The generation of each layer stapling depends only on its lower and upper stapling. The added PG can be shifted to find a DRC clean location. If a DRC clean location is not found, the added PG of this pin is removed and kept open. The length of the `Mx` layer depends on location of the `Mx-1` and `Mx+1` layers, as shown in the figure below. The number of wires created on the `Mx-1` and `Mx+1` layers needs to fulfill the defined count number criteria.



Note: This parameter is exclusive to the `-stack_layer_config` parameter.

`-target_layer {layer1 layer2}`	Defines one or two destination power/ground stripes by specifying the target layer names. In case two target layers are specified, those should be adjacent. In such a case, the software connects to the closet wires of these two adjacent target layers with DRC clean. The directions of these two target layers are orthogonal. The configuration file is created based on the higher of these two layers. The lower target layer uses its own configuration file and the configuration files of the layers between the cell pin.
	For example, the `stack.cfg` configuration file for a stack is created based on the target layer `M9`. Its target layer `M8` uses the configuration files of the layers from `M3` to `M7`, as shown below:
	`add_target_pg -nets {VDD2} -target_layer {M9 M8} -pin_layer M2 -stack_layer_config stack.cfg`
	Following are the contents of the `stack.cfg` configuration file:
	`STACKLAYER COUNT SPACING WIDTH PITCH`
	`M3 2 0.12 0.04 0.36`
	`M4 2 0.12 0.04 0.9`
	`M5 - - 0.04 0.36`
	`M6 2 0.12 0.04 0.9`
	`M7 2 0.2 0.2 1.2`
	`M8 - 0.2 0.2 1.2`
	`END_STACK_LAYER_CONFIG`
	Following is the output of the above command:
	 	As shown in the above output, since the first layer is not DRC clean, the software searches for the second closest target stripe to connect.

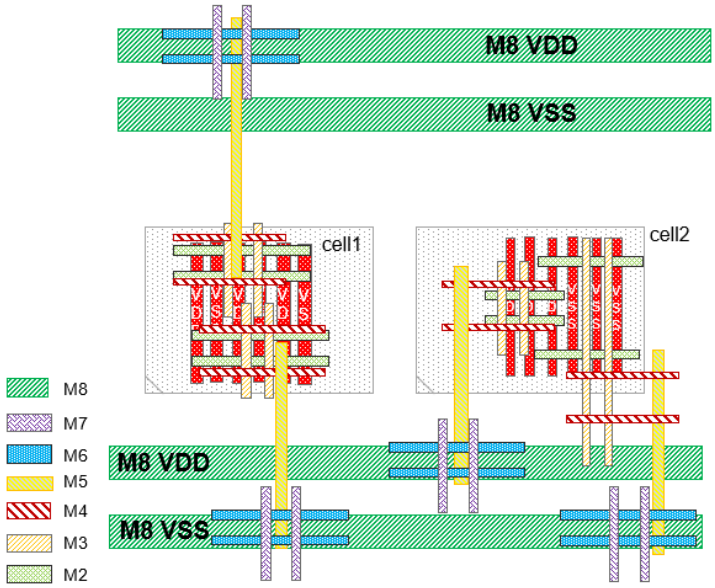
`-uda subclass_string`	Indicates the name string of the user-defined attribute subcalss of wires to route.

Examples

- The following command connects different cells and pins specifying the `-target_layer` as `M8` and `-pin_layer` as `M1`:
  `set_add_target_pg_mode -pins {cell1:VDD cell1:VSS cell2:VDD cell2:VSS} -share_resource false`
  `add_target_pg -nets {VDD VSS} -target_layer M8 -pin_layer M1 -stack_layer_config_file target_pg.config`
  Following are the `target_pg.config` file contents:

```
STACKLAYER    COUNT         SPACING           WIDTH
M2            2             0.06              0.04
M3            2             0.12              -
M4            2             0.12              0.04
M5            -             -                 0.04
M6            2             0.12              0.04
M7            2             0.2               0.2
END STACKLAYER
```

Following is the output of this example:



- The following set of commands connect different cells and pins specifying the `-target_layer` as `M8` and `-pin_layer` as `M2`:

```
set_add_target_pg_mode -pins {cell:VDD} -share_resource true
add_target_pg -nets {VDD} -target_layer M8 -pin_layer M2 -stack_layer_config_file  target_pg.config
```

Following are the `target_pg.config` file contents:

```
STACKLAYER    COUNT         SPACING       WIDTH         PITCH
M3            3             0.12          -             -
M4            2             0.12          0.04          0.5
M5            2             0.12          0.04          -
M6            2             -             0.08          0.5
M7            2             0.2           0.2           -
END STACKLAYER
```

Following is the output of this example:

```

Creates rings for specified nets around the core boundary or selected blocks and groups of core rows. Use this command after creating an initial floorplan.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `addRing` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man addRing`
`-around`	Specifies the objects around which to create rings. This parameter is used in conjunction with the `-type` parameter. Specify one of the following: • `each_block|each_reef|power_domain`: Creates rings around each power domain or around each fence that surrounds a soft block in the design. This option can only be used if you also specify `-type block_rings`. • `default_power_domain`: Generates ring around a default power domain. • `selected|cluster|shared_cluster`: Creates rings around all selected blocks with shared edges residing in the middle of the common areas between adjacent blocks. This option can only be used if you also specify `-type block_rings`. • `user_defined`: Creates rings around user-defined blocks.
`-center {0 | 1}`	Specifies whether to center the core rings between the I/O pads and core boundaries. If you do not specify this parameter with a value of 1, you must specify the parameter `-offset {value | {top top_offset bottom bottom_offset left left_offset right right_offset}`. *Default:* `0`

`-exclude_selected {0 | 1}`	Specifies whether the core ring should be created so that selected objects (blocks and power domains) are not included within its boundary. *Default:* `0`
`-extend_corner {[tl] [tr] [bl] [bt] [lt] [lb] [rt] [rb]}`	
	Extends the specified segment of the ring to the specified direction. Following are the parameter values: • `bl`: Extends the bottom segment of the ring to the left until encountering a target. • `br`: Extends the bottom segment of the ring to the right until encountering a target. • `lb`: Extends the left segment of the ring to the bottom until encountering a target. • `lt`: Extends the left segment of the ring to the top until encountering a target. • `rb`: Extends the right segment of the ring to the bottom until encountering a target. • `rt`: Extends the right segment of the ring to the top until encountering a target. • `tl`: Extends the top segment of the ring to the left until encountering a target. • `tr`: Extends the top segment of the ring to the right until encountering a target.
`-follow {core | io}`	Specifies whether core rings are placed along the core boundary or the I/O boundary. This parameter is used only with the `-type core_rings` parameter. *Default:* `core`
`-jog_distance value`	Specifies the least amount of jog allowed (to follow the contour of the referenced object) before a jog is removed. This value is in micrometers. If the ring would need to jog a distance equal to or less than this value in order to follow the contour of the object, the ring will not jog. *Default:* If you do not specify this parameter, the jog distance value is automatically calculated based on the worst spacing in the technology file.
`-layer {layer | {top top_layer bottom bottom_layer left left_layer right right_layer}}`	

	Can now be used to replace old options: `-layer_top / - layer_bottom / - layer_left / -layer_right` `-layer metal7` means all four sides of the ring will use layer metal7. **Example:** • `-layer metal7` : all four sides of the ring will use layer metal7. • `-layer {top metal7 bottom metal7 left metal8 right metal8}`: top and bottom ring wires will be generated on metal7, left and right ring wires will be on metal8. The following types of formulas are supported: 1. Lefname 2. Metal layer number **Example:** If Metal2 is named by 'MET2' in LEF file, then you can use 1. MET2 2. 2 to identify metal2.
`-nets` *list_of_nets*	Specifies the names of the nets for which power rings are to be created. You must enclose the list of net names within curly braces.
`-offset_adjustment` *automatic* | *fixed*	
	Specifies whether the offset is automatically adjusted when you change the width or spacing values. *Default:* `automatic`
`-offset {value | {top top_offset bottom bottom_offset left left_offset right right_offset}}`	
	Can now be used to replace old options: `-offset_top / -offset_bottom / -offset_left / -offset_right` `-offset 5` means all four sides of the ring will use 5um offset. Example: • `-offset 5`: 5 means all four sides of the ring will use 5um offset. (existing) • `-offset {top 5 bottom 6 left 7 right 8}`: top ring wires will use 5um offset, bottom ring wires will use 6 um offset, left ring wires will use 7 um offset, right ring wires will use 8 um offset.
`-rectangle {0 | 1}`	If set to `1`, creates rectangular rings only. *Default:* If you do not specify this parameter or if you specify it with a value of `0`, the creation of rectilinear rings is permitted.
`-skip_side`	Can now be used to replace old options: `-top / -bottom / -left / -right` `-skip_side {left}` has is the same as `-left 0` in the old behavior.
`-snap_wire_center_to_grid {`*None* | *Grid* | *Half_Grid* | *Either*`}`	

	Controls the snapping of the center of the rings. If you do not specify this parameter, rings are not snapped to the routing grid. Specify one of the following values: • `None`: Does no snapping of the wires. • `Grid`: Snaps the centers of the wires to the routing grid of the same layer as the wire. • `Half_Grid`: Snaps the centers of the wires to the half-routing grid. The half-routing grid is a virtual grid with the tracks at the center of every two adjacent tracks of the routing grid. • `Either`: Snaps the centers of the wires to the closer of the routing grid or half-grid track.
`-spacing` *spacing*	Can now be used to replace old options: `-spacing _top / -spacing _bottom / -spacing _left / -spacing _right` `-spacing 1` means all four sides of the ring will use 1um for the spacing. Example: • `-spacing 1` : all four sides of the ring will use 1um for the spacing. (existing) • `-spacing {top 1 bottom 1 left 2 right 2}` : top ring wires will use 1um for the spacing, bottom ring wires will use 1 um for the spacing, left ring wires will use 2 um for the spacing, right ring wires will use 2 um for the spacing.
`-threshold {`*value* `|` *auto*`}`	• `value:` Specifies the least amount of spacing allowed between ring segments of adjacent blocks before the rings are merged. If the spacing is less than this value, the common sides of the rings are merged. Units in micrometers. • `auto:` Specifies that the Innovus will automatically determine where to merge the wires being created with the prerouted wires. *Default:* 10 µm (if you do not specify this parameter, rings farther than 10 µm from each other are not merged).
`-type` *core_rings* `|` *block_rings*	
	Specifies the ring type to create. *Default:* If you do not specify this parameter, core rings are created. Specify one of the following values: Creates core rings that follow the contour of the core boundary or the I/O boundary. If you specify `core_rings`, then you must specify either the `-follow` parameter or the `-around user_defined` parameter. *Default:* The ring is offset from the core, based on offset values that you specify in the `-offset` parameters. `block_rings` Creates block rings that follow the contour of the specified objects. If you specify `block_rings`, then you must specify the `-around` argument with one of its required options.
`-uda` *subclass_string*	Displays the user defined attribute attached to each created ring segment.
`-user_defined_region {`*x1 y1 x2 y2 …*`}`	

	Specifies the coordinates for a rectilinear region if you use the `-around user_defined` parameter. You must specify at least four sets of coordinates and the coordinate list must be enclosed within curly braces. You must also specify the coordinates in a linear sequence. For example, you cannot specify the coordinates in a sequence such as bottom left, top right, bottom right, top left.
`-use_interleaving_wire_group {0 | 1}`	
	If set to 1, connects multiple wires from the same net together, even if separated by wires from a different net. You can only specify this parameter if you also specify `-use_wire_group 1`. *Default:* If you do not specify this parameter or if you specify it with a value of `0`, interleaving wire groups are not used.
`-use_wire_group {0 | 1}`	If set to `1`, connects multiple wires from the same net together. **Note:** For stripes to connect to rings using wire groups, you must specify `-useWireGroup` in both the `addRing` and `addStripe` commands. The following figure shows the difference in the connections. *Default:* If you do not specify this parameter or if you specify it with a value of `0`, wire groups are not used.
`-use_wire_group_bits` *integer*	
	Specifies how many nets are to be included in the wire group. You can only specify this parameter if you also specify `-use_wire_group 1`. *Default:* The same number of nets as specified in the `-nets` parameter.
`-use_wire_group_reinforcement {0 | 1}`	
	Specifies reinforcement stripes. The option is boolean and optional. *Default:* 0
`-use_wire_group_reinforcement_group_via {0 | 1}`	
	Creates group vias for wire group corners along with reinforcement stripes placed in the horizontal and vertical directions for the same wires. You can use this parameter to improve the yield and reliability issues associated with vias and reinforcement stripes by ensuring that if one of the vias or reinforcement stripes produces a void, the contact will be maintained through one of the adjoining vias or reinforcement stripes. *Default:* `0`
`-use_wire_group_reinforcement_spacing_width` *spacing width*	
	Creates group vias for wire group corners along with reinforcement stripes placed in the spacing and width for the same wires. You can use this parameter to improve the yield and reliability issues associated with vias and reinforcement stripes by ensuring that if one of the vias or reinforcement stripes produces a void, the contact will be maintained through one of the adjoining vias or reinforcement stripes.

`-width width`	Can now be used to replace old options: `-width_top / -width_bottom / -width_left / -width_right` `-width 4` means that four sides of the ring will use 4um metal width. Example: • `-width 4` : all four sides of the ring will use 4um metal width. (existing) • `-width {top 4 bottom 4 left 6 right 6}` : top ring wires will use 4um metal width, bottom ring wires will use 4um metal width, left ring wires will use 6um metal width, right ring wires will use 6um metal width.

Examples

- The following command adds a core ring to the `vdd` and `gnd` nets on layers `METAL5` and `METAL6`:
  ```
  addRing -nets {vdd gnd} -type core_rings -center 1 -layer {top METAL6 bottom METAL6 right METAL5 left METAL5} -width 10 -spacing 2
  ```
  This ring is centered between the I/O pad area and the core boundary, has a width of 10 µm, and is located at least 2 µm away from any other ring.
- A user may use `addRing -nets {VSS VDD} -layer {top metal5 bottom metal5 left metal6 right metal6} …` instead of `addRing -nets {VSS VDD} -layer {top {metal5 metal5} bottom {metal5 metal5} left {metal6 metal6} right {metal6 metal6}} …`
- Per Old behavior:
  ```
  addRing -nets {VSS VDD} -width_bottom 5 -width_top 5 -width_right 5 -width_left 5 -layer_top Metal5 -layer_bottom Metal5 -layer_left Metal6 -layer_right Metal6 -offset_top 2 -offset_bottom 2 -offset_left 2 -offset_right 2 -spacing_top 1 -spacing_bottom 1 -spacing_left 1 -spacing_right 1
  ```
- Per New behavior:
  ```
  addRing -nets {VSS VDD} -width 5 -layer {top Metal5 left Metal6 bottom Metal5 right metal6} -offset 2 -spacing 1
  ```

addSpecialRoute

```
addSpecialRoute
[-help]
filename
```

Incrementally adds special route information from a file. This includes only special route wires, vias, and metal fill. If the specified filename is compressed (with the `.gz` extension), the file is read in directly. Use this command after you have imported a design.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `addSpecialRoute` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man addSpecialRoute`.
`filename`	Specifies the name of the file that contains special route information, to be used as input for the design. Only `.spr` files are supported.

addSplitPowerVia

```
addSplitPowerVia
[-help]
[-delete | -wires_only]
[-edgeLength {layer1 value1 layer2 value2 ...}]
[-forceCount]
[-localCheckerBoard]
[-master cell_name]
[-maxViaSize {x y}]
[-maxWireLength {layer1 value1 layer2 value2 ...}]
[-maxWireSpacing {layer1 value1 layer2 value2 ...}]
[-mergeCount {x y}]
[-mergeDistance {x y}]
[-minEnclosure]
[-minViaSize {x y}]
[-minWireLength {layer1 value1 layer2 value2 ...}]
[-minWireSpacing {layer1 value1 layer2 value2 ...}]
[-pinLayer {layer1 layer2 ...}]
[-prerouteAlign {none samelayer alllayer}]
[-snap_wire_center_to_grid {layer1 {none|grid|half_grid|either} layer2 {none|grid|half_grid|either}} ...]
[-stackedCheckerBoard]
[-uda <userDefinedAttribute>]
[-wireCount {layer1 value1|auto layer2 value2|auto … }]
[-wireOffset {layer1 value1 layer2 value2 ...}]
[-wireWidth {layer1 value1 layer2 value2 ...}]
```

Adds or deletes Jenga vias and does not modify vias. It passes on all Jenga parameters to separate options.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `addSplitPowerVia` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man addSplitPowerVia`.
`-delete`	Deletes the via for selected wires/objects. This is a boolean value and is optional.
`-edgeLength {layer1 value1 layer2 value2 ...}`	
	Sets extension length of the wires for each layer in um. The value is a string and is optional.
`-forceCount`	Forces the tool to generate the given wirecount even if the wires extend beyond the overlap area. This is a boolean value and is optional.
`-localCheckerBoard`	Allows local checkerboard cut generation instead of matching the global checkerboard pattern.
`-master cell_name`	Passes the selected wires through the specified cells.
`-maxViaSize {x y}`	Displays the maximum via size. This value is in points and is optional.
`-maxWireLength {layer1 value1 layer2 value2 ...}`	
	Sets the maximum length of the wires for each layer in um. This value is a string and is optional.
`-maxWireSpacing {layer1 value1 layer2 value2 ...}`	
	Sets the maximum wire spacing of wires for each layer in um. The value is in strings and is optional.
`-mergeCount {x y}`	Merges the neighboring wire count. The value is an integer and is optional.
`-mergeDistance {x y}`	
	Merges the distance in x and y direction. The value is in points and is optional.
`-minEnclosure`	Creates the shortest wires that meet DRC rules rather than the default wire length of the entire overlap area. This is a boolean value and is optional.
`-minViaSize {x y}`	Sets the minimum via size. The value is in point and is optional.
`-minWireSpacing {layer1 value1 layer2 value2 ...}`	
	Sets the minimum wire spacing of wires for each layer in um. The value is a string and is optional.
`-minWireLength {layer1 value1 layer2 value2 ...}`
